$$\tilde{X} := H_{(0)}^s \times H_{(0)}^{s-2}((0, 1), \mathbb{R}) \text{ for } s \in \mathbb{N}^*, s \geq 3$$

instead of  $X$ . Indeed,

- $\mathcal{A}$  generates a  $C^0$ -semigroup of bounded linear operators of  $\tilde{X}$  (we refer to Remark 1 in section 2 for a justification of this statement),
- for  $w = (w_1, w_2)^t \in \tilde{X}$ ,  $\mathcal{B}w = (0, -w_2'')^t$  belongs to  $H_{(0)}^s \times H^{s-2}((0, 1), \mathbb{R})$ ,
- but in general  $w_2''$  does not vanish at  $x = 0, 1$ , so  $\mathcal{B}w$  does not belong to  $\tilde{X}$  (see (1.4)), and thus  $\mathcal{B}$  does not map  $\tilde{X}$  into  $\tilde{X}$ .

Notice that Theorem 2 does not apply either with

$$\overline{X} := H_{(0)}^3 \times H^1((0, 1), \mathbb{R})$$

(which is a space such that  $\mathcal{B}$  maps  $\overline{X}$  into  $\overline{X}$ ) instead of  $X$ , because  $\mathcal{A}$  does not generate a  $C^0$  semigroup of bounded operators of  $\overline{X}$  (we refer to Proposition 8 for a proof of this statement).

In this article, we prove a local controllability result in  $H_{(0)}^{5+\epsilon} \times H_{(0)}^{3+\epsilon}((0, 1), \mathbb{R})$ , with  $\epsilon > 0$  and with control functions  $p$  in  $H_{loc}^1(\mathbb{R}_+, \mathbb{R})$ . Thus, the noncontrollability result proved by Ball, Marsden, and Slemrod relies on the fact that the choice of functional spaces does not allow controllability. In order to state affirmative controllability results, one must

- either control  $(u, u_t)$  in  $H_0^2 \times L^2((0, 1), \mathbb{R})$  but with a control functions set larger than  $\cup_{r>0} L_{loc}^r(\mathbb{R}_+, \mathbb{R})$ , for example,  $H_{loc}^{-1}(\mathbb{R}_+, \mathbb{R})$ ,
- or control  $(u, u_t)$  using the control functions set  $L_{loc}^2(\mathbb{R}_+, \mathbb{R})$  but in a smaller space than  $H_0^2 \times L^2((0, 1), \mathbb{R})$ , for example,  $H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$ .

**1.3. Sketch of the proof.** The result of Theorem 1 is a local controllability result, in time  $T = 8/\pi$ , around the trajectory  $(u^{ref}, \dot{u}^{ref}, p \equiv 0)$  for the nonlinear control system  $(\Sigma)$ . It is equivalent to a local surjectivity property for the map

$$(1.8) \quad \Phi_T : (u_0, \dot{u}_0, p) \mapsto (u_0, \dot{u}_0, u(T), u_t(T)),$$

where  $T = 8/\pi$  and  $u$  is a solution of  $(\Sigma)$  with initial condition  $u(0) = u_0$ ,  $u_t(0) = \dot{u}_0$ . For the proof of such results, there exists a classical approach which consists of

- first proving the global controllability of the linearized system around the trajectory considered (which corresponds to the surjectivity of  $d\Phi_T(u^{ref}(0), u_t^{ref}(0), 0)$ ) and
- then applying the inverse mapping theorem to the nonlinear map  $\Phi_T$ , which gives a local surjectivity property for  $\Phi_T$  around  $(u_0^{ref}, \dot{u}_0^{ref}, 0)$ .

The general strategy adopted in this article is this one, but we will see that the classical inverse mapping theorem is not sufficient to conclude. Thus, we use a more elaborate version of the inverse mapping theorem, namely, the Nash–Moser implicit functions theorem. This strategy has already been used for Schrödinger equations in [3], [4], [2].

First, we consider the linearized system around the trajectory  $(u^{ref}, \dot{u}^{ref}, p \equiv 0)$  defined by (1.5), which is

$$(\Sigma_l^{ref}) \begin{cases} U_{tt} + U_{xxxx} + P(t)u_{xx}^{ref} = 0, (t, x) \in (0, \infty) \times \mathbb{R}, \\ U = U_x = 0 \text{ at } x = 0, 1. \end{cases}$$

It is a linear control system where

- the state is the couple  $(U, U_t)$  and
- the control is the real-valued function  $t \mapsto P(t)$ .

We prove the following controllability result for this system.

THEOREM 3. (1) For every  $T > \pi/\sqrt{\lambda_2}$ , for every  $(U_T, \dot{U}_T) \in H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$ , there exists  $P \in L^2((0, T), \mathbb{R})$  such that the solution of  $(\Sigma_l^{ref})$  with  $(U(0), \dot{U}(0)) = (0, 0)$  and control  $P$  satisfies  $(U(T), \dot{U}(T)) = (U_T, \dot{U}_T)$ .

(2) For every  $T > 0$ , there exists  $(U_T, \dot{U}_T) \in H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$ , (resp.,  $(U_T, \dot{U}_T) \in H_0^2 \times L^2((0, 1), \mathbb{R})$ ) such that, for every  $P \in H^1((0, T), \mathbb{R})$  (resp.,  $P \in L^2((0, T), \mathbb{R})$ ), the solution of  $(\Sigma_l^{ref})$  with  $(U(0), \dot{U}(0)) = (0, 0)$  and control  $P$  satisfies  $(U(T), \dot{U}(T)) \neq (U_T, \dot{U}_T)$ .

Therefore, the linear system  $(\Sigma_l^{ref})$  is controllable in  $H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$  with control functions in  $L^2((0, T), \mathbb{R})$ , but it is neither controllable in  $H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$  with control functions in  $H^1((0, T), \mathbb{R})$  nor controllable in  $H_0^2 \times L^2((0, 1), \mathbb{R})$  with control functions in  $L^2((0, T), \mathbb{R})$ . As we will see precisely in section 4, statement (2) of Theorem 3 shows that the local controllability around  $(u^{ref}, \dot{u}^{ref}, 0)$  cannot be obtained by applying the classical inverse mapping theorem. Roughly speaking, the controls built for the control of the linearized system are not smooth enough for the application of the inverse mapping theorem.

Thus, in order to prove Theorem 1, we use a Nash–Moser theorem. This theorem is an elaborate version of the inverse mapping theorem. It gives the local surjectivity of a nonlinear map  $\Theta$  around a point  $x^{ref}$  thanks to essentially 3 assumptions:

- (1) There exist decreasing sequences of spaces  $(E_a)_{a \geq 0}$ ,  $(F_b)_{b \geq 0}$  such that
  - $\Theta : E_a \rightarrow F_a$  is  $C^2$  for every  $a$ ,
  - there exist smoothing linear operators  $(S_\theta)_{\theta > 0}$  (resp.,  $(\tilde{S}_\theta)_{\theta > 0}$ ) defined on the spaces  $E_a$  (resp.,  $F_b$ ) with  $S_\theta \rightarrow Id$  (resp.,  $\tilde{S}_\theta \rightarrow Id$ ) when  $\theta \rightarrow +\infty$ ,
  - the norms of the operators  $Id - S_\theta, S_\theta : E_a \rightarrow E_A$  for  $a \neq A$  (resp.,  $Id - \tilde{S}_\theta, \tilde{S}_\theta : F_b \rightarrow F_B$  for  $b \neq B$ ) are bounded by an explicit expression in terms of  $\theta, a, A$  (resp.,  $\theta, b, B$ )
- (2) one knows a particular explicit bound on the second differential  $d^2\Theta(x)$  for  $x$  in a neighborhood of  $x^{ref}$ ;
- (3) for every  $x$  in a neighborhood of  $x^{ref}$ , the differential  $d\Theta(x)$  has a right inverse  $d\Theta(x)^{-1} : F_{b_1} \rightarrow E_{a_1}$ , where  $a_1 < b_1$ , that satisfies particular explicit estimates, called “tame estimates.”

We refer to section 5 to see more precisely what the explicit expressions mentioned above look like (the bounds on the smoothing operators mentioned in (1) are given in (5.1), (5.2), (5.3), (5.4); the bound of the second differential mentioned in (2) is given in (5.6); the tame estimates mentioned in (3) are given in (5.7), (5.8)).

The main differences between the inverse mapping theorem and the Nash–Moser theorem are the following:

- The Nash–Moser theorem needs a weaker surjectivity property on  $d\Theta(x^{ref})$ . Indeed, the inverse mapping theorem needs the surjectivity of the map  $d\Theta(x^{ref}) : E_{a_1} \rightarrow F_{a_1}$  (with the same index  $a_1$  in both sides; i.e., the nonlinear map  $\Theta$  has to be  $C^1$  between  $E_{a_1}$  and  $F_{a_1}$ ), whereas the Nash–Moser theorem needs the existence of a right inverse  $d\Theta(x^{ref})^{-1}$  defined on a space  $F_{b_1}$  strictly included in  $F_{a_1}$ , with values in  $E_{a_1}$ . Thus  $d\Theta(x^{ref})$  does not need to be surjective from  $E_{a_1}$  to  $F_{a_1}$ .
- The Nash–Moser theorem needs a surjectivity property for all of the differentials  $d\Theta(x)$  for  $x$  in a neighborhood of  $x^{ref}$ , whereas the inverse mapping theorem requires the surjectivity of the differential  $d\Theta(x)$  only at the point  $x = x^{ref}$ . This assumption is often the most difficult to check in the applications of this theorem.

The rest of the paper is organized as follows.

In section 2, we give the definition of solutions for the nonlinear system  $(\Sigma)$ , and we recall classical results about the existence, the uniqueness, and the regularity of these solutions. We also prove bounds on those solutions that will be used many times in this article. Finally, we define spaces  $E_a$  and  $F_b$  such that the map  $\Phi_T$  defined by (1.8) is a  $C^1$  map from  $E_a$  to  $F_a$  for every  $a$ .

Section 3 is devoted to the proof of Theorem 3. In subsection 3.1, we state and prove some preliminary results about the eigenvalues and eigenvectors of the operator  $A$  defined by (1.1). In subsection 3.2, we prove Theorem 3.

In section 4, we explain in detail why Theorem 1 cannot be deduced from the first statement of Theorem 3 by applying the classical inverse mapping theorem to the map  $\Phi_T$ .

In section 5, we state and prove a Nash–Moser implicit function theorem inspired by [20]. The following sections are dedicated to the verification of each assumption of this theorem, i.e., points (1), (2), and (3) presented above.

In section 6, we present a construction of smoothing operators  $S_\theta$ , on the spaces  $E_a$  and  $F_b$  (defined in section 2), with the desired explicit bounds in terms of  $\theta$ ,  $a$ , and  $A$  for the linear map  $S_\theta : E_a \rightarrow E_A$ ,  $a < A$  (i.e., point (1)).

In section 7, we prove a bound on the second differential  $d^2\Phi_T$  (i.e., point (2)).

In section 8, we prove the existence of a right inverse for  $d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0)$  with tame estimates (i.e., the case  $x = x^{ref}$  in point (3)).

In section 9, we prove the existence of a right inverse for  $d\Phi_T(u_0, \dot{u}_0, p)$  with tame estimates, for every  $(u_0, \dot{u}_0, p)$  in a small neighborhood of  $(u_0^{ref}, \dot{u}_0^{ref}, 0)$  (i.e., point (3)). This part of the proof is the most technical one.

Finally, in section 10, we give some remarks, conjectures, and prospects.

In this work, we use the same letter  $C$  to denote different constants. The value of  $C$  can change from one expression to another.

**2. Regularity and bound for the solutions of the nonlinear system.** This section is dedicated to the statement of existence, uniqueness, regularity results, and bounds for the solutions of the Cauchy problem

$$(CY) : \begin{cases} u_{tt} + u_{xxxx} + p(t)u_{xx} + f(t) = 0, & x \in (0, 1), t \in \mathbb{R}_+, \\ u = u_x = 0 \text{ at } x = 0, 1, \\ u(0, x) = u_0(x), \dot{u}(0, x) = \dot{u}_0(x). \end{cases}$$

These bounds, presented in subsection 2.1, will be used many times in this article. Then, in subsection 2.2, we deduce the spaces  $E_a$  and  $F_b$  between which the map  $\Phi_T$  defined by (1.8) is of class  $C^1$ .

All of these results are classical, but we give proofs for the sake of completeness. The reading of the proofs in this section is not necessary for the understanding of the next sections of this article.

**2.1. Existence, uniqueness, regularity, and bounds.** We introduce the first order Cauchy problem

$$(CY) : \begin{cases} \frac{dw}{dt} = -\mathcal{A}w - p(t)\mathcal{B}w + F(t), \\ w(0) = w_0, \end{cases}$$

where  $\mathcal{A}$  and  $\mathcal{B}$  are linear operators with domains

$$D(\mathcal{A}) := H_{(0)}^4 \times H_0^2((0, 1), \mathbb{R}), \quad D(\mathcal{B}) := H_0^2 \times L^2((0, 1), \mathbb{R})$$

defined by

$$\mathcal{A} \begin{pmatrix} w^1 \\ w^2 \end{pmatrix} := \begin{pmatrix} -w^2 \\ w^1_{xxxx} \end{pmatrix}, \quad \mathcal{B} \begin{pmatrix} w^1 \\ w^2 \end{pmatrix} := \begin{pmatrix} 0 \\ w^1_{xx} \end{pmatrix},$$

and  $F : (0, T) \rightarrow H_0^2 \times L^2((0, 1), \mathbb{R})$ .

The Cauchy problem (CY) is equivalent to the Cauchy problem (CY) with  $w = (u, u_t)$ ,  $w_0 = (u_0, \dot{u}_0)$ , and  $F = (0, -f)$ . Thus, in this section, we work only on (CY).

The operator  $\mathcal{A}$  generates a  $C^0$ -group of isometries of  $H_0^2 \times L^2((0, 1), \mathbb{R})$  with the following explicit expression

$$(2.1) \quad e^{-t\mathcal{A}} \begin{pmatrix} u_0 \\ \dot{u}_0 \end{pmatrix} = \begin{pmatrix} \sum_{k=1}^{\infty} \left( \langle u_0, \varphi_k \rangle \cos(\sqrt{\lambda_k}t) + \frac{1}{\sqrt{\lambda_k}} \langle \dot{u}_0, \varphi_k \rangle \sin(\sqrt{\lambda_k}t) \right) \varphi_k \\ \sum_{k=1}^{\infty} \left( -\sqrt{\lambda_k} \langle u_0, \varphi_k \rangle \sin(\sqrt{\lambda_k}t) + \langle \dot{u}_0, \varphi_k \rangle \cos(\sqrt{\lambda_k}t) \right) \varphi_k \end{pmatrix}$$

for every  $(u_0, \dot{u}_0) \in H_0^2 \times L^2((0, 1), \mathbb{R})$ , where  $\langle \cdot, \cdot \rangle$  denotes the usual  $L^2((0, 1), \mathbb{R})$ -scalar product.

*Remark 1.* With this explicit expression of the  $C^0$ -group generated by  $\mathcal{A}$ , it is clear that  $e^{-\mathcal{A}t}$  is an isometry of  $H_{(0)}^{s+2} \times H_{(0)}^s((0, 1), \mathbb{R})$  for every  $s \in \mathbb{N}^*$  (with the definition (1.2) and (1.3)) as claimed in section 1.2.

**PROPOSITION 1.** *Let  $T > 0$ ,  $p \in L^1((0, T), \mathbb{R})$ ,  $w_0 \in H_0^2 \times L^2((0, 1), \mathbb{R})$ , and  $F \in L^1((0, T), H_0^2 \times L^2((0, 1), \mathbb{R}))$ . There exists a unique weak solution of (CY), i.e., a function  $w \in C^0([0, T], H_0^2 \times L^2((0, 1), \mathbb{R}))$ , such that the following equality holds in  $H_0^2 \times L^2((0, 1), \mathbb{R})$  for every  $t \in [0, T]$ :*

$$(2.2) \quad w(t) = e^{-t\mathcal{A}}w_0 + \int_0^t e^{-(t-s)\mathcal{A}}[-p(s)\mathcal{B}w(s) + F(s)]ds.$$

Moreover, it satisfies

$$(2.3) \quad \|w\|_{C^0([0, T], H_0^2 \times L^2)} \leq \left( \|w_0\|_{H_0^2 \times L^2} + \|F\|_{L^1((0, T), H_0^2 \times L^2)} \right) e^{\|p\|_{L^1((0, T), \mathbb{R})}}.$$

*Proof of Proposition 1.* The existence and uniqueness result comes from a fixed point argument on the map  $\Theta : C^0([0, T], H_0^2 \times L^2) \rightarrow C^0([0, T], H_0^2 \times L^2)$ ,  $\Theta(\xi) = w$ , where  $w$  is defined by

$$w(t) = e^{-\mathcal{A}t}w_0 + \int_0^t e^{-\mathcal{A}(t-s)}[-p(s)\mathcal{B}\xi(s) + F(s)]ds.$$

When  $\|p\|_{L^1((0, T), \mathbb{R})}$  is small enough,  $\Theta$  is a contraction of  $C^0([0, T], H_0^2 \times L^2)$ , and thus it has a unique fixed point  $w \in C^0([0, T], H_0^2 \times L^2)$  that satisfies (2.2). If  $\|p\|_{L^1((0, T), \mathbb{R})}$  is not small enough, one may use  $0 = T_0 < T_1 < \dots < T_n = T$  where, for  $i = 0, \dots, n-1$ ,  $\|p\|_{L^1((T_i, T_{i+1}), \mathbb{R})}$  is small enough so that the previous result holds on  $[T_i, T_{i+1}]$  for  $i = 0, \dots, n-1$ . Then we glue the solutions defined on  $[T_0, T_1], [T_1, T_2], \dots, [T_{n-1}, T_n]$ . We deduce from the equality (2.2) that

$$\|w(t)\|_{H_0^2 \times L^2} \leq \|w_0\|_{H_0^2 \times L^2} + \int_0^t [p(s)\|w(s)\|_{H_0^2 \times L^2} + \|F(s)\|_{H_0^2 \times L^2}]ds,$$

and thus

$$\|w(t)\|_{H_0^2 \times L^2} \leq \|w_0\|_{H_0^2 \times L^2} + \|F\|_{L^1((0, T), H_0^2 \times L^2)} + \int_0^t p(s)\|w(s)\|_{H_0^2 \times L^2}ds,$$

and Gronwall's Lemma gives (2.3).  $\square$

PROPOSITION 2. Let  $T > 0$ ,  $p \in W^{1,1}((0, T), \mathbb{R})$ ,  $w_0 \in H_{(0)}^4 \times H_0^2((0, 1), \mathbb{R})$ , and  $F \in W^{1,1}((0, T), H_0^2 \times L^2((0, 1), \mathbb{R}))$ . The solution  $w$  of (2.2) belongs to  $C^1([0, T], H_0^2 \times L^2)$  and to  $C^0([0, T], H_{(0)}^4 \times H_0^2)$ . Moreover, for every  $r > 0$ , there exists  $C(r) > 0$  such that, when  $\|p\|_{W^{1,1}} \leq r$ , the quantities

$$(2.4) \quad \|w\|_{C^0([0, T], H_{(0)}^4 \times H_0^2)} \text{ and } \|w\|_{C^1([0, T], H_0^2 \times L^2)}$$

are bounded by

$$(2.5) \quad C(r)[\|w_0\|_{H_{(0)}^4 \times H_0^2} + \|F\|_{W^{1,1}((0, T), H_0^2 \times L^2)}].$$

*Proof of Proposition 2.* Under the assumptions of Proposition 2, one can prove, by using the equality (2.2), that  $w \in C^1([0, T], H_0^2 \times L^2)$  and that

$$(2.6) \quad \frac{dw}{dt}(t) = -\mathcal{A}w(t) - p(t)\mathcal{B}w(t) + F(t) \text{ in } H_0^2 \times L^2((0, 1), \mathbb{R}) \quad \forall t \in [0, T].$$

We also have

$$\begin{aligned} \frac{dw}{dt}(t) &= e^{-\mathcal{A}t}[-\mathcal{A}w_0 - p(0)\mathcal{B}w_0 + F(0)] \\ &\quad + \int_0^t e^{-\mathcal{A}(t-s)} \left[ -p(s)\mathcal{B} \frac{dw}{dt}(s) - \dot{p}(s)\mathcal{B}w(s) + \dot{F}(s) \right] ds. \end{aligned}$$

By applying Proposition 1 to  $\frac{dw}{dt}$ , we get  $\frac{dw}{dt} \in C^0([0, T], H_0^2 \times L^2)$  and

$$\begin{aligned} \left\| \frac{dw}{dt} \right\|_{C^0([0, T], H_0^2 \times L^2)} &\leq C \left[ \|w_0\|_{H_{(0)}^4 \times H_0^2} + |p(0)| \|w_0\|_{H_0^2 \times L^2} + |F(0)|_{H_0^2 \times L^2} \right. \\ &\quad \left. + \|\dot{p}\|_{L^1} \|w\|_{C^0([0, T], H_0^2 \times L^2)} + \|\dot{F}\|_{L^1((0, T), H_0^2 \times L^2)} \right] e^{\|p\|_{L^1}}. \end{aligned}$$

Therefore, by using (2.3), we get a universal constant  $C_1 > 0$  such that

$$\begin{aligned} (2.7) \quad \left\| \frac{dw}{dt} \right\|_{C^0([0, T], H_0^2 \times L^2)} &\leq C_1 [\|w_0\|_{H_{(0)}^4 \times H_0^2} + \|p\|_{W^{1,1}} \|w_0\|_{H_0^2 \times L^2} + |F(0)|_{H_0^2 \times L^2} \\ &\quad + \|F\|_{W^{1,1}((0, T), H_0^2 \times L^2)} + \|p\|_{W^{1,1}} \|F\|_{L^1((0, T), H_0^2 \times L^2)}] e^{2\|p\|_{L^1}}. \end{aligned}$$

Then by using (2.6), we get  $w \in C^0([0, T], H_{(0)}^4 \times H_0^2((0, 1), \mathbb{R}))$  and

$$\begin{aligned} \|\mathcal{A}w\|_{C^0([0, T], H_0^2 \times L^2)} &= \left\| \frac{dw}{dt} + p\mathcal{B}w - F \right\|_{C^0([0, T], H_0^2 \times L^2)} \\ &\leq \left\| \frac{dw}{dt} \right\|_{C^0([0, T], H_0^2 \times L^2)} + \|p\|_{W^{1,1}} \|w\|_{C^0([0, T], H_0^2 \times L^2)} \\ &\quad + \|F\|_{C^0([0, T], H_0^2 \times L^2)}. \end{aligned}$$

Thanks to (2.7) and (2.3), the quantities in (2.4) are bounded by

$$\begin{aligned} C'(r)[\|w_0\|_{H_{(0)}^4 \times H_0^2} + \|p\|_{W^{1,1}} \|w_0\|_{H_0^2 \times L^2} + \|F\|_{W^{1,1}((0, T), H_0^2 \times L^2)} \\ + \|p\|_{W^{1,1}} \|F\|_{L^1((0, T), H_0^2 \times L^2)}] \end{aligned}$$

when  $\|p\|_{L^1((0, T), \mathbb{R})} \leq r$ , where  $C'(r) > 0$ . Finally, (2.5) is a direct consequence of the previous inequality.  $\square$

PROPOSITION 3. Let  $T > 0$ ,  $p \in W^{2,1}((0, T), \mathbb{R})$ , with  $p(0) = p(T) = 0$ ,  $w_0 \in H_{(0)}^6 \times H_{(0)}^4((0, 1), \mathbb{R})$ , and  $F \in W^{2,1}((0, T), H_0^2 \times L^2) \cap C^0([0, T], H^4 \times H^2)$ , with  $F(0), F(T) \in H_{(0)}^4 \times H_{(0)}^2((0, 1), \mathbb{R})$ . The solution  $w$  of (2.2) belongs to  $C^2([0, T], H_0^2 \times L^2)$ ,  $C^1([0, T], H_{(0)}^4 \times H_{(0)}^2)$ ,  $C^0([0, T], H^6 \times H^4)$ , and  $w(T) \in H_{(0)}^6 \times H_{(0)}^4$ . Moreover, for every  $r > 0$ , there exists  $C(r) > 0$  such that, when  $\|p\|_{W^{1,1}} \leq r$ , the quantities

$$\|w\|_{C^0([0, T], H^6 \times H^4)}, \|w\|_{C^1([0, T], H^4 \times H^2)}, \text{ and } \|w\|_{C^2([0, T], H_0^2 \times L^2)}$$

are bounded by

$$(2.8) \quad C(r)[\|w_0\|_{H_{(0)}^6 \times H_{(0)}^4} + \|p\|_{W^{2,1}}\|w_0\|_{H_0^2 \times L^2} + \|F\|_{W^{2,1}((0, T), H_0^2 \times L^2)} + \|p\|_{W^{2,1}}\|F\|_{L^1((0, T), H_0^2 \times L^2)} + \|F\|_{C^0([0, T], H^4 \times H^2)}].$$

*Proof of Proposition 3.* By applying Proposition 2 to  $\frac{dw}{dt}$ , we get  $\frac{dw}{dt} \in C^0([0, T], H_{(0)}^4 \times H_0^2) \cap C^1([0, T], H_0^2 \times L^2)$ . Notice that the assumptions  $p(0) = 0$  and  $F(0) \in H_{(0)}^4 \times H_{(0)}^2((0, 1), \mathbb{R})$  are useful to ensure that the initial condition

$$\frac{dw}{dt}(0) = -\mathcal{A}w_0 - p(0)\mathcal{B}w_0 + F(0)$$

belongs to  $H_{(0)}^4 \times H_0^2$ . Indeed, when  $w = (w_1, w_2) \in H_{(0)}^6 \times H_{(0)}^4((0, 1), \mathbb{R})$ , then  $w_1'' \in H^2((0, 1), \mathbb{R})$ , but in general  $w_1''$  does not vanish at  $x = 0, 1$ , and thus  $\mathcal{B}w$  does not belong to  $H_{(0)}^4 \times H_0^2((0, 1), \mathbb{R})$ . Proposition 2 also gives the existence of a constant  $C(r) > 0$  such that, when  $\|p\|_{W^{1,1}((0, T), \mathbb{R})} \leq r$ , the quantities

$$(2.9) \quad \left\| \frac{dw}{dt} \right\|_{C^0([0, T], H_{(0)}^4 \times H_0^2)} \text{ and } \left\| \frac{dw}{dt} \right\|_{C^1([0, T], H_0^2 \times L^2)}$$

are bounded by

$$\begin{aligned} & C \left[ \left\| \frac{dw}{dt}(0) \right\|_{H_{(0)}^4 \times H_0^2} + \|\dot{p}w - \dot{F}\|_{W^{1,1}((0, T), H_0^2 \times L^2)} \right] \\ & \leq C \left[ \|w_0\|_{H_{(0)}^6 \times H_{(0)}^4} + \|F(0)\|_{H_{(0)}^4 \times H_0^2} + \|p\|_{W^{2,1}}\|w\|_{C^0([0, T], H_0^2 \times L^2)} \right. \\ & \quad \left. + \|p\|_{W^{1,1}} \left\| \frac{dw}{dt} \right\|_{C^0([0, T], H_0^2 \times L^2)} + \|F\|_{W^{2,1}((0, T), H_0^2 \times L^2)} \right]. \end{aligned}$$

By using (2.3) and (2.5), we get the following bounds for the quantities written in (2.9):

$$(2.10) \quad C \left[ \|w_0\|_{H^6 \times H^4} + \|p\|_{W^{2,1}}\|w_0\|_{H_0^2 \times L^2} + \|F(0)\|_{H_{(0)}^4 \times H_0^2} + \|F\|_{W^{2,1}((0, T), H_0^2 \times L^2)} + \|p\|_{W^{2,1}}\|F\|_{L^1((0, T), H_0^2 \times L^2)} \right].$$

Now, by using (2.6), we deduce that  $\mathcal{A}w \in C^0([0, T], H^4 \times H^2)$  and  $\mathcal{A}w(T) \in H_{(0)}^4 \times H_0^2$  because  $p(T) = 0$  and  $F(T) \in H_{(0)}^4 \times H_0^2$ . Moreover,

$$\begin{aligned} \|\mathcal{A}w\|_{C^0([0, T], H^4 \times H^2)} & \leq \left\| \frac{dw}{dt} \right\|_{C^0([0, T], H_{(0)}^4 \times H_0^2)} + \|p\|_{W^{1,1}}\|w\|_{C^0([0, T], H_{(0)}^4 \times H_0^2)} \\ & \quad + \|F\|_{C^0([0, T], H^4 \times H^2)}. \end{aligned}$$

Thanks to the previous inequality, (2.10), and (2.5), we get (2.8).  $\square$

PROPOSITION 4. Let  $T > 0$ ,  $p \in W^{3,1}((0, T), \mathbb{R})$ , with  $p(0) = p(T) = \dot{p}(0) = \dot{p}(T) = 0$ ,  $w_0 \in H_{(0)}^8 \times H_{(0)}^6((0, 1), \mathbb{R})$ , and  $F \in W^{3,1}((0, T), H_0^2 \times L^2) \cap C^1([0, T], H^4 \times H^2) \cap C^0([0, T], H^6 \times H^4)$ , with  $F(0), F(T) \in H_{(0)}^6 \times H_{(0)}^4((0, 1), \mathbb{R})$ ,  $\dot{F}(0), \dot{F}(T) \in H_{(0)}^4 \times H_{(0)}^2((0, 1), \mathbb{R})$ . The solution  $w$  of (2.2) belongs to  $C^3([0, T], H_0^2 \times L^2)$ ,  $C^2([0, T], H_{(0)}^4 \times H_{(0)}^2)$ ,  $C^1([0, T], H^6 \times H^4)$ ,  $C^0([0, T], H^8 \times H^6)$ , and  $w(T) \in H_{(0)}^8 \times H_{(0)}^6$ . Moreover, for every  $r > 0$ , there exists  $C(r) > 0$  such that, when  $\|p\|_{W^{1,1}} \leq r$ , the quantities

$$\|w\|_{C^0([0, T], H^8 \times H^6)}, \|w\|_{C^1([0, T], H^6 \times H^4)}, \|w\|_{C^2([0, T], H^4 \times H^2)}, \text{ and } \|w\|_{C^3([0, T], H_0^2 \times L^2)}$$

are bounded by

$$(2.11) \quad C(r) \left[ \|w_0\|_{H^8 \times H^6} + \|p\|_{W^{2,1}} \|w_0\|_{H_{(0)}^4 \times H^2} + \|p\|_{W^{3,1}} \|w_0\|_{H_0^2 \times L^2} \right. \\ \left. + \|F\|_{W^{3,1}((0, T), H_0^2 \times L^2)} + \|p\|_{W^{2,1}} \|F\|_{W^{1,1}((0, T), H_0^2 \times L^2)} \right. \\ \left. + \|p\|_{W^{3,1}} \|F\|_{L^1((0, T), H_0^2 \times L^2)} \right. \\ \left. \|F\|_{C^0([0, T], H^6 \times H^4)} + \|p\|_{W^{2,1}} \|F\|_{C^0((0, T), H_0^2 \times L^2)} + \|F\|_{C^1([0, T], H^4 \times H^2)} \right].$$

*Proof of Proposition 4.* We apply Proposition 3 to  $\frac{dw}{dt}$ .  $\square$

**2.2. Spaces between which  $\Phi_T$  is  $C^1$ .** For  $T > 0$  fixed, we introduce the spaces

$$(2.12) \quad \begin{aligned} E_2 &:= H_0^2((0, 1), \mathbb{R}) \times L^2((0, 1), \mathbb{R}) \times L^2((0, T), \mathbb{R}), \\ E_4 &:= H_{(0)}^4((0, 1), \mathbb{R}) \times H_0^2((0, 1), \mathbb{R}) \times H^1((0, T), \mathbb{R}), \\ E_6 &:= H_{(0)}^6((0, 1), \mathbb{R}) \times H_{(0)}^4((0, 1), \mathbb{R}) \times H^2 \cap H_0^1((0, T), \mathbb{R}), \\ E_8 &:= H_{(0)}^8((0, 1), \mathbb{R}) \times H_{(0)}^6((0, 1), \mathbb{R}) \times H^3 \cap H_0^2((0, T), \mathbb{R}), \end{aligned}$$

and, for  $s > 0$ ,

$$(2.13) \quad F_s := H_{(0)}^s((0, 1), \mathbb{R}) \times H_{(0)}^{s-2}((0, 1), \mathbb{R}) \times H_{(0)}^s((0, 1), \mathbb{R}) \times H_{(0)}^{s-2}((0, 1), \mathbb{R}),$$

where  $H_{(0)}^s((0, 1), \mathbb{R})$  is defined by (1.2). Notice that the spaces  $E_a$  depend on  $T$  and should be called  $E_{a,T}$ . However, since no confusion is possible, we omit the subscript  $T$  in order to simplify the notations.

PROPOSITION 5. For every  $T > 0$  and for every  $a \in \{2, 4, 6, 8\}$ , the map  $\Phi_T$  defined by (1.8) is  $C^1$  from  $E_a$  to  $F_a$ , and, for every  $(u_0, \dot{u}_0, p) \in E_a$ ,  $d\Phi_T(u_0, \dot{u}_0, p) \cdot (U_0, \dot{U}_0, P) = (U_0, \dot{U}_0, U(T), U_t(T))$ , where  $U$  is the weak solution of

$$(2.14) \quad \begin{cases} U_{tt} + U_{xxxx} + p(t)U_{xx} + P(t)u_{xx} = 0, x \in (0, 1), t \in [0, T], \\ U = U_x = 0 \text{ at } x = 0, 1, \\ U(0, x) = U_0(x), \\ U_t(0, x) = \dot{U}_0(x), \end{cases}$$

and  $u$  is the weak solution of

$$(2.15) \quad \begin{cases} u_{tt} + u_{xxxx} + p(t)u_{xx} = 0, x \in (0, 1), t \in [0, T], \\ u = u_x = 0 \text{ at } x = 0, 1, \\ u(0, x) = u_0(x), \\ u_t(0, x) = \dot{u}_0(x). \end{cases}$$

*Proof of Proposition 5.* By using Propositions 1, 2, and 3 we see that  $\Phi_T : E_a \rightarrow F_a$  is continuous for  $a = 2, 4, 6$ . Let us prove that  $\Phi_T : E_2 \rightarrow F_2$  is  $C^1$  (the cases  $a =$

4, 6, 8 can be treated in the same way). Let  $(u_0, \dot{u}_0, p), (U_0, \dot{U}_0, P) \in E_2$ ,  $u$  be the weak solutions of (2.15),  $U$  be the weak solutions of (2.14), and  $\tilde{u}$  be the weak solution of

$$\begin{cases} \tilde{u}_{tt} + \tilde{u}_{xxxx} + (p + P)(t)\tilde{u}_{xx} = 0, x \in (0, 1), t \in [0, T], \\ \tilde{u} = \tilde{u}_x = 0 \text{ at } x = 0, 1, \\ \tilde{u}(0, x) = (u_0 + U_0)(x), \\ \tilde{u}_t(0, x) = (\dot{u}_0 + \dot{U}_0)(x). \end{cases}$$

Then  $\Delta := \tilde{u} - u - U$  is the weak solution of

$$\begin{cases} \Delta_{tt} + \Delta_{xxxx} + p(t)\Delta_{xx} + P(t)(\tilde{u} - u)_{xx} = 0, x \in (0, 1), t \in [0, T], \\ \Delta = \Delta_x = 0 \text{ at } x = 0, 1, \\ \Delta(0, x) = 0, \\ \Delta_t(0, x) = 0. \end{cases}$$

Thus, Proposition 1 gives

$$(2.16) \quad \begin{aligned} \|\Delta(T)\|_{H_0^2} + \|\Delta_t(T)\|_{L^2} &\leq \|P(t)(\tilde{u} - u)_{xx}\|_{L^1((0,T),L^2)} e^{\|p\|_{L^1}} \\ &\leq C\|P\|_{L^1}\|\tilde{u} - u\|_{C^0([0,T],H^2)}. \end{aligned}$$

Moreover,  $\tilde{u} - u$  is the weak solution of

$$\begin{cases} (\tilde{u} - u)_{tt} + (\tilde{u} - u)_{xxxx} + p(t)(\tilde{u} - u)_{xx} + P(t)\tilde{u}_{xx} = 0, x \in (0, 1), t \in [0, T], \\ \tilde{u} - u = (\tilde{u} - u)_x = 0 \text{ at } x = 0, 1, \\ (\tilde{u} - u)(0, x) = U_0(x), \\ (\tilde{u} - u)_t(0, x) = \dot{U}_0(x). \end{cases}$$

Thus, Proposition 1 gives

$$(2.17) \quad \|\tilde{u} - u\|_{C^0([0,T],H^2)} \leq \left( \|(U_0, \dot{U}_0)\|_{H^2 \times L^2} + \|P\|_{L^1} \|\tilde{u}_{xx}\|_{C^0([0,T],L^2)} \right) e^{\|p\|_{L^1}}.$$

Again, thanks to Proposition 1, we have

$$(2.18) \quad \|\tilde{u}\|_{C^0([0,T],H^2)} \leq \|(u_0 + U_0, \dot{u}_0 + \dot{U}_0)\|_{H^2 \times L^2} e^{\|p+P\|_{L^1}}.$$

Therefore, by using (2.16), (2.17), and (2.18), we get

$$\|\Delta(T)\|_{H_0^2} + \|\Delta_t(T)\|_{L^2} = o\left(\|(U_0, \dot{U}_0, P)\|_{E_2}\right)$$

when  $\|(U_0, \dot{U}_0, P)\|_{E_2} \rightarrow 0$ . This proves that  $\Phi_T$  is differentiable at  $(u_0, \dot{u}_0, p)$  and that

$$d\Phi_T(u_0, \dot{u}_0, p).(U_0, \dot{U}_0, P) = (U_0, \dot{U}_0, U(T), U_t(T)).$$

The continuity of the map

$$\begin{aligned} E_2 &\rightarrow \mathcal{L}(E_2, F_2) \\ (u_0, \dot{u}_0, p) &\mapsto d\Phi_T(u_0, \dot{u}_0, p) \end{aligned}$$

is a consequence of the estimate (2.3).  $\square$

### 3. Controllability of the linearized system around $(u^{ref}, \dot{u}^{ref}, p \equiv 0)$ .

The aim of this section is the proof of Theorem 3. First, in subsection 3.1, we prove some preliminary results, mainly about the eigenvalues and the eigenvectors of the operator  $A$  defined by (1.1). The reading of the proofs in this subsection is not necessary for the understanding of the next sections. Then, in subsection 3.2, we prove Theorem 3.

### 3.1. Preliminaries.

PROPOSITION 6. *The eigenvalues  $(\lambda_n)_{n \in \mathbb{N}^*}$  of the operator  $A$  are the numbers*

$$(3.1) \quad \lambda_n = \nu_n^4,$$

where  $(\nu_n)_{n \in \mathbb{N}^*}$  is the increasing sequence of positive solutions of the equation

$$(3.2) \quad \cos(\nu_n) \cosh(\nu_n) = 1.$$

We have, for every  $k \in \mathbb{N}^*$ ,

$$(3.3) \quad \nu_{2k-1} \in (2k\pi - \pi/2, 2k\pi - \pi/4), \quad \nu_{2k} \in (2k\pi + \pi/4, 2k\pi + \pi/2).$$

We have, for every  $n \in \mathbb{N}^*$ ,

$$(3.4) \quad \nu_n = \frac{\pi}{2}(2n+1) - (-1)^n x_n, \text{ where } 0 < x_n < \frac{\pi}{2 \cosh(\nu_n)},$$

$$(3.5) \quad \left| \sqrt{\lambda_n} - \frac{\pi^2}{4} K_n \right| < \frac{\pi^2}{16},$$

where, for every  $n \in \mathbb{N}^*$ ,

$$(3.6) \quad K_n := (2n+1)^2.$$

For every  $n \in \mathbb{N}^*$ , the function

$$(3.7) \quad v_n := \xi_n(\cos(\nu_n x) - \cosh(\nu_n x)) + \zeta_n(\sin(\nu_n x) - \sinh(\nu_n x)),$$

where

$$(3.8) \quad \xi_n := \sin(\nu_n) - \sinh(\nu_n), \quad \zeta_n := -\cos(\nu_n) + \cosh(\nu_n),$$

is an eigenvector of  $A$  associated to the eigenvalue  $\lambda_n$  and satisfies

$$(3.9) \quad v_n(1-x) = (-1)^n v_n(x).$$

Moreover, there exists a constant  $C \in \mathbb{R}^*$  such that, when  $n \rightarrow +\infty$ ,

$$(3.10) \quad \|v_n\|_{L^2((0,1),\mathbb{R})} \sim C e^{\nu_n}.$$

*Proof of Proposition 6.* The relation (3.2) comes from the condition  $v = v' = 0$  on  $x = 0, 1$  imposed on any eigenvector  $v$  of the operator  $A$ . The intermediate values theorem gives (3.3). Equation (3.2) provides, for every  $n \in \mathbb{N}^*$ ,

$$(3.11) \quad \sin(x_n) \cosh(\nu_n) = 1,$$

which gives (3.4) thanks to the convexity inequality

$$(3.12) \quad x \leq \frac{\pi}{2} \sin(x) \quad \forall x \in [0, \pi/2].$$

For every  $n \in \mathbb{N}^*$ , we have

$$\sqrt{\lambda_n} - \frac{\pi^2}{4} K_n = \pi(2n+1)x_n - (-1)^n x_n^2.$$

Thus, we just need to justify that, for every  $n \in \mathbb{N}^*$ ,

$$\frac{2(2n+1)}{\cosh \nu_n} + \frac{1}{\cosh(\nu_n)^2} < \frac{1}{4}.$$

This can be proved for  $n = 1$  by using  $\nu_1 > 3\pi/2$  and for  $n \geq 2$  by using  $\nu_n \geq n\pi$ . The property (3.9) comes from the explicit expression (3.7) together with (3.2) and the relation  $\sin(\nu_n) = (-1)^n \sqrt{1 - \cos(\nu_n)^2}$ , which is a consequence of (3.3). By using (3.7) and a change of variable, we get

$$\int_0^1 v_n(x)^2 dx = \frac{\xi_n^2}{\nu_n} I_1(\nu_n) + \frac{\zeta_n^2}{\nu_n} I_2(\nu_n) + \frac{2\xi_n \zeta_n}{\nu_n} I_3(\nu_n),$$

where

$$\begin{aligned} I_1(\nu) &:= \int_0^\nu [\cos(y) - \cosh(y)]^2 dy \\ &= \frac{\sinh(2\nu)}{4} + \nu - \sin(\nu) \cosh(\nu) - \cos(\nu) \sinh(\nu) + \frac{\sin(2\nu)}{4}, \\ I_2(\nu) &:= \int_0^\nu [\sin(y) - \sinh(y)]^2 dy \\ &= \frac{\sinh(2\nu)}{4} - \sin(\nu) \cosh(\nu) + \cos(\nu) \sinh(\nu) - \frac{\sin(2\nu)}{4}, \\ I_3(\nu) &:= \int_0^\nu [\cos(y) - \cosh(y)][\sin(y) - \sinh(y)] dy \\ &= \frac{\cosh(2\nu)}{4} - \sin(\nu) \sinh(\nu) - \frac{\cos(2\nu)}{4}. \end{aligned}$$

By using the following behaviors, when  $n \rightarrow +\infty$ ,

$$(3.13) \quad \begin{aligned} \cos(\nu_n) &= O(e^{-\nu_n}), & \sin(\nu_n) &= (-1)^n + O(e^{-2\nu_n}), \\ \sin(2\nu_n) &= O(e^{-\nu_n}), & \cos(2\nu_n) &= -1 + O(e^{-2\nu_n}), \end{aligned}$$

which are consequences of (3.4), we get

$$\int_0^1 v_n(x)^2 dx \sim C e^{2\nu_n}. \quad \square$$

The orthonormal basis  $(\varphi_n)_{n \in \mathbb{N}^*}$  of  $L^2((0,1), \mathbb{R})$  made of eigenvectors of  $A$  has been introduced in section 1.1. Up to a change of sign, one may assume that

$$(3.14) \quad \varphi_n = \frac{v_n}{\|v_n\|_{L^2((0,1), \mathbb{R})}}.$$

This equality will be assumed in the remainder of this article.

**PROPOSITION 7.** *Let  $m \in \mathbb{N}^*$ . For every  $n \in \mathbb{N}^*$ , we have*

$$(3.15) \quad \langle \varphi_m'', \varphi_n \rangle \neq 0 \text{ iff } m \text{ and } n \text{ have the same parity.}$$

Moreover, there exists a constant  $C_m$  such that, when  $n$  tends to  $+\infty$  with the same parity as  $m$ ,

$$(3.16) \quad \langle \varphi_m'', \varphi_n \rangle \sim \frac{C_m}{n}.$$

*Proof of Proposition 7.* When  $m$  and  $n$  have different parities, the equality  $\langle \varphi_m'', \varphi_n \rangle = 0$  comes from (3.14) and (3.9). We have

$$\langle \varphi_m'', \varphi_m \rangle = - \int_0^1 |\varphi_m'(x)|^2 dx < 0.$$

Let  $n \in \mathbb{N}^*$  with the same parity as  $m$  and different from  $m$ . Thanks to integrations by parts and (3.9), we get

$$(\lambda_n - \lambda_m) \langle v_m'', v_n \rangle = 2(v_m''' v_n'' - v_m'' v_n''')(0).$$

The explicit expression (3.7) leads to

$$(3.17) \quad (\lambda_n - \lambda_m) \langle v_m'', v_n \rangle = 8\nu_m^2 \nu_n^2 (-\xi_m \nu_n \zeta_n + \zeta_m \nu_m \xi_n).$$

The function  $f : \mathbb{R}_+ \rightarrow \mathbb{R}$  defined by

$$f(x) := \frac{\sinh(x) - \sin(x)}{x(\cosh(x) - \cos(x))}$$

decreases on  $\mathbb{R}_+$ . If  $n < m$  (resp.,  $n > m$ ), the inequality  $f(\nu_n) > f(\nu_m)$  (resp.,  $f(\nu_n) < f(\nu_m)$ ) provides  $-\xi_m \nu_n \zeta_n + \zeta_m \nu_m \xi_n < 0$  (resp.,  $> 0$ ). Thus  $\langle v_m'', v_n \rangle \neq 0$ . Thanks to (3.8), we get

$$(3.18) \quad \langle v_m'', v_n \rangle \sim -\frac{4\nu_m^2 \xi_m}{\nu_n} e^{\nu_n} \text{ when } n \rightarrow +\infty, \text{ with the same parity as } m,$$

which together with (3.10) gives the asymptotic behavior (3.16).  $\square$

At this step, one can justify the following property, claimed in section 1.2.

**PROPOSITION 8.** *The operator  $\mathcal{A}$  defined by (1.7) and (1.1) does not generate a  $C^0$ -semigroup of bounded operators of  $\bar{X} := H_{(0)}^3 \times H^1((0, 1), \mathbb{R})$ .*

*Proof of Proposition 8.* We argue by contradiction. Let us assume that  $\mathcal{A}$  generates a  $C^0$ -semigroup of bounded operators of  $\bar{X}$ . Then there exists  $m > 0$  such that, for every  $t \in [0, 1]$ , for every  $(u_0, \dot{u}_0) \in H_{(0)}^3 \times H^1((0, 1), \mathbb{R})$ ,

$$e^{-t\mathcal{A}} \begin{pmatrix} u_0 \\ \dot{u}_0 \end{pmatrix} \in H_{(0)}^3 \times H^1((0, 1), \mathbb{R})$$

and

$$(3.19) \quad \left\| e^{-t\mathcal{A}} \begin{pmatrix} u_0 \\ \dot{u}_0 \end{pmatrix} \right\|_{H_{(0)}^3 \times H^1} \leq m \|(u_0, \dot{u}_0)\|_{H_{(0)}^3 \times H^1}.$$

Let us consider  $(u_0, \dot{u}_0) \in H_{(0)}^3 \times H^1((0, 1), \mathbb{R})$  defined by  $u_0 := 0$  and  $\dot{u}_0 := \varphi_1''$ . By using (2.1), we get

$$e^{-t\mathcal{A}} \begin{pmatrix} u_0 \\ \dot{u}_0 \end{pmatrix} = \begin{pmatrix} \sum_{k=1}^{\infty} \frac{1}{\sqrt{\lambda_k}} \langle \varphi_1'', \varphi_k \rangle \sin(\sqrt{\lambda_k} t) \varphi_k \\ \sum_{k=1}^{\infty} \langle \varphi_1'', \varphi_k \rangle \cos(\sqrt{\lambda_k} t) \varphi_k \end{pmatrix}.$$

Thanks to (3.19), the  $H_{(0)}^3((0, 1), \mathbb{R})$ -norm of the first component of the right-hand side is bounded by  $m\|\varphi_1''\|_{H^1}$  for every  $t \in [0, 1]$ ; i.e., (see (1.3) for the definition of the  $H_{(0)}^3((0, 1), \mathbb{R})$ -norm)

$$(3.20) \quad \sum_{k=1}^{\infty} |\lambda_k^{1/4} \langle \varphi_1'', \varphi_k \rangle \sin(\sqrt{\lambda_k} t)|^2 \leq m^2 \|\varphi_1''\|_{H^1}^2 \quad \forall t \in [0, 1].$$

Thanks to (3.1), (3.3), and Proposition 7, there exists an odd integer  $N_0 \in \mathbb{N}^*$  and  $C_0 > 0$  such that

$$(3.21) \quad |\lambda_k^{1/4} \langle \varphi_1'', \varphi_k \rangle|^2 \geq C_0 \quad \forall k \geq N_0, k \text{ odd}.$$

Thus, (3.20) and (3.21) imply

$$(3.22) \quad C_0 \sum_{k=N_0, k \text{ odd}}^{\infty} |\sin(\sqrt{\lambda_k} t)|^2 \leq m^2 \|\varphi_1''\|_{H^1}^2 \quad \forall t \in [0, 1].$$

Let  $N \in \mathbb{N}^*$  be such that  $N \geq N_0$  and  $\pi/(2\sqrt{\lambda_N}) \leq 1$ . Let  $t_N := \pi/(2\sqrt{\lambda_N})$ . For every  $k \in \mathbb{N}^*$ , odd with  $N_0 \leq k \leq N$ , we have  $\sqrt{\lambda_k} t_N \in (0, \pi/2)$ , and thus  $\sin(\sqrt{\lambda_k} t_N) \geq (2/\pi)\sqrt{\lambda_k} t_N$ . We also have  $t_N \in [0, 1]$ , so we deduce from (3.22) that

$$\frac{1}{2} C_0 \left( \frac{2}{\pi} \right)^2 \sum_{k=N_0}^N \lambda_k t_N^2 \leq m^2 \|\varphi_1''\|_{H^1}^2.$$

Thanks to (3.1), (3.3), and the definition of  $t_N$ , there exists  $C_1 > 0$  such that

$$\sum_{k=N_0}^N \lambda_k t_N^2 \geq \frac{C_1}{N^4} \sum_{k=N_0}^N k^4 \geq \frac{C_1}{N^4} \int_{N_0}^N x^4 dx \geq \frac{C_1}{5N^4} (N^5 - N_0^5).$$

We have proved that, for every  $N \in \mathbb{N}^*$  such that  $N \geq N_0$  and  $\pi/(2\sqrt{\lambda_N}) \leq 1$ , the following inequality holds:

$$\frac{1}{2} C_0 \left( \frac{2}{\pi} \right)^2 \frac{C_1}{5N^4} (N^5 - N_0^5) \leq m^2 \|\varphi_1''\|_{H^1}^2.$$

We get a contradiction by considering large enough  $N$ .  $\square$

LEMMA 1. *The frequencies*

$$0, 2\sqrt{\lambda_2}, 2\sqrt{\lambda_3}, \sqrt{\lambda_3} \pm \sqrt{\lambda_1}, \sqrt{\lambda_4} \pm \sqrt{\lambda_2}, \sqrt{\lambda_{2k}} \pm \sqrt{\lambda_2}, \sqrt{\lambda_{2k-1}} \pm \sqrt{\lambda_3}$$

for  $k \in \mathbb{N}^*, k \geq 3$ ,

are all different.

*Proof of Lemma 1.* First, we claim that the nonnegative integers

$$0, 2K_2, 2K_3, K_3 \pm K_1, K_4 \pm K_2, K_{2k-1} \pm K_3, K_{2k} \pm K_2 \text{ for } k \in \mathbb{N}^*, k \geq 3,$$

where  $K_n$  is defined by (3.6), are all different. First, for every  $k \geq 5$ , we have

$$K_{2k-1} + K_3 < K_{2k} - K_2 < K_{2k} + K_2 < K_{2k+1} - K_3.$$

Indeed, for  $k \geq 5$ , we have

$$\begin{aligned} (K_{2k} - K_2) - (K_{2k-1} + K_3) &= (4k+1)^2 - (4k-1)^2 - 25 - 49 \geq 16k - 74 \geq 6, \\ (K_{2k+1} - K_3) - (K_{2k} + K_2) &= (4k+3)^2 - (4k+1)^2 - 25 - 49 \geq 16k - 66 \geq 14. \end{aligned}$$

Moreover, we have

$$\begin{aligned} 2K_2 &= 50, & 2K_3 &= 98, & K_3 - K_1 &= 40, & K_3 + K_1 &= 58, \\ K_4 - K_2 &= 56, & K_4 + K_2 &= 106, & K_5 - K_3 &= 72, & K_5 + K_3 &= 170, \\ K_6 - K_2 &= 144, & K_6 + K_2 &= 194, & K_7 - K_3 &= 176, & K_7 + K_3 &= 274, \\ K_8 - K_2 &= 264, & K_8 + K_2 &= 314, & K_9 - K_3 &= 312, & & \end{aligned}$$

and thus the claim is proved. We deduce Lemma 1 from the previous result and the inequality (3.5).  $\square$

### 3.2. Proof of Theorem 3.

*Proof of statement (1) of Theorem 3.* Since the system  $(\Sigma_l^{ref})$  is linear and  $e^{-T\mathcal{A}}$  is a bounded operator of  $H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$ , it is sufficient to prove Theorem 3 with  $U_0 = \dot{U}_0 = 0$ .

Let  $T > 0$  and  $U$  be a solution of  $(\Sigma_l^{ref})$  for some  $P \in L^2((0, T), \mathbb{R})$ , with  $U(0) = \dot{U}(0) = 0$ . Then  $(U, U_t) \in C^0([0, T], H_0^2 \times L^2((0, 1), \mathbb{R}))$ . The family  $(\varphi_k)_{k \in \mathbb{N}^*}$  is an orthonormal basis of  $L^2((0, 1), \mathbb{R})$ , and thus, for every  $t \in [0, T]$ ,

$$U(t) = \sum_{k=1}^{\infty} x_k(t) \varphi_k, \text{ where } x_k(t) := \int_0^1 U(t, x) \varphi_k(x) dx.$$

By recalling that  $u^{ref}$  is given by (1.5), the partial differential equation satisfied by  $U$  provides, for every  $k \in \mathbb{N}^*$ , the following explicit expression:

$$x_k(t) = -\frac{1}{\sqrt{\lambda_k}} \int_0^t P(\tau) [b_k \sin(\sqrt{\lambda_2} \tau) + c_k \sin(\sqrt{\lambda_3} \tau)] \sin[\sqrt{\lambda_k}(t - \tau)] d\tau,$$

where, for every  $k \in \mathbb{N}^*$ ,

$$b_k := \langle \varphi_2'', \varphi_k \rangle, \quad c_k := \langle \varphi_3'', \varphi_k \rangle.$$

The equality  $(U(T), \dot{U}(T)) = (U_T, \dot{U}_T)$  is equivalent to

$$(3.23) \quad \begin{aligned} & \int_0^T P(t) [b_k \sin(\sqrt{\lambda_2} t) + c_k \sin(\sqrt{\lambda_3} t)] e^{-i\sqrt{\lambda_k} t} dt \\ &= -e^{-i\sqrt{\lambda_k} T} \left( \langle \dot{U}_T, \varphi_k \rangle + i\sqrt{\lambda_k} \langle U_T, \varphi_k \rangle \right) \quad \forall k \in \mathbb{N}^*. \end{aligned}$$

Thanks to Proposition 7, the equality (3.23) is satisfied if  $P$  solves the following moment problem:

$$(3.24) \quad \begin{cases} \int_0^T P(t) \sin(\sqrt{\lambda_3} t) e^{-i\sqrt{\lambda_{2k-1}} t} dt = d_{2k-1}(U_T, \dot{U}_T) \quad \forall k \in \mathbb{N}^*, \\ \int_0^T P(t) \sin(\sqrt{\lambda_2} t) e^{-i\sqrt{\lambda_{2k}} t} dt = d_{2k}(U_T, \dot{U}_T) \quad \forall k \in \mathbb{N}^*, \end{cases}$$

where, for every  $k \in \mathbb{N}^*$ ,

$$\begin{aligned} d_{2k-1}(U_T, \dot{U}_T) &:= -\frac{e^{-i\sqrt{\lambda_{2k-1}} T}}{c_{2k-1}} \left( \langle \dot{U}_T, \varphi_{2k-1} \rangle + i\sqrt{\lambda_{2k-1}} \langle U_T, \varphi_{2k-1} \rangle \right), \\ d_{2k}(U_T, \dot{U}_T) &:= -\frac{e^{-i\sqrt{\lambda_{2k}} T}}{b_{2k}} \left( \langle \dot{U}_T, \varphi_{2k} \rangle + i\sqrt{\lambda_{2k}} \langle U_T, \varphi_{2k} \rangle \right). \end{aligned}$$

The moment problem (3.24) is satisfied, in particular, when

$$(3.25) \quad \begin{cases} \int_0^T P(t) dt = 0, \\ \int_0^T P(t) e^{-i2\sqrt{\lambda_3} t} dt = -2id_3, \\ \int_0^T P(t) e^{i(-\sqrt{\lambda_{2k-1}} \pm \sqrt{\lambda_3}) t} dt = \pm id_{2k-1}(U_T, \dot{U}_T) \quad \forall k \in \mathbb{N}^*, k \neq 2, \\ \int_0^T P(t) e^{-i2\sqrt{\lambda_2} t} dt = -2id_2, \\ \int_0^T P(t) e^{i(-\sqrt{\lambda_{2k}} \pm \sqrt{\lambda_2}) t} dt = \pm id_{2k}(U_T, \dot{U}_T) \quad \forall k \in \mathbb{N}^*, k \neq 1. \end{cases}$$

Let  $(\omega_n)_{n \in \mathbb{N}}$  be the nondecreasing sequence of the frequencies appearing in the previous moment problem, written in the following way:

$$\int_0^T P(t) e^{i\omega_n t} dt = \delta_n \quad \forall n \in \mathbb{N}.$$

For large enough indexes, the successive terms of the sequence  $(\omega_n)_{n \in \mathbb{N}}$  are

$$\sqrt{\lambda_{2k-1}} - \sqrt{\lambda_3} < \sqrt{\lambda_{2k-1}} + \sqrt{\lambda_3} < \sqrt{\lambda_{2k}} - \sqrt{\lambda_2} < \sqrt{\lambda_{2k}} + \sqrt{\lambda_2} < \sqrt{\lambda_{2k+1}} - \sqrt{\lambda_3} < \dots.$$

The gap between the first and the second terms (resp., the third and the fourth terms) is  $2\sqrt{\lambda_3}$  (resp.,  $2\sqrt{\lambda_2}$ ). The gap between the second and the third terms (resp., the fourth and the fifth terms) tends to  $+\infty$  when  $k \rightarrow +\infty$ ; indeed, by using (3.1) and (3.3), we have

$$\begin{aligned} (\sqrt{\lambda_{2k}} - \sqrt{\lambda_2}) - (\sqrt{\lambda_{2k-1}} + \sqrt{\lambda_3}) &= \nu_{2k}^2 - \nu_{2k-1}^2 - \nu_2^2 - \nu_3^2 \\ &= (\nu_{2k} - \nu_{2k-1})(\nu_{2k} + \nu_{2k-1}) - \nu_2^2 - \nu_3^2 \\ &\geq \frac{\pi}{2} \left( 4k\pi - \frac{\pi}{4} \right) - \nu_2^2 - \nu_3^2, \\ (\sqrt{\lambda_{2k+1}} - \sqrt{\lambda_3}) - (\sqrt{\lambda_{2k}} + \sqrt{\lambda_2}) &= \nu_{2k+1}^2 - \nu_{2k}^2 - \nu_2^2 - \nu_3^2 \\ &= (\nu_{2k+1} - \nu_{2k})(\nu_{2k+1} + \nu_{2k}) - \nu_2^2 - \nu_3^2 \\ &\geq \pi \left( 4k\pi + \frac{7\pi}{4} \right) - \nu_2^2 - \nu_3^4. \end{aligned}$$

Thus,

$$\liminf_{n \rightarrow +\infty} (\omega_{n+1} - \omega_n) = 2\sqrt{\lambda_2}.$$

The frequencies appearing in (3.25) are all different (see Lemma 1), and thus the moment problem (3.25) has a solution  $P \in L^2((0, T), \mathbb{R})$  when  $T > \pi/\sqrt{\lambda_2}$  and  $(d_n(U_T, \dot{U}_T))_{n \in \mathbb{N}^*}$  belongs to  $l^2(\mathbb{N}^*, \mathbb{C})$  (see [22, Chap. 1.2]). Thanks to (3.16), the assumption that  $(U_T, \dot{U}_T) \in H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$  guarantees that  $(d_n(U_T, \dot{U}_T))_{n \in \mathbb{N}^*}$  belongs to  $l^2(\mathbb{N}^*, \mathbb{C})$ .  $\square$

*Proof of statement (2) of Theorem 3.* We assume that the system  $(\Sigma_l^{ref})$  is controllable in  $H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$  with control functions in  $H^1((0, T), \mathbb{R})$ . Thanks to the equivalence between the controllability of  $(\Sigma_l^{ref})$  and the solvability of the moment problem (3.24), we deduce that, for every  $d = (d_k)_{k \in \mathbb{N}^*} \in l^2(\mathbb{N}^*, \mathbb{C})$ , there exists  $P \in H^1((0, T), \mathbb{R})$  such that

$$(3.26) \quad \int_0^T P(t) \sin(\sqrt{\lambda_3} t) e^{-i\sqrt{\lambda_{2k-1}} t} dt = d_k \quad \forall k \in \mathbb{N}^*.$$

However, thanks to (3.1) and (3.3), for any  $P \in H^1((0, T), \mathbb{R})$ , an integration by parts shows that

$$\left| \int_0^T P(t) \sin(\sqrt{\lambda_3} t) e^{-i\sqrt{\lambda_{2k-1}} t} dt \right| \leq \frac{C}{k^2} \|P\|_{H^1((0, T), \mathbb{R})}.$$

Thus, for every  $d = (d_k)_{k \in \mathbb{N}^*} \in l^2(\mathbb{N}^*, \mathbb{C})$ , there exists  $C > 0$  such that

$$|d_k| \leq \frac{C}{k^2}.$$

We get a contradiction by considering, for example,  $d_k = 1/k$ . Therefore, the system  $(\Sigma_l^{ref})$  is not controllable in  $H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$  with control functions in  $H^1((0, T), \mathbb{R})$ .

We assume that the system  $(\Sigma_l^{ref})$  is controllable in  $H_0^2 \times L^2((0, 1), \mathbb{R})$  with control functions in  $L^2((0, T), \mathbb{R})$ . Then, for every  $d = (d_k)_{k \in \mathbb{N}^*} \in h^{-1}(\mathbb{N}^*, \mathbb{C})$ , i.e.,

$$\sum_{k=1}^{\infty} \left| \frac{1}{k} d_k \right|^2 < \infty,$$

there exists  $P \in L^2((0, T), \mathbb{R})$  such that (3.26) holds. However, for any  $P \in L^2((0, T), \mathbb{R})$ , the Cauchy–Schwarz inequality shows that

$$\left| \int_0^T P(t) \sin(\sqrt{\lambda_3} t) e^{-i\sqrt{\lambda_{2k-1}} t} dt \right| \leq \sqrt{T} \|P\|_{L^2((0, T), \mathbb{R})}.$$

Thus, for every  $d \in h^{-1}(\mathbb{N}^*, \mathbb{C})$ , there exists  $C > 0$  such that  $|d_k| \leq C$  for every  $k \in \mathbb{N}^*$ . We get a contradiction by considering, for example,  $d_k = k^{1/4}$ . Therefore, the system  $(\Sigma_l^{ref})$  is not controllable in  $H_0^2 \times L^2((0, 1), \mathbb{R})$  with control functions in  $L^2((0, T), \mathbb{R})$ .  $\square$

**4. Why the inverse mapping theorem does not apply.** As we have seen in Proposition 5, for every  $T > 0$ , the map  $\Phi_T$  defined by (1.8) is  $C^1$  between the following spaces:

$$H_0^2((0, 1), \mathbb{R}) \times L^2((0, 1), \mathbb{R}) \times L^2((0, T), \mathbb{R}) \rightarrow H_0^2 \times L^2 \times H_0^2 \times L^2((0, 1), \mathbb{R}).$$

In the same way we proved that  $\Phi_T$  is  $C^1$  from  $H_{(0)}^4((0, 1), \mathbb{R}) \times H_{(0)}^2((0, 1), \mathbb{R}) \times H^1((0, T), \mathbb{R})$  to  $H_{(0)}^4 \times H_{(0)}^2 \times H_{(0)}^4 \times H_{(0)}^2((0, 1), \mathbb{R})$ , one can prove that  $\Phi_T$  is  $C^1$  between the following spaces:

$$H_{(0)}^3((0, 1), \mathbb{R}) \times H_0^1((0, 1), \mathbb{R}) \times H^1((0, T), \mathbb{R}) \rightarrow H_{(0)}^3 \times H_0^1 \times H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R}).$$

Thus, in order to apply the inverse mapping theorem on the map  $\Phi_T$ , one needs to prove the surjectivity of  $d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0)$

- from  $H_0^2((0, 1), \mathbb{R}) \times L^2((0, 1), \mathbb{R}) \times L^2((0, T), \mathbb{R})$  to  $H_0^2 \times L^2 \times H_0^2 \times L^2((0, 1), \mathbb{R})$
- or from  $H_{(0)}^3((0, 1), \mathbb{R}) \times H_0^1((0, 1), \mathbb{R}) \times H^1((0, T), \mathbb{R})$  to  $H_{(0)}^3 \times H_0^1 \times H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R})$ .

It means that one needs to prove the controllability of the linear system  $(\Sigma_l^{ref})$

- in  $H_0^2 \times L^2$  with controls in  $L^2$
- or in  $H_{(0)}^3 \times H_0^1$  with controls in  $H^1$ .

However, as seen in statement (2) of Theorem 3, this is impossible. Thus the inverse mapping theorem cannot be applied with these spaces.

Let us emphasize that the inverse mapping theorem could be applied if we could prove that the map  $\Phi_T$  is well-defined and  $C^1$  between the following spaces:

$$H_{(0)}^3((0, 1), \mathbb{R}) \times H_0^1((0, 1), \mathbb{R}) \times L^2((0, T), \mathbb{R}) \rightarrow H_{(0)}^3 \times H_0^1 \times H_{(0)}^3 \times H_0^1((0, 1), \mathbb{R}).$$

With further developments, one can prove that the map  $\Phi_T$  is well-defined between these spaces but it is not  $C^1$ . Thus, we have the same pathology as in [8], [3], [4], [2]. The strategy developed in this article to solve this pathology is different from the one of [8] and similar to the one of [3], [4], [2].

**5. The Nash–Moser theorem used.** In order to get local controllability for the nonlinear system  $(\Sigma)$  around  $(u^{ref}, \dot{u}^{ref}, p \equiv 0)$ , we use a Nash–Moser theorem given by Hörmander in [20]. In this section, we recall the context and the statement of this theorem. We repeat the proof in order to justify that, in our situation, we need only a finite number of bounds on the right inverse of the differential map.

We consider a family of Hilbert spaces  $(E_a)_{a \in [2,8]}$  with continuous injections  $E_b \rightarrow E_a$  of norm  $\leq 1$  when  $b \geq a$ . We suppose that we have linear operators  $S_\theta : E_2 \rightarrow E_8$  for  $\theta \geq 1$ . We also assume that there exists a constant  $K > 0$  such that, for every  $a, b \in [2, 8]$  and for every  $u \in E_a$ ,

$$(5.1) \quad \|S_\theta u\|_b \leq K \|u\|_a \text{ when } b \leq a,$$

$$(5.2) \quad \|S_\theta u\|_b \leq K \theta^{b-a} \|u\|_a \text{ when } b > a,$$

$$(5.3) \quad \|u - S_\theta u\|_b \leq K \theta^{b-a} \|u\|_a \text{ when } b < a,$$

$$(5.4) \quad \left\| \frac{d}{d\theta} S_\theta u \right\|_b \leq K \theta^{b-a-1} \|u\|_a.$$

We fix a sequence  $(\theta_j)_{j \in \mathbb{N}}$  of the form  $\theta_j := (j+1)^\delta$  where  $0 < \delta$ , and we set, for every  $j \in \mathbb{N}$ ,  $\Delta_j := \theta_{j+1} - \theta_j$ . For every  $u \in E_a$ , we have a decomposition

$$u = \sum_{j=0}^{\infty} \Delta_j R_j u$$

with convergence in  $E_b$  when  $b < a$ , where

$$R_j u := \frac{1}{\Delta_j} (S_{\theta_{j+1}} - S_{\theta_j}) u \text{ if } j > 0 \text{ and } R_0 u := \frac{1}{\Delta_0} S_{\theta_1} u.$$

Moreover there exists a constant  $K'$  such that, for every  $b \in [2, 8]$ ,

$$\|R_j u\|_b \leq K' \theta_j^{b-a-1} \|u\|_a.$$

From (5.2) and (5.3), we get the logarithmic convexity of the norms: There exists a constant  $c \geq 1$  such that, for every  $a, b \in [2, 8]$  with  $a < b$ ,  $\lambda \in [0, 1]$ , and  $u \in E_b$ ,

$$(5.5) \quad \|u\|_{\lambda a + (1-\lambda)b} \leq c \|u\|_a^\lambda \|u\|_b^{1-\lambda}.$$

We refer to [20] for the proof of the two previous properties.

We have another family  $(F_a)_{a \in [2,8]}$  with the same properties as above, and we use the same notations for the smoothing operators. Moreover, we assume that the injection  $F_b \rightarrow F_a$  is compact when  $b > a$ .

**THEOREM 4.** *Let  $\beta$  be a real number such that*

$$5 < \beta < 6.$$

*Let  $V$  be a  $E_4$ -neighborhood of zero and  $\Phi$  a map from  $V$  to  $F_4$  which is twice differentiable and satisfies*

$$(5.6) \quad \|\Phi''(u; v, w)\|_6 \leq C \sum (1 + \|u\|_m) \|v\|_{m'} \|w\|_{m''},$$

where the sum is taken over the following values:

$m$	$m'$	$m''$
6	2	2
4	6	2
4	2	6

We assume that  $\Phi : E_4 \rightarrow F_4$  is continuous for every  $a \in [2, 8]$ . We assume that, for every  $v \in V \cap E_8$ ,  $\Phi'(v)$  has a right inverse  $\psi(v) : F_7 \rightarrow E_6$ , that  $(v, g) \mapsto \psi(v, g)$  is continuous from  $(V \cap E_6) \times F_7 \rightarrow E_6$ , and that there exists a constant  $C$  such that, for every  $(v, g) \in (V \cap E_6) \times F_7$ ,

$$(5.7) \quad \|\psi(v)g\|_2 \leq C\|g\|_3,$$

$$(5.8) \quad \|\psi(v)g\|_6 \leq C[\|g\|_7 + \|v\|_8\|g\|_3].$$

Then, for every  $f \in F_\beta$  with a sufficiently small norm, there exists  $u \in E_4$  such that  $\Phi(u) = \Phi(0) + f$ .

*Remark 2.* The differences between the previous statement and Hörmander's statement are the following ones:

- First, here we do not use the weak spaces  $E'_a$  defined by Hörmander, which simplifies the statement a little bit;
- then, here, the number of tame estimates to be proved is finite, which is more practical for the application of the theorem.

*Proof of Theorem 4.* Let  $g \in F_\beta$ . We have a decomposition

$$(5.9) \quad g = \sum_{j=0}^{\infty} \Delta_j g_j, \text{ with } \|g_j\|_b \leq K' \|g\|_\beta \theta_j^{b-\beta-1} \quad \forall b \in [2, 8],$$

where  $g_j := R_j g$  for every  $j \in \mathbb{N}$ . We claim that, when  $\|g\|_\beta$  is small enough, we can define a sequence  $(u_j)_{j \in \mathbb{N}}$  with  $u_0 = 0$  and the recursive formula

$$u_{j+1} := u_j + \Delta_j \dot{u}_j, \quad \dot{u}_j := \psi(v_j)g_j, \quad v_j := S_{\theta_j} u_j.$$

We also claim that there exist constants  $C_1, C_2, C_3, C_4$  such that, for every  $j \in \mathbb{N}^*$ ,

$$(5.10) \quad \|\dot{u}_j\|_a \leq C_1 \|g\|_\beta \theta_j^{a-\beta} \quad \forall a \in \{2, 4, 6\},$$

$$(5.11) \quad \|u_j\|_4 \leq C_2 \|g\|_\beta \text{ and } \|u_j\|_6 \leq C_2 \|g\|_\beta \theta_j^{7-\beta},$$

$$(5.12) \quad \|v_j\|_4 \leq C_3 \|g\|_\beta, \quad \|v_j\|_a \leq C_3 \|g\|_\beta \theta_j^{a-\beta+1} \quad \forall a \in \{6, 8\},$$

$$(5.13) \quad \|u_j - v_j\|_a \leq C_4 \|g\|_\beta \theta_j^{a-\beta+1} \quad \forall a \in \{2, 4, 6\}.$$

More precisely, we prove by induction on  $k \in \mathbb{N}$  the following property:

$$\begin{aligned} \mathcal{P}_k : u_j \text{ is well-defined for } j = 0, \dots, k+1, \\ (5.10) \text{ is satisfied for } j = 0, \dots, k, \\ (5.11), (5.12), \text{ and } (5.13) \text{ are satisfied for } j = 0, \dots, k+1. \end{aligned}$$

We introduce  $r > 0$  such that, for every  $u \in E_4$ ,  $\|u\|_\alpha < r$  implies  $u \in V$ .

Property  $\mathcal{P}_0$  is obvious. Let  $k \in \mathbb{N}^*$ . We assume that property  $\mathcal{P}_{k-1}$  is satisfied. Let us prove  $\mathcal{P}_k$ .

The vector  $u_{k+1}$  is well-defined if  $v_k \in V$ . By using (5.1) and (5.10), we get

$$\|v_k\|_4 \leq KC_1 \|g\|_\beta \sum_{j=0}^{k-1} \Delta_j \theta_j^{4-\beta}.$$

Since  $\beta < 5$ , the sum

$$S := \sum_{j=0}^{\infty} \Delta_j \theta_j^{4-\beta}$$

is convergent. Therefore, when

$$\|g\|_\beta \leq \frac{r}{C_1 K S},$$

$v_k \in V$  and  $u_{k+1}$  is well-defined.

Let us prove (5.10) for  $j = k$ . By using (5.7) and (5.9), we get

$$\|\dot{u}_k\|_2 \leq CK' \|g\|_\beta \theta_k^{2-\beta}.$$

By using (5.8), (5.12), and (5.9), we get

$$\|\dot{u}_k\|_6 \leq CK' \|g\|_\beta [\theta_k^{6-\beta} + C_3 \|g\|_\beta \theta_k^{9-\beta} \theta_k^{2-\beta}] \leq 2CK' \|g\|_\beta \theta_k^{6-\beta},$$

when  $\|g\|_\beta < 1/C_3$ . The convexity of the norm (5.5) provides

$$\|\dot{u}_k\|_4 \leq c\sqrt{2}CK' \|g\|_\beta \theta_k^{4-\beta}.$$

Therefore, we have (5.10) for  $j = k$ , when  $\|g\|_\beta < 1/C_3$  for  $C_1 = \max\{2, c\sqrt{2}\}CK'$ .

Let us prove (5.11) for  $j = k + 1$ . As noticed at the beginning of the proof by induction, we have

$$\|u_{k+1}\|_4 \leq C_1 \|g\|_\beta \sum_{j=0}^k \Delta_j \theta_j^{4-\beta} \leq C_1 \|g\|_\beta S.$$

Thanks to (5.10), we have

$$\|u_{k+1}\|_6 \leq C_1 \|g\|_\beta \sum_{j=0}^k \Delta_j \theta_j^{6-\beta} \leq C_1 \|g\|_\beta \frac{\theta_{k+1}^{7-\beta}}{7-\beta}.$$

Therefore, we have (5.11) for  $j = k + 1$ , with

$$C_2 := C_1 \max \left\{ S, \frac{1}{7-\beta} \right\}.$$

We get (5.12) for  $j = k + 1$  thanks to (5.1) and (5.2), with  $C_3 := KC_2$ . We get (5.13) for  $j = k + 1$  thanks to (5.11) and (5.12) for  $a = 6$  and thanks to (5.3) and (5.11) for  $a \in \{2, 4\}$ , with  $C_4 := \max\{C_2 + C_3; KC_2\}$ .

Inequality (5.10) proves that  $(u_k)$  converges in  $E_4$  toward

$$u := \sum_{j=0}^{\infty} \Delta_j \dot{u}_j.$$

The continuity of the map  $\Phi : E_4 \rightarrow F_4$  implies that  $\Phi(u_k)$  converges to  $\Phi(u)$  in  $F_4$ .

Let us study the limit of the sequence  $(\Phi(u_k))_{k \in \mathbb{N}}$  in a different way. We have

$$\Phi(u_{j+1}) - \Phi(u_j) = \Delta_j(e'_j + e''_j + g_j),$$

where

$$\begin{aligned} e'_j &:= \frac{1}{\Delta_j} (\Phi(u_j + \Delta_j \dot{u}_j) - \Phi(u_j) - \Phi'(u_j) \Delta_j \dot{u}_j) \\ &= \Delta_j \int_0^1 (1-t) \Phi''(u_j + t \Delta_j \dot{u}_j; \dot{u}_j, \dot{u}_j) dt, \\ e''_j &:= (\Phi'(u_j) - \Phi'(v_j)) \dot{u}_j = \int_0^1 \Phi''(v_j + t(u_j - v_j); u_j - v_j, \dot{u}_j) dt. \end{aligned}$$

Thanks to (5.6), we have

$$\begin{aligned} \|e'_j\|_6 &\leq C \sum (1 + \|u_j\|_m + \Delta_j \|\dot{u}_j\|_m) \|\dot{u}_j\|_{m'} \|\dot{u}_j\|_{m''} \\ &\leq C[(1 + (C_1 + C_2) \|g\|_\beta \theta_j^{7-\beta}) C_1^2 \|g\|_\beta^2 \theta_j^{4-2\beta} \\ &\quad + 2(1 + (C_1 + C_2) \|g\|_\beta) C_1^2 \|g\|_\beta^2 \theta_j^{8-2\beta}] \\ &\leq C \|g\|_\beta^2 \theta_j^{8-2\beta}, \\ \|e''_j\|_6 &\leq C \sum (1 + \|v_j\|_m + \|u_j - v_j\|_m) \|u_j - v_j\|_{m'} \|\dot{u}_j\|_{m''} \\ &\leq C[(1 + (C_3 + C_4) \|g\|_\beta \theta_j^{7-\beta}) C_1 C_4 \|g\|_\beta^2 \theta_j^{5-2\beta} \\ &\quad + 2(1 + (C_3 + C_4) \|g\|_\beta) C_1 C_4 \|g\|_\beta^2 \theta_j^{9-2\beta}] \\ &\leq C \|g\|_\beta^2 \theta_j^{9-2\beta}. \end{aligned}$$

Since  $9 - 2\beta < -1$ , then  $\sum \Delta_j(e'_j + e''_j)$  converges in  $F_6$  and

$$\left\| \sum_{j=0}^{\infty} \Delta_j(e'_j + e''_j) \right\|_6 \leq C \|g\|_\beta^2.$$

The uniqueness of the limit of the sequence  $(\Phi(u_k))_{k \in \mathbb{N}}$  gives the following equality in  $F_4$ :

$$\Phi(u) = g + \mathcal{T}(g),$$

where  $\mathcal{T}(g) \in F_6$  and

$$\|\mathcal{T}(g)\|_6 \leq C \|g\|_\beta^2.$$

We conclude by applying the Leray–Schauder fixed point theorem.  $\square$

*Remark 3.* The proof can also be done thanks to the Banach fixed point theorem, instead of the Leray–Schauder fixed point theorem, provided one adds new assumptions (see [3, Appendix C]). In this situation, one does not need any longer the compactness of the injections  $F_b \rightarrow F_a$  for  $b > a$ .

**6. Smoothing operators.** In this section, we build smoothing operators on the spaces  $E_a$  and  $F_b$  defined by (2.12) and (2.13). First, we smooth the functions in  $H_{(0)}^a((0, 1), \mathbb{R})$  for every integer  $a \in \{2, \dots, 8\}$ . Let  $s \in C^\infty(\mathbb{R}, \mathbb{R})$  be such that

$$s = 1 \text{ on } [0, 1], 0 \leq s \leq 1, s = 0 \text{ on } [2, +\infty).$$

We define

$$S_\theta u := \sum_{k=1}^{\infty} s\left(\frac{k}{\theta}\right) \langle u, \varphi_k \rangle \varphi_k.$$

The proof of the following proposition is easy.

**PROPOSITION 9.** *There exists a constant  $K > 0$  such that, for every integer  $a \in \{2, \dots, 8\}$ , for every  $u \in H_{(0)}^a((0, 1), \mathbb{R})$  and for every  $\theta \geq 1$ , we have*

$$\begin{aligned} \|S_\theta u\|_{H^b((0,1),\mathbb{R})} &\leq K \|u\|_{H^a((0,1),\mathbb{R})} \text{ for every } b \in \{2, \dots, a\}, \\ \|S_\theta u\|_{H^b((0,1),\mathbb{R})} &\leq K \theta^{b-a} \|u\|_{H^a((0,1),\mathbb{R})} \text{ for every } b \in \{a+1, \dots, 8\}, \\ \|u - S_\theta u\|_{H^b((0,1),\mathbb{R})} &\leq K \theta^{b-a} \|u\|_{H^a((0,1),\mathbb{R})} \text{ for every } b \in \{2, \dots, a-1\}, \\ \left\| \frac{d}{d\theta} S_\theta u \right\|_{H^b((0,1),\mathbb{R})} &\leq K \theta^{b-a-1} \|u\|_{H^a((0,1),\mathbb{R})} \text{ for every } b \in \{2, \dots, 8\}. \end{aligned}$$

Suitable smoothing operators for the control function  $p$  can be built with convolution products and truncations with  $C^\infty$ -function having compact support as in [3, sect. 3.3.2]. This construction is inspired by [19].

**7. Bound on  $\Phi_T''$ .** The aim of this section is the proof of inequality (5.6) on the map  $\Phi_T$  defined by (1.8). More precisely, we prove the following proposition.

**PROPOSITION 10.** *Let  $T > 0$ . The map  $\Phi_T : E_6 \mapsto F_6$  is twice differentiable, and, for every  $(u_0, \dot{u}_0, p), (\lambda_0, \dot{\lambda}_0, \rho), (\mu_0, \dot{\mu}_0, \theta) \in E_6$ ,*

$$\Phi_T''(u_0, \dot{u}_0, p) \cdot ((\lambda_0, \dot{\lambda}_0, \rho), (\mu_0, \dot{\mu}_0, \theta)) = (0, 0, h(T), h_t(T)),$$

where

$$\begin{cases} u_{tt} + u_{xxxx} + p(t)u_{xx} = 0, \\ u = u_x = 0 \text{ at } x = 0, 1, \\ u(0) = u_0, \dot{u}(0) = \dot{u}_0, \end{cases} \quad \begin{cases} \lambda_{tt} + \lambda_{xxxx} + p(t)\lambda_{xx} + \rho(t)u_{xx} = 0, \\ \lambda = \lambda_x = 0 \text{ at } x = 0, 1, \\ \lambda(0) = \lambda_0, \dot{\lambda}(0) = \dot{\lambda}_0, \end{cases} \\ \begin{cases} \mu_{tt} + \mu_{xxxx} + p(t)\mu_{xx} + \theta(t)u_{xx} = 0, \\ \mu = \mu_x = 0 \text{ at } x = 0, 1, \\ \mu(0) = \mu_0, \dot{\mu}(0) = \dot{\mu}_0, \end{cases} \\ \begin{cases} h_{tt} + h_{xxxx} + p(t)h_{xx} + \rho(t)\mu_{xx} + \theta(t)\lambda_{xx} = 0, \\ h = h_x = 0 \text{ at } x = 0, 1, \\ h(0) = 0, \dot{h}(0) = 0. \end{cases} \end{cases}$$

For every  $r > 0$ , there exists a constant  $C(r) > 0$  such that, for every  $(u_0, \dot{u}_0, p), (\lambda_0, \dot{\lambda}_0, \rho), (\mu_0, \dot{\mu}_0, \theta) \in E_6$ , with  $\|(u_0, \dot{u}_0, p)\|_4 \leq r$ ,

$$(7.1) \quad \begin{aligned} &\|\Phi_T''(u_0, \dot{u}_0, p) \cdot ((\lambda_0, \dot{\lambda}_0, \rho), (\mu_0, \dot{\mu}_0, \theta))\|_6 \\ &\leq C(r) \sum (1 + \|(u_0, \dot{u}_0, p)\|_m) \|(\lambda_0, \dot{\lambda}_0, \rho)\|_{m'} \|(\mu_0, \dot{\mu}_0, \theta)\|_{m''} \end{aligned}$$

where the sum is taken over the following values:

$m$	$m'$	$m''$
6	2	2
4	6	2
4	2	6

*Proof of Proposition 10.* The regularity  $C^2$  of the map  $\Phi_T$  can be proved thanks to Propositions 1, 2, and 3 in a very similar way as for the regularity  $C^1$  in Proposition 5. Here we only justify (7.1). By applying Proposition 3 (which is possible because  $\|p\|_{W^{1,1}((0,T),\mathbb{R})} \leq \sqrt{T}\|p\|_{H^1((0,T),\mathbb{R})} \leq \sqrt{T}r$ ) we get  $C = C(r) > 0$  such that

$$(7.2) \quad \begin{aligned} & \| (h, h_t) \|_{C^0([0,T], H^6 \times H^4)} \\ & \leq C \left[ \|f\|_{W^{2,1}((0,T), L^2)} + \|p\|_{W^{2,1}} \|f\|_{L^1((0,T), L^2)} + \|f\|_{C^0([0,T], H^2)} \right], \end{aligned}$$

where  $f(t) := \rho(t)\mu_{xx}(t) + \theta(t)\lambda_{xx}(t)$ . Let us define  $f_1(t) := \rho(t)\mu_{xx}(t)$  and  $f_2(t) := \theta(t)\lambda_{xx}(t)$ . We work only on  $f_1$ , and we deduce the same results for  $f_2$  just by exchanging  $(\mu, \rho)$  and  $(\lambda, \theta)$ . By using Propositions 1, 2, and 3, we get constants  $C = C(r)$  such that, when  $\|(u_0, \dot{u}_0, p)\|_{E_4} \leq r$ ,

$$\begin{aligned} \|f_1\|_{L^1((0,T), L^2)} & \leq C \|\rho\|_{L^1} \|\mu\|_{C^0((0,T), H^2)}, \\ \|f_1\|_{W^{2,1}((0,T), L^2)} & \leq C [\|\rho\|_{H^2} \|\mu\|_{C^0([0,T], H^2)} + \|\rho\|_{H^1} \|\mu\|_{C^1([0,T], H^2)} \\ & \quad + \|\rho\|_{L^2} \|\mu\|_{C^2([0,T], H^2)}], \\ \|f_1\|_{C^0([0,T], H^2)} & \leq C \|\rho\|_{H^1} \|\mu\|_{C^0([0,T], H^4)}, \end{aligned}$$

where

$$\begin{aligned} \|\mu\|_{C^0([0,T], H^2)} & \leq C [\|(\mu_0, \dot{\mu}_0)\|_{H_0^2 \times L^2} + \|\theta u_{xx}\|_{L^1((0,T), L^2)}] \\ & \leq C [\|(\mu_0, \dot{\mu}_0)\|_{H_0^2 \times L^2} + \|\theta\|_{L^2} \|(u_0, \dot{u}_0)\|_{H_0^2 \times L^2}] \\ & \leq C \|(\mu_0, \dot{\mu}_0, \theta)\|_{E_2}, \\ \|\mu\|_{C^0([0,T], H^4)}, \|\mu\|_{C^1([0,T], H^2)} & \leq C [\|(\mu_0, \dot{\mu}_0)\|_{H_{(0)}^4 \times H_0^2} + \|\theta u_{xx}\|_{W^{1,1}((0,T), L^2)}] \\ & \leq C [\|(\mu_0, \dot{\mu}_0)\|_{H_{(0)}^4 \times H_0^2} + \|\theta\|_{H^1} \|(u_0, \dot{u}_0)\|_{H_0^2 \times L^2} \\ & \quad + \|\theta\|_{L^1} \|(u_0, \dot{u}_0)\|_{H_{(0)}^4 \times H_0^2}] \\ & \leq C \|(\mu_0, \dot{\mu}_0, \theta)\|_{E_4}, \\ \|\mu\|_{C^2([0,T], H^2)} & \leq C [\|(\mu_0, \dot{\mu}_0)\|_{H_{(0)}^6 \times H_{(0)}^4} + \|p\|_{W^{2,1}} \|(\mu_0, \dot{\mu}_0)\|_{H_0^2 \times L^2} \\ & \quad + \|\theta u_{xx}\|_{W^{2,1}((0,T), L^2)} + \|p\|_{W^{2,1}} \|\theta u_{xx}\|_{L^1((0,T), L^2)} \\ & \quad + \|\theta u_{xx}\|_{C^0([0,T], H^2)}]. \end{aligned}$$

We have

$$\begin{aligned} \|\theta u_{xx}\|_{W^{2,1}((0,T), L^2)} & \leq C [\|\theta\|_{H^2} \|u\|_{C^0([0,T], H^2)} + \|\theta\|_{H^1} \|u\|_{C^1([0,T], H^2)} \\ & \quad + \|\theta\|_{L^2} \|u\|_{C^2([0,T], H^2)}] \\ & \leq C \{ \|\theta\|_{H^2} \|(u_0, \dot{u}_0)\|_{H_0^2 \times L^2} + \|\theta\|_{H^1} \|(u_0, \dot{u}_0)\|_{H_{(0)}^4 \times H_0^2} \\ & \quad + \|\theta\|_{L^2} [\|(u_0, \dot{u}_0)\|_{H_{(0)}^6 \times H_{(0)}^4} + \|p\|_{W^{2,1}} \|(u_0, \dot{u}_0)\|_{H_0^2 \times L^2}] \} \\ & \leq C [\|\theta\|_{H^2} + \|\theta\|_{L^2} \|(u_0, \dot{u}_0, p)\|_{E_6}], \\ \|\theta u_{xx}\|_{L^1((0,T), L^2)} & \leq C \|\theta\|_{L^2} \|(u_0, \dot{u}_0)\|_{H_0^2 \times L^2} \\ & \leq C \|\theta\|_{L^2}, \\ \|\theta u_{xx}\|_{C^0([0,T], H^2)} & \leq C \|\theta\|_{H^1} \|(u_0, \dot{u}_0)\|_{H_{(0)}^4 \times H_0^2} \\ & \leq C \|\theta\|_{H^1}, \end{aligned}$$

and thus

$$\|\mu\|_{C^2([0,T], H^2)} \leq C [\|(\mu_0, \dot{\mu}_0, \theta)\|_{E_6} + \|(u_0, \dot{u}_0, p)\|_{E_6} \|(\mu_0, \dot{\mu}_0, \theta)\|_{E_2}].$$

We deduce from the previous computations that

$$\begin{aligned}
 \|f_1\|_{L^1((0,T),L^2)} &\leq C\|\rho\|_{L^2}\|(\mu_0, \dot{\mu}_0, \theta)\|_{E_2}, \\
 \|f_1\|_{W^{2,1}((0,T),L^2)} &\leq C\{\|\rho\|_{H^2}\|(\mu_0, \dot{\mu}_0, \theta)\|_{E_2} + \|\rho\|_{H^1}\|(\mu_0, \dot{\mu}_0, \theta)\|_{E_4} \\
 (7.3) \quad &\quad + \|\rho\|_{L^2}\|(\mu_0, \dot{\mu}_0, \theta)\|_{E_6} \\
 &\quad + \|\rho\|_{L^2}\|(u_0, \dot{u}_0, p)\|_{E_6}\|(\mu_0, \dot{\mu}_0, \theta)\|_{E_2}\}, \\
 \|f_1\|_{C^0([0,T],H^2)} &\leq C\|\rho\|_{H^1}\|(\mu_0, \dot{\mu}_0, \theta)\|_{E_4}.
 \end{aligned}$$

The inequalities (7.2) and (7.3) give the conclusion.  $\square$

**8. Controllability of the linearized system around  $(u^{ref}, \dot{u}^{ref}, p \equiv 0)$  with Nash–Moser bounds.** In all of this section,  $T := 8/\pi$ . We recall that the spaces  $E_a$  and  $F_b$  are defined by (2.12) and (2.13). The goal of this section is the proof of the following result.

**PROPOSITION 11.** *There exists  $C > 0$  such that the map  $d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0)$  has a right inverse*

$$d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0)^{-1} : F_7 \rightarrow E_6$$

and, for every  $(U_0, \dot{U}_0, U_T, \dot{U}_T) \in F_7$ ,

$$\begin{aligned}
 \|d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0)^{-1} \cdot (U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{E_2} &\leq C\|(U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{F_3}, \\
 \|d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0)^{-1} \cdot (U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{E_6} &\leq C\|(U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{F_7}.
 \end{aligned}$$

We introduce the linear map  $M$ , defined on  $L^2((0,T), \mathbb{R})$  by  $M(P) = (M(P)_k)_{k \in \mathbb{N}^*}$ ,

$$\begin{aligned}
 M(P)_{2k-1} &:= \frac{1}{T} \int_0^T P(t) \sin(\sqrt{\lambda_3}t) e^{-i\sqrt{\lambda_{2k-1}}t} dt \quad \forall k \in \mathbb{N}^*, \\
 M(P)_{2k} &:= \frac{1}{T} \int_0^T P(t) \sin(\sqrt{\lambda_2}t) e^{-i\sqrt{\lambda_{2k}}t} dt \quad \forall k \in \mathbb{N}^*.
 \end{aligned}$$

For  $s > 0$ , we introduce the space

$$h^s(\mathbb{N}^*, \mathbb{C}) := \left\{ d = (d_n)_{n \in \mathbb{N}^*}; \sum_{n=1}^{\infty} |n^s d_n|^2 < +\infty \right\}.$$

Thanks to the equivalence between the controllability of the linearized system  $(\Sigma_l^{ref})$  and the solvability of the moment problem (3.24) (which is explained in the proof of statement (1) of Theorem 3, in section 3.2), Proposition 11 is a consequence of the following result.

**PROPOSITION 12.** *There exists  $C > 0$  such that the map  $M$  has a right inverse*

$$M^{-1} : h^4(\mathbb{N}^*, \mathbb{C}) \rightarrow H_0^2((0,T), \mathbb{R})$$

and, for every  $d \in h^4(\mathbb{N}^*, \mathbb{C})$ ,

$$\|M^{-1}(d)\|_{L^2((0,T), \mathbb{R})} \leq C\|d\|_{l^2(\mathbb{N}^*, \mathbb{C})},$$

$$\|M^{-1}(d)\|_{H_0^2((0,T), \mathbb{R})} \leq C\|d\|_{h^4(\mathbb{N}^*, \mathbb{C})}.$$

Proposition 11 is a consequence of Proposition 12, but they are not equivalent. Indeed, Proposition 12 provides a right inverse  $d\Phi_T(u_0, \dot{u}_0, 0)^{-1}$  defined on  $F_7$  with values in  $H_{(0)}^7((0, 1), \mathbb{R}) \times H_{(0)}^5((0, 1), \mathbb{R}) \times H_0^2((0, T), \mathbb{R})$  which is strictly smaller than  $E_6$  (see (2.12) for a definition of  $E_6$ ).

We will prove Proposition 12 by using an auxiliary linear map  $\widetilde{M}$ , which is easier to deal with than  $M$  and close enough to  $M$  so that the surjectivity of  $\widetilde{M}$  implies the surjectivity of  $M$ . Let us introduce the map  $\widetilde{M} : L^2((0, T), \mathbb{R}) \rightarrow l^2(\mathbb{N}^*, \mathbb{C})$  defined by

$$(8.1) \quad \begin{aligned} \widetilde{M}(P)_{2k-1} &:= \frac{1}{T} \int_0^T P(t) \sin\left(\frac{\pi^2}{4} K_3 t\right) e^{-i \frac{\pi^2}{4} K_{2k-1} t} dt \quad \forall k \in \mathbb{N}^*, \\ \widetilde{M}(P)_{2k} &:= \frac{1}{T} \int_0^T P(t) \sin\left(\frac{\pi^2}{4} K_2 t\right) e^{-i \frac{\pi^2}{4} K_{2k} t} dt \quad \forall k \in \mathbb{N}^*, \end{aligned}$$

where  $(K_n)_{n \in \mathbb{N}^*}$  is defined by (3.6). The linear map  $\widetilde{M}$  maps  $L^2((0, T), \mathbb{R})$  into  $l^2(\mathbb{N}^*, \mathbb{C})$ ,  $H_0^1((0, T), \mathbb{R})$  into  $h^2(\mathbb{N}^*, \mathbb{C})$ , and  $H_0^2((0, T), \mathbb{R})$  into  $h^4(\mathbb{N}^*, \mathbb{C})$ . Indeed, each term of the sequence is the sum of two Fourier coefficients of  $P$ . Note that  $T = 8/\pi$  is chosen so that, for every  $n \in \mathbb{N}^*$ ,  $e^{i \frac{\pi^2}{4} K_n t}$  is  $T$ -periodic. Thus, the previous statement is a consequence of Bessel Parseval equality and integrations by parts.

For technical reasons, the space  $h^s(\mathbb{N}^*, \mathbb{C})$  is equipped with the unusual norm

$$\|d\|_{h^s(\mathbb{N}^*, \mathbb{C})} := \left( \sum_{n=1}^{\infty} |K_n^{s/2} d_n|^2 \right)^{1/2}.$$

On the spaces  $L^2((0, T), \mathbb{R})$ ,  $H_0^1((0, T), \mathbb{R})$ , and  $H_0^2((0, T), \mathbb{R})$  we use

$$\begin{aligned} \|f\|_{L^2((0, T), \mathbb{R})} &:= \left( \frac{1}{T} \int_0^T |f(t)|^2 dt \right)^{1/2}, \\ \|f\|_{H_0^1((0, T), \mathbb{R})} &:= \|f'\|_{L^2((0, T), \mathbb{R})}, \quad \|f\|_{H_0^2((0, T), \mathbb{R})} := \|f''\|_{L^2((0, T), \mathbb{R})}. \end{aligned}$$

More precisely, we prove Proposition 12 by applying the next proposition to  $\mathcal{M} = M$  and  $\widetilde{\mathcal{M}} = \widetilde{M}$ .

**PROPOSITION 13.** *Let  $\mathcal{M}$  and  $\widetilde{\mathcal{M}}$  be continuous linear maps from  $L^2((0, T), \mathbb{R})$  to  $l^2(\mathbb{N}^*, \mathbb{C})$ , from  $H_0^1((0, T), \mathbb{R})$  to  $h^2(\mathbb{N}^*, \mathbb{C})$ , and from  $H_0^2((0, T), \mathbb{R})$  to  $h^4(\mathbb{N}^*, \mathbb{C})$ . We assume that there exist positive constants  $C_0, C_1, C_2, C$  such that  $\widetilde{\mathcal{M}}$  has a right inverse*

$$\widetilde{\mathcal{M}}^{-1} : h^4(\mathbb{N}^*, \mathbb{C}) \rightarrow H_0^2((0, T), \mathbb{R})$$

which satisfies, for every  $d \in h^4(\mathbb{N}^*, \mathbb{C})$ ,

$$\begin{aligned} \|\widetilde{\mathcal{M}}^{-1}(d)\|_{L^2((0, T), \mathbb{R})} &\leq C_0 \|d\|_{l^2(\mathbb{N}^*, \mathbb{C})}, \\ \|\widetilde{\mathcal{M}}^{-1}(d)\|_{H_0^1((0, T), \mathbb{R})} &\leq C_1 \|d\|_{h^2(\mathbb{N}^*, \mathbb{C})} + C \|d\|_{l^2(\mathbb{N}^*, \mathbb{C})}, \\ \|\widetilde{\mathcal{M}}^{-1}(d)\|_{H_0^2((0, T), \mathbb{R})} &\leq C_2 \|d\|_{h^4(\mathbb{N}^*, \mathbb{C})} + C \|d\|_{h^2(\mathbb{N}^*, \mathbb{C})}. \end{aligned}$$

We also assume that there exist positive constants  $C_0, C_1, C_2, C_3, C_4, C_5$  such that, for

every  $P \in H_0^2((0, T), \mathbb{R})$ ,

$$\|(\widetilde{\mathcal{M}} - \mathcal{M})(P)\|_{l^2(\mathbb{N}^*, \mathbb{C})} \leq \mathcal{C}_0 \|P\|_{L^2((0, T), \mathbb{R})},$$

$$\|(\widetilde{\mathcal{M}} - \mathcal{M})(P)\|_{h^2(\mathbb{N}^*, \mathbb{C})} \leq \mathcal{C}_1 \|P\|_{H_0^1((0, T), \mathbb{R})} + \mathcal{C}_3 \|P\|_{L^2((0, T), \mathbb{R})},$$

$$\|(\widetilde{\mathcal{M}} - \mathcal{M})(P)\|_{h^4(\mathbb{N}^*, \mathbb{C})} \leq \mathcal{C}_2 \|P\|_{H_0^2((0, T), \mathbb{R})} + \mathcal{C}_4 \|P\|_{H_0^1((0, T), \mathbb{R})} + \mathcal{C}_5 \|P\|_{L^2((0, T), \mathbb{R})}.$$

We assume that  $C_0\mathcal{C}_0$ ,  $C_1\mathcal{C}_1$ , and  $C_2\mathcal{C}_2$  are  $< 1$ . Then there exists a constant  $m > 0$  such that  $\mathcal{M}$  has a right inverse

$$\mathcal{M}^{-1} : h^4(\mathbb{N}^*, \mathbb{C}) \rightarrow H_0^2((0, T), \mathbb{R})$$

which satisfies, for every  $d \in h^4(\mathbb{N}^*, \mathbb{C})$ ,

$$\begin{aligned} \|\mathcal{M}^{-1}(d)\|_{L^2((0, T), \mathbb{R})} &\leq m \|d\|_{l^2(\mathbb{N}^*, \mathbb{C})}, \\ \|\mathcal{M}^{-1}(d)\|_{H_0^1((0, T), \mathbb{R})} &\leq m \|d\|_{h^2(\mathbb{N}^*, \mathbb{C})}, \\ \|\mathcal{M}^{-1}(d)\|_{H_0^2((0, T), \mathbb{R})} &\leq m \|d\|_{h^4(\mathbb{N}^*, \mathbb{C})}. \end{aligned}$$

*Remark 4.* One of the interests of this proposition, when we apply it, is that the constants  $C$  and  $\mathcal{C}_j$  for  $j = 3, 4, 5$  can be large. In the application of this proposition to the maps  $M$  and  $\widetilde{M}$ , we will put all of the possible terms in the factor with  $C$  or  $\mathcal{C}_j$  for  $j = 3, 4, 5$  in order to reduce  $\mathcal{C}_1$  and  $\mathcal{C}_2$  and ensure  $C_1\mathcal{C}_1 < 1$  and  $C_2\mathcal{C}_2 < 1$ .

*Proof of Proposition 13.* We introduce  $\Delta_i := C_i\mathcal{C}_i$  for  $i = 0, 1, 2$ . Let  $d \in h^4(\mathbb{N}^*, \mathbb{C})$ . We define by induction the sequence  $(w_n)_{n \in \mathbb{N}}$  in  $H_0^2((0, T), \mathbb{R})$  by

$$\begin{cases} w_0 := \widetilde{\mathcal{M}}^{-1}(d), \\ w_{n+1} := \widetilde{\mathcal{M}}^{-1}[(\widetilde{\mathcal{M}} - \mathcal{M})(w_n)]. \end{cases}$$

Then we have, for every  $n \in \mathbb{N}^*$ ,

$$\|w_n\|_{L^2((0, T), \mathbb{R})} \leq C_0 \Delta_0^n \|d\|_{l^2(\mathbb{N}^*, \mathbb{C})},$$

$$\|w_n\|_{H_0^1((0, T), \mathbb{R})} \leq C_1 \Delta_1^n \|d\|_{h^2(\mathbb{N}^*, \mathbb{C})} + x_n \|d\|_{l^2(\mathbb{N}^*, \mathbb{C})},$$

$$\|w_n\|_{H_0^2((0, T), \mathbb{R})} \leq C_2 \Delta_2^n \|d\|_{h^4(\mathbb{N}^*, \mathbb{C})} + y_n \|d\|_{h^2(\mathbb{N}^*, \mathbb{C})} + z_n \|d\|_{l^2(\mathbb{N}^*, \mathbb{C})},$$

where  $x_0 = y_0 = C$ ,  $z_0 = 0$ , and, for every  $n \in \mathbb{N}^*$ ,

$$x_{n+1} = \Delta_1 x_n + XC_0 \Delta_0^n, \quad y_{n+1} = \Delta_2 y_n + YC_1 \Delta_1^n, \quad z_{n+1} = \Delta_2 z_n + Yx_n + ZC_0 \Delta_0^n,$$

$$X := CC_0 + C_1\mathcal{C}_3, \quad Y := C_2\mathcal{C}_4 + CC_1, \quad Z := C_2\mathcal{C}_5 + C\mathcal{C}_3.$$

Under the assumption that  $\Delta_i < 1$  for  $i = 0, 1, 2$ , the sums  $\sum x_n$ ,  $\sum y_n$ , and  $\sum z_n$  converge and

$$\begin{aligned} (1 - \Delta_1) \sum_{n=0}^{\infty} x_n &= C + \frac{XC_0}{1 - \Delta_0}, & (1 - \Delta_2) \sum_{n=0}^{\infty} y_n &= C + \frac{YC_1}{1 - \Delta_1}, \\ (1 - \Delta_2) \sum_{n=0}^{\infty} z_n &= Y \sum_{n=0}^{\infty} x_n + \frac{ZC_0}{1 - \Delta_0}. \end{aligned}$$

Thus  $\sum w_n$  converges in  $H_0^2((0, T), \mathbb{R})$  to a function  $w$  which satisfies

$$\begin{aligned} \|w\|_{L^2((0, T), \mathbb{R})} &\leq \frac{C_0}{1 - \Delta_0} \|d\|_{l^2}, \\ \|w\|_{H_0^1((0, T), \mathbb{R})} &\leq \frac{C_1}{1 - \Delta_1} \|d\|_{h^2} + \frac{1}{1 - \Delta_1} \left( C + \frac{XC_0}{1 - \Delta_0} \right), \\ \|w\|_{H_0^2((0, T), \mathbb{R})} &\leq \frac{C_2}{1 - \Delta_2} \|d\|_{h^4} + \frac{1}{1 - \Delta_1} \left( C + \frac{YC_1}{1 - \Delta_1} \right) \|d\|_{h^2} \\ &\quad + \frac{1}{1 - \Delta_2} \left[ \frac{Y}{1 - \Delta_1} \left( C + \frac{XC_0}{1 - \Delta_0} \right) + \frac{ZC_0}{1 - \Delta_0} \right] \|d\|_{l^2}. \end{aligned}$$

For every  $n \in \mathbb{N}^*$ , we have

$$\mathcal{M} \left( \sum_{k=0}^n w_k \right) = d + (\mathcal{M} - \widetilde{\mathcal{M}})(w_n),$$

where  $(\mathcal{M} - \widetilde{\mathcal{M}})(w_n) \rightarrow 0$  in  $l^2$  because  $w_n \rightarrow 0$  in  $L^2$  and  $(\mathcal{M} - \widetilde{\mathcal{M}})$  is continuous from  $L^2$  to  $l^2$ , and thus  $\mathcal{M}(w) = d$ .  $\square$

In the next proposition, we check the first assumption of Proposition 13 with  $\widetilde{\mathcal{M}} = \widetilde{M}$ .

**PROPOSITION 14.** *The linear map  $\widetilde{M}$  defined by (8.1) has a right inverse  $\widetilde{M}^{-1} : h^4(\mathbb{N}^*, \mathbb{C}) \rightarrow H_0^2((0, T), \mathbb{R})$  such that, for every  $d \in h^4(\mathbb{N}^*, \mathbb{C})$ ,*

$$(8.2) \quad \|\widetilde{M}^{-1}(d)\|_{L^2((0, T), \mathbb{R})} \leq C_0 \|d\|_{l^2(\mathbb{N}^*, \mathbb{C})},$$

$$(8.3) \quad \|\widetilde{M}^{-1}(d)\|_{H_0^1((0, T), \mathbb{R})} \leq C_1 \|d\|_{h^2(\mathbb{N}^*, \mathbb{C})} + C \|d\|_{l^2(\mathbb{N}^*, \mathbb{C})},$$

$$(8.4) \quad \|\widetilde{M}^{-1}(d)\|_{H_0^2((0, T), \mathbb{R})} \leq C_2 \|d\|_{h^4(\mathbb{N}^*, \mathbb{C})} + C \|d\|_{h^2(\mathbb{N}^*, \mathbb{C})},$$

where  $C_0 := 2\sqrt{3}$ ,  $C_1 := \frac{\sqrt{3}}{2\sqrt{2}}\pi^2$ ,  $C_2 := \frac{\sqrt{3}}{8\sqrt{2}}\pi^4$ , and  $C$  is a positive constant.

*Proof of Proposition 14.* Let  $d \in h^4(\mathbb{N}^*, \mathbb{C})$ . For a function  $P \in H_0^2((0, T), \mathbb{R})$ , the equality  $\widetilde{M}(P) = d$  is satisfied in particular when

$$(8.5) \quad \begin{cases} \frac{1}{T} \int_0^T P(t) dt = 0, \\ \frac{1}{T} \int_0^T P(t) e^{-i\frac{\pi^2}{4} 2K_3 t} dt = -2id_3, \\ \frac{1}{T} \int_0^T P(t) e^{-i\frac{\pi^2}{4} (K_{2k-1} - K_3) t} dt = id_{2k-1} \quad \forall k \in \mathbb{N}^* \text{ such that } k \neq 2, \\ \frac{1}{T} \int_0^T P(t) e^{-i\frac{\pi^2}{4} (K_{2k-1} + K_3) t} dt = -id_{2k-1} \quad \forall k \in \mathbb{N}^* \text{ such that } k \neq 2, \\ \frac{1}{T} \int_0^T P(t) e^{-i\frac{\pi^2}{4} 2K_2 t} dt = -2id_2, \\ \frac{1}{T} \int_0^T P(t) e^{-i\frac{\pi^2}{4} (K_{2k} - K_2) t} dt = id_{2k} \quad \forall k \in \mathbb{N}^* \text{ such that } k \neq 2, \\ \frac{1}{T} \int_0^T P(t) e^{-i\frac{\pi^2}{4} (K_{2k} + K_2) t} dt = -id_{2k} \quad \forall k \in \mathbb{N}^* \text{ such that } k \neq 2. \end{cases}$$

Let us consider the candidate

$$\begin{aligned} P(t) := 2\Re &\left[ -2id_3 e^{i\frac{\pi^2}{4} 2K_3 t} - 2id_2 e^{i\frac{\pi^2}{4} 2K_2 t} \right. \\ &+ \sum_{k=1, k \neq 2}^{\infty} id_{2k-1} \left( e^{i\frac{\pi^2}{4} (K_{2k-1} - K_3) t} - e^{i\frac{\pi^2}{4} (K_{2k-1} + K_3) t} \right) \\ &\left. + \sum_{k=2}^{\infty} id_{2k} \left( e^{i\frac{\pi^2}{4} (K_{2k} - K_2) t} - e^{i\frac{\pi^2}{4} (K_{2k} + K_2) t} \right) \right] \frac{1}{2} (1 - e^{i\frac{\pi^2}{4} t}) (1 - e^{-i\frac{\pi^2}{4} t}). \end{aligned}$$

Then  $P \in H_0^2((0, T), \mathbb{R})$  because  $d \in h^4(\mathbb{N}^*, \mathbb{C})$  and  $t \mapsto (1 - e^{i\pi^2 t/4})(1 - e^{-i\pi^2 t/4})$  belongs to  $H_0^2((0, T), \mathbb{R})$ . The positive integers

$$2K_3, 2K_3 \pm 1, 2K_2, 2K_2 \pm 1, K_3 \pm K_1, K_3 \pm K_1 \pm 1, K_4 \pm K_2, K_4 \pm K_2 \pm 1, \\ K_{2k-1} \pm K_3, K_{2k-1} \pm K_3 \pm 1, K_{2k} \pm K_2, K_{2k} \pm K_2 \pm 1, \text{ for } k \in \mathbb{N} \text{ such that } k \geq 3,$$

are all different except  $K_3 + K_1 - 1 = K_4 - K_2 + 1$  (which concerns the coefficients  $d_1$  and  $d_4$  in  $P$ ) and  $K_8 + K_2 - 1 = K_9 - K_3 + 1$  (which concerns the coefficients  $d_8$  and  $d_9$  in  $P$ ). This statement can be proved in the same way as the claim in the proof of Lemma 1. Thanks to the orthogonality of the different terms in  $P$ , the function  $P$  solves the moment problem (8.5). We have

$$\begin{aligned} & \frac{2id_3 e^{i\frac{\pi^2}{4} 2K_3 t} (1 - e^{i\frac{\pi^2}{4} t})(1 - e^{-i\frac{\pi^2}{4} t})}{2} \\ &= 2id_3 \left[ -\frac{1}{2} e^{i\frac{\pi^2}{4} (2K_3+1)t} + e^{i\frac{\pi^2}{4} 2K_3 t} - \frac{1}{2} e^{i\frac{\pi^2}{4} (2K_3-1)t} \right], \end{aligned}$$

where all of the terms are orthogonal, and thus

$$\begin{aligned} \left\| 2\Re[2id_3 e^{i\frac{\pi^2}{4} 2K_3 t}] \frac{(1 - e^{i\frac{\pi^2}{4} t})(1 - e^{-i\frac{\pi^2}{4} t})}{2} \right\|_{L^2((0, T), \mathbb{R})}^2 &= 4|d_3|^2 \left( \frac{1}{4} + 1 + \frac{1}{4} \right) * 2 \\ &= 12|d_3|^2. \end{aligned}$$

For the same reason, we have

$$\left\| 2\Re[2id_2 e^{i\frac{\pi^2}{4} 2K_2 t}] \frac{(1 - e^{i\frac{\pi^2}{4} t})(1 - e^{-i\frac{\pi^2}{4} t})}{2} \right\|_{L^2((0, T), \mathbb{R})}^2 = 12|d_2|^2.$$

We have

$$\begin{aligned} & id_{2k} \left( e^{i\frac{\pi^2}{4} (K_{2k}-K_2)t} - e^{i\frac{\pi^2}{4} (K_{2k}+K_2)t} \right) \frac{(1 - e^{i\frac{\pi^2}{4} t})(1 - e^{-i\frac{\pi^2}{4} t})}{2} \\ &= id_{2k} \left[ -\frac{1}{2} e^{i\frac{\pi^2}{4} (K_{2k}-K_2-1)t} + e^{i\frac{\pi^2}{4} (K_{2k}-K_2)t} - \frac{1}{2} e^{i\frac{\pi^2}{4} (K_{2k}-K_2+1)t} \right] \\ &\quad - id_{2k} \left[ -\frac{1}{2} e^{i\frac{\pi^2}{4} (K_{2k}+K_2-1)t} + e^{i\frac{\pi^2}{4} (K_{2k}+K_2)t} - \frac{1}{2} e^{i\frac{\pi^2}{4} (K_{2k}+K_2+1)t} \right], \end{aligned}$$

where the terms are orthogonal, and thus

$$\begin{aligned} & \left\| 2\Re \left[ id_{2k} \left( e^{i\frac{\pi^2}{4} (K_{2k}-K_2)t} - e^{i\frac{\pi^2}{4} (K_{2k}+K_2)t} \right) \right] \frac{(1 - e^{i\frac{\pi^2}{4} t})(1 - e^{-i\frac{\pi^2}{4} t})}{2} \right\|_{L^2((0, T), \mathbb{R})}^2 \\ &= |d_{2k}|^2 \left( \frac{1}{4} + 1 + \frac{1}{4} \right) * 4 = 6|d_{2k}|^2. \end{aligned}$$

For the same reason, we have

$$\begin{aligned} & \left\| 2\Re \left[ id_{2k-1} \left( e^{i\frac{\pi^2}{4} (K_{2k-1}-K_3)t} - e^{i\frac{\pi^2}{4} (K_{2k-1}+K_3)t} \right) \right] \frac{(1 - e^{i\frac{\pi^2}{4} t})(1 - e^{-i\frac{\pi^2}{4} t})}{2} \right\|_{L^2((0, T), \mathbb{R})}^2 \\ &= 6|d_{2k-1}|^2. \end{aligned}$$

Since  $K_8 + K_2 - 1 = K_9 - K_3 + 1$ , we have

$$\begin{aligned}
 & \left[ id_8 \left( e^{i\frac{\pi^2}{4}(K_8-K_2)t} - e^{i\frac{\pi^2}{4}(K_8+K_2)t} \right) \right. \\
 & \quad \left. + id_9 \left( e^{i\frac{\pi^2}{4}(K_9-K_3)t} - e^{i\frac{\pi^2}{4}(K_9+K_3)t} \right) \right] \frac{(1 - e^{i\frac{\pi^2}{4}t})(1 - e^{-i\frac{\pi^2}{4}t})}{2} \\
 &= id_8 \left[ -\frac{1}{2} e^{i\frac{\pi^2}{4}(K_8-K_2-1)t} + e^{i\frac{\pi^2}{4}(K_8-K_2)t} - \frac{1}{2} e^{i\frac{\pi^2}{4}(K_8-K_2+1)t} \right] \\
 & \quad - id_8 \left[ e^{i\frac{\pi^2}{4}(K_8+K_2)t} - \frac{1}{2} e^{i\frac{\pi^2}{4}(K_8+K_2+1)t} \right] \\
 & \quad + id_9 \left[ -\frac{1}{2} e^{i\frac{\pi^2}{4}(K_9-K_3-1)t} + e^{i\frac{\pi^2}{4}(K_9-K_3)t} \right] \\
 & \quad - id_9 \left[ -\frac{1}{2} e^{i\frac{\pi^2}{4}(K_9+K_3-1)t} + e^{i\frac{\pi^2}{4}(K_9+K_3)t} - \frac{1}{2} e^{i\frac{\pi^2}{4}(K_9+K_3+1)t} \right] \\
 & \quad + i(d_8 - d_9) \frac{1}{2} e^{i\frac{\pi^2}{4}(K_8+K_2-1)t},
 \end{aligned}$$

where all of the terms are orthogonal, and thus

$$\begin{aligned}
 & \left\| 2\Re \left[ id_8 \left( e^{i\frac{\pi^2}{4}(K_8-K_2)t} - e^{i\frac{\pi^2}{4}(K_8+K_2)t} \right) \right. \right. \\
 & \quad \left. \left. + id_9 \left( e^{i\frac{\pi^2}{4}(K_9-K_3)t} - e^{i\frac{\pi^2}{4}(K_9+K_3)t} \right) \right] \frac{(1 - e^{i\frac{\pi^2}{4}t})(1 - e^{-i\frac{\pi^2}{4}t})}{2} \right\|_{L^2((0,T),\mathbb{R})}^2 \\
 &= [|d_8|^2 + |d_9|^2] * \frac{11}{4} * 2 + |d_8 - d_9|^2 * \frac{1}{4} * 2 \\
 &\leq \frac{13}{2} [|d_8|^2 + |d_9|^2].
 \end{aligned}$$

For the same reasons, we have

$$\begin{aligned}
 & \left\| 2\Re \left[ id_4 \left( e^{i\frac{\pi^2}{4}(K_4-K_2)t} - e^{i\frac{\pi^2}{4}(K_4+K_2)t} \right) \right. \right. \\
 & \quad \left. \left. + id_1 \left( e^{i\frac{\pi^2}{4}(K_1-K_3)t} - e^{i\frac{\pi^2}{4}(K_1+K_3)t} \right) \right] \frac{(1 - e^{i\frac{\pi^2}{4}t})(1 - e^{-i\frac{\pi^2}{4}t})}{2} \right\|_{L^2((0,T),\mathbb{R})}^2 \\
 &\leq \frac{13}{2} [|d_1|^2 + |d_4|^2].
 \end{aligned}$$

Thus, we have

$$\|P\|_{L^2}^2 \leq 12 \sum_{n \in \{1,2,3,4,8,9\}} |d_n|^2 + 6 \sum_{n \in \mathbb{N}^*, n \notin \{1,2,3,4,8,9\}} |d_n|^2$$

which justifies (8.2) with  $C_0 = 2\sqrt{3}$ . For the computation of  $\|P'\|_{L^2}^2$ , we use the same kind of arguments together with

$$\begin{aligned}
 & (K_n - K_j)^2 + (K_n + K_j)^2 \\
 & \quad + \frac{(K_n - K_j - 1)^2 + (K_n + K_j + 1)^2 + (K_n - K_j + 1)^2 + (K_n + K_j - 1)^2}{4} \\
 &= 3 \left( K_n^2 + K_j^2 + \frac{1}{3} \right).
 \end{aligned}$$

This gives (8.3) with  $C_1 = \pi^2 \sqrt{3}/(2\sqrt{2})$ . For the computation of  $\|P''\|_{L^2}^2$ , we also use the same kind of arguments, together with

$$\begin{aligned} & (K_n - K_j)^4 + (K_n + K_j)^4 \\ & + \frac{(K_n - K_j - 1)^4 + (K_n + K_j + 1)^4 + (K_n - K_j + 1)^4 + (K_n + K_j - 1)^4}{4} \\ & = 3K_n^4 + 6K_n^2(3K_j^2 + 1) + 3K_j^4 + 6K_j^2 + 1. \end{aligned}$$

This gives (8.4) with  $C_2 = \pi^4 \sqrt{3}/(8\sqrt{2})$ .  $\square$

In the next proposition, we check the second assumption of Proposition 13 with  $\widetilde{\mathcal{M}} = \widetilde{M}$  and  $\mathcal{M} = M$ .

PROPOSITION 15. *For every  $P \in H_0^2((0, T), \mathbb{R})$ , we have*

$$\|(\widetilde{M} - M)(P)\|_{l^2(\mathbb{N}^*, \mathbb{C})} \leq \mathcal{C}_0 \|P\|_{L^2((0, T), \mathbb{R})},$$

$$\|(\widetilde{M} - M)(P)\|_{h^2(\mathbb{N}^*, \mathbb{C})} \leq \mathcal{C}_1 \|P\|_{H_0^1((0, T), \mathbb{R})} + \mathcal{C}_3 \|P\|_{L^2((0, T), \mathbb{R})},$$

$$\|(\widetilde{M} - M)(P)\|_{h^4(\mathbb{N}^*, \mathbb{C})} \leq \mathcal{C}_2 \|P\|_{H_0^2((0, T), \mathbb{R})} + \mathcal{C}_4 \|P\|_{H_0^1((0, T), \mathbb{R})} + \mathcal{C}_5 \|P\|_{L^2((0, T), \mathbb{R})},$$

where

$$\begin{aligned} \mathcal{C}_0 &:= \sqrt{S_0} + \frac{T}{\sqrt{2}} \left( \left| \sqrt{\lambda_3} - \frac{\pi^2}{4} K_3 \right|^2 + \left| \sqrt{\lambda_2} - \frac{\pi^2}{2} K_2 \right|^2 \right)^{1/2}, \quad \mathcal{C}_2 := \frac{4}{\pi^2} \mathcal{C}_1, \\ \mathcal{C}_1 &:= \frac{2\sqrt{2}}{\pi^2} T \left( \left| \sqrt{\lambda_3} - \frac{\pi^2}{4} K_3 \right| + \left| \sqrt{\lambda_2} - \frac{\pi^2}{2} K_2 \right| \right), \\ S_0 &:= 2 \sum_{n=1}^{\infty} \left( 1 - \operatorname{sinc} \left[ T \left( \sqrt{\lambda_n} - \frac{\pi^2}{4} K_n \right) \right] \right), \end{aligned}$$

$\operatorname{sinc}(x) := \sin(x)/x$ , and  $\mathcal{C}_j$  is a positive constant for  $j = 3, 4, 5$ .

*Proof of Proposition 15.* By using decompositions of the form

$$\begin{aligned} (M - \widetilde{M})(P)_{2k-1} &= \frac{1}{T} \int_0^T P(t) \sin(\sqrt{\lambda_3} t) (e^{-i\sqrt{\lambda_{2k-1}} t} - e^{-i\frac{\pi^2}{4} K_{2k-1} t}) dt \\ (8.6) \quad &+ \frac{1}{T} \int_0^T P(t) \left[ \sin(\sqrt{\lambda_3} t) - \sin\left(\frac{\pi^2}{4} K_3 t\right) \right] e^{-i\frac{\pi^2}{4} K_{2k-1} t} dt, \end{aligned}$$

the Cauchy–Schwarz inequality, and Bessel Parseval inequality, we get

$$\begin{aligned} \|(M - \widetilde{M})(P)\|_{l^2(\mathbb{N}^*, \mathbb{C})} &\leq \left( \frac{1}{2} \left\| P(t) \left[ \sin(\sqrt{\lambda_3} t) - \sin\left(\frac{\pi^2}{4} K_3 t\right) \right] \right\|_{L^2}^2 \right. \\ &\quad \left. + \frac{1}{2} \left\| P(t) \left[ \sin(\sqrt{\lambda_2} t) - \sin\left(\frac{\pi^2}{4} K_2 t\right) \right] \right\|_{L^2}^2 \right)^{1/2} \\ &\quad + \|P\|_{L^2} \left( \sum_{n=1}^{\infty} \frac{1}{T} \int_0^T |e^{-i\sqrt{\lambda_n} t} - e^{-i\frac{\pi^2}{4} K_n t}|^2 dt \right)^{1/2} \end{aligned}$$

(the factor  $\frac{1}{2}$  comes from the fact that we sum only positive frequencies of a real-valued function), which gives the first bound of the proposition. By using decompositions of the form (8.6), the triangular inequality, the Cauchy–Schwarz inequality, and integrations by parts, we get

$$\begin{aligned} \|(M - \widetilde{M})(P)\|_{h^2} &\leq \|P\|_{L^2} \sqrt{S_1} + \frac{2\sqrt{2}}{\pi^2} \left( \left\| \frac{d}{dt} \left\{ P(t) \left[ \sin(\sqrt{\lambda_3}t) - \sin\left(\frac{\pi^2}{4}K_3t\right) \right] \right\} \right\|_{L^2} \right. \\ &\quad \left. + \left\| \frac{d}{dt} \left\{ P(t) \left[ \sin(\sqrt{\lambda_2}t) - \sin\left(\frac{\pi^2}{4}K_2t\right) \right] \right\} \right\|_{L^2} \right), \end{aligned}$$

where

$$S_1 := \sum_{n=1}^{\infty} K_n^2 \frac{1}{T} \int_0^T \left| e^{-i\sqrt{\lambda_n}t} - e^{-i\frac{\pi^2}{4}K_nt} \right|^2 dt.$$

In the same way, we get

$$\begin{aligned} \|(M - \widetilde{M})(P)\|_{h^4} &\leq \|P\|_{L^2} \sqrt{S_2} + \frac{8\sqrt{2}}{\pi^4} \left( \left\| \frac{d^2}{dt^2} \left\{ P(t) \left[ \sin(\sqrt{\lambda_3}t) - \sin\left(\frac{\pi^2}{4}K_3t\right) \right] \right\} \right\|_{L^2} \right. \\ &\quad \left. + \left\| \frac{d^2}{dt^2} \left\{ P(t) \left[ \sin(\sqrt{\lambda_2}t) - \sin\left(\frac{\pi^2}{4}K_2t\right) \right] \right\} \right\|_{L^2} \right), \end{aligned}$$

where

$$S_2 := \sum_{n=1}^{\infty} K_n^4 \frac{1}{T} \int_0^T \left| e^{-i\sqrt{\lambda_n}t} - e^{-i\frac{\pi^2}{4}K_nt} \right|^2 dt. \quad \square$$

Finally, in the next proposition, we check the last assumption of Proposition 13 with  $\widetilde{\mathcal{M}} = \widetilde{M}$  and  $\mathcal{M} = M$ .

**PROPOSITION 16.** *The constants  $C_0, C_1, C_2, \mathcal{C}_0, \mathcal{C}_1, \mathcal{C}_2$  defined in Propositions 14 and 15 satisfy  $C_1\mathcal{C}_1 = C_2\mathcal{C}_2$ ,  $C_0\mathcal{C}_0 < 1$ , and  $C_1\mathcal{C}_1 < 1$ .*

*Proof of Proposition 16.* First, let us give a bound on the last term in  $\mathcal{C}_0$ . We have

$$\begin{aligned} \cos\left(\frac{5\pi}{2}\right) \cosh\left(\frac{5\pi}{2}\right) &= 0 < 1, \\ \cos\left(\frac{5\pi}{2} - \frac{1}{1000}\right) \cosh\left(\frac{5\pi}{2} - \frac{1}{1000}\right) &= 1.286\dots > 1, \end{aligned}$$

and thus, thanks to the intermediate values theorem,  $x_2 \in (0, 1/1000)$ . We have

$$\sqrt{\lambda_2} - \frac{\pi^2}{4}K_2 = \left(\frac{5\pi}{2} - x_2\right)^2 - \frac{\pi^2}{4}K_2 = -5\pi x_2 + x_2^2.$$

The two terms of the right-hand side have different signs and  $x_2 < 5\pi$ , and thus

$$(8.7) \quad \left(\sqrt{\lambda_2} - \frac{\pi^2}{4}K_2\right)^2 < (5\pi x_2)^2 < 25\pi^2 10^{-6}.$$

In the same way, we deduce from

$$\cos\left(\frac{7\pi}{2}\right)\cosh\left(\frac{7\pi}{2}\right) = 0 < 1$$

and  $\cos\left(\frac{7\pi}{2} + \frac{1}{10000}\right)\cosh\left(\frac{7\pi}{2} + \frac{1}{10000}\right) = 2.98\dots > 1$

that  $x_3 \in (0, 1/10000)$ . Moreover,

$$\sqrt{\lambda_3} - \frac{\pi^2}{4}K_3 = \left(\frac{7\pi}{2} + x_3\right)^2 - \frac{\pi^2}{4}K_3 = 7\pi x_3 + x_3^2,$$

and thus

$$\left(\sqrt{\lambda_3} - \frac{\pi^2}{4}K_3\right)^2 < (7\pi 10^{-4} + 10^{-8})^2 < \pi^2 10^{-6}.$$

Therefore

$$(8.8) \quad \frac{T}{\sqrt{2}} \left[ \left(\sqrt{\lambda_2} - \frac{\pi^2}{4}K_2\right)^2 + \left(\sqrt{\lambda_3} - \frac{\pi^2}{4}K_3\right)^2 \right]^{1/2} < \frac{1}{\sqrt{2}} \frac{8}{\pi} (26\pi^2 10^{-6})^{1/2} = 8\sqrt{13} * 10^{-3}.$$

Now let us give a bound on  $S_0$ . We have

$$(8.9) \quad S_0 \leq 2 \sum_{n=1}^{\infty} \frac{1}{6} \left[ T \left( \sqrt{\lambda_n} - \frac{\pi^2}{4}K_n \right) \right]^2 \leq \frac{T^2}{3} \sum_{n=1}^{\infty} \left( \sqrt{\lambda_n} - \frac{\pi^2}{4}K_n \right)^2.$$

First, we study the cases where  $n$  is odd. We have

$$\nu_{2k-1} = 2k\pi - \frac{\pi}{2} + x_{2k-1} = (4k-1)\frac{\pi}{2} + x_{2k-1},$$

and thus

$$\left(\sqrt{\lambda_{2k-1}} - \frac{\pi^2}{4}K_{2k-1}\right)^2 = (\pi(4k-1)x_{2k-1} + x_{2k-1}^2)^2.$$

For every  $k \geq 2$ , we have  $x_{2k-1} \leq \pi(4k-1)$ , and thus, by using (3.3) and (3.4), we get

$$\begin{aligned} \left(\sqrt{\lambda_{2k-1}} - \frac{\pi^2}{4}K_{2k-1}\right)^2 &\leq [2\pi(4k-1)x_{2k-1}]^2 \\ &\leq 4 \left[ \pi(4k-1) \frac{\pi}{2 \cosh(\nu_{2k-1})} \right]^2 \\ &\leq \pi^2 \frac{[(4k-1)\pi]^2}{\cosh(2k\pi - \pi/2)^2} \\ &\leq \frac{\pi^2}{a} \frac{1}{\cosh(2k\pi - \pi/2)} \\ &\leq \frac{2\pi^2}{a} e^{-2k\pi + \frac{\pi}{2}}, \end{aligned}$$

where

$$a := \frac{1}{2(7\pi)^2} \left( e^{\frac{7\pi}{2}} - 1 - \frac{7\pi}{2} \right).$$

Indeed, for  $k \geq 2$ , we have

$$\begin{aligned} \cosh \left( 2k\pi - \frac{\pi}{2} \right) &= \cosh \left( (4k-1) \frac{\pi}{2} \right) \\ &\geq \frac{1}{2} \sum_{n=2}^{\infty} \frac{1}{n!} \left( (4k-1) \frac{\pi}{2} \right)^2 \left( \frac{7\pi}{2} \right)^{n-2} \\ &\geq \frac{1}{2} \left( \frac{2}{7\pi} \right)^2 \left( e^{\frac{7\pi}{2}} - 1 - \frac{7\pi}{2} \right) \left( (4k-1) \frac{\pi}{2} \right)^2 \\ &\geq a[(4k-1)\pi]^2. \end{aligned}$$

Thus,

$$\frac{T^2}{3} \sum_{n=1, n \text{ odd}}^{\infty} \left( \sqrt{\lambda_n} - \frac{\pi^2}{4} K_n \right)^2 \leq \frac{T^2}{3} \left\{ \left( \sqrt{\lambda_1} - \frac{\pi^2}{4} K_1 \right)^2 + \frac{2\pi^2}{a} \int_1^{\infty} e^{-2\pi x + \frac{\pi}{2}} dx \right\},$$

We have

$$\cos \left( \frac{3\pi}{2} + \frac{1}{55} \right) \cosh \left( \frac{3\pi}{2} + \frac{1}{55} \right) = 1.030 \dots > 1,$$

and thus  $x_1 \in (0, 1/55)$ . Therefore

$$(8.10) \quad \frac{T^2}{3} \sum_{n=1, n \text{ odd}}^{\infty} \left( \sqrt{\lambda_n} - \frac{\pi^2}{4} K_n \right)^2 \leq \frac{1}{3} \left( \frac{8}{\pi} \right)^2 \left\{ \left( \frac{3\pi}{55} + \left( \frac{1}{55} \right)^2 \right)^2 + \frac{\pi}{a} e^{-3\pi/2} \right\}$$

Now we deal with even integers in the sum  $S_0$ . We have

$$\nu_{2k} = 2k\pi + \frac{\pi}{2} - x_{2k} = (4k+1) \frac{\pi}{2} - x_{2k},$$

and thus, for  $k \geq 2$ , by using (3.4), we get

$$\begin{aligned} \left( \sqrt{\lambda_{2k}} - \frac{\pi^2}{4} K_{2k} \right)^2 &= (\pi(4k+1)x_{2k} - x_{2k}^2)^2 \\ &\leq (\pi(4k+1)x_{2k})^2 \\ &\leq \frac{\pi^2}{4} \frac{[(4k+1)\pi]^2}{\cosh(2k\pi + \pi/4)^2} \\ &\leq \frac{\pi^2}{4b} \frac{1}{\cosh(2k\pi + \pi/4)} \\ &\leq \frac{\pi^2}{2b} e^{-2k\pi - \pi/4}, \end{aligned}$$

where

$$b := \frac{2}{(18\pi)^2} \left( e^{17\pi/4} - 1 - \frac{17\pi}{4} \right).$$

Indeed, for  $k \geq 2$ , we have

$$\begin{aligned} \cosh \left[ 2k\pi + \frac{\pi}{4} \right] \cosh \left[ \left( 4k + \frac{1}{2} \right) \frac{\pi}{2} \right] \\ \geq \frac{1}{2} \sum_{n=2}^{\infty} \frac{1}{n!} \left[ \left( 4k + \frac{1}{2} \right) \frac{\pi}{2} \right]^2 \left( \frac{17\pi}{4} \right)^{n-2} \\ \geq \frac{1}{2} \left( \frac{4}{17\pi} \right)^2 \left\{ e^{\frac{17\pi}{4}} - 1 - \frac{17\pi}{4} \right\} \left( \frac{4k + \frac{1}{2}}{4k + 1} \right)^2 \left( (4k + 1) \frac{\pi}{2} \right)^2 \\ \geq \frac{1}{2} \left( \frac{4}{17\pi} \right)^2 \left\{ e^{\frac{17\pi}{4}} - 1 - \frac{17\pi}{4} \right\} \left( \frac{17}{18} \right)^2 \left( (4k + 1) \frac{\pi}{2} \right)^2 \\ \geq b[(4k + 1)\pi]^2. \end{aligned}$$

Thus,

$$(8.11) \quad \frac{T^2}{3} \sum_{n=2, n \text{ even}}^{\infty} \left( \sqrt{\lambda_n} - \frac{\pi^2}{4} K_n \right)^2 \leq \frac{T^2}{3} \left\{ \left( \sqrt{\lambda_2} - \frac{\pi^2}{4} K_2 \right)^2 + \frac{\pi^2}{2b} \int_1^{\infty} e^{-2\pi x - \frac{\pi}{2}} dx \right\}.$$

Thanks to (8.11), we get

$$(8.12) \quad \frac{T^2}{3} \sum_{n=2, n \text{ even}}^{\infty} \left( \sqrt{\lambda_n} - \frac{\pi^2}{4} K_n \right)^2 \leq \frac{1}{3} \left( \frac{8}{\pi} \right)^2 \left\{ 25\pi^2 10^{-6} + \frac{\pi}{4b} e^{-5\pi/2} \right\}.$$

Thanks to the explicit expression of  $C_0$  and  $\mathcal{C}_0$  and the inequalities (8.8), (8.9), (8.10), and (8.12), we get

$$C_0 \mathcal{C}_0 = 0.9847 \dots < 1.$$

Finally, we have

$$\begin{aligned} C_2 \mathcal{C}_2 = C_1 \mathcal{C}_1 &= \frac{\sqrt{3}}{2\sqrt{2}} \pi^2 \frac{2\sqrt{2}}{\pi^2} \frac{8}{\pi} (5\pi x_2 + 7\pi x_3 + x_3^2) \\ &\leq \sqrt{3} \frac{8}{\pi} \left( \frac{5\pi}{1000} + \frac{14\pi}{10000} \right) = 0.0886 \dots < 1. \end{aligned}$$

In this proof, there are two numerical values. They were computed thanks to the software Maple, with a precision that guarantees the validity of the first decimals.  $\square$

**9. Controllability of the linearized system around  $(u, u_t, p)$ .** In all of this section,  $T := 8/\pi$ . The goal of this section is the proof of the following result, which is the only assumption of Theorem 4 which is missing, for its application to the map  $\Phi_T$ , defined by (1.8).

PROPOSITION 17. *There exist  $\delta^* > 0$ ,  $C > 0$  such that*

- *for every  $(u_0, \dot{u}_0, p) \in E_8 \cap V$ , where*

$$V := \{(u_0, \dot{u}_0, p) \in E_4; \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_4} < \delta^*\},$$

*the map  $d\Phi_T(u_0, \dot{u}_0, p)$  has a right inverse*

$$d\Phi_T(u_0, \dot{u}_0, p)^{-1} : F_7 \rightarrow E_6$$

such that, for every  $(U_0, \dot{U}_0, U_T, \dot{U}_T) \in F_7$ ,

$$\begin{aligned} \|d\Phi_T(u_0, \dot{u}_0, p)^{-1} \cdot (U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{E_2} &\leq C \|(U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{E_3}, \\ \|d\Phi_T(u_0, \dot{u}_0, p)^{-1} \cdot (U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{E_6} &\leq C [\|(U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{E_7} \\ &\quad + \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_8} \|(U_0, \dot{U}_0, U_T, \dot{U}_T)\|_{E_3}] \end{aligned}$$

• and the map

$$\begin{array}{ccc} E_8 \cap V & \times & F_7 \\ ((u_0, \dot{u}_0, p) & , & (U_0, \dot{U}_0, U_T, \dot{U}_T)) \end{array} \begin{array}{c} \rightarrow \\ \mapsto \end{array} \begin{array}{c} E_6 \\ d\Phi_T(u_0, \dot{u}_0, p)^{-1} \cdot (U_0, \dot{U}_0, U_T, \dot{U}_T) \end{array}$$

is continuous.

*Remark 5.* A natural strategy for proving Proposition 17 consists in deducing it from Proposition 11 together with an argument of close linear maps. Indeed, if we prove that, for  $(u_0, \dot{u}_0, p) \in E_8 \cap V$ ,  $d\Phi_T(u_0, \dot{u}_0, p)$  is a continuous linear map from  $E_6$  to  $F_7$  such that

$$(9.1) \quad \left\| d\Phi_T(u_0, \dot{u}_0, p) - d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0) \right\|_{\mathcal{L}(E_6, F_7)} < 1,$$

then we know that  $d\Phi_T(u_0, \dot{u}_0, p)$  has a right inverse  $d\Phi_T(u_0, \dot{u}_0, p)^{-1} : F_7 \rightarrow E_6$ . This strategy is more or less the one used in this section. However, we chose to use the closeness between moment problems (associated to the controllability of the linearized systems) instead of the closeness between  $d\Phi_T(u_0, \dot{u}_0, p)$  and  $d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0)$ . Note that the results of section 2 are not sufficient to prove (9.1). Indeed, Proposition 3 ensures only that  $d\Phi_T(u_0, \dot{u}_0, p)$  is a continuous linear map from  $E_6$  to  $F_6$  (and not  $F_7$ ) and provides bounds only for

$$(9.2) \quad \left\| d\Phi_T(u_0, \dot{u}_0, p) - d\Phi_T(u_0^{ref}, \dot{u}_0^{ref}, 0) \right\|_{\mathcal{L}(E_6, F_6)}.$$

Therefore, in order to get (9.1), we need to work more.

In subsection 9.1, we detail the strategy of the proof. We explain that the proof of Proposition 17 is the consequence of two other results stated in Proposition 20s and 21. The proof of these propositions needs preliminary work done in subsection 9.2. Finally, in subsection 9.3, we prove Proposition 20, and, in subsection 9.4, we prove Proposition 21.

**9.1. Strategy.** In order to prove Proposition 17, we will transform the controllability of the linearized system around a trajectory  $(u, u_t, p)$  into the solvability of a “generalized moment problem.” Then we will use the closeness between the generalized moment problem associated to the linearized system around  $(u, u_t, p)$  and the moment problem associated to the linearized system around  $(u^{ref}, u_t^{ref}, 0)$  to deduce the solvability of the first one from the solvability of the second one (which was proved in the previous section).

First, let us write the controllability of the linearized system around a trajectory  $(u, u_t, p)$  into a generalized moment problem. In order to do that, we need some new notations. For  $\gamma \in \mathbb{R}$ , we introduce the operator  $A_\gamma$  defined by

$$D(A_\gamma) := H^4 \cap H_0^2((0, 1), \mathbb{C}), \quad A_\gamma u := u_{xxxx} + \gamma u_{xx}.$$

It is a symmetric unbounded operator on  $L^2((0, 1), \mathbb{R})$ . Let  $(\lambda_{k, \gamma})_{k \in \mathbb{N}^*}$  be the non-decreasing sequence of the eigenvalues of  $A_\gamma$  and  $(\varphi_{k, \gamma})_{k \in \mathbb{N}^*}$  associated eigenvectors,

which form an orthonormal basis of  $L^2((0, 1), \mathbb{R})$ . The maps  $\gamma \mapsto \lambda_{k,\gamma}$  and  $\gamma \mapsto \varphi_{k,\gamma}$  are analytic, which gives a sense to the notations

$$\left. \frac{d\varphi_{k,\gamma}}{d\gamma} \right|_{\gamma_1} \quad \text{and} \quad \left. \frac{d}{d\gamma} \left[ \frac{1}{\sqrt{\lambda_{k,\gamma}}} \varphi_{k,\gamma} \right] \right|_{\gamma_1},$$

which are, respectively, the derivative of the map  $\gamma \mapsto \varphi_{k,\gamma}$  considered at the point  $\gamma = \gamma_1$  and the derivative of the map  $\gamma \mapsto \varphi_{k,\gamma}/\sqrt{\lambda_{k,\gamma}}$  considered at the point  $\gamma = \gamma_1$ .

Now we transform the controllability of the linearized system around a trajectory  $(u, u_t, p)$  into a generalized moment problem. Let  $(u_0, \dot{u}_0, p) \in E_8$  and  $u \in C^0([0, T], H^8((0, 1), \mathbb{R}))$  be the solution of

$$\begin{cases} u_{tt} + u_{xxxx} + p(t)u_{xx} = 0, x \in (0, 1), t \in (0, T), \\ u = u_x = 0 \text{ at } x = 0, 1, \\ u(0) = u_0, u_t(0) = \dot{u}_0. \end{cases}$$

Let  $(U_0, \dot{U}_0, P) \in E_6$ . We have

$$d\Phi_T(u_0, \dot{u}_0, P) \cdot (U_0, \dot{U}_0, P) = (U_0, \dot{U}_0, U(T), U_t(T)),$$

where  $U \in C^0([0, T], H^6((0, 1), \mathbb{R}))$  is the solution of

$$\begin{cases} U_{tt} + U_{xxxx} + p(t)U_{xx} + P(t)u_{xx} = 0, x \in (0, 1), t \in (0, T), \\ U = U_x = 0 \text{ at } x = 0, 1, \\ U(0) = U_0, U_t(0) = \dot{U}_0. \end{cases}$$

We have, for every  $t \in [0, T]$ ,

$$(9.3) \quad \begin{pmatrix} U(t) \\ U_t(t) \end{pmatrix} = \sum_{k=1}^{\infty} 2\Re(x_k(t)X_{k,p(t)}),$$

where, for every  $k \in \mathbb{N}^*$ ,

$$(9.4) \quad x_k(t) := \frac{1}{2} \int_0^1 \left[ U(t, x)\varphi_{k,p(t)}(x) - \dot{U}(t, x) \frac{1}{i\sqrt{\lambda_{k,p(t)}}} \varphi_{k,p(t)}(x) \right] dx,$$

$$(9.5) \quad X_{k,\gamma} := \begin{pmatrix} \varphi_{k,\gamma} \\ -i\sqrt{\lambda_{k,\gamma}}\varphi_{k,\gamma} \end{pmatrix}.$$

By using the partial differential equation solved by  $U$ , we get

$$\begin{aligned} \dot{x}_k &= \frac{1}{2} \int_0^1 \left( U_t \varphi_{k,p} + [U_{xxxx} + p(t)U_{xx} + P(t)u_{xx}] \frac{\varphi_{k,p}}{i\sqrt{\lambda_{k,p}}} \right) dx \\ &\quad + \frac{\dot{p}}{2} \int_0^1 \left( U \left[ \frac{d\varphi_{k,\gamma}}{d\gamma} \right]_{p(t)} - U_t \frac{d}{d\gamma} \left[ \frac{\varphi_{k,\gamma}}{i\sqrt{\lambda_{k,\gamma}}} \right]_{p(t)} \right) dx \\ &= -i\sqrt{\lambda_{k,p(t)}}x_k(t) - \frac{i}{2}P(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle \\ &\quad + \frac{1}{2}\dot{p}(t) \left( \left\langle U(t), \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{p(t)} + i \left\langle \dot{U}(t), \frac{d}{d\gamma} \left[ \frac{\varphi_{k,\gamma}}{\sqrt{\lambda_{k,\gamma}}} \right]_{p(t)} \right\rangle \right). \end{aligned}$$

This first order ordinary differential equation can be solved explicitly. Then the equality

$$d\Phi_T(u_0, \dot{u}_0, p) \cdot (U_0, \dot{U}_0, P) = (U_0, \dot{U}_0, U_T, \dot{U}_T)$$

is equivalent to  $(U(T), \dot{U}(T)) = (U_T, \dot{U}_T)$ , which is equivalent to the generalized moment problem

$$\Upsilon_{(u_0, \dot{u}_0, p)}(P) = d(U_0, \dot{U}_0, U_T, \dot{U}_T),$$

where  $\Upsilon_{(u_0, \dot{u}_0, p)}(P) := (\Upsilon_{(u_0, \dot{u}_0, p)}(P)_k)_{k \in \mathbb{N}^*}$ ,  $d(U_0, \dot{U}_0, U_T, \dot{U}_T) := (d(U_0, \dot{U}_0, U_T, \dot{U}_T)_k)_{k \in \mathbb{N}^*}$ , and, for every  $k \in \mathbb{N}^*$ ,

(9.6)

$$\begin{aligned} \Upsilon_{(u_0, \dot{u}_0, p)}(P)_k &:= \int_0^T \left\{ \frac{-i}{2} P(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle + \frac{1}{2} \dot{p}(t) \left\langle U(t), \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{p(t)} \right. \\ &\quad \left. + \frac{i}{2} \dot{p}(t) \left\langle \dot{U}(t), \frac{d}{d\gamma} \left[ \frac{\varphi_{k,\gamma}}{\sqrt{\lambda_{k,\gamma}}} \right]_{p(t)} \right\rangle \right\} e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt, \\ d(U_0, \dot{U}_0, U_T, \dot{U}_T)_k &:= \frac{1}{2} e^{i \int_0^T \sqrt{\lambda_{k,p(s)}} ds} \left[ \langle U_T, \varphi_k \rangle - \frac{1}{i\sqrt{\lambda_k}} \langle \dot{U}_T, \varphi_k \rangle \right] \\ &\quad - \frac{1}{2} \left[ \langle U_0, \varphi_k \rangle - \frac{1}{i\sqrt{\lambda_k}} \langle \dot{U}_0, \varphi_k \rangle \right]. \end{aligned}$$

Notice that the right-hand side  $d(U_0, \dot{U}_0, U_T, \dot{U}_T)$  belongs to  $h^7(\mathbb{N}^*, \mathbb{C})$  when  $(U_0, \dot{U}_0, U_T, \dot{U}_T) \in F_7$ . Thus, Proposition 17 is equivalent to the following proposition.

PROPOSITION 18. *There exist  $\delta^* > 0$ ,  $C > 0$  such that*

- *for every  $(u_0, \dot{u}_0, p) \in E_8 \cap V$ , where*

$$V := \{(u_0, \dot{u}_0, p) \in E_4; \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_4} < \delta^*\},$$

*the map  $\Upsilon_{(u_0, \dot{u}_0, p)}$  has a right inverse*

$$\Upsilon_{(u_0, \dot{u}_0, p)}^{-1} : h^7(\mathbb{N}^*, \mathbb{C}) \rightarrow H^2 \cap H_0^1((0, T), \mathbb{R})$$

*such that, for every  $d \in h^7(\mathbb{N}^*, \mathbb{C})$ ,*

$$\|\Upsilon_{(u_0, \dot{u}_0, p)}^{-1} \cdot d\|_{L^2((0, T), \mathbb{R})} \leq C \|d\|_{h^3},$$

$$\|\Upsilon_{(u_0, \dot{u}_0, p)}^{-1} \cdot d\|_{H^2} \leq C [\|d\|_{h^7} + \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_8} \|d\|_{h^3}],$$

- *the map*

$$\begin{array}{ccc} E_8 \cap V & \times & h^7(\mathbb{N}^*, \mathbb{C}) \rightarrow H^2 \cap H_0^1((0, T), \mathbb{R}) \\ ((u_0, \dot{u}_0, p) & , & d) \mapsto \Upsilon_{(u_0, \dot{u}_0, p)}^{-1} \cdot d \end{array}$$

*is continuous.*

We will get Proposition 18 by applying the following proposition with  $\widetilde{\mathcal{M}}$  replaced by  $\Upsilon_{(u_0^{ref}, \dot{u}_0^{ref}, 0)}$ ,  $\mathcal{M}$  replaced by  $\Upsilon_{(u_0, \dot{u}_0, p)}$ ,  $\Delta_4$  replaced by  $C\|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_4}$ , and  $\Delta_8$  replaced by  $C\|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_8}$ .

PROPOSITION 19. Let  $\widetilde{\mathcal{M}}$  be a continuous linear map  $L^2((0, T), \mathbb{R}) \rightarrow h^3(\mathbb{N}^*, \mathbb{C})$  and  $H_0^2((0, T), \mathbb{R}) \rightarrow h^7(\mathbb{N}^*, \mathbb{C})$  that has a continuous right inverse  $\widetilde{\mathcal{M}}^{-1} : h^7(\mathbb{N}^*, \mathbb{C}) \rightarrow H_0^2((0, T), \mathbb{R})$  satisfying, for every  $d \in h^7(\mathbb{N}^*, \mathbb{C})$ ,

$$\begin{aligned}\|\widetilde{\mathcal{M}}^{-1}(d)\|_{L^2} &\leq C_0 \|d\|_{h^3}, \\ \|\widetilde{\mathcal{M}}^{-1}(d)\|_{H_0^2} &\leq C_0 \|d\|_{h^7},\end{aligned}$$

with some positive constant  $C_0$ .

(1) Every linear map  $\mathcal{M}$  for which there exists  $\Delta_4, \Delta_8 > 0$ , with  $C_0 \Delta_4 < 1$  such that, for every  $P \in H_0^2((0, T), \mathbb{R})$ ,

$$(9.7) \quad \begin{aligned}\|(\widetilde{\mathcal{M}} - \mathcal{M})(P)\|_{h^3} &\leq \Delta_4 \|P\|_{L^2}, \\ \|(\widetilde{\mathcal{M}} - \mathcal{M})(P)\|_{h^7} &\leq \Delta_4 \|P\|_{H_0^2} + \Delta_8 \|P\|_{L^2},\end{aligned}$$

has a right inverse  $\mathcal{M}^{-1} : h^7(\mathbb{N}^*, \mathbb{C}) \rightarrow H_0^2((0, T), \mathbb{R})$  such that, for every  $d \in h^7(\mathbb{N}^*, \mathbb{C})$ ,

$$(9.8) \quad \begin{aligned}\|\mathcal{M}^{-1}(d)\|_{L^2} &\leq \frac{C_0}{1 - C_0 \Delta_4} \|d\|_{h^3}, \\ \|\mathcal{M}^{-1}(d)\|_{H_0^2} &\leq \frac{C_0}{1 - C_0 \Delta_4} \|d\|_{h^7} + \left( \frac{C_0}{1 - C_0 \Delta_4} + \frac{C_0 \Delta_8}{(1 - C_0 \Delta_4)^2} \right) \|d\|_{h^3}.\end{aligned}$$

(2) Let  $(\mathcal{M}_\epsilon)_{\epsilon>0}$ ,  $\mathcal{M}$  be linear maps that satisfy the assumptions of statement (1) with constants  $\Delta_4^\epsilon, \Delta_8^\epsilon, \Delta_4, \Delta_8$ . Let  $(d_\epsilon)_{\epsilon>0}, d \in h^7(\mathbb{N}^*, \mathbb{C})$ . We assume the following:

- (a)  $\mathcal{M}_\epsilon \rightarrow \mathcal{M}$  weakly in  $\mathcal{L}(H_0^2((0, T), \mathbb{R}), h^7(\mathbb{N}^*, \mathbb{C}))$ , i.e., for every  $P \in H_0^2((0, T), \mathbb{R})$ ,  $\mathcal{M}_\epsilon(P) \rightarrow \mathcal{M}(P)$  in  $h^7(\mathbb{N}^*, \mathbb{C})$  when  $\epsilon \rightarrow 0$ ;
- (b)  $d_\epsilon \rightarrow d$  in  $h^7(\mathbb{N}^*, \mathbb{C})$  when  $\epsilon \rightarrow 0$ ;
- (c) there exists  $\Delta_4^*, \Delta_8^* > 0$  such that  $C_0 \Delta_4^* < 1$ , and for every  $\epsilon > 0$ ,  $\Delta_4^\epsilon \leq \Delta_4^*$  and  $\Delta_8^\epsilon \leq \Delta_8^*$ .

Then  $\mathcal{M}_\epsilon^{-1}(d_\epsilon) \rightarrow \mathcal{M}^{-1}(d)$  in  $H_0^2((0, T), \mathbb{R})$ .

*Proof of Proposition 19.* First, we prove statement (1). Let  $d \in h^7(\mathbb{N}^*, \mathbb{C})$ . We define a sequence  $(P_n)_{n \in \mathbb{N}^*} \subset H_0^2((0, T), \mathbb{R})$  by

$$\begin{cases} P_0 := \widetilde{\mathcal{M}}^{-1}(P_0), \\ P_{n+1} := \widetilde{\mathcal{M}}^{-1}[(\widetilde{\mathcal{M}} - \mathcal{M})(P_n)] \quad \forall n \in \mathbb{N}. \end{cases}$$

Then, for every  $n \in \mathbb{N}$ , we have

$$(9.9) \quad \mathcal{M} \left( \sum_{k=0}^n P_k \right) = d + (\mathcal{M} - \widetilde{\mathcal{M}})(P_n).$$

Thanks to (9.7), we have, for every  $n \in \mathbb{N}$ ,

$$(9.10) \quad \begin{aligned}\|P_n\|_{L^2} &\leq C_0 (C_0 \Delta_4)^n \|d\|_{h^3}, \\ \|P_n\|_{H_0^2} &\leq C_0 (C_0 \Delta_4)^n \|d\|_{h^7} + y_n \|d\|_{h^3},\end{aligned}$$

where  $(y_n)_{n \in \mathbb{N}} \subset \mathbb{R}$  is defined by

$$(9.11) \quad \begin{cases} y_0 = C_0, \\ y_{n+1} = C_0 \Delta_4 y_n + C_0 \Delta_8 (C_0 \Delta_4)^{n+1} \quad \forall n \in \mathbb{N}. \end{cases}$$

Since  $C_0\Delta_4 < 1$ , then  $\sum P_n$  converges in  $H_0^2((0, T), \mathbb{R})$  to  $P := \sum_{n=0}^{\infty} P_n$ . By using (9.9), the convergence of  $P_n$  to zero in  $H_0^2((0, T), \mathbb{R})$ , and the continuity of  $\mathcal{M} - \widetilde{\mathcal{M}} : H_0^2 \rightarrow h^7$ , we get  $\mathcal{M}(P) = d$ . Moreover, we have

$$\begin{aligned} \|P\|_{L^2} &\leq \sum_{n=0}^{\infty} \|P_n\|_{L^2} \leq \sum_{n=0}^{\infty} C_0(C_0\Delta_4)^n \|d\|_{h^3} \leq \frac{C_0}{1 - C_0\Delta_4} \|d\|_{h^3}, \\ \|P\|_{H_0^2} &\leq \sum_{n=0}^{\infty} \|P_n\|_{H_0^2} \leq \frac{C_0}{1 - C_0\Delta_4} \|d\|_{h^7} + \left( \sum_{n=0}^{\infty} y_n \right) \|d\|_{h^3}. \end{aligned}$$

By using (9.11), we get

$$\left( \sum_{n=0}^{\infty} y_n \right) - C_0 = C_0\Delta_4 \left( \sum_{n=0}^{\infty} y_n \right) + \frac{C_0^2\Delta_4\Delta_8}{1 - C_0\Delta_4},$$

which gives (9.8).

Now we prove statement (2). Let  $P^\epsilon := \mathcal{M}_\epsilon^{-1}(d_\epsilon)$ ,  $P := \mathcal{M}^{-1}(d) \in H_0^2((0, T), \mathbb{R})$  built with the previous construction, i.e.,  $P^\epsilon = \sum_{n=0}^{\infty} P_n^\epsilon$  and  $P = \sum_{n=0}^{\infty} P_n$ . We want to prove that  $P^\epsilon \rightarrow P$  in  $H_0^2((0, T), \mathbb{R})$  when  $\epsilon \rightarrow 0$ .

First we prove by induction on  $n \in \mathbb{N}$  that, for every  $n \in \mathbb{N}$ ,

$$\mathbf{H}(n) : P_n^\epsilon \rightarrow P_n \text{ in } H_0^2((0, T), \mathbb{R}) \text{ when } \epsilon \rightarrow 0.$$

It is clear that  $P_0^\epsilon := \widetilde{\mathcal{M}}^{-1}(d_\epsilon)$  converges to  $P_0 = \widetilde{\mathcal{M}}^{-1}(d)$  in  $H_0^2((0, T), \mathbb{R})$ . Indeed,  $\widetilde{\mathcal{M}}^{-1} : h^7 \rightarrow H_0^2$  is continuous and  $d_\epsilon \rightarrow d$  in  $h^7$ . This proves  $\mathbf{H}(0)$ .

Let  $n \in \mathbb{N}$ . We assume  $\mathbf{H}(n)$ . Let us recall that

$$P_{n+1}^\epsilon = \widetilde{\mathcal{M}}^{-1}[(\widetilde{\mathcal{M}} - \mathcal{M}_\epsilon)(P_n^\epsilon)].$$

Since

$$\widetilde{\mathcal{M}} - \mathcal{M}_\epsilon \rightarrow \widetilde{\mathcal{M}} - \mathcal{M} \text{ weakly in } \mathcal{L}(H_0^2, h^7) \text{ when } \epsilon \rightarrow 0,$$

and  $P_n^\epsilon \rightarrow P_n$  strongly in  $H_0^2$ , then

$$(\widetilde{\mathcal{M}} - \mathcal{M}_\epsilon)(P_n^\epsilon) \rightarrow (\widetilde{\mathcal{M}} - \mathcal{M})(P_n) \text{ in } h^7 \text{ when } \epsilon \rightarrow 0.$$

Thanks to the continuity of  $\widetilde{\mathcal{M}}^{-1} : h^7 \rightarrow H_0^2$ , we deduce that  $\mathbf{H}(n+1)$  holds. This ends the proof by induction.

Now, let us prove statement (2) thanks to the dominated convergence theorem. For every  $\epsilon > 0$ , for every  $n \in \mathbb{N}^*$ , we know that

$$\|P_n^\epsilon\|_{H_0^2} \leq C_0(C_0\Delta_4^\epsilon)^n \|d\|_{h^7} + y_n^\epsilon \|d\|_{h^3},$$

where  $(y_n^\epsilon)_{\epsilon>0} \subset \mathbb{R}$  is defined by

$$\begin{cases} y_0^\epsilon = C_0, \\ y_{n+1}^\epsilon = C_0\Delta_4^\epsilon y_n^\epsilon + C_0\Delta_8^\epsilon (C_0\Delta_4^\epsilon)^n \quad \forall n \in \mathbb{N}. \end{cases}$$

Let  $(y_n^*)_{\epsilon>0} \subset \mathbb{R}$  be defined by

$$\begin{cases} y_0^* = C_0, \\ y_{n+1}^* = C_0\Delta_4^* y_n^* + C_0\Delta_8^* (C_0\Delta_4^*)^n. \end{cases}$$

Since  $C_0\Delta_4^* < 1$ , then  $(y_n^*)_{n \in \mathbb{N}} \in l^1(\mathbb{N}, \mathbb{C})$ . Moreover, for every  $\epsilon > 0$ , for every  $n \in \mathbb{N}$ ,  $y_n^\epsilon \leq y_n^*$ . Therefore, we have

- $P_n^\epsilon \rightarrow P_n$  in  $H_0^2((0, T), \mathbb{R})$  when  $\epsilon \rightarrow 0$ ,
- and for every  $\epsilon > 0$  and for every  $n \in \mathbb{N}$ ,

$$\|P_n^\epsilon\|_{H_0^2} \leq C_0(C_0\Delta_4^*)^n \|d\|_{h^7} + C_0\Delta_8^* y_n^* \|d\|_{h^3}.$$

The right-hand side of the previous inequality defines a sequence in  $l^1(\mathbb{N}, \mathbb{C})$ , and thus the dominated convergence theorem allows one to conclude that

$$P^\epsilon = \sum_{n=0}^{\infty} P_n^\epsilon \rightarrow \sum_{n=0}^{\infty} P_n = P \text{ in } H_0^2((0, T), \mathbb{R}) \text{ when } \epsilon \rightarrow 0.$$

This ends the proof of Proposition 19.  $\square$

Now let us explain how we apply Proposition 19 with  $\widetilde{\mathcal{M}} = \Upsilon_{(u_0^{ref}, \dot{u}_0^{ref}, 0)}$ ,  $\mathcal{M} = \Upsilon_{(u_0, \dot{u}_0, p)}$ ,  $\mathcal{M}_\epsilon = \Upsilon_{(u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon)}$ , where  $(u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon) \rightarrow (u_0, \dot{u}_0, p)$  in  $E_8$ . First, note that the first assumption of Proposition 19, with  $\widetilde{\mathcal{M}} = \Upsilon_{(u_0^{ref}, \dot{u}_0^{ref}, 0)}$ , holds thanks to Proposition 12. In order to prove the estimate (9.7), we use the following decomposition:

$$\begin{aligned} & (\Upsilon_{(u_0, \dot{u}_0, p)} - \Upsilon_{(u^{ref}(0), \dot{u}^{ref}(0), 0)})(P) \\ &= \frac{-i}{2} \Upsilon_{(u_0, \dot{u}_0, p)}^1(P) + \frac{1}{2} \Upsilon_{(u_0, \dot{u}_0, p)}^2(P) + \frac{i}{2} \Upsilon_{(u_0, \dot{u}_0, p)}^3(P), \end{aligned}$$

where, for every  $k \in \mathbb{N}^*$ ,

$$\begin{aligned} \Upsilon_{(u_0, \dot{u}_0, p)}^1(P)_k &:= \int_0^T P(t) \left( \left\langle u_{xx}(t), \frac{\varphi_{k,p}(t)}{\sqrt{\lambda_{k,p}(t)}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p}(s)} ds} - \left\langle u_{xx}^{ref}(t), \frac{\varphi_k}{\sqrt{\lambda_k}} \right\rangle e^{i \sqrt{\lambda_k} t} \right) dt, \\ \Upsilon_{(u_0, \dot{u}_0, p)}^2(P)_k &:= \int_0^T \dot{p}(t) \left\langle U(t), \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{p(t)} e^{i \int_0^t \sqrt{\lambda_{k,p}(s)} ds} dt, \\ \Upsilon_{(u_0, \dot{u}_0, p)}^3(P)_k &:= \int_0^T \dot{p}(t) \left\langle \dot{U}(t), \frac{d}{d\gamma} \left[ \frac{\varphi_{k,\gamma}}{\sqrt{\lambda_{k,\gamma}}} \right]_{p(t)} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p}(s)} ds} dt. \end{aligned}$$

In sections 9.3 and 9.4, we prove the following proposition that allows us to deduce Proposition 18 from Proposition 19.

**PROPOSITION 20.** *There exist  $\delta^* > 0$ ,  $C > 0$  such that, for every  $j \in \{1, 2, 3\}$ , for every  $(u_0, \dot{u}_0, p) \in E_8$ , and for every  $P \in H_0^2((0, T), \mathbb{R})$ ,*

$$\|\Upsilon_{(u_0, \dot{u}_0, p)}^j(P)\|_{h^3(\mathbb{N}^*, \mathbb{C})} \leq C \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_4} \|P\|_{L^2},$$

$$\begin{aligned} & \|\Upsilon_{(u_0, \dot{u}_0, p)}^j(P)\|_{h^7(\mathbb{N}^*, \mathbb{C})} \\ & \leq C [\|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_8} \|P\|_{L^2} + \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_4} \|P\|_{H_0^2}]. \end{aligned}$$

**PROPOSITION 21.** *Let  $((u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon))_{\epsilon>0}$ ,  $(u_0, \dot{u}_0, p)$  in  $E_8$  such that  $(u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon) \rightarrow (u_0, \dot{u}_0, p)$  in  $E_8$  when  $\epsilon \rightarrow 0$ . Then  $\Upsilon_{(u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon)} \rightarrow \Upsilon_{(u_0, \dot{u}_0, p)}$  weakly in  $\mathcal{L}(H_0^2, h^7)$ , when  $\epsilon \rightarrow 0$ .*

The proofs of Propositions 20 and 21 need preliminary work that is developed in the next subsection.

**9.2. Preliminaries.** In this subsection, we prove technical results which are useful for the proof of Propositions 20 and 21.

**9.2.1. Technical results about  $\lambda_{k,\gamma}$  and  $\varphi_{k,\gamma}$ .** In this section, we state some useful results on the eigenvalues  $(\lambda_{k,\gamma})_{k \in \mathbb{N}^*}$  and eigenfunctions  $(\varphi_{k,\gamma})_{k \in \mathbb{N}^*}$  introduced in section 9.1. When  $\gamma = 0$ , we write  $\lambda_k$  and  $\varphi_k$  instead of  $\lambda_{k,0}$  and  $\varphi_{k,0}$ . In this case, explicit expressions and asymptotic behaviors are given in Proposition 6. It is well known that  $\varphi_{k,\gamma}$  and  $\lambda_{k,\gamma}$  are analytic functions of the parameter  $\gamma$ :

$$(9.12) \quad \begin{aligned} \varphi_{k,\gamma} &= \varphi_k + \gamma \varphi_k^{(1)} + \gamma^2 \varphi_k^{(2)} + \gamma^3 \varphi_k^{(3)} + \cdots, \\ \lambda_{k,\gamma} &= \lambda_k + \gamma \lambda_k^{(1)} + \gamma^2 \lambda_k^{(2)} + \gamma^3 \lambda_k^{(3)} + \cdots. \end{aligned}$$

LEMMA 2. *There exists  $c \in (0, 1)$  such that, for every  $j, k \in \mathbb{N}^*$  with the same parity*

$$(9.13) \quad (1 - c)\pi|k - j| \leq |\nu_k - \nu_j| \leq (1 + c)\pi|k - j|,$$

$$(9.14) \quad (1 - c) \left( \frac{\pi}{2} \right)^4 |(2k + 1)^4 - (2j + 1)^4| \leq |\lambda_k - \lambda_j| \leq (1 + c) \left( \frac{\pi^2}{2} \right)^4 |(2k + 1)^4 - (2j + 1)^4|.$$

*Proof of Lemma 2.* When  $k, j \in \mathbb{N}^*$ ,  $k \neq j$ , and  $k, j$  have the same parity, thanks to (3.3), we have

$$\frac{\pi}{2}|k - j| \leq |\nu_k - \nu_j| \leq 2\pi|k - j|$$

and

$$\begin{aligned} & \left| (\lambda_k - \lambda_j) - \left( \frac{\pi}{2} \right)^4 [(2k + 1)^4 - (2j + 1)^4] \right| \\ & \leq \max \left\{ \left| \lambda_k - \left( \frac{\pi}{2} (2k + 1) \right)^4 \right|, \left| \lambda_j - \left( \frac{\pi}{2} (2j + 1) \right)^4 \right| \right\}. \end{aligned}$$

Moreover, by using (3.4), we get

$$\begin{aligned} \left| \lambda_k - \left( \frac{\pi}{2} (2k + 1) \right)^4 \right| & \leq 15 \left( \frac{\pi}{2} (2k + 1) \right)^3 x_k \text{ because } 0 < x_k < 1 \\ & \leq \left( \frac{\pi}{2} \right)^4 m \frac{15}{2320} \frac{(2k + 1)^3}{\cosh(k\pi)}, \end{aligned}$$

where  $m := \inf\{|(2l + 1)^4 - (2i + 1)^4|; l \neq i \in \mathbb{N}^* \text{ with the same parity}\} = 2320$ . Thus,

$$\begin{aligned} \left| \lambda_k - \left( \frac{\pi}{2} (2k + 1) \right)^4 \right| & \leq \left( \frac{\pi}{2} \right)^4 m c_1 \\ & \leq \left( \frac{\pi}{2} \right)^4 |(2k + 1)^4 - (2j + 1)^4| c_1, \end{aligned}$$

where

$$c_1 := \sup \left\{ \frac{15}{2320} \frac{(2k + 1)^3}{\cosh(\pi)}; k \in \mathbb{N}^* \right\} = \frac{81}{464 \cosh(\pi)} < 1,$$

which ends the proof.  $\square$

PROPOSITION 22. *For every  $k \in \mathbb{N}^*$ , we have*

$$(9.15) \quad \frac{d^4 \varphi_k^{(1)}}{dx^4} + \frac{d^2 \varphi_k}{dx^2} = \lambda_k \varphi_k^{(1)} + \lambda_k^{(1)} \varphi_k,$$

$$(9.16) \quad \lambda_k^{(1)} = -\|\varphi_k'\|_{L^2((0,1),\mathbb{R})}^2,$$

$$(9.17) \quad \varphi_k^{(1)} = \sum_{j \in \mathbb{N}^*, j \neq k, P(j)=P(k)} x_{k,j} \varphi_j, \text{ where } x_{k,j} := \frac{\langle \varphi_k'', \varphi_j \rangle}{(\lambda_k - \lambda_j)},$$

where the sum is taken over all of the integers  $j$  different from  $k$ , with the same parity as  $k$ . There exists a constant  $C > 0$  such that, for every  $k \in \mathbb{N}^*$ ,

$$(9.18) \quad |\lambda_k^{(1)}| \leq Ck^2,$$

$$(9.19) \quad \|\varphi_k^{(1)}\|_{L^2((0,1),\mathbb{R})} \leq \frac{C}{k}.$$

*Proof of Proposition 22.* Equation (9.15) corresponds to the term of first order with respect to  $\gamma$ , in the equality  $A_\gamma \varphi_{k,\gamma} = \lambda_{k,\gamma} \varphi_{k,\gamma}$  developed thanks to (9.12). Notice that the equality

$$\|\varphi_{k,\gamma}\|_{L^2((0,1),\mathbb{R})} = 1$$

implies  $\langle \varphi_k^{(1)}, \varphi_k \rangle = 0$ . Then we get (9.16) by taking the  $L^2$ -scalar product of (9.15) with the vector  $\varphi_k$ . The expression (9.17) comes from (9.15), and the parity of the functions  $\varphi_j$  justify that half of the components vanish.

Thanks to (9.16), the convexity of the  $H^s$ -norms, the behavior (3.3), and the equalities

$$\|\varphi_k\|_{L^2((0,1),\mathbb{R})} = 1, \quad \left\| \frac{d^4 \varphi_k}{dx^4} \right\|_{L^2((0,1),\mathbb{R})} = \lambda_k,$$

we get (9.18). By using (9.14) and  $\|\varphi_k''\|_{L^2} = \sqrt{\lambda_k} \leq Ck^2$ , we get

$$\begin{aligned} \|\varphi_k^{(1)}\|_{L^2((0,1),\mathbb{R})} &= \left[ \sum_{j \in \mathbb{N}^*, j \neq k, P(j)=P(k)} \left( \frac{\langle \varphi_k'', \varphi_j \rangle}{\lambda_k - \lambda_j} \right)^2 \right]^{1/2} \\ &\leq Ck^2 \left[ \sum_{j \in \mathbb{N}^*, j \neq k, P(j)=P(k)} \frac{1}{[(2k+1)^4 - (2j+1)^4]^2} \right]^{1/2}. \end{aligned}$$

Thanks to the explicit expression for  $x > 0$ ,  $x \neq K$ ,

$$\begin{aligned} \int \frac{dx}{(x^4 - K^4)^2} &= \frac{3}{16K^7} \ln \left( \frac{x+K}{|x-K|} \right) \\ &\quad - \frac{1}{16K^6} \frac{2x}{x^2 - K^2} + \frac{3}{8K^7} \arctan \left( \frac{x}{K} \right) + \frac{1}{8K^6} \frac{x}{x^2 + K^2} \end{aligned}$$

we get

$$(9.20) \quad \sum_{j \in \mathbb{N}^*, j \neq k, P(j)=P(k)} \frac{1}{[(2k+1)^4 - (2j+1)^4]^2} \leq \frac{C}{k^6},$$

which gives the conclusion.  $\square$

COROLLARY 1. *There exist  $\gamma^* > 0$  and  $C > 0$  such that, for every  $\gamma_1 \in (-\gamma^*, \gamma^*)$ , for every  $k \in \mathbb{N}^*$ , we have*

$$(9.21) \quad \|\varphi_{k,\gamma_1} - \varphi_k\|_{H^s((0,1),\mathbb{R})} \leq C|\gamma_1|k^{s-1} \text{ for every integer } s \in [0, 4],$$

$$(9.22) \quad |\lambda_{k,\gamma_1} - \lambda_k| \leq C|\gamma_1|k^2,$$

$$(9.23) \quad |\sqrt{\lambda_{k,\gamma_1}} - \sqrt{\lambda_k}| \leq C|\gamma_1|.$$

*Proof of Corollary 1.* The inequalities (9.22) and (9.23) are consequences of (9.18). The inequality (9.21) for  $s = 0$  is a consequence of (9.19). By using the equation

$$\frac{d^4}{dx^4} [\varphi_{k,\gamma_1} - \varphi_k] + \gamma_1 \varphi_{k,\gamma_1}'' = \lambda_{k,\gamma_1} (\varphi_{k,\gamma_1} - \varphi_k) + (\lambda_{k,\gamma_1} - \lambda_k) \varphi_k,$$

we get (9.21) for  $s = 4$ . Indeed, we have (9.22) and

$$\|\varphi_{k,\gamma_1}''\|_{L^2((0,1),\mathbb{R})} = \sqrt{\lambda_{k,\gamma_1}} \leq Ck^2.$$

Then (9.21) for  $s = 2, 3$  comes from the logarithmic convexity of the  $H^s$ -norm.  $\square$

PROPOSITION 23. *For every  $k \in \mathbb{N}^*$ , we have*

$$(9.24) \quad \frac{d^4 \varphi_k^{(2)}}{dx^4} + \frac{d^2 \varphi_k^{(1)}}{dx^2} = \lambda_k \varphi_k^{(2)} + \lambda_k^{(1)} \varphi_k^{(1)} + \lambda_k^{(2)} \varphi_k,$$

$$(9.25) \quad \lambda_k^{(2)} = \left\langle \frac{d^2 \varphi_k^{(1)}}{dx^2}, \varphi_k \right\rangle,$$

$$(9.26) \quad \varphi_k^{(2)} = -\frac{1}{2} \|\varphi_k^{(1)}\|_{L^2}^2 \varphi_k + \sum_{j \in \mathbb{N}^*, j \neq k, P(j)=P(k)} \frac{\langle \frac{d^2 \varphi_k^{(1)}}{dx^2}, \varphi_j \rangle - \lambda_k^{(1)} x_{k,j}}{(\lambda_k - \lambda_j)} \varphi_j.$$

*There exists a constant  $C > 0$  such that, for every  $k \in \mathbb{N}^*$ ,*

$$(9.27) \quad \|\varphi_k^{(2)}\|_{L^2((0,1),\mathbb{R})} \leq \frac{C}{k^2},$$

$$(9.28) \quad |\lambda_k^{(2)}| \leq Ck.$$

*Proof of Proposition 23.* The proof of this proposition is very similar to the one of Proposition 22; thus, here, we justify only the bound (9.27). By using (9.14), we get

$$\|\varphi_k^{(2)}\|_{L^2} \leq \frac{1}{2} \|\varphi_k^{(1)}\|_{L^2}^2 + C \left( \left\| \frac{d^2 \varphi_k^{(1)}}{dx^2} \right\|_{L^2} + |\lambda_k^{(1)}| \|\varphi_k^{(1)}\|_{L^2} \right) \left[ \sum_{j=1, j \neq k, P(j)=P(k)}^{\infty} \frac{1}{[(2k+1)^4 - (2j+1)^4]^2} \right]^{1/2}.$$

Equation (9.24) gives

$$\left\| \frac{d^4 \varphi_k^{(1)}}{dx^4} \right\|_{L^2} \leq Ck^3,$$

which, with (9.19) and the convexity of the norms, leads to

$$\left\| \frac{d^2 \varphi_k^{(1)}}{dx^2} \right\|_{L^2} \leq Ck.$$

We conclude by using also (9.18), (9.19), and (9.20).  $\square$

The vectors  $\varphi_k$  and the real numbers  $\lambda_{k,\gamma}$  are analytic functions of the parameter  $\gamma$ , so we can consider their derivatives with respect to  $\gamma$ . We introduce the notations

$$\left. \frac{d^j \varphi_{k,\gamma}}{d\gamma^j} \right]_{\gamma_1}$$

for the  $j$ th derivative of the function  $\gamma \mapsto \varphi_{k,\gamma}$  evaluated at the point  $\gamma = \gamma_1$  and

$$\lambda'_{k,\gamma_1}, \lambda''_{k,\gamma_1}$$

for the first and the second derivative, respectively, of the function  $\gamma \mapsto \lambda_{k,\gamma}$  evaluated at the point  $\gamma = \gamma_1$ .

**COROLLARY 2.** *There exist  $\gamma^* > 0$ ,  $C > 0$ , and  $l \in \mathbb{R}$  such that, for every  $\gamma_1 \in (-\gamma^*, \gamma^*)$ , for every  $k \in \mathbb{N}^*$ , we have*

$$(9.29) \quad \left\| \left[ \frac{d\varphi_{k,\gamma}}{d\gamma} \right]_{\gamma_1} - \frac{d\varphi_{k,\gamma}}{d\gamma} \right\|_{H^s((0,1),\mathbb{R})} \leq C|\gamma_1|k^{s-2} \text{ for every integer } s \in [0,4],$$

$$(9.30) \quad \left\| \left[ \frac{d\varphi_{k,\gamma}}{d\gamma} \right]_{\gamma_1} \right\|_{H^s((0,1),\mathbb{R})} \leq Ck^{s-1},$$

$$(9.31) \quad \|\varphi_{k,\gamma_1} - \varphi_k - \gamma_1 \varphi_k^{(1)}\|_{L^2((0,1),\mathbb{R})} \leq C \frac{|\gamma_1|^2}{k^2},$$

$$(9.32) \quad |\lambda'_{k,\gamma_1} - \lambda'_k| \leq C|\gamma_1|k \text{ and } |\lambda'_{k,\gamma_1}| \leq Ck^2,$$

$$(9.33) \quad \left| \sqrt{\lambda_{k,\gamma_1}} - \sqrt{\lambda_k} - \gamma_1 l \right| \leq C \frac{|\gamma_1|}{k}.$$

*Proof of Corollary 2.* The proof of Corollary 2 is similar to the one of Corollary 1; thus we justify only (9.33). We deduce from (9.28) that there exist  $C > 0$  and  $\gamma^* > 0$  such that, for every  $\gamma \in (-\gamma^*, \gamma^*)$ , for every  $k \in \mathbb{N}^*$ ,

$$\left| \sqrt{\lambda_{k,\gamma}} - \sqrt{\lambda_k} - \gamma \frac{\lambda'_k}{2\sqrt{\lambda_k}} \right| \leq C \frac{\gamma^2}{k}.$$

Thus, we need only to prove the existence of constants  $C > 0$  and  $l \in \mathbb{R}$  such that, for every  $k \in \mathbb{N}^*$ ,

$$(9.34) \quad \left| \frac{\lambda'_k}{2\sqrt{\lambda_k}} - l \right| \leq \frac{C}{k}.$$

By using (9.16), (3.7), and (3.14), we get

$$\frac{\lambda'_k}{\sqrt{\lambda_k}} = -\frac{1}{\nu_k \|v_k\|_{L^2}^2} (\xi_k^2 I_1(\nu_k) + \zeta_k I_2(\nu_k) + 2\xi_k \zeta_k I_3(\nu_k)),$$

where

$$\begin{aligned}
 I_1(x) &:= \int_0^x (\sin(y) + \sinh(y))^2 dy \\
 &= \frac{\sinh(2x)}{4} + \sin(x) \cosh(x) - \cos(x) \sinh(x) - \frac{\sin(2x)}{4}, \\
 I_2(x) &:= \int_0^x (\cos(y) - \cosh(y))^2 dy \\
 &= \frac{\sinh(2x)}{4} - \cos(x) \sinh(x) - \sin(x) \cosh(x) + x + \frac{\sin(2x)}{4}, \\
 I_3(x) &:= \int_0^x (\sin(y) + \sinh(y))(-\cos(y) + \cosh(y)) dy \\
 &= \frac{\cosh(2x)}{4} - \cos(x) \cosh(x) + \frac{1}{4} + \frac{\cos(x)^2}{2}.
 \end{aligned}$$

We get (9.34) thanks to (3.8) and the asymptotic behaviors (3.13).  $\square$

In the same way as we proved the two previous propositions, we can get the next one.

PROPOSITION 24. *There exists  $C > 0$  such that, for every  $k \in \mathbb{N}^*$ ,*

$$\|\varphi_k^{(3)}\|_{L^2} \leq \frac{C}{k^2}.$$

Thus, there exist  $\gamma^* > 0$  and  $C > 0$  such that, for every  $\gamma \in (-\gamma^*, \gamma^*)$ , for every  $k \in \mathbb{N}^*$ , we have

$$(9.35) \quad \left\| \left[ \frac{d^2 \varphi_{k,\gamma}}{d\gamma^2} \right]_{\gamma_1} \right\|_{L^2} \leq \frac{C}{k^2}.$$

**9.2.2. Technical results about sequences with the same form as  $\Upsilon_{(u_0, \dot{u}_0, p)}(P)$ .** In this section, we prove bounds for the  $h^1$ - or  $h^3$ -norm of sequences  $S = (S_k)_{k \in \mathbb{N}^*}$  that have a form similar to the one of  $\Upsilon_{(u_0, \dot{u}_0, p)}(P)$ . For example,

$$S_k := \int_0^T w(t) \left\langle f(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds},$$

where  $p, w : [0, T] \rightarrow \mathbb{R}$  and  $f : [0, T] \rightarrow L^2((0, 1), \mathbb{R})$ .

LEMMA 3. *Let  $\gamma^*$  be as in Corollaries 1 and 2. There exists  $C > 0$  such that, for every  $\gamma_1 \in (-\gamma^*, \gamma^*)$ , for every  $f \in L^2((0, 1), \mathbb{R})$ ,*

$$(9.36) \quad \sum_{k=1}^{\infty} \left| k \left\langle f, \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{\gamma_1} \right|^2 \leq C \|f\|_{L^2((0,1),\mathbb{R})}^2,$$

$$(9.37) \quad \sum_{k=1}^{\infty} \left| k \langle f, \varphi_{k,\gamma_1} - \varphi_k \rangle \right|^2 \leq C \gamma_1^2 \|f\|_{L^2((0,1),\mathbb{R})}^2.$$

*Proof of Lemma 3.* Note that, in order to get (9.36), it is sufficient to prove it with  $\gamma_1 = 0$ . Indeed, by using Corollary 2, we have, for  $\gamma_1 \in (-\gamma^*, \gamma^*)$  and  $f \in L^2((0, 1), \mathbb{R})$ ,

$$\left| k \left\langle f, \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{\gamma_1} - \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_0 \right| \leq \|f\|_{L^2((0,1),\mathbb{R})} \frac{C|\gamma_1|}{k}.$$

For  $f \in L^2((0, 1), \mathbb{R})$ , we have

$$\sum_{k=1}^{\infty} \left| k \left\langle f, \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_0 \right|^2 = \sum_{k=1}^{\infty} \left| \sum_{j=1, j \neq k, P(j)=P(k)}^{\infty} a_{k,j} \langle f, \varphi_j \rangle \right|^2,$$

where the second sum is taken over all  $j \in \mathbb{N}^*$  having the same parity as  $k$  such that  $j \neq k$ ,  $a_{k,j} := kx_{k,j}$ ,  $x_{k,j}$  is defined in (9.17) when  $P(k) = P(j)$ , and  $a_{k,j} = 0$  when  $P(k) \neq P(j)$ .

If we prove that there exists  $C > 0$  such that

$$(9.38) \quad \forall j \in \mathbb{N}^* \quad \sum_{k \in \mathbb{N}^*, k \neq j, P(k)=P(j)} |a_{k,j}| \leq C \text{ and } \forall k \in \mathbb{N}^* \quad \sum_{j \in \mathbb{N}^*, j \neq k, P(j)=P(k)} |a_{k,j}| \leq C,$$

then Cauchy–Schwarz inequality provides

$$\forall (x_j)_{j \in \mathbb{N}^*} \in l^2(\mathbb{N}^*, \mathbb{C}), \quad \sum_{k=1}^{\infty} \left| \sum_{j=1}^{\infty} a_{j,k} x_j \right| \leq C^2 \sum_{j=1}^{\infty} |x_j|^2,$$

which gives the conclusion. Let us prove (9.38).

By using (3.14), (3.10), (3.17), and (9.14), we get

$$|a_{k,j}| \leq C \frac{k^3 j^2 \max\{k, j\}}{[(2k+1)^4 - (2j+1)^4]^2} \text{ when } P(k) \neq P(j).$$

Thus, we have, for every  $k \in \mathbb{N}^*$ ,

$$\begin{aligned} \sum_{j=1}^{\infty} |a_{k,j}| &\leq Ck^4 \sum_{j < k, P(j)=P(k)}^{\infty} \frac{j^2}{[(2k+1)^4 - (2j+1)^4]^2} \\ &\quad + Ck^3 \sum_{j > k, P(j)=P(k)}^{\infty} \frac{j^3}{[(2j+1)^4 - (2k+1)^4]^2} \\ &\leq Ck^4 \int_3^{2k} \frac{x^2}{[(2k+1)^4 - x^4]^2} dx + Ck^3 \int_{2k+2}^{\infty} \frac{x^3}{[(2k+1)^4 - x^4]^2} dx \leq C. \end{aligned}$$

For every  $j \in \mathbb{N}^*$ , we have

$$\begin{aligned} \sum_{k=1}^{\infty} |a_{k,j}| &\leq Cj^3 \sum_{k < j, P(j)=P(k)}^{\infty} \frac{k^3}{[(2j+1)^4 - (2k+1)^4]^2} \\ &\quad + Cj^2 \sum_{k > j, P(j)=P(k)}^{\infty} \frac{k^4}{[(2j+1)^4 - (2k+1)^4]^2} \\ &\leq Cj^3 \int_3^{2j} \frac{x^3}{[(2j+1)^4 - x^4]^2} dx + Cj^2 \int_{2j+2}^{\infty} \frac{x^4}{[(2j+1)^4 - x^4]^2} dx \leq C. \end{aligned}$$

Now let us prove (9.37). We use the decomposition

$$\varphi_{k,\gamma_1} - \varphi_k = \left( \varphi_{k,\gamma_1} - \varphi_k - \gamma_1 \frac{d\varphi_{k,\gamma}}{d\gamma} \right)_0 + \gamma_1 \frac{d\varphi_{k,\gamma}}{d\gamma} \Big|_0.$$

For the first term, we use (9.31), and, for the second one, we apply (9.36).  $\square$

LEMMA 4. Let  $\gamma^*$  be as in Corollaries 1 and 2. There exists  $C > 0$  such that, for every  $\gamma_1 \in (-\gamma^*, \gamma^*)$ , for every  $f \in H_0^2((0, 1), \mathbb{R})$ ,

$$(9.39) \quad \sum_{k=1}^{\infty} \left| k^3 \left\langle f, \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{\gamma_1} \right|^2 \leq C \|f\|_{H_0^2((0,1),\mathbb{R})}^2.$$

*Proof of Lemma 4.* First, we prove Lemma 4 for  $\gamma_1 = 0$  with the same argument as for the previous lemma. For  $f \in H_0^2((0, 1), \mathbb{R})$ , thanks to integrations by parts, we get

$$\sum_{k=1}^{\infty} \left| k^3 \left\langle f, \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_0 \right|^2 = \sum_{k=1}^{\infty} \left| \sum_{j=1}^{\infty} b_{k,j} \left\langle f'', \frac{\varphi_j''}{\sqrt{\lambda_j}} \right\rangle \right|^2,$$

where

$$b_{k,j} := \frac{k^3}{\sqrt{\lambda_j}} x_{k,j} \text{ when } P(k) = P(j), k \neq j,$$

$b_{k,j} = 0$  in the other cases, and  $x_{k,j}$  is defined in (9.17). Note that  $(\varphi_j''/\sqrt{\lambda_j})_{j \in \mathbb{N}^*}$  is an orthonormal family of  $L^2((0, 1), \mathbb{R})$ , and thus

$$\sum_{j=1}^{\infty} \left| \left\langle f'', \frac{\varphi_j''}{\sqrt{\lambda_j}} \right\rangle \right|^2 \leq \|f\|_{H_0^2((0,1),\mathbb{R})}^2.$$

We have

$$|b_{k,j}| \leq C \frac{k^5 \max\{k, j\}}{[(2k+1)^4 - (2j+1)^4]^2} \text{ when } P(k) \neq P(j).$$

We have, for every  $k \in \mathbb{N}^*$ ,

$$\begin{aligned} \sum_{j=1}^{\infty} |b_{k,j}| &\leq Ck^6 \sum_{j < k, P(j)=P(k)}^{\infty} \frac{1}{[(2k+1)^4 - (2j+1)^4]^2} \\ &\quad + Ck^5 \sum_{j > k, P(j)=P(k)}^{\infty} \frac{j}{[(2j+1)^4 - (2k+1)^4]^2} \\ &\leq Ck^6 \int_3^{2k} \frac{1}{[(2k+1)^4 - x^4]^2} dx + Ck^5 \int_{2k+2}^{\infty} \frac{x}{[(2k+1)^4 - x^4]^2} dx \leq C. \end{aligned}$$

For every  $j \in \mathbb{N}^*$ , we have

$$\begin{aligned} \sum_{k=1}^{\infty} |b_{k,j}| &\leq Cj \sum_{k < j, P(j)=P(k)}^{\infty} \frac{k^5}{[(2j+1)^4 - (2k+1)^4]^2} \\ &\quad + C \sum_{k > j, P(j)=P(k)}^{\infty} \frac{k^6}{[(2j+1)^4 - (2k+1)^4]^2} \\ &\leq Cj \int_3^{2j} \frac{x^5}{[(2j+1)^4 - x^4]^2} dx + C \int_{2j+2}^{\infty} \frac{x^6}{[(2j+1)^4 - x^4]^2} dx \leq C. \end{aligned}$$

This gives the conclusion for  $\gamma_1 = 0$ .

Now let us prove that, for  $\gamma_1 \in (-\gamma^*, \gamma^*)$  and  $f \in H_0^2((0, 1), \mathbb{C})$ , we have

$$(9.40) \quad \left| \left\langle f, \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{\gamma_1} - \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_0 \right| \leq \frac{C|\gamma_1|}{k^4} \|f\|_{H_0^2((0,1),\mathbb{R})},$$

which gives the conclusion. Thanks to the equation

$$A_{\gamma_1} \frac{d\varphi_{k,\gamma}}{d\gamma} \Big|_{\gamma_1} + \varphi_{k,\gamma_1}'' = \lambda_{k,\gamma_1} \frac{d\varphi_{k,\gamma}}{d\gamma} \Big|_{\gamma_1} + \lambda_{k,\gamma_1}' \varphi_{k,\gamma_1},$$

we have

$$\begin{aligned} \left\langle f, \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{\gamma_1} - \frac{d\varphi_{k,\gamma}}{d\gamma} \Big|_0 \right\rangle &= \frac{1}{\lambda_{k,\gamma_1}} \left\langle f'', \left( \frac{d\varphi_{k,\gamma}}{d\gamma} \right)_{\gamma_1} - \frac{d\varphi_{k,\gamma}}{d\gamma} \Big|_0 \right\rangle'' \\ &\quad + \frac{\gamma_1}{\lambda_{k,\gamma_1}} \left\langle f'', \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{\gamma_1} \\ &\quad + \frac{1}{\lambda_{k,\gamma_1}} \langle f'', \varphi_{k,\gamma_1} - \varphi_k \rangle - \frac{\lambda_{k,\gamma_1}'}{\lambda_{k,\gamma_1}} \langle f, \varphi_{k,\gamma_1} - \varphi_k \rangle \\ &\quad + \left( \frac{1}{\lambda_{k,\gamma_1}} - \frac{1}{\lambda_k} \right) \left( \left\langle f'', \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_0 \right)'' + \langle f'', \varphi_k \rangle \\ &\quad - \left( \frac{\lambda_{k,\gamma_1}'}{\lambda_{k,\gamma_1}} - \frac{\lambda_k'}{\lambda_k} \right) \langle f, \varphi_k \rangle. \end{aligned}$$

We get (9.40) by using (9.29), (9.30), (9.21), (9.22), and (9.32).  $\square$

**PROPOSITION 25.** *There exists a constant  $C > 0$  such that, for every  $w \in L^2((0, T), \mathbb{R})$  and for every  $f \in C^0([0, T], H^1((0, 1), \mathbb{R}))$ , the  $h^1(\mathbb{N}^*, \mathbb{C})$ -norm of the sequence  $(S_k)_{k \in \mathbb{N}^*}$  defined by*

$$S_k := \int_0^T w(t) \langle f(t), \varphi_k \rangle e^{-i\sqrt{\lambda_k}t} dt$$

*is bounded by*

$$C \|w\|_{L^2((0,T),\mathbb{R})} \|f\|_{C^0((0,T),H^1((0,T),\mathbb{R}))}.$$

*Proof of Proposition 25.* We introduce the function  $g \in C^0([0, T], H_0^1((0, T), \mathbb{R}))$  defined by

$$g(t, x) := f(t, x) - f(t, 0)(1 - x) - f(t, 1)x.$$

We have

$$\begin{aligned} (9.41) \quad S_k &= \int_0^T w(t) \langle g(t), \varphi_k \rangle e^{-i\sqrt{\lambda_k}t} dt \\ &\quad + \langle (1 - x), \varphi_k \rangle \int_0^T w(t) f(t, 0) e^{-i\sqrt{\lambda_k}t} + \langle x, \varphi_k \rangle \int_0^T w(t) f(t, 1) e^{-i\sqrt{\lambda_k}t}. \end{aligned}$$

Thanks to Cauchy–Schwarz inequality in  $L^2((0, T), \mathbb{R})$ , we get the following bound for the  $h^1$ -norm of the first term of the right-hand side of (9.41):

$$\|w\|_{L^2} \left( \int_0^T \sum_{k=1}^{\infty} |k \langle g(t), \varphi_k \rangle|^2 dt \right)^{1/2} \leq C \|w\|_{L^2} \|g\|_{C^0([0, T], H_0^1((0, 1), \mathbb{R}))}.$$

Thanks to (3.7), (3.8), and (3.10) we get

$$(-1)^k \langle (1-x), \varphi_k \rangle = \langle x, \varphi_k \rangle \sim \frac{C}{\nu_k},$$

which gives the conclusion.  $\square$

**PROPOSITION 26.** *Let  $\gamma^*$  be as in Corollaries 1 and 2. There exists a constant  $C > 0$  such that, for every  $p \in H^1((0, T), \mathbb{R})$ , with  $\|p\|_{L^\infty((0, T), \mathbb{R})} < \gamma^*$ , for every  $w \in L^2((0, T), \mathbb{R})$ , and for every  $f \in C^0([0, T], H^1((0, 1), \mathbb{R}))$ , the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of the sequences  $(S_k)_{k \in \mathbb{N}^*}$ ,  $(\tilde{S}_k)_{k \in \mathbb{N}^*}$  defined by*

$$S_k := \int_0^T w(t) \left\langle f(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{-i\sqrt{\lambda_k}t} dt,$$

$$\tilde{S}_k := \int_0^T w(t) \left\langle f(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{-i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt$$

are bounded by

$$C \|w\|_{L^2((0, T), \mathbb{R})} \|f\|_{C^0([0, T], H^1((0, T), \mathbb{R}))},$$

and, moreover,

$$\|S - \tilde{S}\|_{h^3} \leq C \|p\|_{L^\infty} \|w\|_{L^2} \|f\|_{C^0([0, T], L^2)}.$$

*Proof of Proposition 26.* Let us consider the decomposition  $S_k = S^1 + S^2 + S^3$ , where, for every  $k \in \mathbb{N}^*$ ,

$$(9.42) \quad \begin{aligned} S_k^1 &:= \int_0^T w(t) \left( \frac{1}{\sqrt{\lambda_{k,p(t)}}} - \frac{1}{\sqrt{\lambda_k}} \right) \langle f(t), \varphi_{k,p(t)} \rangle e^{i\sqrt{\lambda_k}t} dt, \\ S_k^2 &:= \frac{1}{\sqrt{\lambda_k}} \int_0^T w(t) \langle f(t), \varphi_{k,p(t)} - \varphi_k \rangle e^{i\sqrt{\lambda_k}t} dt, \\ S_k^3 &:= \frac{1}{\sqrt{\lambda_k}} \int_0^T w(t) \langle f(t), \varphi_k \rangle e^{i\sqrt{\lambda_k}t} dt. \end{aligned}$$

Thanks to (9.23) we have

$$\left| \frac{1}{\sqrt{\lambda_{k,p(t)}}} - \frac{1}{\sqrt{\lambda_k}} \right| \leq \frac{C|p(t)|}{k^4}.$$

Thus, thanks to the Cauchy–Schwarz inequality, the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of  $S^1$  is bounded by

$$C \|w\|_{L^2} \|p\|_{L^\infty} \|f\|_{C^0([0, T], L^2)} \leq C \|w\|_{L^2} \|f\|_{C^0([0, T], L^2)}.$$

Thanks to Lemma 3, the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of  $S^2$  is bounded by

$$C\|w\|_{L^2}\|p\|_{L^\infty}\|f\|_{C^0([0,T],L^2)} \leq C\|w\|_{L^2}\|f\|_{C^0([0,T],L^2)}.$$

We conclude the study of  $S$  by applying Proposition 25 to  $S^3$ .

By using (see Corollary 1)

$$(9.43) \quad \sqrt{\lambda_{k,p(s)}} = \sqrt{\lambda_k} + p(s)l + \epsilon_k(s), \text{ where } l \in \mathbb{R} \text{ and } |\epsilon_k(s)| \leq C \frac{\|p\|_{L^\infty}}{k},$$

we get  $\tilde{S} - S = \delta S^1 + \delta S^2$ , where, for every  $k \in \mathbb{N}^*$ ,

$$(9.44) \quad \begin{aligned} \delta S_k^1 &:= \int_0^T w(t) (e^{il \int_0^t p(s) ds} - 1) \left\langle f(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i\sqrt{\lambda_k}t} dt \\ \delta S_k^2 &:= \int_0^T w(t) e^{il \int_0^t p(s) ds} \left\langle f(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i\sqrt{\lambda_k}t} [e^{i \int_0^t \epsilon_k(s) ds} - 1] dt. \end{aligned}$$

The first part of Proposition 26 gives the following bound for the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of  $\delta S^1$ :

$$C\|w\|_{L^2}\|p\|_{L^\infty}\|f\|_{C^0([0,T],H^1)}.$$

Thanks to Cauchy-Schwarz inequality and the bound on  $\epsilon_k$  given in (9.43), we get the following bound for the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of  $\delta S^2$ :

$$C\|w\|_{L^2}\|p\|_{L^\infty}\|f\|_{C^0([0,T],L^2)}. \quad \square$$

**9.3. Proof of Proposition 20.** In all of this section,  $(u_0, \dot{u}_0, p) \in E_8$  is fixed, and we use the notations

$$(9.45) \quad \begin{aligned} \delta_4 &:= \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_4}, \\ \delta_6 &:= \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_6}, \\ \delta_8 &:= \|(u_0 - u_0^{ref}, \dot{u}_0 - \dot{u}_0^{ref}, p)\|_{E_8}. \end{aligned}$$

We assume that  $\delta_4 \in [0, 1]$  and that  $\delta_4$  is small enough so that  $\|p\|_{L^\infty((0,T),\mathbb{R})} < \gamma^*$ , where  $\gamma^*$  is given in Corollaries 1 and 2. We write  $\Upsilon^j$  instead of  $\Upsilon_{(u_0, \dot{u}_0, p)}^j(P)$ .

*Proof of Proposition 20 for  $j = 1$ .* For the study of  $\Upsilon^1$  in  $h^3(\mathbb{N}^*, \mathbb{C})$ , we consider the decomposition

$$(9.46) \quad \begin{aligned} \Upsilon^1(P)_k &= \int_0^T P(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle [e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} - e^{i\sqrt{\lambda_k}t}] dt \\ &+ \int_0^T P(t) \left( \frac{1}{\sqrt{\lambda_{k,p(t)}}} - \frac{1}{\sqrt{\lambda_k}} \right) \langle u_{xx}(t), \varphi_{k,p(t)} \rangle e^{i\sqrt{\lambda_k}t} dt \\ &+ \frac{1}{\sqrt{\lambda_k}} \int_0^T P(t) \langle u_{xx}(t), \varphi_{k,p(t)} - \varphi_k \rangle e^{i\sqrt{\lambda_k}t} dt \\ &+ \int_0^T P(t) \left\langle (u - u^{ref})_{xx}(t), \frac{\varphi_k}{\sqrt{\lambda_k}} \right\rangle e^{i\lambda_k t} dt. \end{aligned}$$

Thanks to Proposition 26, we have the following bound for the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of the first term of the right-hand side of (9.46):

$$C\|P\|_{L^2}\|p\|_{L^\infty}\|u\|_{C^0([0,T],H^2)} \leq C\delta_4(1+\delta_4)\|P\|_{L^2} \leq C\delta_4\|P\|_{L^2}.$$

Thanks to (9.23) and Proposition 1, the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of the second term of the right-hand side of (9.46) is bounded by

$$C\|P\|_{L^2}\|p\|_{L^\infty}\|u\|_{C^0([0,T],H^2)} \leq C\delta_4(1+\delta_4)\|P\|_{L^2} \leq C\delta_4\|P\|_{L^2}.$$

Thanks to Lemma 3 and Proposition 1, we have the following bound for the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of the third term of the right-hand side of (9.46):

$$C\|P\|_{L^2}\|p\|_{L^\infty}\|u\|_{C^0([0,T],H^2)} \leq C\delta_4(1+\delta_4)\|P\|_{L^2} \leq C\delta_4\|P\|_{L^2}.$$

Thanks to Propositions 25 and 2, we have the following bound for the  $h^3(\mathbb{N}^*, \mathbb{C})$ -norm of the last term of the right-hand side of (9.46):

$$C\|P\|_{L^2}\|(u - u^{ref})_{xx}\|_{C^0([0,T],H^1)} \leq C\|P\|_{L^2}\delta_4.$$

In conclusion, we have proved that

$$\|\Upsilon^1\|_{h^3} \leq C\delta_4\|P\|_{L^2}.$$

In order to study  $\Upsilon^1$  in  $h^7$ , first we study it in  $h^5(\mathbb{N}^*, \mathbb{C})$ . By using an integration by parts, one gets

$$\begin{aligned} (9.47) \quad -\Upsilon_k^1 = & \frac{1}{i\sqrt{\lambda_k}} \int_0^T \dot{P}(t) \left( \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} - \langle u_{xx}^{ref}(t), \varphi_k \rangle e^{i\lambda_k t} \right) dt \\ & + \int_0^T \left( \frac{1}{i\sqrt{\lambda_{k,p(t)}}} - \frac{1}{i\sqrt{\lambda_k}} \right) \dot{P}(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ & + \frac{1}{i\sqrt{\lambda_k}} \int_0^T P(t) \left( \left\langle \dot{u}_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} - \left\langle \dot{u}_{xx}^{ref}(t), \frac{\varphi_k}{\sqrt{\lambda_k}} \right\rangle e^{i\lambda_k t} \right) dt \\ & + \int_0^T \left( \frac{1}{i\sqrt{\lambda_{k,p(t)}}} - \frac{1}{i\sqrt{\lambda_k}} \right) P(t) \left\langle \dot{u}_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ & + i \int_0^T P(t) \dot{p}(t) \frac{\lambda'_{k,p(t)}}{\lambda_{k,p(t)}^2} \langle u_{xx}(t), \varphi_{k,p(t)} \rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ & + \int_0^T P(t) \dot{p}(t) \frac{1}{i\lambda_{k,p(t)}} \left\langle u_{xx}(t), \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{p(t)} e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt. \end{aligned}$$

Thanks to the study of  $\Upsilon^1$  in  $h^3(\mathbb{N}^*, \mathbb{C})$ , we have the following bound for the  $h^5(\mathbb{N}^*, \mathbb{C})$ -norm of the first (resp., third) term of the right-hand side of (9.47):

$$C\|P\|_{H_0^1}\delta_4 \text{ (resp., } C\|P\|_{L^2}\delta_6).$$

Thanks to (9.23), we get the following bound for the  $h^5(\mathbb{N}^*, \mathbb{C})$ -norm of the second (resp., fourth) term of the right-hand side of (9.47):

$$C\|P\|_{H_0^1}\delta_4 \text{ (resp., } C\|P\|_{L^2}\delta_4).$$

Thanks to (9.32), we get the following bound for the  $h^5(\mathbb{N}^*, \mathbb{C})$ -norm of the fifth term of the right-hand side of (9.47):

$$C\|P\|_{L^2}\|p\|_{H^2}\|u\|_{C^0([0,T],H^2)} \leq C\|P\|_{L^2}\delta_6.$$

Thanks to Lemma 3, we get the following bound for the  $h^5(\mathbb{N}^*, \mathbb{C})$ -norm of the last term of the right-hand side of (9.47):

$$C\|P\|_{L^2}\delta_4.$$

In conclusion, we have proved that

$$\|\Upsilon^1\|_{h^5(\mathbb{N}^*, \mathbb{C})} \leq C[\|P\|_{L^2}\delta_6 + \|P\|_{H_0^1}\delta_6].$$

Finally, let us study  $\Upsilon^1$  in  $h^7(\mathbb{N}^*, \mathbb{C})$ . Thanks to the study of  $\Upsilon^1$  in  $h^5(\mathbb{N}^*, \mathbb{C})$ , we have the following bound for the  $h^7(\mathbb{N}^*, \mathbb{C})$ -norm of the first (resp., third) term of the right-hand side of (9.47):

$$C[\|P\|_{H_0^1}\delta_6 + \|P\|_{H_0^2}\delta_4] \text{ (resp., } C[\|P\|_{L^2}\delta_8 + \|P\|_{H_0^1}\delta_6]).$$

The study of the second and fourth terms of the right-hand side of (9.47) can be done in the same way. Let us work on the first one. We use (9.43). We have (9.48)

$$\begin{aligned} & \int_0^T \frac{lp(t) + \epsilon_k(t)}{\sqrt{\lambda_{k,p(t)}}\lambda_k} \dot{P}(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt = \\ & \frac{l}{\lambda_k} \int_0^T \dot{P}(t)p(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ & + \frac{l}{\sqrt{\lambda_k}} \int_0^T \left( \frac{1}{\sqrt{\lambda_{k,p(t)}}} - \frac{1}{\sqrt{\lambda_k}} \right) \dot{P}(t)p(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ & + \int_0^T \frac{\epsilon_k(s)}{\sqrt{\lambda_k}\sqrt{\lambda_{k,p(t)}}} \dot{P}(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt. \end{aligned}$$

Thanks to Proposition (26), we get the following bound for the  $h^7(\mathbb{N}^*, \mathbb{C})$ -norm of the first term of the right-hand side of (9.48):

$$C\|P\|_{H_0^1}\|p\|_{L^\infty}\|u\|_{C^0([0,T],H^3)} \leq C\delta_4(1 + \delta_4)\|P\|_{H_0^1} \leq C\delta_4\|P\|_{H_0^1}.$$

By using (9.23), we get the following bound for the  $h^7(\mathbb{N}^*, \mathbb{C})$ -norm of the second term of the right-hand side of (9.48):

$$C\|P\|_{H_0^1}\|p\|_{L^\infty}\|u\|_{C^0([0,T],H^2)} \leq C\delta_4\|P\|_{H_0^1}.$$

Thanks to the asymptotic behavior of  $\epsilon_k$ , we get the same bound for the  $h^7(\mathbb{N}^*, \mathbb{C})$ -norm of the last term of the right-hand side of (9.48).

Finally, we get the following bound for the  $h^7(\mathbb{N}^*, \mathbb{C})$ -norm of the second (resp., fourth) term of the right-hand side of (9.47):

$$C\|P\|_{H_0^1}\delta_4 \text{ (resp., } C\|P\|_{L^2}\delta_6).$$

For the study of the fifth term of the right-hand side of (9.47), we consider the decomposition

$$\begin{aligned} & \int_0^T P(t) \dot{p}(t) \frac{\lambda'_{k,p(t)}}{\lambda_{k,p(t)}^2} \langle u_{xx}(t), \varphi_{k,p(t)} \rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ &= \frac{\lambda'_k}{\lambda_k^{3/2}} \int_0^T P(t) \dot{p}(t) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ &+ \int_0^T P(t) \dot{p}(t) \left( \frac{\lambda'_{k,p(t)}}{\lambda_{k,p(t)}^{3/2}} - \frac{\lambda'_k}{\lambda_k^{3/2}} \right) \left\langle u_{xx}(t), \frac{\varphi_{k,p(t)}}{\sqrt{\lambda_{k,p(t)}}} \right\rangle e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt. \end{aligned}$$

We study the first term of this decomposition with Proposition 26 and (9.32) and the second one with (9.32); then we get the following bound for the  $h^7(\mathbb{N}^*, \mathbb{C})$ -norm of the fifth term of the right-hand side of (9.47):

$$C \|P\|_{L^2} \delta_6.$$

For the last term of the right-hand side of (9.47), we cannot apply Lemma 4 because  $u_{xx} \notin H_0^2((0, 1), \mathbb{R})$ ; thus, we perform another integration by parts:

$$\begin{aligned} & -i \int_0^T P(t) \dot{p}(t) \frac{1}{\lambda_{k,p(t)}} \left\langle u_{xx}(t), \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{p(t)} e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ &= \int_0^T [\dot{P}(t) \dot{p}(t) + P(t) \ddot{p}(t)] \frac{1}{(\lambda_{k,p(t)})^{3/2}} \left\langle u_{xx}(t), \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{p(t)} e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ (9.49) \quad &+ \int_0^T P(t) \dot{p}(t) \frac{1}{(\lambda_{k,p(t)})^{3/2}} \left\langle \dot{u}_{xx}(t), \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{p(t)} e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ &- \int_0^T P(t) \dot{p}(t)^2 \frac{3\lambda'_{k,p(t)}}{2(\lambda_{k,p(t)})^{5/2}} \left\langle u_{xx}(t), \frac{d\varphi_{k,\gamma}}{d\gamma} \right\rangle_{p(t)} e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt \\ &+ \int_0^T P(t) \dot{p}(t)^2 \frac{1}{(\lambda_{k,p(t)})^{3/2}} \left\langle u_{xx}(t), \frac{d^2\varphi_{k,\gamma}}{d\gamma^2} \right\rangle_{p(t)} e^{i \int_0^t \sqrt{\lambda_{k,p(s)}} ds} dt. \end{aligned}$$

We study the first two terms of the right-hand side of (9.49) thanks to Lemma 3 and the last two thanks to (9.32) and (9.35). In conclusion, we have proved that

$$\|\Upsilon^1\|_{h^7(\mathbb{N}^*, \mathbb{C})} \leq C[\|P\|_{L^2} \delta_8 + \|P\|_{H_0^1} \delta_6 + \|P\|_{H_0^2} \delta_4],$$

and the logarithmic convexity of the norms justifies that

$$\|\Upsilon^1\|_{h^7(\mathbb{N}^*, \mathbb{C})} \leq C[\|P\|_{L^2} \delta_8 + \|P\|_{H_0^2} \delta_4]. \quad \square$$

*Proof of Proposition 20 for  $j = 2, 3$ .* Lemma 4 gives the bound in  $h^3(\mathbb{N}^*, \mathbb{C})$  for  $\Upsilon^2$ . As in the previous proof, one can study  $\Upsilon^2$  in  $h^5$  thanks to an integration by parts. Then we deduce the bound in  $h^7(\mathbb{N}^*, \mathbb{C})$ . The study of  $\Upsilon^3$  can be done in the same way.  $\square$

**9.4. Proof of Proposition 21.** The goal of this section is to sketch the proof of Proposition 21. Let  $((u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon))_{\epsilon>0}$ ,  $(u_0, \dot{u}_0, p) \in E_8$  such that  $(u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon) \rightarrow (u_0, \dot{u}_0, p)$  in  $E_8$  and  $P \in H_0^2((0, T), \mathbb{R})$ . By doing again for

$$\Upsilon_{(u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon)}(P) - \Upsilon_{(u_0, \dot{u}_0, p)}(P)$$

the same analysis we did for

$$\Upsilon_{(u_0, \dot{u}_0, p)}(P) - \Upsilon_{(u_0^{ref}, \dot{u}_0^{ref}, 0)}(P)$$

in the previous subsection, one can prove that

$$\Upsilon_{(u_0^\epsilon, \dot{u}_0^\epsilon, p^\epsilon)}(P) \rightarrow \Upsilon_{(u_0, \dot{u}_0, p)}(P) \text{ in } h^7(\mathbb{N}^*, \mathbb{C}) \text{ when } \epsilon \rightarrow 0.$$

**10. Remarks, conjectures, prospects.** In Theorem 1, the regularity assumption  $H_{(0)}^{5+\epsilon} \times H_{(0)}^{3+\epsilon}((0, 1), \mathbb{R})$ , with  $\epsilon > 0$ , is technical and related to the use of the Nash–Moser theorem. We conjecture that  $(\Sigma)$  is controllable

- in  $H_{(0)}^3 \times H_{(0)}^1((0, 1), \mathbb{R})$  with control functions in  $L_{loc}^2(\mathbb{R}, \mathbb{R})$ ,
- in  $H_{(0)}^5 \times H_{(0)}^3((0, 1), \mathbb{R})$  with control functions in  $H_{loc}^1(\mathbb{R}, \mathbb{R})$ ,
- in  $H_{(0)}^7 \times H_{(0)}^5((0, 1), \mathbb{R})$  with control functions in  $H_{loc}^2(\mathbb{R}, \mathbb{R})$ , etc.,

because it is the case for the linearized system studied in section 3.

Theorem 1 provides the local controllability in time  $T := 8/\pi$ . This choice ( $T := 8/\pi$ ) is also technical. The existence of a minimal time for the controllability of this system is an open problem.

Most probably, the proof presented in this article also works for the proof of the local controllability of the same system around

$$\varphi_k(x) \left\{ \begin{array}{c} \cos(\sqrt{\lambda_k}t) \\ \text{or} \\ \sin(\sqrt{\lambda_k}t) \end{array} \right\} + \varphi_j(x) \left\{ \begin{array}{c} \cos(\sqrt{\lambda_j}t) \\ \text{or} \\ \sin(\sqrt{\lambda_j}t) \end{array} \right\}$$

when  $k$  and  $j$  are integers with different parities. The same argument should also be adaptable to the beam equation with follower loads

$$\left\{ \begin{array}{l} u_{tt} + u_{xxxx} + p(t)u_{xx} = 0, (t, x) \in \mathbb{R}_+ \times (0, 1), \\ u = u_x = 0 \text{ at } x = 0, \\ u_{xx} = u_{xxx} = 0 \text{ at } x = 1, \end{array} \right.$$

which is also proved to be not controllable in  $H^2 \times L^2((0, 1), \mathbb{R})$  with  $L_{loc}^r(\mathbb{R}, \mathbb{R})$ -control functions, in [1].

Since the coefficients  $\langle \varphi_1'', \varphi_k \rangle$  vanish when  $k$  is even, the linearized system of  $(\Sigma)$  around the trajectory  $(u(t, x) = \varphi_1(x) \sin(\sqrt{\lambda_1}t), p \equiv 0)$  is not controllable. In order to prove the local controllability of  $(\Sigma)$  around this trajectory, the return method would probably work, as in [3]. This method was introduced by Coron in [5] in order to solve a stabilization problem. It has been used in order to get controllability results for partial differential equations by Coron in [8], [6], [7], by Coron and Fursikov in [9], by Fursikov and Imanuvilov in [11], by Glass in [12], [14], [16], [13], [15], [17], [18], and by Horsin in [21]; see also the book [10] by Coron.

The strategy developed in [4] could be used in order to prove steady-state controllability results of the type: For every  $k, l \in \mathbb{N}^*$ , there exists  $T > 0$  and  $p \in H_0^1((0, T), \mathbb{R})$  such that the solution of  $(\Sigma)$  with  $u(0) = \varphi_k$  and control  $p$  satisfies  $u(T) = \varphi_l$ .

**Acknowledgments.** The author thanks J.-M. Coron for fruitful discussions and advice on this work, E. Zuazua for having attracted her attention to this controllability problem, and O. Glass for interesting remarks.

## STOCHASTIC CONTROL WITH IMPERFECT MODELS\*

ARNAB BASU<sup>†</sup> AND VIVEK S. BORKAR<sup>‡</sup>

**Abstract.** We consider the problem of worst case performance estimation for a stochastic dynamic model in the presence of model uncertainty. This is cast as a nonclassical controlled diffusion problem. An infinite dimensional linear programming formulation is given and its dual is derived. The dual is successively approximated on a bounded domain by a semi-infinite and a finite linear program. This uses function approximation based on a reproducing kernel Hilbert space. Error analysis for the approximation is provided along with an estimate of the sample complexity.

**Key words.** worst case performance, controlled diffusion, approximation of linear programs, reproducing kernel Hilbert spaces, sample complexity, credit risk

**AMS subject classifications.** Primary, 93E20; Secondary, 93E25, 90C48

**DOI.** 10.1137/060667049

**1. Introduction.** An important problem in finance as well as several other areas is that of estimating risk (or more generally, an appropriate performance index) under model uncertainty. We consider this problem in the context of an underlying state process that is a continuous time diffusion. We take the “worst case” approach, that is, we estimate the minimal performance ( $\approx$  negative of maximal risk in risk estimation) over the allowed class of models.

We identify the following two basic forms of uncertainties (see section 2):

- The first is the *modelling uncertainty* wherein the drift and diffusion coefficients of the diffusion are not exactly known. We model this by introducing a hypothetical control process. This changes it to a controlled diffusion model. We then minimize the performance over the allowed control processes. With finance applications in mind, we consider this problem with additional constraints, thereby making it a “constrained” control problem [9].
- The second form of uncertainty has to do with *unmodelled dynamics*. Here we assume that there may be certain state variables about whose dynamics something is known, but these are not observed. On the other hand, certain other state variables are observed and are modelled *separately* by Markov diffusions, but there is uncertainty about their dependence structure. We call this scenario “uncertainty in dynamics.” This formulation is explicitly motivated by problems arising in credit risk (see, e.g., [22, Chap. 9]), where stochastic dynamic models for two or more processes are separately available, but their dependence structure is unknown.

Combining both of these, we cast the problem as an abstract linear program over appropriately defined “occupation measures” (see section 3). This is an infinite

dimensional linear program over a space of functions with an unbounded domain. Motivated by computational considerations, we restrict these functions to a bounded domain. The resulting approximate linear program is then successively approximated further first by a semi-infinite linear program and then by a finite linear program using a specific function approximation scheme based on reproducing kernel Hilbert spaces (RKHS). Error estimates for the approximation (see section 4) provide a rigorous justification for its use. Section 5 of this paper deals with the calculation of the sample complexity required to achieve a specified tolerance on the approximation error for RKHS functions (as described above) defined on a compact domain with a smooth boundary. Section 6 sketches an extension to Markov-modulated diffusions, which capture the regime-switching phenomena.

This work is purely theoretical. In a related work [3], we also present some preliminary computational results for the simplest case of modelling uncertainty alone. To put this work in context, we briefly mention some relevant literature that it builds upon. The constrained nature of the above problem and the unmodelled dynamics make the problem inconvenient for a dynamic programming based approach. This suggests a linear programming formulation. The linear programming approach to discrete time or state stochastic control is by now classical [21] and its extensions to continuous state space have been extensively developed in [8], [15], [16], and [17]. Similar developments are available in continuous time as well (see [5], [13], [28]).

Another important antecedent to our work is the work on the celebrated Monge–Kantorovich optimal mass transportation problem [2]. Here the objective is to maximize or minimize the expected value of a function of two random variables over all possible joint distributions thereof, subject to the constraint that they have prescribed marginals. Our formulation can be viewed as a dynamic version of this with the additional provision for constraints and unmodelled components, as will become clear later.

As these are perforce infinite dimensional problems, considerable attention has been devoted in recent times to approximation issues (see [14], [18], [19], [24]). Our approach is that of [18], [19], except that we specialize to a specific form of function approximation: We approximate functions by finite linear combinations of translates of a  $C^\infty$  Mercer kernel. This procedure is justified by the theory of RKHS associated with such kernels. These functions are attractive on many grounds. First and foremost, the “best” approximation turns out to be simply a linear combination of the *same* kernel function centered at the sampled points. This offers tremendous computational advantages. This fact has driven the extensive use of RKHS in signal processing. Further, a rich theory recently developed in statistical learning theory literature (wherein the applications of RKHS are motivated by similar considerations) allows us to obtain precise error estimates (see [10], [25], [26], [27], [30]).

To summarize, the main contributions of this article are the following:

- A novel and comprehensive formulation of the risk/performance estimation problem under uncertainty;
- conversion thereof to an infinite dimensional linear program that subsumes classical linear programming formulations of stochastic control;
- a rigorous approximation theory for the same.

We qualify the last of the above by observing that our error analysis for the approximation yields only “order of magnitude” estimates of the kind prevalent in theoretical computer science, not the tight bounds that numerical analysts love. Nevertheless, we feel that this is an important first step, as such bounds did not seem to be around

until now. Furthermore, our approach charts out a step-by-step procedure for error analysis, many features of which are bound to have a much broader applicability.

**2. Problem formulation.** Our underlying state process is a  $d$ -dimensional diffusion process  $x(\cdot) = [x_1(\cdot), \dots, x_d(\cdot)]^T$  described by the stochastic differential equation (SDE)

$$(1) \quad dx(t) = m^*(x(t))dt + \sigma^*(x(t))dW(t), \quad x(0) = x_0, \quad t \geq 0,$$

where  $W(\cdot)$  is a standard Brownian motion in  $\mathcal{R}^d$  and the drift vector  $m^*(\cdot) : \mathcal{R}^d \rightarrow \mathcal{R}^d$  and the diffusion matrix  $\sigma^*(\cdot) : \mathcal{R}^d \rightarrow \mathcal{R}^{d \times d}$  are assumed to be Lipschitz. This ensures the well-posedness of (1), but can be relaxed in special cases. (Alternatively, one may invoke the “genericity” arguments of [20].) The law of  $x_0$  is fixed, say,  $\phi_0$ . The two forms of uncertainty we consider are captured by the following two basic formulations.

**Problem 1: Model uncertainty.** Here we suppose that  $m^*, \sigma^*$  are not known exactly, but only up to a certain approximation. The latter is captured by the conditions

$$(2) \quad m^*(x) \in m(x, U), \quad (\sigma^*(\sigma^*)^T)(x) \in (\sigma\sigma^T)(x, U) \quad \forall x,$$

where

- $U$  is a prescribed compact metric space;
- $m(\cdot, \cdot) = [m_1(\cdot, \cdot), \dots, m_d(\cdot, \cdot)]^T : \mathcal{R}^d \times U \rightarrow \mathcal{R}^d$  is continuous and Lipschitz in the first argument uniformly w.r.t. the second, and, in addition,  $m(x, U)$  is convex for each  $x$ ;
- $\sigma(\cdot, \cdot) = [[\sigma_{ij}(\cdot, \cdot)]]_{1 \leq i, j \leq d} : \mathcal{R}^d \times U \rightarrow \mathcal{R}^{d \times d}$  is continuous and Lipschitz in the first argument uniformly w.r.t. the second, and, in addition,  $(\sigma\sigma^T)(x, U)$  is convex for each  $x$ . Also, the *nondegeneracy* condition holds, i.e., there exists a constant  $c > 0$  such that for all  $(x, u) \in \mathcal{R}^d \times U$  and  $\xi \in \mathcal{R}^d$ ,

$$(3) \quad \xi^T \sigma \sigma^T(x, u) \xi \geq c|\xi|^2.$$

Familiar “measurable selection” arguments from stochastic control (see, e.g., [6, Chaps. I–II]) then allow us to replace (1) by

$$(4) \quad dx(t) = m(x(t), u'(t))dt + \sigma(x(t), u''(t))dW(t),$$

where  $u'(t), u''(t)$  are  $U$ -valued processes of the form  $v'(x(t)), v''(x(t))$ ,  $t \geq 0$ , for some measurable  $v', v'' : \mathcal{R}^d \rightarrow U$ . One can be a bit more ambitious and allow for “model drift,” thus permitting  $u'(t), u''(t)$  of the form  $v'(x(t), t), v''(x(t), t)$  for measurable  $v', v'' : \mathcal{R}^d \times \mathcal{R}^+ \rightarrow U$ . This in fact will also be more convenient, as explicit time dependence is hard to suppress in our formulation. The final liberty we take is to permit more general arbitrary nonanticipative  $u'(\cdot), u''(\cdot)$ , i.e., satisfying that  $u'(\cdot), u''(\cdot)$  have measurable paths and that for any  $t \geq 0$ ,  $W(t + \cdot) - W(t)$  is independent of  $x_0, u'(s), u''(s), W(s), s \leq t$ . But this relaxation is no relaxation at all, as we shall soon observe. We shall refer to  $[u'(\cdot), u''(\cdot)]$  of the form  $[v'(x(\cdot), \cdot), v''(x(\cdot), \cdot)]$  as *Markov controls*.

Fix the time horizon  $T > 0$  and let  $Z \stackrel{\text{def}}{=} [0, T] \times \mathcal{R}^d$ . Let  $u(t) = [u'(t), u''(t)]$ , viewed as a  $U^2$ -valued process. Further, by abuse of terminology, we shall replace  $U$  by  $U^2$ , using the former symbol to mean the latter, and write  $m(x, u), \sigma(x, u)$  for  $m(x, u'), \sigma(x, u'')$ , respectively, with  $u = [u', u'']$ . For a Polish space  $S$ , let  $\mathcal{P}(S)$  denote the Polish space of probability measures on  $S$  with the Prohorov topology (see [7, Chap. 2]). Associated with (4) is the *occupation measure*  $\nu \in \mathcal{P}(Z \times U)$  defined by

$$(5) \quad \int_{Z \times U} f d\nu \stackrel{\text{def}}{=} \frac{1}{T} E \left[ \int_0^T f(t, x(t), u(t)) dt \right], \quad f \in C_b(Z \times U).$$

Associated with  $x(\cdot)$  is the controlled extended generator  $\mathcal{L} : \mathcal{D}(\mathcal{L}) \stackrel{\text{def}}{=} \{f \in C_b^{1,2}([0, T] \times \mathcal{R}^d) : f(T, \cdot) \equiv 0\} \rightarrow C_b(Z \times U)$  given by

$$\mathcal{L}g(t, x, u) \stackrel{\text{def}}{=} \frac{\partial g}{\partial t}(t, x) + \langle m(x, u), \nabla g(t, x) \rangle + \frac{1}{2} \text{tr}(\sigma(x, u) \sigma^T(x, u) \nabla^2 g(t, x)).$$

Let  $\mathcal{M}$  denote the set of occupation measures.

LEMMA 2.1.  $\mathcal{M}$  is convex compact and is characterized by

$$\mathcal{M} = \left\{ \nu \in \mathcal{P}(Z \times U) : T \int_{Z \times U} \mathcal{L}g d\nu = - \int_{\mathcal{R}^d} g(0, \cdot) d\phi_0 \quad \forall g \in \mathcal{D}(\mathcal{L}) \right\}.$$

Furthermore, this set does not change if we restrict  $u(\cdot)$  to the class of Markov controls.

This is proved in [5]. The second half of the lemma justifies our relaxation to nonanticipative controls without loss of generality. Our goal will be to estimate a performance metric of the form

$$(6) \quad \int_{Z \times U} k d\nu \equiv \frac{1}{T} E \left[ \int_0^T k(t, x(t), u(t)) dt \right]$$

for a prescribed  $k(\cdot) \in C_b(Z \times U)$ , for  $x(\cdot)$  described by (1). Without loss of generality, we can assume  $k(\cdot) > 0$ . In view of the uncertainty about the coefficients in (1), we take a “worst case” viewpoint and estimate the minimum of this functional over all possible solutions to (4), i.e., over  $\mathcal{M}$ . As  $\mathcal{M}$  is characterized by linear constraints, this is an infinite dimensional linear program.

We qualify this formulation further by including additional constraints

$$(7) \quad \int_{Z \times U} k_i d\nu = c_i, \quad 1 \leq i \leq m.$$

Here  $k_i(\cdot) \in C_b(Z \times U)$  for all  $i$ , and the  $c_i$ ’s are prescribed values. Again, without loss of generality, we can assume  $k_i(\cdot) > 0, 1 \leq i \leq m$ . (One can also consider *inequalities* in (7). The analysis will be similar.) Note that  $k_i(\cdot) > 0$  implies that  $c_i > 0$ . We also assume

$$(\dagger) \quad c \stackrel{\text{def}}{=} [c_1, \dots, c_m] \text{ is an interior point of the set } \left\{ \left[ \int k_1 d\mu, \dots, \int k_m d\mu \right] : \mu \in \mathcal{M} \right\} \subset \mathcal{R}^m.$$

This is the *constrained control* problem studied in [9] and has found many applications. The inclusion of (7) complicates the dynamic programming approach to such problems, but makes only a small alteration to the linear programming approach.

Note that if it were a cost or risk rather than a (positive) performance metric, one would consider the maximum thereof. This can be reduced to the above framework by taking negative risk as the performance metric.

**Problem 2: Unmodelled dynamics.** Here we assume that we can *separately* observe for some integer  $l \geq 1$  only the following:

$$(8) \quad \tilde{x}_j(\cdot) \stackrel{\text{def}}{=} \left[ x_{\sum_{k=1}^{j-1} \tilde{d}_{k+1}}(\cdot), \dots, x_{\sum_{k=1}^j \tilde{d}_k}(\cdot) \right], \quad 1 \leq j \leq l, \quad \tilde{d}_j \geq 1, \quad \sum_{k=1}^l \tilde{d}_k \leq d.$$

Let  $\tilde{\nu}_j \in \mathcal{P}(\tilde{Z}_j)$  for  $\tilde{Z}_j \stackrel{\text{def}}{=} [0, T] \times \mathcal{R}^{\tilde{d}_j}$  denote the corresponding occupation measures defined by

$$(9) \quad \int_{\tilde{Z}_j} f d\tilde{\nu}_j \stackrel{\text{def}}{=} \frac{1}{T} \tilde{E}_j \left[ \int_0^T f(t, \tilde{x}_j(t)) dt \right], \quad f \in C_b(\tilde{Z}_j), \quad 1 \leq j \leq l.$$

We posit that observing samples of  $\tilde{x}_j(\cdot)$  allows us to estimate  $\tilde{\nu}_j$ . On the other hand, Lemma 2.1 allows us to mimic  $\tilde{\nu}_j$  by a  $\tilde{d}_j$ -dimensional diffusion  $\hat{x}_j(\cdot)$  given by (say)

$$(10) \quad d\hat{x}_j(t) = \tilde{m}_j(t, \hat{x}_j(t))dt + \tilde{\sigma}_j(t, \hat{x}_j(t))d\tilde{W}_j(t), \quad 1 \leq j \leq l.$$

Here  $\tilde{W}_j(\cdot)$  is a  $\tilde{d}_j$ -dimensional standard Brownian motion and the law  $\tilde{\phi}_{0j}$  of  $\hat{x}_j(0)$  is the image of  $\phi_0$  under the projection  $\mathcal{R}^d \rightarrow \mathcal{R}^{\tilde{d}_j}$ .

We view (10) as the *model fitted to the observed data*  $\tilde{x}_j(\cdot)$ . The justification for this is twofold. First, as already observed, Lemma 2.1 does justify a model such as (10) as long as we are interested in only the occupation measures. Second, fitting such a model is precisely what one does in much of time series analysis.

Finally, the unobserved components  $[x_{\sum_{k=1}^l \tilde{d}_{k+1}}(\cdot), \dots, x_d(\cdot)]$  then correspond to *unmodelled dynamics*, a notion familiar from robust control literature.

*Remark 1.* It is important to note that there is a compatibility issue here. Not every  $\tilde{\nu}_j$  as above will be compatible with the feasible  $\nu$ 's in the background. We assume that the feasible set  $\mathcal{M}'$  defined below is nonempty. This is reasonable in view of our underlying premise that the  $\tilde{\nu}_j$ 's have been arrived at empirically and therefore are perforce compatible with the underlying dynamics.

If  $l = 2$  and  $\tilde{d}_1 + \tilde{d}_2 = d$ , then we have models for two component processes whose dependence structure is unknown. This is the typical situation in credit risk problems, which is generalized above. It is also the exact dynamic counterpart of the Monge–Kantorovich optimal mass transportation problem.

We shall assume that for all  $j = 1, \dots, l$ ,  $\tilde{m}_j, \tilde{\sigma}_j$  are continuous and Lipschitz in the space variable uniformly w.r.t. the time variable. This is not free, i.e., it does not follow from our assumptions until now, but is an additional assumption. It is not unreasonable in view of the fact that one usually fits “nice” models (linear, composition of sigmoids, etc.) to data. Its main purpose here is to simplify the well-posedness issues, which now become nonissues. More generally, one must allow for measurable coefficients, in which case one may need to invoke genericity arguments for well-posedness facilitated by [20]. We avoid the additional complications implicit therein by taking this simple and not entirely unreasonable option. Also, we assume the *nondegeneracy* condition similar to (3) for the  $\tilde{\sigma}_j$ 's.

Let  $\tilde{\mathcal{L}}_j, 1 \leq j \leq l$ , denote the extended generator of  $\hat{x}_j(\cdot)$ ,

$$\tilde{\mathcal{L}}_j f(t, x) \stackrel{\text{def}}{=} \frac{\partial f}{\partial t}(t, x) + \langle \tilde{m}_j(t, x), \nabla f(t, x) \rangle + \frac{1}{2} \text{tr}(\tilde{\sigma}_j(t, x) \tilde{\sigma}_j^T(t, x) \nabla^2 f(t, x))$$

for all  $f \in C_b^{1,2}([0, T] \times \mathcal{R}^{\tilde{d}_j})$ . Let  $\mathcal{D}(\tilde{\mathcal{L}}_j) \stackrel{\text{def}}{=} \{f \in C_b^{1,2}([0, T] \times \mathcal{R}^{\tilde{d}_j}) : f(T, \cdot) \equiv 0\}$ . Then  $\tilde{\nu}_j$  is characterized by

$$T \int \tilde{\mathcal{L}}_j f d\tilde{\nu}_j = - \int f(0, \cdot) d\tilde{\phi}_{0j} \quad \forall f \in \mathcal{D}(\tilde{\mathcal{L}}_j).$$

This is the same as

$$(11) \quad \begin{aligned} & T \int \tilde{\mathcal{L}}_j f \nu(dtdx^j \times \mathcal{R}^{d-\tilde{d}_j} \times U) \\ &= - \int f(0, \cdot) \phi_0(dx^j \times \mathcal{R}^{d-\tilde{d}_j}) \quad \forall f \in \mathcal{D}(\tilde{\mathcal{L}}_j), \end{aligned}$$

where we partition  $x \in \mathcal{R}^d \approx \mathcal{R}^{\tilde{d}_1} \times \cdots \times \mathcal{R}^{\tilde{d}_j} \times \cdots \times \mathcal{R}^{\tilde{d}_l} \times \mathcal{R}^{d-\sum_{j=1}^l \tilde{d}_j}$  as  $x = [x^1 : \cdots : x^j : \cdots : x^l : y]$ , with  $x^j \in \mathcal{R}^{\tilde{d}_j}, y \in \mathcal{R}^{d-\sum_{j=1}^l \tilde{d}_j}$ . The goal then is to minimize  $\int_{Z \times U} k d\nu$  over a convex compact set  $\mathcal{M}'$  defined as

$$\mathcal{M}' \stackrel{\text{def}}{=} \{\nu \in \mathcal{M} : (11) \text{ holds for } 1 \leq j \leq l\}.$$

In the remainder of this paper, we consider a combined problem that has both features. That is, our problem is as follows:

$$\text{Minimize } \int_{Z \times U} k d\nu \text{ over } \mathcal{M}^* \stackrel{\text{def}}{=} \{\nu \in \mathcal{M}' : (7) \text{ holds}\}.$$

We shall assume that the *feasibility* condition holds; i.e., the *feasible* set of the above minimization problem is a nonempty subset of  $\mathcal{M}'$  (see Remark 1 above). It is clear that  $\mathcal{M}^*$  is closed compact and  $\int k d\nu$  is a continuous linear functional over  $\mathcal{M}^*$ . Thus by Weierstrass' theorem, we get the following.

LEMMA 2.2. *There exists a  $\nu^* \in \mathcal{M}^*$  such that*

$$\int_{Z \times U} k d\nu^* = \min_{\nu \in \mathcal{M}^*} \int_{Z \times U} k d\nu.$$

We conclude this section with a remark on notation. Superscript “\*” will stand for the formal adjoint of an operator throughout and  $\mathcal{D}(A)$  for the domain of an operator  $A$ .  $\langle \cdot, \cdot \rangle_{X,Y}$  denotes the standard pairing (bilinear form) between two topological vector spaces  $X, Y$  in duality.

**3. Dual linear programs.** We now consider the dual linear program associated with the above problem and its approximation. The advantages of working with a dual are that, first of all, it provides an approximate lower bound. In the kind of applications we have in mind, this is more useful than an approximate upper bound that the primal might provide. Furthermore, when additional constraints as in (7) are present, it converts a “min-max” problem into a pure maximization problem, because the Lagrange multipliers associated with these constraints are not being dualized.

We introduce the following notation:  $X \stackrel{\text{def}}{=} \mathcal{P}(Z \times U)$ ,  $Y \stackrel{\text{def}}{=} C_b(Z \times U)$ ,  $\Gamma \stackrel{\text{def}}{=} \mathcal{D}(\mathcal{L})^*$ ,  $\tilde{\Gamma}_j \stackrel{\text{def}}{=} \mathcal{D}(\tilde{\mathcal{L}}_j)^*$ ,  $1 \leq j \leq l$ . Given  $k(\cdot) \in C_b(Z \times U)$ , our primal problem can be stated as follows: Find

$$(12) \quad \inf_{\nu \in X} \langle k, \nu \rangle : F\nu = \delta_0 \times \phi_0, \tilde{F}_j \nu = \delta_0 \times \tilde{\phi}_{0j}, F_c \nu = -c, 1 \leq j \leq l,$$

where

- $F : X \rightarrow \Gamma$  is defined by  $F\nu = \mu$ , where

$$\langle g, \mu \rangle_{\mathcal{D}(\mathcal{L}), \Gamma} = -T \int_{Z \times U} \mathcal{L} g d\nu \quad \forall g \in \mathcal{D}(\mathcal{L}).$$

- $\tilde{F}_j : X \rightarrow \tilde{\Gamma}_j$  is defined by  $\tilde{F}_j \nu = \mu_j$ , where

$$\langle \tilde{g}_j, \mu_j \rangle_{\mathcal{D}(\tilde{\mathcal{L}}_j), \tilde{\Gamma}_j} = -T \int_{Z \times U} \tilde{\mathcal{L}}_j \tilde{g}_j d\nu \quad \forall \tilde{g}_j \in \mathcal{D}(\tilde{\mathcal{L}}_j), 1 \leq j \leq l.$$

- $c \stackrel{\text{def}}{=} [c_1, \dots, c_m]^T \in \mathcal{R}^m$  and  $F_c : X \rightarrow \mathcal{R}^m$  is defined by  $F_c \nu = r$ , where

$$r = [-\int k_1 d\nu, \dots, -\int k_m d\nu].$$

Following the developments of Chapter 3 of [2], the dual program is to find

$$(13) \quad \sup_{g \in \mathcal{D}(\mathcal{L}), \tilde{g}_j \in \mathcal{D}(\tilde{\mathcal{L}}_j) \forall j, \lambda \in \mathcal{R}^m} \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \sum_{i=1}^m \lambda_i c_i$$

$$: \frac{k(x, u) + \sum_{i=1}^m \lambda_i k_i(x, u)}{T} + \mathcal{L}g(x, u)$$

$$+ \sum_{j=1}^l \tilde{\mathcal{L}}_j \tilde{g}_j(\tilde{x}_j) \geq 0, (x, u) \in Z \times U$$

for  $\tilde{x}_j$  as defined in (8). In view of the comments that follow Remark 1 above, this may be viewed as the dynamic version of the Kantorovich dual in mass transportation theory (see, e.g., [29]). Hence we dub it the *generalized Kantorovich dual*.

**THEOREM 3.1.** *There exists strong duality between (12) and (13).*

*Proof.* It is easy to verify that the set

$$\{(F\nu, \tilde{F}_1\nu, \dots, \tilde{F}_l\nu, F_c\nu, \langle k, \nu \rangle_{Y,X}) : \nu \in X\}$$

is closed. Then the result follows from [2, Theorem 3.22, p. 61] and the discussion following it.  $\square$

Let  $\mathcal{D} \stackrel{\text{def}}{=} C_b^{1,2}(Z) \times C_b^{1,2}(\tilde{Z}_1) \times \dots \times C_b^{1,2}(\tilde{Z}_l)$  equipped with the product Sobolev norm defined by

$$\|(g, \tilde{g}_1, \dots, \tilde{g}_l)\|_{C_b^{1,2}} \stackrel{\text{def}}{=} \max\left(\|g\|_{C_b^{1,2}}, \max_{1 \leq j \leq l} \|\tilde{g}_j\|_{C_b^{1,2}}\right),$$

where  $\|f\|_{C_b^{1,2}} \stackrel{\text{def}}{=} (\max_{0 \leq |\alpha| \leq 2} \|D_x^\alpha f\|_\infty) \vee \|D_t f\|_\infty$ . (Here  $D_t$  denotes the time derivative and  $D_x^\alpha$  the space derivative of multi-index  $\alpha$ .) Let

$$BLR \stackrel{\text{def}}{=} \{(g, \tilde{g}_1, \dots, \tilde{g}_l) \in \mathcal{D} : \|(g, \tilde{g}_1, \dots, \tilde{g}_l)\|_{C_b^{1,2}} \leq R\}.$$

We have the following trivial consequence of Lemma 2.2 and Theorem 3.1, stated here for later use.

(\*) There exists a *large enough*  $R^* < \infty$ ,<sup>1</sup> and a *sufficiently large* compact subset  $\Lambda \subset \mathcal{R}^m$ , such that the supremum in (13) is attained at some  $(g^*, \tilde{g}_1^*, \dots, \tilde{g}_l^*, \lambda^*) \in BLR^* \times \Lambda$ , with  $g^* \in \mathcal{D}(\mathcal{L})$  and  $\tilde{g}_j^* \in \mathcal{D}(\tilde{\mathcal{L}}_j)$ ,  $1 \leq j \leq l$ .

#### 4. Approximation of dual programs.

**4.1. Bounded domain approximation.** We shall now describe the approximation scheme for (13) in several steps. Let  $\Omega_M \stackrel{\text{def}}{=} [-M, M]^d$ . As a first step of approximation, we can take  $Z_M \stackrel{\text{def}}{=} [0, T] \times \Omega_M$  for some  $M \gg 0$ ,  $T > 0$ . We assume that  $\text{support}(\phi_0) \subset \Omega_M$ . (Otherwise, there is an additional error term, which

<sup>1</sup>See also Lemma 4.5.

can be easily handled.) Let  $\partial Z_M \stackrel{\text{def}}{=} \{T\} \times \Omega_M \cup [0, T] \times \partial\Omega_M$ . Let  $\tilde{Z}_{Mj}$  denote the projection of  $Z_M$  on  $[0, T] \times \mathcal{R}^{\tilde{d}_j}$ ,  $1 \leq j \leq l$ . We define  $\partial\tilde{Z}_{Mj}$  similarly. Let  $\tau_M \stackrel{\text{def}}{=} \inf\{t \geq 0 : X(t) \notin \Omega_M\}$ . We shall now, in a manner analogous to the previous section, define  $\mathcal{M}_M, \mathcal{M}'_M, \mathcal{M}^*_M, \mathcal{D}_M(\mathcal{L}), \mathcal{D}_M(\tilde{\mathcal{L}}_j), \mathcal{D}_M$ , etc. Define the occupation measure  $\nu_M$  by

$$\int f d\nu_M \stackrel{\text{def}}{=} \frac{1}{T} E \left[ \int_0^{T \wedge \tau_M} f(t, x(t), u(t)) dt \right], \quad f \in C_b(Z_M \times U).$$

Let  $\mathcal{D}_M(\mathcal{L}) \stackrel{\text{def}}{=} \{f \in C_b^{1,2}(Z_M) : f|_{\partial Z_M} \equiv 0\}$ . Then the set of occupation measures  $\mathcal{M}_M$  is equivalently defined as

$$\mathcal{M}_M = \left\{ \nu_M \in \mathcal{P}(Z_M \times U) : T \int \mathcal{L} g d\nu_M = - \int g(0, \cdot) d\phi_0 \quad \forall g \in \mathcal{D}_M(\mathcal{L}) \right\}.$$

Our additional constraints (7) become

$$(14) \quad \int_{Z_M \times U} k_i d\nu_M = c_i, \quad 1 \leq i \leq m.$$

Once again, we assume the following counterpart of (†), which is reasonable for large  $M$ , as the  $\nu_M$ 's are then close to the corresponding  $\nu$ 's:

$$(††) \quad c \stackrel{\text{def}}{=} [c_1, \dots, c_m] \text{ is an interior point of the set } \left\{ \left[ \int k_1 d\mu, \dots, \int k_m d\mu \right] : \mu \in \mathcal{M}_M \right\} \subset \mathcal{R}^m.$$

For (9), (10), let  $\tilde{\nu}_{Mj} \in \mathcal{P}(\tilde{Z}_{Mj})$  denote the corresponding occupation measures defined by

$$(15) \quad \int f d\tilde{\nu}_{Mj} \stackrel{\text{def}}{=} \frac{1}{T} \tilde{E}_j \left[ \int_0^{\tau_M \wedge T} f(t, \tilde{x}_j(t)) dt \right], \quad f \in C_b(\tilde{Z}_{Mj}), \quad 1 \leq j \leq l.$$

Let  $\mathcal{D}_M(\tilde{\mathcal{L}}_j) \stackrel{\text{def}}{=} \{f \in C_b^{1,2}(\tilde{Z}_{Mj}) : f|_{\partial\tilde{Z}_{Mj}} \equiv 0\}$ . Then  $\tilde{\nu}_{Mj}$  is characterized by

$$T \int \tilde{\mathcal{L}}_j f d\tilde{\nu}_{Mj} = - \int f(0, \cdot) d\tilde{\phi}_{0j} \quad \forall f \in \mathcal{D}_M(\tilde{\mathcal{L}}_j).$$

This is the same as, for all  $f \in \mathcal{D}_M(\tilde{\mathcal{L}}_j)$ ,

$$(16) \quad T \int \tilde{\mathcal{L}}_j f \nu_M (dt dx^j \times \Omega_M^{d-\tilde{d}_j} \times U) = - \int f(0, \cdot) \phi_0 (dx^j \times \Omega_M^{d-\tilde{d}_j}),$$

where we partition  $x \in \Omega_M \approx \Omega_M^{\tilde{d}_1} \times \dots \times \Omega_M^{\tilde{d}_l} \times \Omega_M^{d-\sum_{j=1}^l \tilde{d}_j}$  as  $x = [x^1 : \dots : x^j : \dots : x^l : y]$  with  $x^j \in \Omega_M^{\tilde{d}_j}$ ,  $y \in \Omega_M^{d-\sum_{j=1}^l \tilde{d}_j}$  and  $\Omega_M^{\tilde{d}_j}$  denotes the  $\tilde{d}_j$ -dimensional image of  $\Omega_M$  under the projection to the appropriate factor space. The goal then is to minimize  $\int_{Z_M \times U} k d\nu$  over a convex compact set  $\mathcal{M}'_M$  defined as

$$\mathcal{M}'_M \stackrel{\text{def}}{=} \{\nu_M \in \mathcal{M}_M : (16) \text{ holds for } 1 \leq j \leq l\}.$$

As before, we consider a combined problem that has both constraints (14) and unmodelled dynamics. Then the bounded domain approximation to the original problem (6) is as follows:

Minimize over  $\mathcal{M}_M^* \stackrel{\text{def}}{=} \{\nu_M \in \mathcal{M}'_M : (14) \text{ holds}\}$  the functional

$$(17) \quad \int_{Z_M \times U} k d\nu_M \equiv \frac{1}{T} E \left[ \int_0^{\tau_M \wedge T} k(t, x(t), u(t)) dt \right].$$

As before, define  $\mathcal{D}_M \stackrel{\text{def}}{=} C_b^{1,2}(Z_M) \times C_b^{1,2}(\tilde{Z}_{M1}) \times \cdots \times C_b^{1,2}(\tilde{Z}_{Ml})$  equipped with the appropriate Sobolev norm (see the discussion between Theorem 3.1 and (\*)). The corresponding dual becomes the following: For all  $(x, u) \in Z_M \times U$ ,

$$(18) \quad \begin{aligned} \sup_{g \in \mathcal{D}_M(\mathcal{L}), \tilde{g}_j \in \mathcal{D}_M(\tilde{\mathcal{L}}_j) \forall j, \lambda \in \mathcal{R}^m} & \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \sum_{i=1}^m \lambda_i c_i \\ & : \frac{k(x, u) + \sum_{i=1}^m \lambda_i k_i(x, u)}{T} + \mathcal{L}g(x, u) \\ & + \sum_{j=1}^l \tilde{\mathcal{L}}_j \tilde{g}_j(\tilde{x}_j) \geq 0 \end{aligned}$$

for  $\tilde{x}_j$  defined as in (8). Results analogous to Lemma 2.2, Theorem 3.1, and (\*) also hold. Let us define  $\varepsilon_j(M), 1 \leq j \leq m+1$ , to be

$$\varepsilon_j(M) \stackrel{\text{def}}{=} \left| \frac{1}{T} E \left[ \int_0^T k_j(t, x(t), u(t)) dt \right] - \frac{1}{T} E \left[ \int_0^{\tau_M \wedge T} k_j(t, x(t), u(t)) dt \right] \right|,$$

where  $k_{m+1}(\cdot) \stackrel{\text{def}}{=} k(\cdot)$ . We define the *unconstrained domain approximation error* as

$$(19) \quad \varepsilon(M) \stackrel{\text{def}}{=} \max_{1 \leq j \leq m+1} \varepsilon_j(M).$$

The following lemma shows that (19) goes to zero as  $\Omega_M \uparrow \mathcal{R}^m$  and in the process, gives an upper bound on  $\varepsilon(M)$ .

LEMMA 4.1.  $\varepsilon(M) \xrightarrow{M \uparrow \infty} 0$ .

*Proof.*

$$\begin{aligned} \varepsilon_j(M) &= \left| \frac{1}{T} E \left[ \int_0^T k_j(t, x(t), u(t)) I\{t \geq \tau_M\} dt \right] \right| \\ &\leq \frac{1}{T} E \left[ \int_0^T (k_j(t, x(t), u(t)))^2 dt \right]^{1/2} E \left[ \int_0^T I\{t \geq \tau_M\} dt \right]^{1/2} \\ &= \bar{C}_j \left[ \int_0^T P(T \geq t \geq \tau_M) dt \right]^{1/2} \\ &\leq \bar{C}_j \sqrt{TP} (T \geq \tau_M)^{1/2} \\ &= \bar{C}_j \sqrt{TP} \left( \sup_{t \in [0, T]} \|x(t)\|_\infty \geq M \right)^{1/2} \end{aligned}$$

$$\begin{aligned} &\leq \bar{C}_j \sqrt{T} \frac{E[\sup_{t \in [0, T]} \|x(t)\|_\infty^2]^{1/2}}{M} \\ &\leq \frac{\bar{C}_j \sqrt{T} \tilde{C} (1 + E[\|x(0)\|^2])^{1/2}}{M}, \end{aligned}$$

where  $\bar{C}_j$  is a constant bound on  $k_j(\cdot)$ , and  $\tilde{C}$  is a constant depending on  $T$  and the Lipschitz constant of the drift/diffusion terms in (1). The last inequality is an easy consequence of Gronwall's inequality. Taking  $\bar{C} = \max_{1 \leq j \leq m+1} \bar{C}_j$  we get

$$\varepsilon(M) \leq \frac{\bar{C} \sqrt{T} \tilde{C} (1 + E[\|x(0)\|^2])^{1/2}}{M}.$$

The result follows.  $\square$

Let  $\beta_o$  and  $\beta_d$  denote the optimal values for (13) and (18), respectively. Next we find a bound on the *constrained domain approximation error*  $\zeta(M) \stackrel{\text{def}}{=} |\beta_o - \beta_d|$ . Using (\*), we can write

$$\beta_o = \min_{\nu \in \mathcal{M}^*} \langle \nu, k \rangle,$$

where, as before,  $\mathcal{M}^* = \{\nu \in \mathcal{M}' : \int_{Z \times U} k_j d\nu = c_j, 1 \leq j \leq m\}$ , and

$$\beta_d = \min_{\nu_M \in \mathcal{M}_M^*} \langle \nu_M, k \rangle,$$

where  $\mathcal{M}_M^* = \{\nu_M \in \mathcal{M}'_M : \int_{Z_M \times U} k_j d\nu_M = c_j, 1 \leq j \leq m\}$ .

Let us define a map  $F : \mathcal{M}' \rightarrow \mathcal{R}^{m+1}$  as follows:

$$\begin{aligned} \mathcal{M}' \ni \nu &\longmapsto F\nu = \left[ \int_{Z \times U} k_1 d\nu, \dots, \int_{Z \times U} k_m d\nu, \int_{Z \times U} k d\nu \right] \\ &\equiv [y_1(\nu), \dots, y_m(\nu), y_{m+1}(\nu)] \in \mathcal{R}^{m+1}. \end{aligned}$$

Map  $F'$  is defined over  $\mathcal{M}'_M$  in an analogous manner. Note that  $F, F'$  are bounded linear maps and map the compact convex sets  $\mathcal{M}', \mathcal{M}'_M$ , respectively, to compact convex sets in  $\mathcal{R}^{m+1}$ .

The following lemma is the main result of this subsection.

LEMMA 4.2.  $\zeta(M) \leq C_d \varepsilon(M) \xrightarrow{M \uparrow \infty} 0$  for some constant  $C_d = C_d(M) > 0$  which remains uniformly bounded as  $M \uparrow \infty$ .

*Proof.* Using the definition of  $F, F'$ , we can write

$$\beta_o = \min_{[c_1, \dots, c_m, y_{m+1}(\nu)] \in F(\mathcal{M}')} y_{m+1}(\nu)$$

and

$$\beta_d = \min_{[c_1, \dots, c_m, y_{m+1}(\nu_M)] \in F'(\mathcal{M}'_M)} y_{m+1}(\nu_M).$$

Note that by ( $\dagger\dagger$ ), the hypersurfaces  $y_j(\nu) = c_j, 1 \leq j \leq m$ , generate a  $2^m$ -partition of the compact convex set  $F(\mathcal{M}')$ . Then we must have that  $\beta_o$  = the *minimum* of  $y_{m+1}(\nu)$  over *at least one* of these  $2^m$ -partitions. Without loss of generality, let us assume that this is so for the orthant  $Y_1 \stackrel{\text{def}}{=} \{[y_1(\nu), \dots, y_m(\nu), y_{m+1}(\nu)] \in F(\mathcal{M}') :$

$y_j(\nu) \leq c_j, 1 \leq j \leq m\}$ . Hence for  $\mathcal{M}_1^* \stackrel{\text{def}}{=} F^{-1}(Y_1) = \{\nu \in \mathcal{M}' : \int_{Z \times U} k_j d\nu \leq c_j, 1 \leq j \leq m\}$ , we have

$$(20) \quad \beta_o = \min_{\nu \in \mathcal{M}_1^*} \langle \nu, k \rangle.$$

Using analogous arguments, we suppose that

$$\beta_d = \min_{\nu_M \in \mathcal{M}_{M,1}^*} \langle \nu_M, k \rangle$$

for  $\mathcal{M}_{M,1}^* \stackrel{\text{def}}{=} \{\nu_M \in \mathcal{M}'_M : \int_{Z_M \times U} k_j d\nu_M \leq c_j, 1 \leq j \leq m\}$ . (We have chosen the orthant corresponding to (20) above. This is purely for notational convenience; in reality it could be a different orthant.) Using the Lagrange multiplier formulation we can write

$$\begin{aligned} \beta_o &= \max_{\lambda \geq 0} \min_{\nu \in \mathcal{M}'} \left\{ \langle \nu, k \rangle + \sum_{i=1}^m \int_{Z \times U} \lambda_i k_i d\nu - \langle \lambda, c \rangle \right\}, \\ \beta_d &= \max_{\lambda_M \geq 0} \min_{\nu_M \in \mathcal{M}'_M} \left\{ \langle \nu_M, k \rangle + \sum_{i=1}^m \int_{Z_M \times U} \lambda_{Mi} k_i d\nu_M - \langle \lambda_M, c \rangle \right\}. \end{aligned}$$

Let  $\lambda^*, \lambda_M^* \geq 0$  be the Lagrange multipliers (i.e., the *maximizing* values of  $\lambda, \lambda_M$ , respectively, on the r.h.s.) for the two cases, respectively. By  $(\dagger)$ , there exists an *interior* point  $\bar{\nu}$  of  $\mathcal{M}_1^*$ , i.e.,  $\int_{Z \times U} k_i d\bar{\nu} < c_i, 1 \leq i \leq m$ . Let  $\nu^* = \operatorname{argmin}_{\nu \in \mathcal{M}_1^*} \langle \nu, k \rangle$ . Similarly, by  $(\dagger\dagger)$ , we have an *interior* point  $\bar{\nu}_M \in \mathcal{M}_{M,1}^*$ . Let  $\nu_M^* = \operatorname{argmin}_{\nu_M \in \mathcal{M}_{M,1}^*} \langle \nu_M, k \rangle$ . Suppose  $\beta_o \geq \beta_d$ . Then we have

$$\begin{aligned} |\beta_o - \beta_d| &= \max_{\lambda \geq 0} \min_{\nu \in \mathcal{M}'} \left\{ \langle \nu, k \rangle + \sum_{i=1}^m \int_{Z \times U} \lambda_i k_i d\nu - \langle \lambda, c \rangle \right\} \\ &\quad - \max_{\lambda_M \geq 0} \min_{\nu_M \in \mathcal{M}'_M} \left\{ \langle \nu_M, k \rangle + \sum_{i=1}^m \int_{Z_M \times U} \lambda_{Mi} k_i d\nu_M - \langle \lambda_M, c \rangle \right\} \\ &\leq \min_{\nu \in \mathcal{M}'} \left\{ \langle \nu, k \rangle + \sum_{i=1}^m \int_{Z \times U} \lambda_i^* k_i d\nu - \langle \lambda^*, c \rangle \right\} \\ &\quad - \min_{\nu_M \in \mathcal{M}'_M} \left\{ \langle \nu_M, k \rangle + \sum_{i=1}^m \int_{Z_M \times U} \lambda_i^* k_i d\nu_M - \langle \lambda^*, c \rangle \right\} \\ &\leq \max_{\mathcal{L}(x(\cdot), u(\cdot))} \left| \left( \langle \nu, k \rangle - \langle \nu_M, k \rangle \right) + \sum_{i=1}^m \lambda_i^* (\langle \nu, k_i \rangle - \langle \nu_M, k_i \rangle) \right| \\ &\leq (1 + \|\lambda^*\|_1) \varepsilon(M), \end{aligned}$$

where  $\mathcal{L}(x(\cdot), u(\cdot))$  denotes the joint law of  $(x(\cdot), u(\cdot))$ . (Note that each pair  $(\nu, \nu_M)$  corresponds to one such law.) The  $\beta_d \geq \beta_o$  case is exactly symmetric with  $\lambda_M^*$  in place of  $\lambda^*$ . Hence we have

$$|\beta_o - \beta_d| \leq (1 + (\|\lambda^*\|_1 \vee \|\lambda_M^*\|_1)) \varepsilon(M).$$

Now it follows from Exercise 5.3.1, p. 516 of [4], that

$$\begin{aligned} \|\lambda^*\|_1 &\leq \frac{\langle \bar{\nu}, k \rangle - \langle \nu^*, k \rangle}{\min_{1 \leq i \leq m} (c_i - \int_{Z \times U} k_i d\bar{\nu})}, \\ \|\lambda_M^*\|_1 &\leq \frac{\langle \bar{\nu}_M, k \rangle - \langle \nu_M^*, k \rangle}{\min_{1 \leq i \leq m} (c_i - \int_{Z_M \times U} k_i d\bar{\nu}_M)}. \end{aligned}$$

Since  $k(\cdot) > 0$ , we have  $\langle \nu^*, k \rangle > 0$ ,  $\langle \nu_M^*, k \rangle > 0$ , and hence

$$|\beta_o - \beta_d| \leq (1 + \|k\|_\infty A(c, k_1, \dots, k_m))\varepsilon(M),$$

where

$$A(c, k_1, \dots, k_m) \stackrel{\text{def}}{=} \frac{1}{\min_{1 \leq i \leq m} (c_i - \int_{Z \times U} k_i d\bar{\nu}) \wedge \min_{1 \leq i \leq m} (c_i - \int_{Z_M \times U} k_i d\bar{\nu}_M)}.$$

Also,

$$A(c, k_1, \dots, k_m) \rightarrow \frac{1}{\min_{1 \leq i \leq m} (c_i - \|k_i\|_\infty)} < \infty$$

as  $M \uparrow \infty$ . The result follows.  $\square$

In anticipation of the finite dimensional approximation to be introduced in the next subsection, we will have to specify boundary conditions to be *not exactly zero*, but bounded by a *given small constant*  $\eta > 0$ . This is because the approximation of an RKHS function vanishing on the boundary by one in a finite dimensional subspace thereof will be small but not necessarily zero on the boundary. This converts the problem (18) to the following: For all  $(x, u) \in Z_M \times U$ ,

$$(21) \quad \sup_{(g, \tilde{g}_1, \dots, \tilde{g}_l) \in \mathcal{D}_M, \lambda \in \mathcal{R}^m} \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \sum_{i=1}^m \lambda_i c_i \\ : \frac{k(x, u) + \sum_{i=1}^m \lambda_i k_i(x, u)}{T} + \mathcal{L}g(x, u) \\ + \sum_{j=1}^l \tilde{\mathcal{L}}_j \tilde{g}_j(\tilde{x}_j) \geq 0; \\ |g|_{\partial Z_M} \leq \eta; \quad |\tilde{g}_j|_{\partial \tilde{Z}_{Mj}} \leq \eta \quad \forall j$$

with  $\tilde{x}_j$  as in (8).

Let  $\beta_x$  denote the optimal value for (21). We define the error function  $\hat{\varepsilon}(\eta)$  due to this further approximation as  $\hat{\varepsilon}(\eta) \stackrel{\text{def}}{=} |\beta_d - \beta_x|$ . Define a family of functions

$$F_\eta \stackrel{\text{def}}{=} \{h(\cdot) : Z_M \rightarrow \mathcal{R} \text{ continuous, } |h(x)| \leq \eta \quad \forall x \in \partial Z_M\}.$$

LEMMA 4.3.  $\hat{\varepsilon}(\eta) \leq \eta(l+1)$ .

*Proof.* Let

$$f(x, u) \stackrel{\text{def}}{=} \frac{k(x, u) + \sum_{i=1}^m \lambda_i k_i(x, u)}{T},$$

$$G \stackrel{\text{def}}{=} \left\{ (g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in \mathcal{D}_M \times \mathcal{R}^m : f(x, u) + \mathcal{L}g(x, u) + \sum_{j=1}^l \tilde{\mathcal{L}}_j \tilde{g}_j(\tilde{x}_j) \geq 0 \right\},$$

and

$$G' \stackrel{\text{def}}{=} \{ (g, \tilde{g}_1, \dots, \tilde{g}_l) \in \mathcal{D}_M : \mathcal{L}g(x, u) = 0; \quad \tilde{\mathcal{L}}_j \tilde{g}_j(\tilde{x}_j) = 0 \quad \forall j; \quad g|_{\partial Z_M} = h|_{\partial Z_M}, \\ \tilde{g}_j|_{\partial \tilde{Z}_{Mj}} = h_j|_{\partial \tilde{Z}_{Mj}} \quad \forall j, \quad h, h_j \in F_\eta \}.$$

Then,

$$\begin{aligned}\beta_d &= \sup_{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in G} \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \\ &: \quad g|_{\partial Z_M} \equiv 0, \quad \tilde{g}_j|_{\partial \tilde{Z}_{Mj}} \equiv 0, \\ \beta_x &= \sup_{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in G} \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \\ &: \quad |g|_{\partial Z_M} \leq \eta, \quad |\tilde{g}_j|_{\partial \tilde{Z}_{Mj}} \leq \eta.\end{aligned}$$

Note that  $\beta_x$  can be written as

$$\begin{aligned}\beta_x &= \sup \int (g^1(0, \cdot) + g^2(0, \cdot)) d\phi_0 + \sum_{j=1}^l \int (\tilde{g}_j^1(0, \cdot) + \tilde{g}_j^2(0, \cdot)) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \\ &: \quad (g^1, \tilde{g}_1^1, \dots, \tilde{g}_l^1, \lambda) \in G, \quad g^1|_{\partial Z_M} \equiv 0; \quad \tilde{g}_j^1|_{\partial \tilde{Z}_{Mj}} \equiv 0, \\ &\quad (g^2, \tilde{g}_1^2, \dots, \tilde{g}_l^2) \in G' .\end{aligned}$$

But then  $g_j^2$  is of the form  $\tilde{g}_j^2(\tilde{x}_j) = E_{\tilde{x}_j}[h_j(\hat{X}_j(\tau_M \wedge T))]$ , where  $\hat{X}_j(\cdot)$  is a  $\tilde{d}_j$ -dimensional diffusion given by (10). In particular,  $|g_j^2(\cdot)| \leq \eta$ . Similar results hold for  $g^2(\cdot)$ . So, we get

$$\begin{aligned}|\beta_d - \beta_x| &\leq \sup_{(g^2, \tilde{g}_1^2, \dots, \tilde{g}_l^2) \in G'} \left| \int g^2(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}_j^2(0, \cdot) d\tilde{\phi}_{0j} \right| \\ &= \sup_{h(\cdot), h_1(\cdot), \dots, h_l(\cdot)} \left| \int E_x[h(X(\tau_M \wedge T))] d\phi_0(x) \right. \\ &\quad \left. + \sum_{j=1}^l \int E_{\tilde{x}_j}[h_j(\hat{X}_j(\tau_M \wedge T))] d\tilde{\phi}_{0j}(\tilde{x}_j) \right| \\ &\leq \eta(l+1).\end{aligned}$$

The claim follows.  $\square$

Henceforth we drop the subscript  $M$  in the notation and assume that all definitions are for the bounded domain  $Z_M$  under consideration.

**4.2. Finite dimensional approximation.** In this subsection, we give approximation error bounds for our problem (21) using finite dimensional functions with a finite number of constraints.

Let  $K(x, y)$  denote a  $C^\infty$  Mercer (i.e., continuous, symmetric, and positive definite) kernel on  $Z \times Z$ . Hence so will be its restriction  $\tilde{K}(x, y)$  to  $\tilde{Z}_j \times \tilde{Z}_j$ . Associated with this is a unique *RKHS*  $\mathcal{H}_K$  of functions on  $Z$  and  $\tilde{\mathcal{H}}_{Kj}$  of functions on  $\tilde{Z}_j$ , characterized by ([10, p. 35]):

1. For all  $x \in Z$ ,  $K_x \stackrel{\text{def}}{=} K(x, \cdot) \in \mathcal{H}_K$ ;
2.  $\text{span}\{K_x : x \in Z\}$  is dense in  $\mathcal{H}_K$ ;
3. For all  $f \in \mathcal{H}_K$ ,  $f(x) = \langle K_x, f \rangle$ ,

and likewise for  $\tilde{\mathcal{H}}_{Kj}$ ,  $1 \leq j \leq l$ . The kernel  $K$  defines (see [10, Proposition 1, p. 33]) the Hilbert–Schmidt integral operator  $L_K$  by

$$L_K(f)(z) = \int_Z K(z, t) f(t) d\nu(t), \quad z \in Z, f \in L^2_\nu(Z),$$

with  $\vartheta$  = the Lebesgue measure on  $Z$ . Let  $\{\phi_k\}_{k \geq 1}$  be the eigenvectors corresponding to the eigenvalues  $\{\lambda_k\}_{k \geq 1}$  of  $L_K$ . By [10, Theorem 4, p. 37], the inner product on  $\mathcal{H}_K$  can be defined by

$$\langle f, g \rangle_K = \sum_{k=1}^{\infty} \frac{f_k g_k}{\lambda_k}.$$

Here  $f = \sum_{k=1}^{\infty} f_k \phi_k$ ,  $g = \sum_{k=1}^{\infty} g_k \phi_k$ . The corresponding norm is defined by  $\|f\|_K \stackrel{\text{def}}{=} (\sum_{k=1}^{\infty} \frac{f_k^2}{\lambda_k})^{\frac{1}{2}}$ . Analogous statements hold for  $\tilde{Z}_j, \tilde{\mathcal{H}}_{Kj}$ .

From an approximation point of view, the attractive features of  $\mathcal{H}_K$  are the following:

- They are spanned by the translates of a single function  $K_x$ , and the best least squares estimate of any  $f$  sampled at a discrete subset  $\tilde{Z}$  of  $Z$ , with a regularity penalty, turns out to be a linear combination of the  $K_z, z \in \tilde{Z}$ . The latter is a version of the Shannon sampling theorem (see [25], [26], [27]).
- For any  $n > d + 1$ ,  $\mathcal{H}_K$  is densely embedded in  $H^{\frac{n}{2}}(Z)$  and the embedding is bounded (see the proof of [10, Theorem D, p. 41]). By the Rellich–Kondrachov theorem ([1, Theorem 6.3, part II, p. 168]),  $H^{m+2}(Z)$  is densely embedded in  $C_b^{1,2}(Z)$  and the embedding is compact whenever  $m > \frac{d+1}{2}$ . Thus  $\mathcal{H}_K$  is compactly and densely embedded in  $C_b^{1,2}(Z)$  if we choose  $n = 2m + 4 > d + 5$ . Similar statements apply to  $\tilde{Z}_j, \tilde{d}_j, \tilde{m}_j, \tilde{\mathcal{H}}_{Kj}$  in place of  $Z, d, m, \mathcal{H}_K$ . Thus  $\mathcal{H} \stackrel{\text{def}}{=} \mathcal{H}_K \times \tilde{\mathcal{H}}_{K1} \times \cdots \times \tilde{\mathcal{H}}_{Kl}$  is compactly and densely embedded in  $\mathcal{D}$ . This makes it a convenient space for approximation (*hypothesis space* in the language of statistical learning theory; see [10]).

For future reference, let  $\mathcal{I}$  denote this injection. Let us define the product Sobolev space  $\mathcal{W}$  as follows:

$$(22) \quad \mathcal{W} \stackrel{\text{def}}{=} \left\{ (u, \tilde{u}_1, \dots, \tilde{u}_l) \in H^{m+2}(Z) \times H^{\tilde{m}_1+2}(\tilde{Z}_1) \times \cdots \times H^{\tilde{m}_l+2}(\tilde{Z}_l) \right. \\ \left. : m > \frac{d+1}{2}, \tilde{m}_j > \frac{\tilde{d}_j+1}{2}, 1 \leq j \leq l \right\}.$$

Let  $\bar{Z} \subset Z, \bar{\tilde{Z}}_j \subset \tilde{Z}_j, 1 \leq j \leq l$ , be finite. Define a Hilbert space  $\mathcal{H}_{K,\bar{Z}}$  of functions  $f : Z \rightarrow \mathcal{R}$  as the linear span of  $K(z_i, \cdot), z_i \in \bar{Z}$ , with inner product

$$\left\langle \sum_i a_i K_{z_i}, \sum_j b_j K_{z_j} \right\rangle_{K,\bar{Z}} \stackrel{\text{def}}{=} \sum_{i,j} a_i b_j K(z_i, z_j).$$

This is a finite dimensional Hilbert space of dimension  $|\bar{Z}|$ . The  $|\bar{\tilde{Z}}_j|$ -dimensional Hilbert spaces  $\tilde{\mathcal{H}}_{Kj,\bar{Z}}, 1 \leq j \leq l$ , of functions  $\tilde{f}_j : \tilde{Z}_j \rightarrow \mathcal{R}$  are defined analogously. These norms are compatible with the norms of  $\mathcal{H}_K, \tilde{\mathcal{H}}_{Kj}$ , respectively, relativized to  $\mathcal{H}_{K,\bar{Z}}, \tilde{\mathcal{H}}_{Kj,\bar{Z}}$ , viewed as subspaces thereof.

For  $R > 0$ ,  $B_R \stackrel{\text{def}}{=} \text{the closed ball of radius } R \text{ in } \mathcal{H}, \text{ centered at the origin.}$  By the properties of  $\mathcal{H}$  noted above,  $\overline{\mathcal{I}(B_R)}$  is compact in  $\mathcal{D}$  and  $\cup_{R>0} \overline{\mathcal{I}(B_R)}$  is dense in  $\mathcal{D}$ . For  $R^*$  as in (\*), we shall fix any  $R > 0$  such that  $R \geq \|\mathcal{I}\|^{-1} R^*$ . (See also Lemma 4.5 below for a specific choice.) Thus we get  $BL_{R^*} \subseteq \overline{\mathcal{I}(B_R)}$ . Let  $A^\epsilon$  for any set  $A \subset \mathcal{D}$  denote its  $\epsilon$ -thickening, i.e., the set of all points which are at most  $\epsilon$  away

from  $A$  in the  $\|\cdot\|_{C_b^{1,2}}$  norm. We shall approximate  $\overline{\mathcal{I}(B_R)}$  by its intersection with  $\bar{\mathcal{H}} \stackrel{\text{def}}{=} \mathcal{H}_{K,Z} \times \tilde{\mathcal{H}}_{K1,Z} \times \cdots \times \tilde{\mathcal{H}}_{Kl,Z}$ . The quality of this approximation is described by Theorem 5.1 in section 5. Let the *sampling approximation error*  $\Xi$  be defined as

$$(23) \quad \Xi \stackrel{\text{def}}{=} \sup_{(g, \tilde{g}_1, \dots, \tilde{g}_l) \in \overline{\mathcal{I}(B_R)}} \inf_{(\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l) \in \bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}} \|(g, \tilde{g}_1, \dots, \tilde{g}_l) - (\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l)\|_{C_b^{1,2}}.$$

Using  $R$  fixed as above, we now consider a semi-infinite approximation to (21). This is semi-infinite because, while it has finitely many variables, it still has infinitely many constraints. Specifically, this will be

$$(24) \quad \begin{aligned} & \sup \left\{ \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle : (g, \tilde{g}_1, \dots, \tilde{g}_l) \in \bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}, \right. \\ & \quad \lambda \in \Lambda, \text{ and, } \frac{k(x, u) + \sum_{i=1}^m \lambda_i k_i(x, u)}{T} + \mathcal{L}g(x, u) + \sum_{j=1}^l \tilde{\mathcal{L}}_j \tilde{g}_j(\tilde{x}_j) \geq 0 \\ & \quad \left. \forall (x, u) \in Z \times U, |g|_{\partial Z} \leq \eta, |\tilde{g}_j|_{\partial \tilde{Z}_j} \leq \eta \right\} \end{aligned}$$

with  $\tilde{x}_j$  is defined as in (8). Let  $\beta_s$  denote the optimal value for (24).

Let us now prove two important lemmas. The first is a technical one which is a slight generalization of the result in Exercise 5.3.1, p. 516 of [4]. Let  $G$  be a convex subset of  $\mathcal{D} \times \mathcal{R}^m$ . Let  $\mathcal{F}$  be a concave mapping from  $G$  into  $\mathcal{R}$ . Assume that there exists a  $(\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda}) \in G$  such that  $\mathcal{F}((\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda})) > 0$ . Let  $f$  be a real-valued convex functional on  $G$ . Let

$$\beta^* \stackrel{\text{def}}{=} \operatorname{argmax}_G f(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) : \mathcal{F}(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \geq 0.$$

LEMMA 4.4. *There exists an element  $\nu^* \in C_b(Z)^*$  with  $\nu^* \geq 0$  such that*

$$\|\nu^*\| \leq \frac{\beta^* - f(\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda})}{\min_{x \in Z} \mathcal{F}((\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda}))(x)}.$$

*Proof.* It follows from [23, Theorem 1, p. 217] that there exists  $\nu^* \in C_b(Z)^*$  such that  $\nu^* \geq 0$  and

$$-\beta^* = \inf_{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in G} [-f(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) + \langle -\mathcal{F}((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)), \nu^* \rangle].$$

Then

$$-\beta^* + f(\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda}) \leq \langle -\mathcal{F}((\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda})), \nu^* \rangle.$$

Since  $\min_{x \in Z} \mathcal{F}((\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda}))(x) \leq \mathcal{F}((\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda}))(x)$ , we have

$$\begin{aligned} \beta^* - f(\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda}) & \geq \left( \min_{x \in Z} \mathcal{F}((\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda}))(x) \right) \int_Z d\nu^* \\ & = \|\nu^*\| \left( \min_{x \in Z} \mathcal{F}((\bar{g}, \bar{\tilde{g}}_1, \dots, \bar{\tilde{g}}_l, \bar{\lambda}))(x) \right). \end{aligned}$$

The last equality holds because  $\nu^* \geq 0$ . The claim follows.  $\square$

Now define  $\mathcal{F} : \mathcal{H} \times \mathcal{R}^m \rightarrow C_b(Z)$  as

$$\begin{aligned} \mathcal{F}((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda))(x) \stackrel{\text{def}}{=} \inf_{u \in U} \left( \frac{k(x, u) + \sum_{i=1}^m \lambda_i k_i(x, u)}{T} + \mathcal{L}g(x, u) \right) \\ + \sum_{j=1}^l \tilde{\mathcal{L}}_j \tilde{g}_j(\tilde{x}_j) \quad \forall x \in Z \end{aligned}$$

with  $\tilde{x}_j$  defined as in (8). Note that this is a concave functional. Furthermore,

$$\begin{aligned} \|\mathcal{L}\| &\leq 1 + \sup_{(x,u) \in \Omega_M \times U} |m(x, u)| + \frac{1}{2} \sup_{(x,u) \in \Omega_M \times U} |\text{tr}(\sigma(x, u)\sigma^T(x, u))| \text{ and} \\ \|\tilde{\mathcal{L}}_j\| &\leq 1 + \sup_{(t,x) \in Z} |\tilde{m}_j(t, x)| + \frac{1}{2} \sup_{(t,x) \in Z} |\text{tr}(\tilde{\sigma}_j(t, x)\tilde{\sigma}_j^T(t, x))|, \quad 1 \leq j \leq l. \end{aligned}$$

LEMMA 4.5. *Let  $\Xi = \epsilon$ . Given any  $\xi, \eta > 0$ , for sufficiently small  $\epsilon > 0$ , there exists a solution  $(v, \tilde{v}_1, \dots, \tilde{v}_l, \lambda) \in (\mathcal{H} \cap \mathcal{I}(B_R)) \times \Lambda$  to the inequality*

$$\begin{aligned} \mathcal{F}((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) &\geq \xi(l+1) - \epsilon(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|) > 0, \\ |g|_{\partial Z} &\leq \eta, \\ |\tilde{g}_j|_{\partial \tilde{Z}_j} &\leq \eta, \quad 1 \leq j \leq l, \end{aligned}$$

for large enough  $R^*$ , and  $R$  satisfying  $R \geq \|\mathcal{I}\|^{-1} R^*$ .

*Proof.* Consider the HJB equation

$$\begin{aligned} \inf_{u \in U} \left( \frac{k(t, x, u) + \sum_{i=1}^m \lambda_i k_i(t, x, u)}{T} + \mathcal{L}g(t, x, u) - \xi \right) &= 0, \quad (t, x) \in Z, \\ g|_{\partial Z} &= \frac{\eta}{2}, \end{aligned}$$

for a prescribed  $\xi > 0$ . Since *nondegeneracy* (3) holds, by [12, Theorem 4.2, p. 169], it has a solution  $g(\cdot) \in C_b^{1,2}(Z)$ . By [12, Theorem 3.1, p. 163],

$$g(t, x) = \inf_{u(\cdot)} E_{t,x} \left[ \int_t^{\tau_M \wedge T} \left( \frac{k(s, x(s), u(s)) + \sum_{i=1}^m \lambda_i k_i(s, x(s), u(s))}{T} - \xi \right) dt + \frac{\eta}{2} \right], \quad (25)$$

where  $x(\cdot)$  is a  $d$ -dimensional diffusion given by (4). Similarly, for  $1 \leq j \leq l$ , we get that

$$\begin{aligned} \tilde{\mathcal{L}}_j \tilde{g}_j(t, \tilde{x}_j) &= \xi, \quad (t, \tilde{x}_j) \in \tilde{Z}_j, \\ \tilde{g}_j|_{\partial \tilde{Z}_j} &= \frac{\eta}{2} \end{aligned}$$

has a solution  $\tilde{g}_j(\cdot) \in C_b^{1,2}(\tilde{Z}_j)$  given by

$$\tilde{g}_j(t, \tilde{x}_j) = E_{t, \tilde{x}_j} \left[ - \int_t^{\tau_M \wedge T} \xi dt + \frac{\eta}{2} \right]. \quad (26)$$

Then, adding these equations, we get that

$$\begin{aligned} \inf_{u \in U} \left( \frac{k(t, x, u) + \sum_{i=1}^m \lambda_i k_i(t, x, u)}{T} + \mathcal{L}g(t, x, u) \right) \\ + \sum_{j=1}^l \tilde{\mathcal{L}}_j \tilde{g}_j(t, \tilde{x}_j) = \xi(l+1) > 0, \\ g|_{\partial Z} = \frac{\eta}{2}, \\ \tilde{g}_j|_{\partial \tilde{Z}_j} = \frac{\eta}{2} \end{aligned}$$

has a solution  $(g, \tilde{g}_1, \dots, \tilde{g}_l) \in \mathcal{D}$  such that  $(g, \tilde{g}_1, \dots, \tilde{g}_l) \in B_{\frac{R^*}{2}}$  for  $R^*$  chosen *large enough*. Choose  $\epsilon > 0$  such that

$$(27) \quad \epsilon < \min \left( \frac{\xi(l+1)}{\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|}, \frac{\eta}{2} \right).$$

Since  $\bar{\mathcal{H}} \cap B_{\frac{R^*}{2}}$  is  $\epsilon$ -dense in  $B_{\frac{R^*}{2}}$ , we can find a  $(v, \tilde{v}_1, \dots, \tilde{v}_l) \in \bar{\mathcal{H}} \cap B_{R^*}$  such that

$$\begin{aligned} \inf_{u \in U} \left( \frac{k(t, x, u) + \sum_{i=1}^m \lambda_i k_i(t, x, u)}{T} + \mathcal{L}v(t, x, u) \right) + \sum_{j=1}^l \tilde{\mathcal{L}}_j \tilde{v}_j(t, \tilde{x}_j) \\ \geq \xi(l+1) - \epsilon(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|) > 0, \\ |v|_{\partial Z} \leq \frac{\eta}{2} + \epsilon \leq \eta, \\ \forall j, \quad |\tilde{v}_j|_{\partial \tilde{Z}_j} \leq \frac{\eta}{2} + \epsilon \leq \eta. \end{aligned}$$

The claim follows.  $\square$

We now state the first main result of this section.

**THEOREM 4.6.** *If  $\Xi = \epsilon > 0$  and (27) holds, then  $|\beta_o - \beta_s| \leq C_1(\epsilon + \eta + \frac{1}{M})$  for some  $\eta > 0$  chosen small enough and a constant  $C_1 = C_1(M) > 0$  independent of  $\epsilon, \eta$  which remains uniformly bounded as  $M \uparrow \infty$ .*

*Proof.* Define the concave functional  $\mathcal{F}_\epsilon : \mathcal{H} \times \mathcal{R}^m \rightarrow C_b(Z)$  as

$$\mathcal{F}_\epsilon((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) \stackrel{\text{def}}{=} \mathcal{F}((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) + \epsilon \left( \|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\| \right).$$

Now define

$$\begin{aligned} G_1 \stackrel{\text{def}}{=} \{ (g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in (\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}) \times \Lambda : \mathcal{F}((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) \geq 0; \\ |g|_{\partial Z} \leq \eta; |\tilde{g}_j|_{\partial \tilde{Z}_j} \leq \eta, 1 \leq j \leq l \}, \end{aligned}$$

$$\begin{aligned} G_2 \stackrel{\text{def}}{=} \{ (g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in \overline{\mathcal{I}(B_R)} \times \Lambda : \mathcal{F}((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) \geq 0; \\ |g|_{\partial Z} \leq \eta; |\tilde{g}_j|_{\partial \tilde{Z}_j} \leq \eta, 1 \leq j \leq l \}, \end{aligned}$$

$$\begin{aligned} G_3 \stackrel{\text{def}}{=} \{ (g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in (\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}) \times \Lambda : \mathcal{F}_\epsilon((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) \geq 0; \\ |g|_{\partial Z} \leq \eta; |\tilde{g}_j|_{\partial \tilde{Z}_j} \leq \eta, 1 \leq j \leq l \}, \end{aligned}$$

and

$$G'_3 \stackrel{\text{def}}{=} \{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in (\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}) \times \Lambda : \mathcal{F}_\epsilon((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) \geq 0; \\ |g|_{\partial Z} \leq \eta + \epsilon; |\tilde{g}_j|_{\partial \tilde{Z}_j} \leq \eta + \epsilon, 1 \leq j \leq l\}.$$

Note that these sets are convex and  $G_1, G_3, G'_3$  compact. Let

$$G_1^\epsilon \stackrel{\text{def}}{=} \{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in (\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)})^\epsilon \times \Lambda : \mathcal{F}((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) \geq 0; \\ |g|_{\partial Z} \leq \eta; |\tilde{g}_j|_{\partial \tilde{Z}_j} \leq \eta, 1 \leq j \leq l\}$$

and

$$G_3^\epsilon \stackrel{\text{def}}{=} \{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in (\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)})^\epsilon \times \Lambda : \mathcal{F}_\epsilon((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) \geq 0; \\ |g|_{\partial Z} \leq \eta + \epsilon; |\tilde{g}_j|_{\partial \tilde{Z}_j} \leq \eta + \epsilon, 1 \leq j \leq l\}.$$

Note that these sets are also convex and relatively compact in the  $C_b^{0,1} \times \mathcal{R}^m$  topology. It follows from Lemma 4.5 that all these sets are nonempty. As discussed before, using (\*) and Lemma 4.5, choosing  $R \geq \|\mathcal{I}\|^{-1}R^*$ , and the fact that  $\mathcal{H}$  is dense in  $\mathcal{D}$ , we see that

$$(28) \quad \beta_x = \sup_{G_2} \left( \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \right).$$

Let  $\beta_s, \beta', \beta'', \beta_\epsilon^1, \beta'_\epsilon$ , respectively, denote the supremum of the quantity in parentheses on the right over  $G_1, G_3, G'_3, G_1^\epsilon, G_3^\epsilon$ . Note that  $G_1 \subset G_2 \subset G_1^\epsilon \subset G_3^\epsilon$ . Hence,  $\beta_s \leq \beta_x \leq \beta_\epsilon^1 \leq \beta'_\epsilon$ . Therefore

$$(29) \quad |\beta_x - \beta_s| \leq |\beta_\epsilon^1 - \beta''| + |\beta'' - \beta'| + |\beta' - \beta_s|.$$

Of these,  $\beta_s \leq \beta' \leq \beta''$  as  $G_1 \subset G_3 \subset G'_3$ . An argument similar to the proof of Lemma 4.3 allows us to conclude that

$$|\beta'' - \beta'| \leq \epsilon(l+1).$$

Also,

$$\beta' - \beta_s = |\beta' - \beta_s| \leq (|\nu| \vee |\nu^\epsilon|)(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|)\epsilon$$

by [23, Theorem 1, p. 222], where  $\nu, \nu^\epsilon \geq 0$  are the *minimizing* Lagrange multipliers (measures) for the convex programs

$$\sup_{G_1} \left( \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \right)$$

and

$$\sup_{G_3} \left( \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \right),$$

respectively. It follows from Lemma 4.4 that

$$\|\nu\| \leq \frac{\beta_s - \bar{\beta}}{\min_{x \in Z} \mathcal{F}((\bar{g}, \bar{g}_1, \dots, \bar{g}_l, \bar{\lambda}))(x)},$$

where  $\bar{\beta} = \int \bar{g} d\phi_0 + \sum_{j=1}^l \int \bar{g}_j d\tilde{\phi}_{0j} - \langle \bar{\lambda}, c \rangle$  for some  $(\bar{g}, \bar{g}_1, \dots, \bar{g}_l, \bar{\lambda}) \in G_1$  such that  $\mathcal{F}(\bar{g}, \bar{g}_1, \dots, \bar{g}_l, \bar{\lambda}) \geq \xi(l+1) - \epsilon(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|) > 0$ . That such a  $(\bar{g}, \bar{g}_1, \dots, \bar{g}_l, \bar{\lambda})$  indeed exists is guaranteed by Lemma 4.5. Hence, using the stochastic representation of Lemma 4.5, we have, by the  $\epsilon$ -density of  $\mathcal{H} \cap \mathcal{I}(B_R)$  in  $\mathcal{I}(B_R)$  that

$$\bar{g}(t, x) \geq \inf_{u(\cdot)} E_{t,x} \left[ \int_t^{\tau_M \wedge T} \left( \frac{k(s, x(s), u(s)) + \sum_{i=1}^m \bar{\lambda}_i k_i(s, x(s), u(s))}{T} - \xi \right) dt + \frac{\eta}{2} \right] - \epsilon$$

and

$$\bar{g}_j(t, \tilde{x}_j) \geq E_{t, \tilde{x}_j} \left[ - \int_t^{\tau_M \wedge T} \xi dt + \frac{\eta}{2} \right] - \epsilon.$$

Hence we have

$$\bar{\beta} \geq C_{\bar{\lambda}} - \xi T(l+1) - \epsilon(l+1) + \frac{\eta}{2}(l+1),$$

where

$$C_{\bar{\lambda}} \stackrel{\text{def}}{=} \int \left( \inf_{u(\cdot)} E_{t,x} \left[ \int_0^{\tau_M \wedge T} \left( \frac{k(s, x(s), u(s)) + \sum_{i=1}^m \bar{\lambda}_i k_i(s, x(s), u(s))}{T} \right) dt \right] \right) d\phi_0 - \langle \bar{\lambda}, c \rangle.$$

Since  $\bar{\lambda}$  is fixed, and the  $k(\cdot)$  and the  $k_i(\cdot)$ 's are bounded functions,  $C_{\bar{\lambda}}$  is independent of  $\xi$  and we have  $\frac{C_{\bar{\lambda}}}{\xi} \rightarrow 0$  as  $\xi \uparrow \infty$ . Also,

$$\begin{aligned} \|\nu\| &\leq \frac{\beta_s - \bar{\beta}}{\min_{x \in Z} \mathcal{F}((\bar{g}, \bar{g}_1, \dots, \bar{g}_l, \bar{\lambda}))(x)} \\ &\leq \frac{\beta_s + \xi T(l+1) + \epsilon(l+1) - \frac{\eta}{2}(l+1) - C_{\bar{\lambda}}}{\xi(l+1) - \epsilon(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|)} \\ &\leq T + \frac{\beta_s + \epsilon(l+1) + \frac{\eta}{2}(l+1) + \epsilon T(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|) - C_{\bar{\lambda}}}{\xi(l+1) - \epsilon(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|)}. \end{aligned} \tag{30}$$

Since  $\xi$  can be arbitrarily large, we let  $\xi \uparrow \infty$  (note that  $\epsilon$  remains fixed by (27) as  $\eta$  is fixed) to obtain

$$\|\nu\| \leq T.$$

Similarly, we have

$$\|\nu^\epsilon\| \leq \frac{\beta' - \bar{\beta}_\epsilon}{\min_{x \in Z} \mathcal{F}_\epsilon((\bar{g}_\epsilon, \bar{g}_{\epsilon 1}, \dots, \bar{g}_{\epsilon l}, \bar{\lambda}_\epsilon))(x)},$$

where  $\bar{\beta}_\epsilon = \int \bar{g}_\epsilon d\phi_0 + \sum_{j=1}^l \int \bar{g}_{\epsilon j} d\tilde{\phi}_{0j} - \langle \bar{\lambda}_\epsilon, c \rangle$  for some  $(\bar{g}_\epsilon, \bar{g}_{\epsilon 1}, \dots, \bar{g}_{\epsilon l}, \bar{\lambda}_\epsilon) \in G_3$  such that  $\mathcal{F}_\epsilon(\bar{g}_\epsilon, \bar{g}_{\epsilon 1}, \dots, \bar{g}_{\epsilon l}, \bar{\lambda}_\epsilon) \geq \xi(l+1) - \epsilon(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|) > 0$ . We argue as above to deduce  $\|\nu^\epsilon\| \leq T$ . Thus we have

$$(31) \quad |\beta' - \beta_s| \leq \epsilon T \left( \|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\| \right).$$

On the other hand, let  $(g^*, \tilde{g}_1^*, \dots, \tilde{g}_l^*, \lambda^*) \in G_1^\epsilon$  be such that the value of  $(\int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle)$  at this point is within  $\epsilon$  of its supremum over  $G_1^\epsilon$ . Suppose  $\beta_\epsilon^1 \geq \beta''$ . Then, for any  $(g^\epsilon, \tilde{g}_1^\epsilon, \dots, \tilde{g}_l^\epsilon, \lambda^*) \in G'_3$ , we have

$$\begin{aligned} 0 \leq \beta_\epsilon^1 - \beta'' &= \sup_{G_1^\epsilon} \left( \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \right) \\ &\quad - \sup_{G'_3} \left( \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \right) \\ &\leq \int g^*(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}_j^*(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda^*, c \rangle + \epsilon \\ &\quad - \int g^\epsilon(0, \cdot) d\phi_0 - \sum_{j=1}^l \int \tilde{g}_j^\epsilon(0, \cdot) d\tilde{\phi}_{0j} + \langle \lambda^*, c \rangle \\ &= \int (g^*(0, \cdot) - g^\epsilon(0, \cdot)) d\phi_0 + \sum_{j=1}^l \int (\tilde{g}_j^*(0, \cdot) - \tilde{g}_j^\epsilon(0, \cdot)) d\tilde{\phi}_{0j} + \epsilon. \end{aligned}$$

Now since  $(g^*, \tilde{g}_1^*, \dots, \tilde{g}_l^*, \lambda^*) \in G_1^\epsilon$ , this  $(g^\epsilon, \tilde{g}_1^\epsilon, \dots, \tilde{g}_l^\epsilon, \lambda^*) \in G'_3$  can be chosen such that

$$\|(g^*, \tilde{g}_1^*, \dots, \tilde{g}_l^*) - (g^\epsilon, \tilde{g}_1^\epsilon, \dots, \tilde{g}_l^\epsilon)\|_{C_b^{1,2}} \leq \epsilon.$$

Thus we get

$$\beta_\epsilon^1 - \beta'' \leq \|g^* - g^\epsilon\|_\infty + \sum_{j=1}^l \|\tilde{g}_j^* - \tilde{g}_j^\epsilon\|_\infty + \epsilon \leq 2\epsilon.$$

Now consider the case  $\beta'' \geq \beta_\epsilon^1$ . Then, since  $G'_3 \subset G_3^\epsilon$  we have  $\beta'_\epsilon \geq \beta''$ . Hence

$$0 \leq \beta'' - \beta_\epsilon^1 \leq \beta'_\epsilon - \beta_\epsilon^1 = |\beta'_\epsilon - \beta_\epsilon^1|.$$

Arguments similar to the proofs of Lemmas 4.3 and 4.5 and the analysis exactly as in the derivation of (31) allow us to conclude that

$$|\beta'_\epsilon - \beta_\epsilon^1| \leq \epsilon \left( T(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|) + (l+1) \right).$$

So we have

$$|\beta'_\epsilon - \beta''| \leq \epsilon \left( (T(\|\mathcal{L}\| + \|\tilde{\mathcal{L}}_1\| + \dots + \|\tilde{\mathcal{L}}_l\|) + (l+1)) \vee 2 \right).$$

Also, by Lemmas 4.1 and 4.2, we have

$$|\beta_o - \beta_d| \leq C_d(M) \frac{\bar{C}\sqrt{T}\tilde{C}(1 + E[\|x(0)\|^2])^{1/2}}{M},$$

and by Lemma 4.3, we have

$$|\beta_d - \beta_x| \leq \eta(l+1).$$

From (29), we get

$$|\beta_o - \beta_s| \leq |\beta_o - \beta_d| + |\beta_d - \beta_x| + |\beta_\epsilon^1 - \beta''| + |\beta'' - \beta'| + |\beta' - \beta_s|.$$

Combining both the inequalities above, we get the result.  $\square$

We next prove the second main result of this section. We consider a *finite* linear program that approximates the semi-infinite linear program (24). For this purpose, let  $\bar{Z}_0 \subset Z$  be a finite set such that

$$\Delta \stackrel{\text{def}}{=} \max_{y \in Z} \min_{z \in \bar{Z}_0} \|y - z\| = \delta$$

for a prescribed  $\delta > 0$ . For example,  $\bar{Z}_0$  could be a regular grid of width  $\Delta = \delta$ . By arguments similar to those used to claim a compact embedding of  $\mathcal{H}$  in  $\mathcal{D}$ , one can also claim compact embedding thereof in  $C_b^{1,3}(Z) \times C_b^{1,3}(\bar{Z}_1) \times \cdots \times C_b^{1,3}(\bar{Z}_l)$ , whence there is a common Lipschitz constant  $L$  for  $(f, \tilde{f}_1, \dots, \tilde{f}_l) \in B_R$ . Define  $\mathcal{F}_\delta : \mathcal{H} \times \mathcal{R}^m \rightarrow C_b(Z)$  as

$$\mathcal{F}_\delta((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) \stackrel{\text{def}}{=} \mathcal{F}((g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda)) + L\delta.$$

Note that this is a concave functional. Now define convex compact sets  $G_4, G_5$ , and  $G'_5$  as follows:

$$G_4 \stackrel{\text{def}}{=} \{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in (\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}) \times \Lambda : \mathcal{F}(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \geq 0, x \in \bar{Z}_0, \\ |g|_{\bar{Z}_0 \cap \partial Z} \leq \eta; |\tilde{g}_j|_{Z_0 \cap \partial \bar{Z}_j} \leq \eta, 1 \leq j \leq l\},$$

$$G_5 \stackrel{\text{def}}{=} \{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in (\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}) \times \Lambda : \mathcal{F}_\delta(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \geq 0, x \in Z, \\ |g|_{\partial Z} \leq \eta + L\delta; |\tilde{g}_j|_{\partial \bar{Z}_j} \leq \eta + L\delta, 1 \leq j \leq l\},$$

$$G'_5 \stackrel{\text{def}}{=} \{(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \in (\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}) \times \Lambda : \mathcal{F}_\delta(g, \tilde{g}_1, \dots, \tilde{g}_l, \lambda) \geq 0, x \in Z, \\ |g|_{\partial Z} \leq \eta; |\tilde{g}_j|_{\partial \bar{Z}_j} \leq \eta, 1 \leq j \leq l\}.$$

These are nonempty by Lemma 4.5. Let

$$\beta_f \stackrel{\text{def}}{=} \sup_{G_4} \left( \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \right), \\ \beta_\delta \stackrel{\text{def}}{=} \sup_{G_5} \left( \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \right), \\ \beta'_\delta \stackrel{\text{def}}{=} \sup_{G'_5} \left( \int (0, \cdot) d\phi_0 + \sum_{j=1}^l \int g(0, \cdot) d\phi_0 + \langle \lambda, c \rangle \right).$$

THEOREM 4.7. *Given  $\Xi = \epsilon > 0, \eta > 0$ , as in Theorem 4.6, and grid size  $\Delta = \delta > 0$ , it follows that  $|\beta_o - \beta_f| \leq C_2(\epsilon + \eta + \frac{1}{M} + \delta)$  for some constant  $C_2 = C_2(M) > 0$  independent of  $\epsilon, \eta, \delta$  which remains uniformly bounded as  $M \uparrow \infty$ .*

*Proof.* Note that  $G_1 \subset G_4 \subset G_5$ . Hence,  $\beta_s \leq \beta_f \leq \beta_\delta$ . Therefore,

$$\begin{aligned} |\beta_o - \beta_f| &\leq |\beta_o - \beta_s| + |\beta_s - \beta_f|, \\ |\beta_s - \beta_f| &\leq |\beta_s - \beta_\delta| \leq |\beta_s - \beta'_\delta| + |\beta'_\delta - \beta_\delta|. \end{aligned}$$

An argument similar to the proof of Lemma 4.3 allows us to conclude that

$$|\beta'_\delta - \beta_\delta| \leq L\delta(l+1).$$

Thus the claim follows by arguments similar to those used to prove Theorem 4.6, with  $C_2 \stackrel{\text{def}}{=} L((\|\nu\| \vee \|\nu^\delta\|) + (l+1)) \vee C_1(M)$ , where  $\nu^\delta \geq 0$  is the *minimizing* Lagrange multiplier (measure) for the convex program

$$\sup_{G_5^c} \left( \int g(0, \cdot) d\phi_0 + \sum_{j=1}^l \int \tilde{g}(0, \cdot) d\tilde{\phi}_{0j} - \langle \lambda, c \rangle \right),$$

and  $\nu, C_1(M)$  are as in Theorem 4.6. Note also that by Lemmas 4.4 and 4.5, we have, as in (30),

$$\|\nu^\delta\| \leq T.$$

Thus the claim follows.  $\square$

**5. Estimation of sample complexity.** In this section we calculate the sample complexity for RKHS functions, i.e., the minimum number of sample points (and hence minimum number of basis functions) required to approximate the cost function to a given degree of accuracy. We shall assume the functions to be defined over a set  $Z$  which is now a compact subset of  $[0, T] \times \Omega_M$  with  $C^\infty$  boundary. Hence, by definition, the  $\tilde{Z}_j$ 's are also compact with a  $C^\infty$  boundary. This additional regularity of the boundary is needed for technical reasons. Refer to section 4 for definitions.

Note that the map  $\mathcal{H} \xrightarrow{\mathcal{I}} \mathcal{D}$  can be factored into

$$\mathcal{H} \xrightarrow{\mathcal{J}} \mathcal{W} \xhookrightarrow{J} \mathcal{D},$$

where  $\mathcal{I} = J\mathcal{J}$ . Given a normed space  $S$  with norm  $\|\cdot\|_S$ , let  $B_1 \stackrel{\text{def}}{=} \{x \in S : \|x\|_S \leq 1\}$ . Also, given Banach spaces  $E$  and  $F$  and a linear map  $T : E \rightarrow F$ , let  $e_k(T) \stackrel{\text{def}}{=} e_k(T(B_1))$  for  $k \geq 1$ , where the *entropy number*  $e_k(S)$  is defined as

$$(32) \quad e_k(S) \stackrel{\text{def}}{=} \inf \left\{ \epsilon > 0 : S \subset \bigcup_{j=1}^{2^k-1} (b_j + \epsilon B_1), b_1, \dots, b_{2^k-1} \in S \right\}.$$

Thus under the product topology in  $\mathcal{W}$  and  $\mathcal{D}$ , by taking  $s_1 = m + 2(\tilde{m}_j + 2)$ ,  $p_1 = s_2 = 2, p_2 = \infty$  in a very general “theorem” of [11, p. 105], we get

$$(33) \quad e_k(J) \leq \max \left( C(Z, m) \left( \frac{1}{k} \right)^{m/(d+1)}, \max_{1 \leq j \leq l} \left( C(\tilde{Z}_j, \tilde{m}_j) \left( \frac{1}{k} \right)^{\tilde{m}_j/(\tilde{d}_j+1)} \right) \right)$$

for  $k \geq 1$ , where  $m, d$  and  $\tilde{m}_j, \tilde{d}_j$  satisfy the conditions in definition (22) of  $\mathcal{W}$  above and  $C$  is a constant depending on the  $(Z, m)$  or the  $(\tilde{Z}_j, \tilde{m}_j)$ 's, but not on  $k$ .

Given some  $\eta > 0$  and a bounded set  $A$  in some normed space  $S$  as above, the *covering number*  $\mathcal{N}(A, \eta)$  is the minimum number of  $\eta$ -balls required to cover the set  $A$ , i.e.,

$$(34) \quad \mathcal{N}(A, \eta) \stackrel{\text{def}}{=} \inf \left\{ N > 0 : A \subset \bigcup_{j=1}^N (b_j + \eta B_1), b_1, \dots, b_N \in A \right\},$$

where  $B_1$  is a unit ball in  $S$  as defined above.

Given  $\epsilon > 0$ , the sample complexity is defined as  $d^*(\epsilon) \stackrel{\text{def}}{=}$  the *minimum*  $|\bar{Z}| + \sum_{j=1}^l |\tilde{Z}_j|$  such that the *sampling approximation error*  $\Xi$  satisfies  $\Xi \leq \epsilon$ . We look for a good estimate  $d(\epsilon)$  of  $d^*(\epsilon)$ . First, we state and prove the following theorem.

**THEOREM 5.1.** *Let  $C' \stackrel{\text{def}}{=} \|\mathcal{J}\|$ ,  $C'' \stackrel{\text{def}}{=} \|\mathcal{I}\|$ , and*

$$r \stackrel{\text{def}}{=} \frac{1}{\min(m/(d+1), \min_{1 \leq j \leq l} \tilde{m}_j/(\tilde{d}_j+1))}.$$

*Then*

$$\text{A.} \quad \ln(\mathcal{N}(\overline{\mathcal{I}(B_R)}, 2\epsilon)) < 1 + \left( \frac{RC' \max(C(Z, m), \max_{1 \leq j \leq l} C(\tilde{Z}_j, \tilde{m}_j))}{2\epsilon} \right)^r.$$

$$\text{B.} \quad d^*(\epsilon) \geq \frac{\ln(\mathcal{N}(\overline{\mathcal{I}(B_R)}, 2\epsilon))}{\ln(\frac{4RC''}{\epsilon})}.$$

*Proof.* A. By (33), we get

$$\begin{aligned} e_k(\mathcal{I}) &= e_k(J\mathcal{J}) \leq e_k(J)\|\mathcal{J}\| \\ &\leq C' \max \left( C(Z, m) \left( \frac{1}{k} \right)^{m/(d+1)}, \max_{1 \leq j \leq l} \left( C(\tilde{Z}_j, \tilde{m}_j) \left( \frac{1}{k} \right)^{\tilde{m}_j/(\tilde{d}_j+1)} \right) \right) \\ (35) \quad &\leq C' \max \left( C(Z, m), \max_{1 \leq j \leq l} C(\tilde{Z}_j, \tilde{m}_j) \right) \left( \frac{1}{k} \right)^{1/r} \end{aligned}$$

for  $k \geq 1$ . By [10, Lemma 4, p. 16] we have

$$(36) \quad \mathcal{N}(\overline{\mathcal{I}(B_R)}, 2\epsilon) \leq 2^k - 1 \iff e_k(\overline{\mathcal{I}(B_R)}) = Re_k(\mathcal{I}) \leq 2\epsilon.$$

Let

$$k = \left\lceil \left( \frac{RC' \max(C(Z, m), \max_{1 \leq j \leq l} C(\tilde{Z}_j, \tilde{m}_j))}{2\epsilon} \right)^r \right\rceil.$$

Then from (35) and (36) we have (see [10, Proposition 6, p. 16]),

$$\begin{aligned} \ln(\mathcal{N}(\overline{\mathcal{I}(B_R)}, 2\epsilon)) &= \ln \left( \mathcal{N} \left( \overline{\mathcal{I}(B_1)}, \frac{2\epsilon}{R} \right) \right) \\ &< k < 1 + \left( \frac{RC' \max(C(Z, m), \max_{1 \leq j \leq l} C(\tilde{Z}_j, \tilde{m}_j))}{2\epsilon} \right)^r. \end{aligned} \quad (37)$$

B. Since  $\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}$  is a finite dimensional Banach space, we have by [10, Proposition 5, p. 15] that

$$(38) \quad \ln \mathcal{N}(\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}, \epsilon) \leq d^*(\epsilon) \ln \left( \frac{4R^*}{\epsilon} \right) \leq d^*(\epsilon) \ln \left( \frac{4RC'''}{\epsilon} \right),$$

where the last inequality follows from the fact  $\|\cdot\|_{C_b^{1,2}} \leq C'' \|\cdot\|_{\mathcal{H}}$ . Also since  $\Xi \leq \epsilon$ , i.e., every point in  $\overline{\mathcal{I}(B_R)}$  is at most  $\epsilon$ -distance away from some point in  $\bar{\mathcal{H}} \cap \overline{\mathcal{I}(B_R)}$ , we have

$$(39) \quad \mathcal{N}(\overline{\mathcal{I}(B_R)}, 2\epsilon) \leq \mathcal{N}(\overline{\mathcal{I}(B_R)} \cap \bar{\mathcal{H}}, \epsilon).$$

Assuming  $0 < \epsilon < \frac{R}{2}$  since  $\epsilon$  is sufficiently small, we see, combining (38) and (39), that

$$(40) \quad d^*(\epsilon) \geq \frac{\ln(\mathcal{N}(\overline{\mathcal{I}(B_R)}, 2\epsilon))}{\ln(\frac{4RC'''}{\epsilon})}.$$

Hence we have the claim.  $\square$

*Remark 2.* Note that (37) and (40) together suggest that  $d(\epsilon)$  given by

$$d(\epsilon) = \frac{1 + \left( \frac{RC' \max(C(Z, m), \max_{1 \leq j \leq l} C(\tilde{Z}_j, \tilde{m}_j))}{2\epsilon} \right)^{1/\min(m/(d+1), \min_{1 \leq j \leq l} \tilde{m}_j/(\tilde{d}_j+1))}}{\ln(\frac{4RC'''}{\epsilon})}$$

is a reasonable estimate for  $d^*(\epsilon)$ .

*Remark 3.* The above bound on the sample complexity shows that by choosing  $m > \frac{d+1}{2}$ ,  $\tilde{m}_j > \frac{\tilde{d}_j+1}{2}$  large enough we can make the exponent almost a constant independent of the dimension of the underlying state space. On the other hand, the dependence of the constant  $C$  on  $d, m$  (respectively,  $(\tilde{d}_j, \tilde{m}_j)$ 's) may be exponential as is the case for approximation of  $C^0$  functions on  $[0, 1]^d$  by Gaussian kernels (see [30, Example 4, p. 23]).

**6. Markov-modulated diffusions.** Now we briefly sketch the extension of the foregoing to Markov-modulated diffusions, a popular model when regime-switching phenomena are present. Let  $\alpha(\cdot)$  be a continuous time stationary Markov chain taking values in a finite state space  $\mathcal{S} = \{1, \dots, N\}$ . Let  $W(\cdot)$  be a standard Brownian motion in  $\mathcal{R}^d$  independent of  $\alpha(\cdot)$ . The Markov chain has a generator  $Q^* = [[q_{ij}^*]]_{1 \leq i, j \leq N} \in \mathcal{R}^{N \times N}$ , i.e., its transition probabilities are given by

$$(41) \quad P(\alpha(t + \delta t) = j | \alpha(t) = i) = q_{ij}^* \delta t + o(\delta t), \quad i \neq j, \quad i, j \in \mathcal{S}.$$

We shall assume that our underlying state process is a  $d$ -dimensional process  $x(\cdot) = [x_1(\cdot), \dots, x_d(\cdot)]^T$  described by the SDE

$$(42) \quad dx(t) = m^*(x(t), \alpha(t))dt + \sigma^*(x(t), \alpha(t))dW(t), \quad x(0) = x_0, \quad \alpha(0) = i_0, \quad t \geq 0,$$

where the drift vector  $m^*(\cdot) : \mathcal{R}^d \times \mathcal{S} \rightarrow \mathcal{R}^d$  and the diffusion matrix  $\sigma^*(\cdot) : \mathcal{R}^d \times \mathcal{S} \rightarrow \mathcal{R}^{d \times d}$  are assumed to be Lipschitz. (This ensures the well-posedness of (42) and can be relaxed in special cases.) The law of  $(x_0, i_0)$  is fixed; say,  $\phi_0$ . See section 2 for definitions. The two forms of uncertainty we considered in section 2 are captured by the following two basic formulations.

**Problem 1: Model uncertainty.** We suppose that  $m^*, \sigma^*$ , and  $Q^* = [[q_{ij}^*]]$  are not known exactly, but only approximately. The latter is captured by the conditions

$$(43) \quad m^*(x, i) \in m(x, i, U), \quad (\sigma^*(\sigma^*)^T)(x, i) \in (\sigma\sigma^T)(x, i, U), \quad Q^* \in Q(U) \quad \forall x, i,$$

where

- $U$  is a prescribed compact metric space;
- $m(\cdot, i, \cdot) = [m_1(\cdot, i, \cdot), \dots, m_d(\cdot, i, \cdot)]^T : \mathcal{R}^d \times \mathcal{S} \times U \rightarrow \mathcal{R}^d$  is continuous and Lipschitz in  $x \in \mathcal{R}^d$  uniformly w.r.t.  $u \in U$ , and, in addition,  $m(x, i, U)$  is convex for each  $x$ , for each  $i \in \mathcal{S}$ ;
- $\sigma(\cdot, i, \cdot) = [[\sigma_{ij}(\cdot, i, \cdot)]]_{1 \leq i, j \leq d} : \mathcal{R}^d \times \mathcal{S} \times U \rightarrow \mathcal{R}^{d \times d}$  is continuous and Lipschitz in  $x \in \mathcal{R}^d$  uniformly w.r.t.  $u \in U$ , and, in addition,  $(\sigma\sigma^T)(x, i, U)$  is convex for each  $x$ , for each  $i \in \mathcal{S}$  and satisfies the *nondegeneracy* condition as in (3);
- $Q(\cdot) = [[q_{ij}(\cdot)]]_{1 \leq i, j \leq N} : U \rightarrow \mathcal{R}^{N \times N}$  is bounded and convex.

Now using familiar *measurable selection* arguments as in section 2, we can rewrite the SDE (42) as

$$(44) \quad dx(t) = m(x(t), \alpha(t), u(t))dt + \sigma(x(t), \alpha(t), u(t))dW(t), \quad t \geq 0,$$

where the Markov chain has the controlled extended generator

$$Q(\cdot) = [[q_{ij}(\cdot)]]_{1 \leq i, j \leq N} : U \rightarrow \mathcal{R}^{N \times N}$$

and transition probabilities

$$(45) \quad P(\alpha(t + \delta t) = j | \alpha(t) = i) = q_{ij}(u(t))\delta t + o(\delta t), \quad i \neq j, \quad i, j \in \mathcal{S}.$$

Associated with  $x(\cdot)$  is the controlled extended generator  $\mathcal{A}$ :

$$\begin{aligned} \mathcal{A}g(t, x, i, u) &\stackrel{\text{def}}{=} \frac{\partial g}{\partial t}(t, x, i) + \langle m(x, i, u), \nabla g(t, x, i) \rangle \\ &\quad + \frac{1}{2} \text{tr}(\sigma(x, i, u)\sigma^T(x, i, u)\nabla^2 g(t, x, i)) \\ &\quad + \sum_{j=1}^N q_{ij}(u)g(t, x, j) \end{aligned}$$

for all  $f \in \mathcal{D}(\mathcal{A}) \stackrel{\text{def}}{=} \bigcup_{i \in \mathcal{S}} \mathcal{D}_i(\mathcal{A})$ , where  $\mathcal{D}_i(\mathcal{A}) \stackrel{\text{def}}{=} \{f(\cdot, \cdot, i) \in C_b^{1,2}(Z) : f(T, \cdot, i) \equiv 0\}$ .

**Problem 2: Unmodelled dynamics.** As in section 2, we *separately* observe for a given integer  $l \geq 1$  only  $\tilde{x}_j(\cdot)$ ,  $j = 1, \dots, l$  (see definition (8)) and mimic it by a  $\tilde{d}_j$ -dimensional process given by (say)

$$(46) \quad d\hat{x}_j(t) = \tilde{m}_j(t, \hat{x}_j(t), \tilde{\alpha}_j(t))dt + \tilde{\sigma}_j(t, \hat{x}_j(t), \tilde{\alpha}_j(t))d\tilde{W}_j(t), \quad 1 \leq j \leq l,$$

where, as before,  $\tilde{\alpha}_j(\cdot)$  is the *correspondingly observed*  $\mathcal{S}$ -valued Markov chain with generator  $\tilde{Q}_j(\cdot) = [[\tilde{q}_{kl}^j(\cdot)]]_{1 \leq k, l \leq N} : [0, T] \rightarrow \mathcal{R}^{N \times N}$  and transition probabilities

$$(47) \quad \tilde{P}_j(\tilde{\alpha}_j(t + \delta t) = l | \tilde{\alpha}_j(t) = k) = \tilde{q}_{kl}^j(t)\delta t + o(\delta t), \quad k \neq l, \quad k, l \in \mathcal{S}, \quad 1 \leq j \leq l.$$

We view (46) and (47) as the *model fitted to the observed data*  $(\tilde{x}_j(t), \tilde{\alpha}_j(t))$ . Define

the extended generator  $\tilde{\mathcal{A}}_j$  of  $\hat{x}_j(\cdot)$  by

$$\begin{aligned}\tilde{\mathcal{A}}_j f(t, x, i) &\stackrel{\text{def}}{=} \frac{\partial f}{\partial t}(t, x, i) + \langle \tilde{m}_j(t, x, i), \nabla f(t, x, i) \rangle \\ &\quad + \frac{1}{2} \text{tr}(\tilde{\sigma}_j(t, x, i) \tilde{\sigma}_j^T(t, x, i) \nabla^2 f(t, x, i)) \\ &\quad + \sum_{k=1}^N \tilde{q}_{ik}^j(t) f(t, x, k)\end{aligned}$$

for all  $f \in \mathcal{D}(\tilde{\mathcal{A}}_j) \stackrel{\text{def}}{=} \bigcup_{i \in \mathcal{S}} \mathcal{D}_i(\tilde{\mathcal{A}}_j)$ , where  $\mathcal{D}_i(\tilde{\mathcal{A}}_j) \stackrel{\text{def}}{=} \{f(\cdot, \cdot, i) \in C_b^{1,2}(\tilde{Z}_j) : f(T, \cdot, i) \equiv 0\}$ .

Now define *occupation measures* as in section 2 (see definitions (5) and (9)). Replacing  $\mathcal{L}$  by  $\mathcal{A}$  and the  $\tilde{\mathcal{L}}_j$ 's by  $\tilde{\mathcal{A}}_j$ 's and using the general results of [5], we get the characterizations of the corresponding  $\mathcal{M}$ ,  $\mathcal{M}'$ , and  $\mathcal{M}^*$ . Then the minimization problem becomes

$$\text{minimize } \int k d\nu \text{ over } \mathcal{M}^*.$$

The rest of the analysis is exactly similar and the details are omitted.

In conclusion, we note some potential extensions that hold promise:

1. extensions to SDEs driven by both a Brownian motion and a point process;
2. an additional layer of approximation replacing the differential operators by their finite difference approximations;
3. families of approximating functions other than those from an RKHS.

**Acknowledgment.** The first author thanks Prof. K. T. Joseph for helpful discussions.

# A PRIORI ERROR ESTIMATES FOR SPACE-TIME FINITE ELEMENT DISCRETIZATION OF PARABOLIC OPTIMAL CONTROL PROBLEMS PART II: PROBLEMS WITH CONTROL CONSTRAINTS\*

DOMINIK MEIDNER<sup>†</sup> AND BORIS VEXLER<sup>‡</sup>

**Abstract.** This paper is the second part of our work on a priori error analysis for finite element discretizations of parabolic optimal control problems. In the first part [*SIAM J. Control Optim.*, 47 (2008), pp. 1150–1177] problems without control constraints were considered. In this paper we derive a priori error estimates for space-time finite element discretizations of parabolic optimal control problems with pointwise inequality constraints on the control variable. The space discretization of the state variable is done using usual conforming finite elements, whereas the time discretization is based on discontinuous Galerkin methods. For the treatment of the control discretization we discuss different approaches, extending techniques known from the elliptic case.

**1. Introduction.** In this paper we develop a priori error analysis for space-time finite element discretizations of parabolic optimization problems. We consider the following linear-quadratic optimal control problem for the state variable  $u$  and the control variable  $q$  involving pointwise control constraints:

$$(1.1a) \quad \text{Minimize } J(q, u) = \frac{1}{2} \int_0^T \int_{\Omega} (u(t, x) - \hat{u}(t, x))^2 dx dt + \frac{\alpha}{2} \int_0^T \int_{\Omega} q(t, x)^2 dx dt$$

subject to

$$(1.1b) \quad \begin{aligned} \partial_t u - \Delta u &= f + q && \text{in } (0, T) \times \Omega, \\ u(0) &= u_0 && \text{in } \Omega \end{aligned}$$

and subject to

$$(1.1c) \quad q_a \leq q(t, x) \leq q_b \quad \text{a.e. in } (0, T) \times \Omega,$$

combined with either homogeneous Dirichlet or homogeneous Neumann boundary conditions on  $(0, T) \times \partial\Omega$ . A precise formulation of this problem including a functional analytic setting is given in the next section.

Although the a priori error analysis for finite element discretization of optimal control problems governed by elliptic equations is discussed in many publications (see, e.g., [10, 12, 1, 13, 21, 7]), there are only a few published results on this topic for parabolic problems; see [19, 28, 16, 18, 23].

In the first part of our work on a priori error analysis of parabolic optimal control problems [20], we developed a priori error estimates for problems without control constraints. The consideration of control constraints (1.1c) leads to many additional difficulties. In the absence of inequality constraints the regularity of the optimal solution  $(\bar{q}, \bar{u})$  of (1.1a)–(1.1b) is restricted only by the regularity of the domain  $\Omega$ ; by the regularity of the data  $f, u_0, \hat{u}$ ; and possibly by some compatibility conditions. Therefore, in this case it is reasonable to assume high regularity of  $(\bar{q}, \bar{u})$  leading to a corresponding order of convergence of the finite element discretization; see the discussion in [20].

The presence of control constraints (1.1c) leads to a stronger restriction of the regularity of the optimal solution, which is often reflected in a reduction of the order of convergence of the finite element discretization. For a discussion of the regularity of solutions to parabolic optimal control problems with control constraints, we refer, e.g., to [15].

In order to describe the claims and challenges of a priori error analysis for finite element discretization of (1.1), we first recall some corresponding results in the elliptic case. Using a finite element discretization with discretization parameter  $h$ , one can define a discretized optimal control problem with the discrete solution  $(\bar{q}_h, \bar{u}_h)$ .

Many authors made an effort to analyze the behavior of  $\|\bar{q} - \bar{q}_h\|_{L^2(\Omega)}$  with respect to  $h$ : In the first papers concerning approximation of elliptic optimal control problems (see [10, 12]), the convergence order  $\mathcal{O}(h)$  was established using a cellwise constant discretization of the control variable; see also [8, 1, 7]. For finite element discretization of the control variable by (bi-/tri-)linear  $H^1$ -conforming elements, the convergence order  $\mathcal{O}(h^{\frac{3}{2}})$  can be shown; see, e.g., [5, 24, 2]. Recently, two approaches achieving  $\mathcal{O}(h^2)$ -convergence for the error in the control variable have been established; see [13, 21]. In [13] a *variational approach* is proposed, where no explicit discretization of the control variable is used. The discrete control variable is obtained by the projection of the discretized adjoint state on the set of admissible controls. In [21] a cellwise constant discretization is utilized, and a *postprocessing step* is used to obtain the desired accuracy. The latter technique is extended to optimal control of the Stokes equations in [25].

For discretization of parabolic problems such as (1.1), the state variable has to be discretized with respect to space and time leading to two discretization parameters  $h, k$ ; see section 3 for a detailed description. The solution of the discretized optimal control problem is denoted by  $(\bar{q}_\sigma, \bar{u}_\sigma)$ , where  $\sigma = (k, h, d)$  is a general discretization parameter and  $d$  denotes an abstract discretization parameter for the control space; cf. [20].

The main purpose of this paper is to analyze the behavior of  $\|\bar{q} - \bar{q}_\sigma\|_{L^2(0,T;L^2(\Omega))}$  with respect to all involved discretization parameters. Our aim is to discuss the following four approaches for the discretization of the control variable, which extend some techniques known from the elliptic case:

1. Discretization using cellwise constant ansatz functions with respect to space and time. In this case we obtain, similar to [16, 18], the order of convergence  $\mathcal{O}(h + k)$ : The result is obtained under weaker regularity assumptions than

in [16, 18]. Moreover, we separate the influences of the spatial and temporal regularity on the discretization error; see Corollary 5.3.

2. Discretization using cellwise (bi-/tri-)linear,  $H^1$ -conforming finite elements in space, and piecewise constant functions in time: For this type of discretization we obtain the improved order of convergence  $\mathcal{O}(k + h^{\frac{3}{2} - \frac{1}{p}})$ ; see Corollary 5.8. Here,  $p$  depends on the regularity of the adjoint solution. In two space dimensions we show the assertion for any  $p < \infty$ , whereas in three space dimensions the result is proved for  $p \leq 6$ . Under an additional regularity assumption, one can choose  $p = \infty$  leading to  $\mathcal{O}(k + h^{\frac{3}{2}})$ . Again the influences of spatial and temporal regularity as well as of spatial and temporal discretization are clearly separated.
3. The discretization following the variational approach from [13], where no explicit discretization of the control variable is used: In this case we obtain an optimal result  $\mathcal{O}(k + h^2)$ ; see Corollary 5.11. The usage of this approach requires a nonstandard implementation and more involved stopping criteria for optimization algorithms, since the control variable does not lie in any finite element space associated with the given mesh. However, there are no additional difficulties caused by the time discretization.
4. The postprocessing strategy extending the technique from [21] to parabolic problems: In this case we use the cellwise constant ansatz functions with respect to space and time. For the discrete solution  $(\bar{q}_\sigma, \bar{u}_\sigma)$ , a postprocessing step based on a projection formula is proposed leading to an approximation  $\tilde{q}_\sigma$  with order of convergence  $\|\bar{q} - \tilde{q}_\sigma\|_{L^2(0,T;L^2(\Omega))} = \mathcal{O}(k + h^{2 - \frac{1}{p}})$ ; see Corollary 5.17. Here,  $p$  can be chosen as discussed for the cellwise linear discretization. Under an additional regularity assumption, one can also choose  $p = \infty$  leading to  $\mathcal{O}(k + h^2)$ .

The paper is organized as follows. In the next section, we present a functional analytic setting for the optimal control problem (1.1) and discuss optimality conditions and the regularity of optimal solutions. Section 3 is devoted to the discretization of the considered optimal control problem. Therein, we address the temporal and spatial discretizations of the state equation by Galerkin finite element methods. Moreover, we give a detailed presentation of the four possibilities for discretizing the control variable introduced above. In section 4 we provide basic results on stability and approximation quality proved in the first part of this article [20]. In section 5 we develop our main results on a priori error analysis for the four mentioned types of control discretizations. Finally, we illustrate our theoretical results by numerical experiments.

**2. Optimization.** In this section we briefly discuss the precise formulation of the optimization problem under consideration. Furthermore, we recall theoretical results on existence, uniqueness, and regularity of optimal solutions as well as optimality conditions.

To set up a weak formulation of the state equation (1.1b), we introduce the following notation: For a convex polygonal domain  $\Omega \subset \mathbb{R}^n$ ,  $n = 2, 3$ , we denote  $V$  to be either  $H^1(\Omega)$  or  $H_0^1(\Omega)$  depending on the prescribed type of boundary conditions (homogeneous Neumann or homogeneous Dirichlet). Together with  $H = L^2(\Omega)$ , the Hilbert space  $V$  and its dual  $V^*$  build a Gelfand triple  $V \hookrightarrow H \hookrightarrow V^*$ . Here and in what follows, we employ the usual notion for Lebesgue and Sobolev spaces.

For a time interval  $I = (0, T)$  we introduce the state space

$$X := \{v | v \in L^2(I, V) \text{ and } \partial_t v \in L^2(I, V^*)\}$$

and the control space

$$Q = L^2(I, L^2(\Omega)).$$

In addition, we use the following notation for the inner products and norms on  $L^2(\Omega)$  and  $L^2(I, L^2(\Omega))$ :

$$\begin{aligned} (v, w) &:= (v, w)_{L^2(\Omega)}, & (v, w)_I &:= (v, w)_{L^2(I, L^2(\Omega))}, \\ \|v\| &:= \|v\|_{L^2(\Omega)}, & \|v\|_I &:= \|v\|_{L^2(I, L^2(\Omega))}. \end{aligned}$$

In this setting, a standard weak formulation of the state equation (1.1b) for given control  $q \in Q$ ,  $f \in L^2(I, H)$ , and  $u_0 \in V$  reads as follows: Find a state  $u \in X$  satisfying

$$\begin{aligned} (2.1) \quad & (\partial_t u, \varphi)_I + (\nabla u, \nabla \varphi)_I = (f + q, \varphi)_I \quad \forall \varphi \in X, \\ & u(0) = u_0. \end{aligned}$$

As in Proposition 2.1 in [20] the following result on existence and regularity holds.

**PROPOSITION 2.1.** *For fixed control  $q \in Q$ ,  $f \in L^2(I, H)$ , and  $u_0 \in V$  there exists a unique solution  $u \in X$  of problem (2.1). Moreover, the solution exhibits the improved regularity*

$$u \in L^2(I, H^2(\Omega) \cap V) \cap H^1(I, L^2(\Omega)) \hookrightarrow C(\bar{I}, V).$$

Furthermore, the stability estimate

$$\|\partial_t u\|_I + \|\nabla^2 u\|_I \leq C\{\|f + q\|_I + \|\nabla u_0\|\}$$

holds.

To formulate the optimal control problem we introduce the admissible set  $Q_{\text{ad}}$ , collecting the inequality constraints (1.1c) as

$$Q_{\text{ad}} := \{q \in Q \mid q_a \leq q(t, x) \leq q_b \quad \text{a.e. in } I \times \Omega\},$$

where the bounds  $q_a, q_b \in \mathbb{R}$  fulfill  $q_a < q_b$ .

The weak formulation of the optimal control problem (1.1) is given as follows:

$$(2.2) \quad \text{Minimize } J(q, u) := \frac{1}{2}\|u - \hat{u}\|_I^2 + \frac{\alpha}{2}\|q\|_I^2 \text{ subject to (2.1) and } (q, u) \in Q_{\text{ad}} \times X,$$

where  $\hat{u} \in L^2(I, H)$  is a given desired state and  $\alpha > 0$  is the regularization parameter.

**PROPOSITION 2.2.** *For given  $f, \hat{u} \in L^2(I, H)$ ,  $u_0 \in V$ , and  $\alpha > 0$  the optimal control problem (2.2) admits a unique solution  $(\bar{q}, \bar{u}) \in Q_{\text{ad}} \times X$ .*

For the standard proof we refer, e.g., to [17].

The existence result for the state equation in Proposition 2.1 ensures the existence of a control-to-state mapping  $q \mapsto u = u(q)$  defined through (2.1). By means of this mapping we introduce the reduced cost functional  $j: Q \rightarrow \mathbb{R}$ :

$$j(q) := J(q, u(q)).$$

The optimal control problem (2.2) can then be equivalently reformulated as follows:

$$(2.3) \quad \text{Minimize } j(q) \text{ subject to } q \in Q_{\text{ad}}.$$

The first order necessary optimality condition for (2.3) reads as

$$(2.4) \quad j'(\bar{q})(\delta q - \bar{q}) \geq 0 \quad \forall \delta q \in Q_{\text{ad}}.$$

Due to the linear-quadratic structure of the optimal control problem, this condition is also sufficient for optimality.

Utilizing the adjoint state equation for  $z = z(q) \in X$  given by

$$(2.5) \quad \begin{aligned} -(\varphi, \partial_t z)_I + (\nabla \varphi, \nabla z)_I &= (\varphi, u(q) - \hat{u})_I \quad \forall \varphi \in X, \\ z(T) &= 0, \end{aligned}$$

the first derivative of the reduced cost functional can be expressed as

$$(2.6) \quad j'(q)(\delta q) = (\alpha q + z(q), \delta q)_I.$$

The second derivative  $j''(q)(\cdot, \cdot)$  is independent of  $q$  and positive definite, i.e.,

$$(2.7) \quad j''(q)(p, p) \geq \alpha \|p\|_I^2 \quad \forall p \in Q.$$

Using a pointwise projection on the admissible set  $Q_{\text{ad}}$ ,

$$(2.8) \quad P_{Q_{\text{ad}}} : Q \rightarrow Q_{\text{ad}}, \quad P_{Q_{\text{ad}}}(r)(t, x) = \max(q_a, \min(q_b, r(t, x))),$$

the optimality condition (2.4) can be expressed as

$$(2.9) \quad \bar{q} = P_{Q_{\text{ad}}} \left( -\frac{1}{\alpha} z(\bar{q}) \right).$$

It is well known that the projection  $P_{Q_{\text{ad}}}$  possesses the following property:

$$(2.10) \quad \|\nabla(P_{Q_{\text{ad}}}(v))(t)\|_{L^p(\Omega)} \leq \|\nabla v(t)\|_{L^p(\Omega)} \quad \forall v \in L^2(I, W^{1,p}(\Omega)) \text{ and for a.a. } t \in I.$$

Employing formulation (2.9) of the optimality condition, we obtain the following regularity result.

**PROPOSITION 2.3.** *Let  $(\bar{q}, \bar{u})$  be the solution of the optimization problem (2.2) and  $\bar{z} = z(\bar{q})$  be the corresponding adjoint state. Then there holds*

$$\bar{u}, \bar{z} \in L^2(I, H^2(\Omega)) \cap H^1(I, L^2(\Omega)),$$

$$\bar{q} \in L^2(I, W^{1,p}(\Omega)) \cap H^1(I, L^2(\Omega)) \cap L^\infty(I \times \Omega)$$

for any  $p < \infty$  when  $n = 2$  and  $p \leq 6$  when  $n = 3$ .

*Proof.* The regularity of  $\bar{u}, \bar{z}$  follows directly from Proposition 2.1. The embedding  $H^2(\Omega) \hookrightarrow W^{1,p}(\Omega)$  and property (2.10) imply the desired result for  $\bar{q}$ .  $\square$

**3. Discretization.** In this section we describe the space-time finite element discretization of optimal control problem (2.2).

**3.1. Semidiscretization in time.** At first, we present the semidiscretization in time of the state equation by discontinuous Galerkin methods following along the lines of the first part of this article [20]. We consider a partitioning of the time interval  $\bar{I} = [0, T]$  as

$$(3.1) \quad \bar{I} = \{0\} \cup I_1 \cup I_2 \cup \cdots \cup I_M$$

with subintervals  $I_m = (t_{m-1}, t_m]$  of size  $k_m$  and time points

$$0 = t_0 < t_1 < \cdots < t_{M-1} < t_M = T.$$

We define the discretization parameter  $k$  as a piecewise constant function by setting  $k|_{I_m} = k_m$  for  $m = 1, 2, \dots, M$ . Moreover, we denote by  $k$  the maximal size of the time steps, i.e.,  $k = \max k_m$ .

The semidiscrete trial and test space is given as

$$X_k^r = \left\{ v_k \in L^2(I, V) \mid v_k|_{I_m} \in \mathcal{P}_r(I_m, V), \ m = 1, 2, \dots, M \right\}.$$

Here,  $\mathcal{P}_r(I_m, V)$  denotes the space of polynomials up to order  $r$  defined on  $I_m$  with values in  $V$ . On  $X_k^r$  we use the notation

$$(v, w)_{I_m} := (v, w)_{L^2(I_m, L^2(\Omega))} \quad \text{and} \quad \|v\|_{I_m} := \|v\|_{L^2(I_m, L^2(\Omega))}.$$

To define the discontinuous Galerkin approximation (dG( $r$ )) using the space  $X_k^r$ , we employ the following definition for functions  $v_k \in X_k^r$ :

$$v_{k,m}^+ := \lim_{t \rightarrow 0^+} v_k(t_m + t), \quad v_{k,m}^- := \lim_{t \rightarrow 0^+} v_k(t_m - t) = v_k(t_m), \quad [v_k]_m := v_{k,m}^+ - v_{k,m}^-$$

and define the bilinear form  $B(\cdot, \cdot)$  for  $u_k, \varphi \in X_k^r$  by

$$(3.2) \quad B(u_k, \varphi) := \sum_{m=1}^M (\partial_t u_k, \varphi)_{I_m} + (\nabla u_k, \nabla \varphi)_I + \sum_{m=2}^M ([u_k]_{m-1}, \varphi_{m-1}^+) + (u_{k,0}^+, \varphi_0^+).$$

Then, the dG( $r$ ) semidiscretization of the state equation (2.1) for given control  $q \in Q$  reads as follows: Find a state  $u_k = u_k(q) \in X_k^r$  such that

$$(3.3) \quad B(u_k, \varphi) = (f + q, \varphi)_I + (u_0, \varphi_0^+) \quad \forall \varphi \in X_k^r.$$

The existence and uniqueness of solutions to (3.3) can be shown by using Fourier analysis; see [27] for details.

*Remark 3.1.* Using a density argument, it is possible to show that the exact solution  $u = u(q) \in X$  satisfies the identity

$$B(u, \varphi) = (f + q, \varphi)_I + (u_0, \varphi_0^+) \quad \forall \varphi \in X_k^r.$$

Thus, we have here the property of Galerkin orthogonality

$$B(u - u_k, \varphi) = 0 \quad \forall \varphi \in X_k^r,$$

although the dG( $r$ ) semidiscretization is a nonconforming Galerkin method ( $X_k^r \not\subset X$ ).

Throughout the paper we restrict ourselves to the case  $r = 0$ . The resulting dG(0) scheme is a variant of the implicit Euler method. In this case the semidiscrete state equation (3.3) can be explicitly rewritten as the following time-stepping scheme, using the fact that  $u_k$  is piecewise constant in time. We use the notation  $U_m = u_k|_{I_m} \in V$  and obtain

$$(U_1, \psi) + k_1(\nabla U_1, \nabla \psi) = (f + q, \psi)_{I_m} + (u_0, \psi) \quad \forall \psi \in V,$$

$$(U_m, \psi) + k_m(\nabla U_m, \nabla \psi) = (f + q, \psi)_{I_m} + (U_{m-1}, \psi) \quad \forall \psi \in V, \ m = 2, 3, \dots, M.$$

The semidiscrete optimization problem for the dG(0) time discretization has the following form:

$$(3.4) \quad \text{Minimize } J(q_k, u_k) \text{ subject to (3.3) and } (q_k, u_k) \in Q_{\text{ad}} \times X_k^0.$$

As in Proposition 3.2 in [20] the following result holds.

**PROPOSITION 3.2.** *For  $\alpha > 0$ , the semidiscrete optimal control problem (3.4) admits a unique solution  $(\bar{q}_k, \bar{u}_k) \in Q_{\text{ad}} \times X_k^0$ .*

Note that the optimal control  $\bar{q}_k$  is searched for in the subset  $Q_{\text{ad}}$  of the continuous space  $Q$ , and the subscript  $k$  indicates the usage of the semidiscretized state equation.

Similarly to the continuous case, we introduce the semidiscrete reduced cost functional  $j_k: Q \rightarrow \mathbb{R}$ :

$$j_k(q) := J(q, u_k(q))$$

and reformulate the semidiscrete optimal control problem (3.4) as follows:

$$\text{Minimize } j_k(q_k) \text{ subject to } q_k \in Q_{\text{ad}}.$$

The first order necessary optimality condition reads as

$$(3.5) \quad j'_k(\bar{q}_k)(\delta q - \bar{q}_k) \geq 0 \quad \forall \delta q \in Q_{\text{ad}},$$

and the derivative of  $j_k$  can be expressed as

$$(3.6) \quad j'_k(q)(\delta q) = (\alpha q + z_k(q), \delta q)_I.$$

Here,  $z_k = z_k(q) \in X_k^0$  denotes the solution of the semidiscrete adjoint equation

$$(3.7) \quad B(\varphi, z_k) = (\varphi, u_k(q) - \hat{u})_I \quad \forall \varphi \in X_k^0.$$

As on the continuous level, the second derivative  $j''_k(q)$  is independent of  $q$  and positive definite, i.e.,

$$(3.8) \quad j''_k(q)(p, p) \geq \alpha \|p\|_I^2 \quad \forall p \in Q.$$

Similarly to (2.9), the optimality condition (3.5) can be rewritten as

$$(3.9) \quad \bar{q}_k = P_{Q_{\text{ad}}} \left( -\frac{1}{\alpha} z_k(\bar{q}_k) \right).$$

This projection formula implies particularly that the optimal solution  $\bar{q}_k$  is piecewise constant in time. We will make use of this fact in section 5.

**3.2. Discretization in space.** To define the finite element discretization in space, we consider two or three dimensional shape-regular meshes; see, e.g., [9]. A mesh consists of quadrilateral or hexahedral cells  $K$ , which constitute a non-overlapping cover of the computational domain  $\Omega$ . The corresponding mesh is denoted by  $\mathcal{T}_h = \{K\}$ , where we define the discretization parameter  $h$  as a cellwise constant function by setting  $h|_K = h_K$  with the diameter  $h_K$  of the cell  $K$ . We use the symbol  $h$  also for the maximal cell size, i.e.,  $h = \max h_K$ .

On the mesh  $\mathcal{T}_h$  we construct a conform finite element space  $V_h \subset V$  in a standard way:

$$V_h^s = \{v \in V | v|_K \in \mathcal{Q}_s(K) \text{ for } K \in \mathcal{T}_h\}.$$

Here,  $\mathcal{Q}_s(K)$  consists of shape functions obtained via (bi-/tri-)linear transformations of polynomials in  $\widehat{\mathcal{Q}}_s(\widehat{K})$  defined on the reference cell  $\widehat{K} = (0, 1)^n$ ; cf. section 3.2 in [20].

To obtain the fully discretized versions of the time discretized state equation (3.3), we utilize the space-time finite element space

$$X_{k,h}^{r,s} = \left\{ v_{kh} \in L^2(I, V_h^s) \mid v_{kh}|_{I_m} \in \mathcal{P}_r(I_m, V_h^s) \right\} \subset X_k^r.$$

*Remark 3.3.* Here, the spatial mesh, and therefore also the space  $V_h^s$ , is fixed for all time intervals. We refer to [26] for a discussion of treatment of different meshes  $\mathcal{T}_h^m$  for each of the subintervals  $I_m$ .

The so-called cG( $s$ )dG( $r$ ) discretization of the state equation for given control  $q \in Q$  has the following form: Find a state  $u_{kh} = u_{kh}(q) \in X_{k,h}^{r,s}$  such that

$$(3.10) \quad B(u_{kh}, \varphi) = (f + q, \varphi)_I + (u_0, \varphi_0^+) \quad \forall \varphi \in X_{k,h}^{r,s}.$$

Throughout this paper we will restrict ourselves to the consideration of (bi-/tri-)linear elements, i.e., we set  $s = 1$  and consider the cG(1)dG(0) scheme.

Then, the corresponding optimal control problem is given as follows:

$$(3.11) \quad \text{Minimize } J(q_{kh}, u_{kh}) \text{ subject to (3.10) and } (q_{kh}, u_{kh}) \in Q_{\text{ad}} \times X_{k,h}^{0,1},$$

and by means of the discrete reduced cost functional  $j_{kh}: Q \rightarrow \mathbb{R}$ ,

$$j_{kh}(q) := J(q, u_{kh}(q)),$$

it can be reformulated as follows:

$$\text{Minimize } j_{kh}(q_{kh}) \text{ subject to } q_{kh} \in Q_{\text{ad}}.$$

The uniquely determined optimal solution of (3.11) is denoted by  $(\bar{q}_{kh}, \bar{u}_{kh}) \in Q_{\text{ad}} \times X_{k,h}^{0,1}$ .

The optimal control  $\bar{q}_{kh} \in Q_{\text{ad}}$  fulfills the first order optimality condition

$$(3.12) \quad j'_{kh}(\bar{q}_{kh})(\delta q - \bar{q}_{kh}) \geq 0 \quad \forall \delta q \in Q_{\text{ad}},$$

where  $j'_{kh}(q)(\delta q)$  is given by

$$(3.13) \quad j'_{kh}(q)(\delta q) = (\alpha q + z_{kh}(q), \delta q)_I$$

with the discrete adjoint solution  $z_{kh} = z_{kh}(q) \in X_{k,h}^{0,1}$  of

$$(3.14) \quad B(\varphi, z_{kh}) = (\varphi, u_{kh}(q) - \hat{u})_I \quad \forall \varphi \in X_{k,h}^{0,1}.$$

For the second derivative of  $j_{kh}$  we have, as before,

$$(3.15) \quad j''_{kh}(q)(p, p) \geq \alpha \|p\|_I^2 \quad \forall p \in Q.$$

**3.3. Discretization of the controls.** In this subsection, we describe four different approaches for the discretization of the control variable. Choosing a subspace  $Q_d \subset Q$ , we introduce the corresponding admissible set

$$Q_{d,\text{ad}} = Q_d \cap Q_{\text{ad}}.$$

Note that in what follows, the space  $Q_d$  will be either finite dimensional or the whole space  $Q$ . The optimal control problem on this level of discretization is given as follows:

$$(3.16) \quad \text{Minimize } J(q_\sigma, u_\sigma) \text{ subject to (3.10) and } (q_\sigma, u_\sigma) \in Q_{d,\text{ad}} \times X_{k,h}^{0,1}.$$

The unique optimal solution of (3.16) is denoted by  $(\bar{q}_\sigma, \bar{u}_\sigma) \in Q_{d,\text{ad}} \times X_{k,h}^{0,1}$ , where the subscript  $\sigma$  collects the discretization parameters  $k$ ,  $h$ , and  $d$ . The optimality condition is given using the discrete reduced cost functional  $j_{kh}$  introduced before:

$$(3.17) \quad j'_{kh}(\bar{q}_\sigma)(\delta q - \bar{q}_\sigma) \geq 0 \quad \forall \delta q \in Q_{d,\text{ad}}.$$

**3.3.1. Cellwise constant discretization.** The first possibility for the control discretization is to use cellwise constant functions. Employing the same time partitioning and the same spatial mesh as for the discretization of the state variable, we set

$$Q_d = \left\{ q \in Q \mid q|_{I_m \times K} \in \mathcal{P}_0(I_m \times K), \ m = 1, 2, \dots, M, \ K \in \mathcal{T}_h \right\}.$$

The discretization error for this type of discretization will be analyzed in section 5.1.

**3.3.2. Cellwise linear discretization.** Another possibility for the discretization of the control variable is to choose the same control discretization as for the state variable, i.e., piecewise constant in time and cellwise (bi-/tri-)linear in space. Using a spatial space

$$Q_h = \left\{ v \in C(\bar{\Omega}) \mid v|_K \in \mathcal{Q}_1(K) \text{ for } K \in \mathcal{T}_h \right\},$$

we set

$$Q_d = \left\{ q \in Q \mid q|_{I_m} \in \mathcal{P}_0(I_m, Q_h) \right\}.$$

The state space  $X_{k,h}^{0,1}$  coincides with the control space  $Q_d$  in the case of homogeneous Neumann boundary conditions and is a subspace of it, i.e.,  $Q_d \supset X_{k,h}^{0,1}$  in the presence of homogeneous Dirichlet boundary conditions.

The discretization error for this type of discretization will be analyzed in section 5.2.

**3.3.3. Variational approach.** Extending the discretization approach presented in [13], we can choose  $Q_d = Q$ . In this case the optimization problems (3.11) and (3.16) coincide, and therefore  $\bar{q}_\sigma = \bar{q}_{kh} \in Q_{\text{ad}}$ .

We use the fact that the optimality condition (3.12) can be rewritten employing the projection (2.8) as

$$\bar{q}_{kh} = P_{Q_{\text{ad}}} \left( -\frac{1}{\alpha} z_{kh}(\bar{q}_{kh}) \right),$$

and we obtain that  $\bar{q}_{kh}$  is a piecewise constant function in time. However,  $\bar{q}_{kh}$  is in general not a finite element function corresponding to the spatial mesh  $\mathcal{T}_h$ . This fact requires more care for the construction of algorithms for computation of  $\bar{q}_{kh}$ ; see [13] for details.

The discretization error for this type of discretization will be analyzed in section 5.3.

**3.3.4. Postprocessing strategy.** The strategy described in this section extends the approach from [21] to parabolic problems. For the discretization of the control space we employ the same choice as in section 3.3.1, i.e., cellwise constant discretization. After the computation of the corresponding solution  $\bar{q}_\sigma$ , a better approximation  $\tilde{q}_\sigma$  is constructed by a postprocessing, making use of the projection operator (2.8):

$$(3.18) \quad \tilde{q}_\sigma = P_{Q_{\text{ad}}} \left( -\frac{1}{\alpha} z_{kh}(\bar{q}_\sigma) \right).$$

Note that, similar to the solution obtained by the variational approach in section 3.3.3, the solution  $\tilde{q}_\sigma$  is piecewise constant in time and is generally not a finite element function in space with respect to the spatial mesh  $\mathcal{T}_h$ . This solution can be simply evaluated pointwise; however, the corresponding error analysis requires an additional assumption on the structure of active sets; see the discussion in section 5.4.

**4. Auxiliary results.** In this section we recall some results provided in the first part of this article [20], which will be used in what follows.

The first proposition provides a stability result for the purely time discretized state and adjoint solutions. It follows from Theorems 4.1 and 4.3 and Corollaries 4.2 and 4.5 of [20] as well as from elliptic regularity.

**PROPOSITION 4.1.** *For  $q \in Q$  let the solutions  $u_k(q) \in X_k^0$  and  $z_k(q) \in X_k^0$  be given by the semidiscrete state equation (3.3) and adjoint equation (3.7), respectively. Then it holds that*

$$\begin{aligned} \|\nabla^2 u_k(q)\|_I + \|\nabla u_k(q)\|_I + \|u_k(q)\|_I &\leq C\{\|f + q\|_I + \|\nabla u_0\| + \|u_0\|\}, \\ \|\nabla^2 z_k(q)\|_I + \|\nabla z_k(q)\|_I + \|z_k(q)\|_I &\leq C\|u_k(q) - \hat{u}\|_I. \end{aligned}$$

A similar result holds for the fully discretized solutions of the state and adjoint equations; cf. Theorem 4.6 and Corollary 4.7 in [20].

**PROPOSITION 4.2.** *For  $q \in Q$  let the solutions  $u_{kh}(q) \in X_{k,h}^{0,1}$  and  $z_{kh}(q) \in X_{k,h}^{0,1}$  be given by the discrete state equation (3.10) and adjoint equation (3.14), respectively. Then it holds that*

$$\begin{aligned} \|\nabla u_{kh}(q)\|_I + \|u_{kh}(q)\|_I &\leq C\{\|f + q\|_I + \|\nabla \Pi_h u_0\| + \|\Pi_h u_0\|\}, \\ \|\nabla z_{kh}(q)\|_I + \|z_{kh}(q)\|_I &\leq C\|u_{kh}(q) - \hat{u}\|_I, \end{aligned}$$

where  $\Pi_h: V \rightarrow V_h$  denotes the spatial  $L^2$ -projection.

In the following two propositions, we recall a priori estimates for the errors due to temporal and spatial discretizations of the state and adjoint variables. The assertions are proved in [20] by means of Theorems 5.1 and 5.5 as well as by Lemma 6.2 presented therein.

**PROPOSITION 4.3.** *For  $q \in Q$  let the solutions  $u(q) \in X$  and  $z(q) \in X$  be given by the state equation (2.1) and adjoint equation (2.5), respectively. Moreover, let  $u_k(q) \in X_k^0$  and  $z_k(q) \in X_k^0$  be determined as solutions of the semidiscrete state equation (3.3) and adjoint equation (3.7). Then the following error estimates hold:*

$$\begin{aligned} \|u(q) - u_k(q)\|_I &\leq Ck\|\partial_t u(q)\|_I, \\ \|z(q) - z_k(q)\|_I &\leq Ck\{\|\partial_t u(q)\|_I + \|\partial_t z(q)\|_I\}. \end{aligned}$$

**PROPOSITION 4.4.** *For  $q \in Q$  let the solutions  $u_k(q) \in X_k^0$  and  $z_k(q) \in X_k^0$  be given by the semidiscrete state equation (3.3) and adjoint equation (3.7), respectively.*

Moreover, let  $u_{kh}(q) \in X_{k,h}^{0,1}$  and  $z_{kh}(q) \in X_{k,h}^{0,1}$  be determined as solutions of the discrete state equation (3.10) and adjoint equation (3.14). Then the following error estimates hold:

$$\|u_k(q) - u_{kh}(q)\|_I \leq Ch^2 \|\nabla^2 u_k(q)\|_I,$$

$$\|z_k(q) - z_{kh}(q)\|_I \leq Ch^2 \{ \|\nabla^2 u_k(q)\|_I + \|\nabla^2 z_k(q)\|_I \}.$$

Proposition 4.2 provides a stability result for the discrete adjoint solution with respect to the norm of  $L^2(I, H^1(\Omega))$ . For later use we additionally prove a corresponding result with respect to the norm of  $L^2(I, L^\infty(\Omega))$ .

LEMMA 4.5. For  $q \in Q$  let the solutions  $u_{kh}(q) \in X_{k,h}^{0,1}$  and  $z_{kh}(q) \in X_{k,h}^{0,1}$  be given by the discrete state equation (3.10) and adjoint equation (3.14), respectively. Then it holds that

$$\|z_{kh}(q)\|_{L^2(I, L^\infty(\Omega))} \leq C \|u_{kh}(q) - \hat{u}\|_I.$$

*Proof.* We define an additional adjoint solution  $\tilde{z}_k \in X_k^0$  as solution of

$$B(\varphi, \tilde{z}_k) = (\varphi, u_{kh}(q) - \hat{u})_I \quad \forall \varphi \in X_k^0.$$

Since  $\tilde{z}_k$  and  $z_{kh}(q)$  are given by means of the same right-hand side  $u_{kh}(q) - \hat{u}$ , it is possible to apply standard a priori error estimates to the discretization error  $z_{kh}(q) - \tilde{z}_k$  similar to Proposition 4.4.

By inserting the solution  $\tilde{z}_k$  and utilizing the embedding  $L^2(I, H^2(\Omega)) \hookrightarrow L^2(I, L^\infty(\Omega))$ , we get

$$\begin{aligned} \|z_{kh}(q)\|_{L^2(I, L^\infty(\Omega))} &\leq \|z_{kh}(q) - \tilde{z}_k\|_{L^2(I, L^\infty(\Omega))} + \|\tilde{z}_k\|_{L^2(I, L^\infty(\Omega))} \\ &\leq \|z_{kh}(q) - \tilde{z}_k\|_{L^2(I, L^\infty(\Omega))} + C \|\tilde{z}_k\|_{L^2(I, H^2(\Omega))}. \end{aligned}$$

For the first term we obtain, by inserting a spatial interpolation  $i_h \tilde{z}_k \in X_{k,h}^{0,1}$ ,

$$(4.1) \quad \|z_{kh}(q) - \tilde{z}_k\|_{L^2(I, L^\infty(\Omega))} \leq \|z_{kh}(q) - i_h \tilde{z}_k\|_{L^2(I, L^\infty(\Omega))} + \|i_h \tilde{z}_k - \tilde{z}_k\|_{L^2(I, L^\infty(\Omega))}.$$

For the first term on the right-hand side of (4.1) we proceed by means of an inverse estimate between  $L^\infty(\Omega)$  and  $L^2(\Omega)$  for discrete functions, an estimate for the error due to space discretization (cf. Theorem 5.1 of [20]), and an estimate for the spatial interpolation error as

$$\begin{aligned} \|z_{kh}(q) - i_h \tilde{z}_k\|_{L^2(I, L^\infty(\Omega))}^2 &= \sum_{m=1}^M k_m \|z_{kh}(q)(t_m) - i_h \tilde{z}_k(t_m)\|_{L^\infty(\Omega)}^2 \\ &\leq Ch^{-n} \sum_{m=1}^M k_m \|z_{kh}(q)(t_m) - i_h \tilde{z}_k(t_m)\|^2 \\ &\leq Ch^{-n} \{ \|z_{kh}(q) - \tilde{z}_k\|_I^2 + \|\tilde{z}_k - i_h \tilde{z}_k\|_I^2 \} \\ &\leq Ch^{4-n} \|\nabla^2 \tilde{z}_k\|_I^2. \end{aligned}$$

By standard interpolation estimates, we have for the second term on the right-hand

side of (4.1),

$$\begin{aligned}
 \|i_h \tilde{z}_k - \tilde{z}_k\|_{L^2(I, L^\infty(\Omega))}^2 &= \sum_{m=1}^M k_m \|i_h \tilde{z}_k(t_m) - \tilde{z}_k(t_m)\|_{L^\infty(\Omega)}^2 \\
 &\leq Ch^{4-n} \sum_{m=1}^M k_m \|\nabla^2 \tilde{z}_k(t_m)\|^2 \\
 &= Ch^{4-n} \|\nabla^2 \tilde{z}_k\|_I^2.
 \end{aligned}$$

We complete the proof by collecting all estimates and application of the stability result from Proposition 4.1:

$$\|z_{kh}(q)\|_{L^2(I, L^\infty(\Omega))} \leq Ch^{4-n} \|\nabla^2 \tilde{z}_k\|_I + C \|\tilde{z}_k\|_{L^2(I, H^2(\Omega))} \leq C \|u_{kh}(q) - \hat{u}\|_I. \quad \square$$

**5. Error estimates.** In this section we provide a priori error estimates for the different discretization approaches described in section 3. We start with an assertion of the error between the solution  $\bar{q}$  of the continuous problem (2.2) and the solution  $\bar{q}_k$  of the semidiscretized problem (3.4).

**THEOREM 5.1.** *Let  $\bar{q} \in Q_{ad}$  be the solution of optimization problem (2.2) and  $\bar{q}_k$  be the solution of the semidiscretized problem (3.4). Then the following estimate holds:*

$$\|\bar{q} - \bar{q}_k\|_I \leq \frac{1}{\alpha} \|z(\bar{q}) - z_k(\bar{q})\|_I.$$

*Proof.* Using the optimality conditions (2.4) and (3.5), we obtain the relation

$$-j'_k(\bar{q}_k)(\bar{q} - \bar{q}_k) \leq 0 \leq -j'(\bar{q})(\bar{q} - \bar{q}_k).$$

From (3.8) we have with any  $p \in Q$ :

$$\begin{aligned}
 \alpha \|\bar{q} - \bar{q}_k\|_I^2 &\leq j''_k(p)(\bar{q} - \bar{q}_k, \bar{q} - \bar{q}_k) \\
 &= j'_k(\bar{q})(\bar{q} - \bar{q}_k) - j'_k(\bar{q}_k)(\bar{q} - \bar{q}_k) \\
 &\leq j'_k(\bar{q})(\bar{q} - \bar{q}_k) - j'(\bar{q})(\bar{q} - \bar{q}_k).
 \end{aligned}$$

By means of the representations (2.6) and (3.6) of  $j'$  and  $j'_k$ , respectively, we obtain

$$\alpha \|\bar{q} - \bar{q}_k\|_I^2 \leq (z(\bar{q}) - z_k(\bar{q}), \bar{q} - \bar{q}_k)_I.$$

The desired assertion follows by Cauchy's inequality.  $\square$

**5.1. Cellwise constant discretization.** In this section we are going to prove an estimate for the error  $\|\bar{q} - \bar{q}_\sigma\|_I$  when the control is discretized by cellwise constant polynomials in space and time; see section 3.3.1.

For doing so, we will extend the techniques presented in [8] to the case of parabolic optimal control problems. This demands the introduction of the solution  $\bar{q}_d$  of the following purely control discretized problem:

$$(5.1) \quad \text{Minimize } j(q_d) \text{ subject to } q_d \in Q_{d,ad}.$$

The uniquely determined solution  $\bar{q}_d$  fulfills the optimality condition

$$(5.2) \quad j'(\bar{q}_d)(\delta q - \bar{q}_d) \geq 0 \quad \forall \delta q \in Q_{d,\text{ad}}.$$

To formulate the main result of this section, we introduce the  $L^2$ -projection  $\pi_d: Q \rightarrow Q_d$  and note that, due to the cellwise constant discretization, the following property holds true:

$$\pi_d Q_{\text{ad}} \subset Q_{d,\text{ad}}.$$

**THEOREM 5.2.** *Let  $\bar{q} \in Q_{\text{ad}}$  be the solution of the optimal control problem (2.2), and let  $\bar{q}_\sigma \in Q_{d,\text{ad}}$  be the solution of the discretized problem (3.16), where the cellwise constant discretization for the control variable is employed. Moreover, let  $\bar{q}_d \in Q_{d,\text{ad}}$  be the solution of the purely control discretized problem (5.1). Then the following estimate holds:*

$$\|\bar{q} - \bar{q}_\sigma\|_I \leq \|\bar{q} - \pi_d \bar{q}\|_I + \frac{1}{\alpha} \|z(\bar{q}_d) - \pi_d z(\bar{q}_d)\|_I + \frac{1}{\alpha} \|z(\bar{q}_d) - z_{kh}(\bar{q}_d)\|_I.$$

*Proof.* We split the error

$$\|\bar{q} - \bar{q}_\sigma\|_I \leq \|\bar{q} - \bar{q}_d\|_I + \|\bar{q}_d - \bar{q}_\sigma\|_I$$

and estimate both terms on the right-hand side separately. For treating the first term, we use the fact that  $\pi_d \bar{q} \in Q_{d,\text{ad}}$  and obtain from the optimality conditions (2.4) and (5.2) the inequalities

$$j'(\bar{q})(\bar{q} - \bar{q}_d) \leq 0 \quad \text{and} \quad -j'(\bar{q}_d)(\pi_d \bar{q} - \bar{q}_d) \leq 0.$$

Using (2.7) we proceed with any  $p \in Q$ :

$$\begin{aligned} \alpha \|\bar{q} - \bar{q}_d\|_I^2 &\leq j''(p)(\bar{q} - \bar{q}_d, \bar{q} - \bar{q}_d) \\ &= j'(\bar{q})(\bar{q} - \bar{q}_d) - j'(\bar{q}_d)(\bar{q} - \bar{q}_d) \\ &= j'(\bar{q})(\bar{q} - \bar{q}_d) - j'(\bar{q}_d)(\bar{q} - \pi_d \bar{q}) - j'(\bar{q}_d)(\pi_d \bar{q} - \bar{q}_d) \\ &\leq -j'(\bar{q}_d)(\bar{q} - \pi_d \bar{q}). \end{aligned}$$

By means of the representation of the derivative  $j'$  from (2.6) and the properties of  $\pi_d$ , we have

$$\begin{aligned} \alpha \|\bar{q} - \bar{q}_d\|_I^2 &\leq -j'(\bar{q}_d)(\bar{q} - \pi_d \bar{q}) \\ &= -(\alpha \bar{q}_d + z(\bar{q}_d), \bar{q} - \pi_d \bar{q})_I \\ &= (\pi_d z(\bar{q}_d) - z(\bar{q}_d), \bar{q} - \pi_d \bar{q})_I, \end{aligned}$$

and by Young's inequality we obtain the intermediary result

$$(5.3) \quad \|\bar{q} - \bar{q}_d\|_I^2 \leq \|\bar{q} - \pi_d \bar{q}\|_I^2 + \frac{1}{4\alpha^2} \|z(\bar{q}_d) - \pi_d z(\bar{q}_d)\|_I^2.$$

In order to estimate the term  $\|\bar{q}_d - \bar{q}_\sigma\|_I$  we exploit the optimality conditions (5.2) and (3.17) leading to the following relation:

$$-j'_{kh}(\bar{q}_\sigma)(\bar{q}_d - \bar{q}_\sigma) \leq 0 \leq -j'(\bar{q}_d)(\bar{q}_d - \bar{q}_\sigma).$$

Using (3.15) and the representations (2.6) for  $j'$  and (3.13) for  $j'_{kh}$ , respectively, we obtain

$$\begin{aligned} \alpha \|\bar{q}_d - \bar{q}_\sigma\|_I^2 &\leq j''_{kh}(p)(\bar{q}_d - \bar{q}_\sigma, \bar{q}_d - \bar{q}_\sigma) \\ &= j'_{kh}(\bar{q}_d)(\bar{q}_d - \bar{q}_\sigma) - j'_{kh}(\bar{q}_\sigma)(\bar{q}_d - \bar{q}_\sigma) \\ &\leq j'_{kh}(\bar{q}_d)(\bar{q}_d - \bar{q}_\sigma) - j'(\bar{q}_d)(\bar{q}_d - \bar{q}_\sigma) \\ &\leq \|z(\bar{q}_d) - z_{kh}(\bar{q}_d)\|_I \|\bar{q}_d - \bar{q}_\sigma\|_I. \end{aligned}$$

Thus, we achieve

$$(5.4) \quad \|\bar{q}_d - \bar{q}_\sigma\|_I \leq \frac{1}{\alpha} \|z(\bar{q}_d) - z_{kh}(\bar{q}_d)\|_I.$$

Collecting estimates (5.3) and (5.4), we complete the proof.  $\square$

This theorem directly implies the following result.

**COROLLARY 5.3.** *Under the conditions of Theorem 5.2, the following estimate holds:*

$$\begin{aligned} \|\bar{q} - \bar{q}_\sigma\|_I &\leq \frac{C}{\alpha} k \{ \|\partial_t \bar{q}\|_I + \|\partial_t u(\bar{q}_d)\|_I + \|\partial_t z(\bar{q}_d)\|_I \} \\ &+ \frac{C}{\alpha} h \{ \|\nabla \bar{q}\|_I + \|\nabla z(\bar{q}_d)\|_I + h (\|\nabla^2 u_k(\bar{q}_d)\|_I + \|\nabla^2 z_k(\bar{q}_d)\|_I) \} = \mathcal{O}(k + h). \end{aligned}$$

*Proof.* The assertion follows from Theorem 5.2 by interpolation estimates and Propositions 4.3 and 4.4. Due to the fact that  $\bar{q}, \bar{q}_d \in Q_{\text{ad}}$ , we obtain, using the stability estimates from Proposition 4.1, that all norms involved in this estimate are bounded by a constant independent of all discretization parameters.  $\square$

**5.2. Cellwise linear discretization.** This section is devoted to the error analysis for the discretization of the control variable by piecewise constants in time and cellwise (bi-/tri-)linear functions in space as described in section 3.3.2. To this end we split the error

$$\|\bar{q} - \bar{q}_\sigma\|_I \leq \|\bar{q} - \bar{q}_k\|_I + \|\bar{q}_k - \bar{q}_\sigma\|_I$$

and use the result of Theorem 5.1 for the first part. For treating the error  $\|\bar{q}_k - \bar{q}_\sigma\|_I$  we adapt the technique described in [4] and [6] to parabolic problems.

The analysis in this section is based on an assumption on the structure of the active sets. For each time interval  $I_m$  we group the cells  $K$  of the mesh  $\mathcal{T}_h$  depending on the value of  $\bar{q}_k$  on  $K$  into three sets  $\mathcal{T}_h = \mathcal{T}_{h,m}^1 \cup \mathcal{T}_{h,m}^2 \cup \mathcal{T}_{h,m}^3$  with  $\mathcal{T}_{h,m}^i \cap \mathcal{T}_{h,m}^j = \emptyset$  for  $i \neq j$ . The sets are chosen as follows:

$$\begin{aligned} \mathcal{T}_{h,m}^1 &:= \{K \in \mathcal{T}_h \mid \bar{q}_k(t_m, x) = q_a \text{ or } \bar{q}_k(t_m, x) = q_b \quad \forall x \in K\}, \\ \mathcal{T}_{h,m}^2 &:= \{K \in \mathcal{T}_h \mid q_a < \bar{q}_k(t_m, x) < q_b \quad \forall x \in K\}, \\ \mathcal{T}_{h,m}^3 &:= \mathcal{T}_h \setminus (\mathcal{T}_{h,m}^1 \cup \mathcal{T}_{h,m}^2). \end{aligned}$$

Hence, the set  $\mathcal{T}_{h,m}^3$  consists of the cells which contain the free boundary between the active and the inactive sets for the time interval  $I_m$ .

*Assumption 1.* We assume that there exists a positive constant  $C$  independent of  $k$ ,  $h$ , and  $m$  such that

$$\sum_{K \in \mathcal{T}_{h,m}^3} |K| \leq Ch$$

separately for all  $m = 1, 2, \dots, M$ .

*Remark 5.4.* A similar assumption is used in [21, 25, 2]. This assumption is valid if the boundary of the level sets

$$\{x \in \Omega | \bar{q}_k(t_m, x) = q_a\} \quad \text{and} \quad \{x \in \Omega | \bar{q}_k(t_m, x) = q_b\}$$

consists of a finite number of rectifiable curves.

We consider the usual nodal interpolation operator  $I_d$  which maps into the space of cellwise (bi-/tri-)linear functions  $Q_h$ . It is defined for functions  $g \in C(\Omega)$  by pointwise setting

$$(5.5) \quad I_d g(x_i) = g(x_i) \quad \text{for each node } x_i \text{ of } \mathcal{T}_h.$$

The operator  $I_d$  will also be applied to time-dependent functions  $g$  by the setting  $(I_d g)(t) = I_d g(t)$ .

In the following theorem we provide an assertion on the error  $\|\bar{q}_k - \bar{q}_\sigma\|_I$ .

**THEOREM 5.5.** *Let  $\bar{q}_k \in Q_{ad}$  be the solution of the semidiscretized optimal control problem (3.4) and  $\bar{q}_\sigma \in Q_{d,ad}$  be the solution of the discrete problem (3.16), where the cellwise (bi-/tri-)linear discretization for the control variable is employed. Then the following estimate holds:*

$$\begin{aligned} \|\bar{q}_k - \bar{q}_\sigma\|_I &\leq C \left(1 + \frac{1}{\alpha}\right) \|I_d \bar{q}_k - \bar{q}_k\|_I \\ &\quad + \frac{C}{\alpha} \|z_k(\bar{q}_k) - z_{kh}(\bar{q}_k)\|_I + \frac{C}{\sqrt{\alpha}} (j'_k(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_k))^{\frac{1}{2}}. \end{aligned}$$

*Proof.* We split

$$(5.6) \quad \|\bar{q}_k - \bar{q}_\sigma\|_I \leq \|\bar{q}_k - I_d \bar{q}_k\|_I + \|I_d \bar{q}_k - \bar{q}_\sigma\|_I$$

and estimate the term  $\|I_d \bar{q}_k - \bar{q}_\sigma\|_I$ . Due to the optimality conditions (3.17) and (3.5), and since  $I_d \bar{q}_k \in Q_{d,ad}$ , we have

$$-j'_{kh}(\bar{q}_\sigma)(I_d \bar{q}_k - \bar{q}_\sigma) \leq 0 \leq -j'_k(\bar{q}_k)(\bar{q}_k - \bar{q}_\sigma),$$

and due to (3.15) we obtain for any  $p \in Q$ ,

$$\begin{aligned} \alpha \|I_d \bar{q}_k - \bar{q}_\sigma\|_I^2 &\leq j''_{kh}(p)(I_d \bar{q}_k - \bar{q}_\sigma, I_d \bar{q}_k - \bar{q}_\sigma) \\ &\leq j'_{kh}(I_d \bar{q}_k)(I_d \bar{q}_k - \bar{q}_\sigma) - j'_{kh}(\bar{q}_\sigma)(I_d \bar{q}_k - \bar{q}_\sigma) \\ &\leq j'_{kh}(I_d \bar{q}_k)(I_d \bar{q}_k - \bar{q}_\sigma) - j'_k(\bar{q}_k)(\bar{q}_k - \bar{q}_\sigma) \\ (5.7) \quad &= j'_{kh}(I_d \bar{q}_k)(I_d \bar{q}_k - \bar{q}_\sigma) - j'_{kh}(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_\sigma) \\ &\quad + j'_{kh}(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_\sigma) - j'_k(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_\sigma) \\ &\quad + j'_k(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_k). \end{aligned}$$

The representations (3.6) of  $j'_k$  and (3.13) of  $j'_{kh}$  yield, by means of Proposition 4.2, that for any  $p, q, r \in Q$ ,

$$|j'_{kh}(p)(r) - j'_{kh}(q)(r)| \leq \{\alpha \|p - q\|_I + \|z_{kh}(p) - z_{kh}(q)\|_I\} \|r\|_I \leq (C + \alpha) \|p - q\|_I \|r\|_I$$

and

$$|j'_{kh}(q)(r) - j'_k(q)(r)| \leq \|z_k(q) - z_{kh}(q)\|_I \|r\|_I.$$

Applying these inequalities to the right-hand side of (5.7) leads to

$$\begin{aligned} \alpha \|I_d \bar{q}_k - \bar{q}_\sigma\|_I^2 &\leq (C + \alpha) \|I_d \bar{q}_k - \bar{q}_k\|_I \|I_d \bar{q}_k - \bar{q}_\sigma\|_I \\ &\quad + \|z_k(\bar{q}_k) - z_{kh}(\bar{q}_k)\|_I \|I_d \bar{q}_k - \bar{q}_\sigma\|_I + j'_k(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_k). \end{aligned}$$

With Young's inequality, we obtain

$$\begin{aligned} \|I_d \bar{q}_k - \bar{q}_\sigma\|_I^2 &\leq C \left(1 + \frac{1}{\alpha^2}\right) \|I_d \bar{q}_k - \bar{q}_k\|_I^2 \\ &\quad + \frac{C}{\alpha^2} \|z_k(\bar{q}_k) - z_{kh}(\bar{q}_k)\|_I^2 + \frac{C}{\alpha} j'_k(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_k). \end{aligned}$$

Inserting this estimate into (5.6) completes the proof.  $\square$

In the following two lemmas we provide estimates for the terms  $j'_k(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_k)$  and  $\|I_d \bar{q}_k - \bar{q}_k\|_I$  appearing on the right-hand side of the assertion of Theorem 5.5.

**LEMMA 5.6.** *Let  $\bar{q}_k \in Q_{ad}$  be the solution of the semidiscretized optimization problem (3.4) and  $I_d \bar{q}_k$  be the interpolation constructed by (5.5). Then, if Assumption 1 is fulfilled, the following estimate holds for  $n < p \leq \infty$ , provided  $z_k(\bar{q}_k) \in L^2(I, W^{1,p}(\Omega))$ :*

$$|j'_k(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_k)| \leq \frac{C}{\alpha} h^{3-\frac{2}{p}} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))}^2.$$

*Proof.* Using representation (3.6) of  $j'_k$  we have

$$\begin{aligned} j'_k(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_k) &= (\alpha \bar{q}_k + z_k(\bar{q}_k), I_d \bar{q}_k - \bar{q}_k)_I \\ (5.8) \quad &= \sum_{m=1}^M \int_{I_m} (\alpha \bar{q}_k(t) + z_k(\bar{q}_k)(t), I_d \bar{q}_k(t) - \bar{q}_k(t)) dt \\ &= \sum_{m=1}^M k_m (\alpha \bar{q}_k(t_m) + z_k(\bar{q}_k)(t_m), I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)). \end{aligned}$$

With the abbreviation  $d_m := \alpha \bar{q}_k(t_m) + z_k(\bar{q}_k)(t_m)$  we obtain

$$\begin{aligned} (5.9) \quad (d_m, I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)) &= \sum_{K \in \mathcal{T}_h} (d_m, I_d \bar{q}_k(t_m) - \bar{q}_k(t_m))_{L^2(K)} \\ &= \sum_{K \in \mathcal{T}_{h,m}^3} (d_m, I_d \bar{q}_k(t_m) - \bar{q}_k(t_m))_{L^2(K)}, \end{aligned}$$

since it holds  $I_d \bar{q}_k(t_m) = \bar{q}_k(t_m)$  on  $\mathcal{T}_{h,m}^1$  by construction and  $d_m = 0$  on  $\mathcal{T}_{h,m}^2$  due to representation formula (3.9).

In every cell  $K \in \mathcal{T}_{h,m}^3$  there is a point  $x_K$  with  $d_m(x_K) = 0$ . Thus, we get

$$\begin{aligned} |(d_m, I_d \bar{q}_k(t_m) - \bar{q}_k(t_m))_{L^2(K)}| & \leq |K|^{1-\frac{2}{p}} \|d_m\|_{L^p(K)} \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|_{L^p(K)} \\ & = |K|^{1-\frac{2}{p}} \|d_m - d_m(x_K)\|_{L^p(K)} \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|_{L^p(K)} \\ & \leq Ch^2 |K|^{1-\frac{2}{p}} \|\nabla d_m\|_{L^p(K)} \|\nabla \bar{q}_k(t_m)\|_{L^p(K)}. \end{aligned}$$

Inserting this estimate into (5.9) yields, together with Assumption 1,

$$\begin{aligned} |(d_m, I_d \bar{q}_k(t_m) - \bar{q}_k(t_m))| & \leq Ch^2 \sum_{K \in \mathcal{T}_{h,m}^3} |K|^{1-\frac{2}{p}} \|\nabla d_m\|_{L^p(K)} \|\nabla \bar{q}_k(t_m)\|_{L^p(K)} \\ & \leq Ch^2 \left( \sum_{K \in \mathcal{T}_{h,m}^3} |K| \right)^{1-\frac{2}{p}} \|\nabla d_m\|_{L^p(\Omega)} \|\nabla \bar{q}_k(t_m)\|_{L^p(\Omega)} \\ & \leq Ch^{3-\frac{2}{p}} \|\nabla d_m\|_{L^p(\Omega)} \|\nabla \bar{q}_k(t_m)\|_{L^p(\Omega)}. \end{aligned}$$

Then, the estimate

$$\|\nabla d_m\|_{L^p(\Omega)} \leq \alpha \|\nabla q_k(\bar{q}_k)(t_m)\|_{L^p(\Omega)} + \|\nabla z_k(\bar{q}_k)(t_m)\|_{L^p(\Omega)},$$

representation formula (3.9), and property (2.10) imply

$$|(d_m, I_d \bar{q}_k(t_m) - \bar{q}_k(t_m))| \leq \frac{C}{\alpha} h^{3-\frac{2}{p}} \|\nabla z_k(\bar{q}_k)(t_m)\|_{L^p(\Omega)}^2.$$

Hence, by inserting this last estimate into (5.8) we obtain the proposed assertion

$$\begin{aligned} |j'(\bar{q}_k)(I_d \bar{q}_k - \bar{q}_k)| & \leq \frac{C}{\alpha} h^{3-\frac{2}{p}} \sum_{m=1}^M k_m \|\nabla z_k(\bar{q}_k)(t_m)\|_{L^p(\Omega)}^2 \\ & = \frac{C}{\alpha} h^{3-\frac{2}{p}} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))}^2. \quad \square \end{aligned}$$

**LEMMA 5.7.** *Let  $\bar{q}_k \in Q_{ad}$  be the solution of the semidiscretized optimization problem (3.4) and  $I_d \bar{q}_k$  be the interpolation constructed by (5.5). Then, if Assumption 1 is fulfilled, the following estimate holds for  $n < p \leq \infty$ , provided  $z_k(\bar{q}_k) \in L^2(I, W^{1,p}(\Omega))$ :*

$$\|I_d \bar{q}_k - \bar{q}_k\|_I \leq \frac{C}{\alpha} \{h^2 \|\nabla^2 z_k(\bar{q}_k)\|_I + h^{\frac{3}{2}-\frac{1}{p}} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))}\}.$$

*Proof.* Since  $\bar{q}_k$  is piecewise constant in time we write

$$(5.10) \quad \|I_d \bar{q}_k - \bar{q}_k\|_I^2 = \sum_{m=1}^M \int_{I_m} \|I_d \bar{q}_k(t) - \bar{q}_k(t)\|^2 dt = \sum_{m=1}^M k_m \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|^2.$$

For each  $m = 1, 2, \dots, M$ , we split

$$\begin{aligned}
 \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|^2 &= \sum_{K \in \mathcal{T}_h} \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|_{L^2(K)}^2 \\
 (5.11) \qquad &= \sum_{K \in \mathcal{T}_{h,m}^2} \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|_{L^2(K)}^2 \\
 &\quad + \sum_{K \in \mathcal{T}_{h,m}^3} \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|_{L^2(K)}^2.
 \end{aligned}$$

Here, the sum over  $K \in \mathcal{T}_{h,m}^1$  vanishes since on  $\mathcal{T}_{h,m}^1$  it holds that  $I_d \bar{q}_k = \bar{q}_k$ .

The first term on the right-hand side of (5.11) can be estimated as

$$\begin{aligned}
 \sum_{K \in \mathcal{T}_{h,m}^2} \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|_{L^2(K)}^2 &\leq Ch^4 \sum_{K \in \mathcal{T}_{h,m}^2} \|\nabla^2 \bar{q}_k(t_m)\|_{L^2(K)}^2 \\
 &\leq \frac{C}{\alpha^2} h^4 \|\nabla^2 z_k(\bar{q}_k)(t_m)\|^2,
 \end{aligned}$$

since  $\bar{q}_k(t_m) = -\frac{1}{\alpha} z_k(\bar{q}_k)(t_m)$  on all cells  $K \in \mathcal{T}_{h,m}^2$ . For the second term on the right-hand side of (5.11) we proceed by means of representation formula (3.9), property (2.10), and Assumption 1:

$$\begin{aligned}
 \sum_{K \in \mathcal{T}_{h,m}^3} \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|_{L^2(K)}^2 &\leq \sum_{K \in \mathcal{T}_{h,m}^3} |K|^{1-\frac{2}{p}} \|I_d \bar{q}_k(t_m) - \bar{q}_k(t_m)\|_{L^p(K)}^2 \\
 &\leq Ch^2 \sum_{K \in \mathcal{T}_{h,m}^3} |K|^{1-\frac{2}{p}} \|\nabla \bar{q}_k(t_m)\|_{L^p(K)}^2 \\
 &\leq Ch^2 \left( \sum_{K \in \mathcal{T}_{h,m}^3} |K| \right)^{1-\frac{2}{p}} \|\nabla \bar{q}_k(t_m)\|_{L^p(\Omega)}^2 \\
 &\leq \frac{C}{\alpha^2} h^{3-\frac{2}{p}} \|\nabla z_k(\bar{q}_k)(t_m)\|_{L^p(\Omega)}^2.
 \end{aligned}$$

Inserting the last two estimates into (5.11) and plugging (5.11) into (5.10) implies the stated result.  $\square$

**COROLLARY 5.8.** *Under the conditions of Theorem 5.5 and Lemmas 5.6 and 5.7, the following estimate holds:*

$$\begin{aligned}
 \|\bar{q} - \bar{q}_\sigma\|_I &\leq \frac{C}{\alpha} k \{ \|\partial_t u(\bar{q})\|_I + \|\partial_t z(\bar{q})\|_I \} + \frac{C}{\alpha} \left(1 + \frac{1}{\alpha}\right) \{ h^2 \|\nabla^2 u_k(\bar{q}_k)\|_I \\
 &\quad + h^2 \|\nabla^2 z_k(\bar{q}_k)\|_I + h^{\frac{3}{2}-\frac{1}{p}} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))} \} = \mathcal{O}(k + h^{\frac{3}{2}-\frac{1}{p}}).
 \end{aligned}$$

*Proof.* The result follows directly from Theorems 5.1 and 5.5, Lemmas 5.6 and 5.7, and Proposition 4.4.  $\square$

In what follows we discuss the result from Corollary 5.8 in more details. This result holds under the assumption that  $z_k(\bar{q}_k) \in L^2(I, W^{1,p}(\Omega))$ . From the stability result in Proposition 4.1 and the fact that  $\bar{q}_k \in Q_{\text{ad}}$ , we know that

$$\|z_k(\bar{q}_k)\|_{L^2(I, H^2(\Omega))} \leq C.$$

By a Sobolev embedding theorem we have  $H^2(\Omega) \hookrightarrow W^{1,p}(\Omega)$  for all  $p < \infty$  in two space dimensions and for  $p \leq 6$  in three dimensions. This implies the order of convergence  $\mathcal{O}(k + h^{\frac{3}{2} - \frac{1}{p}})$  for all  $2 < p < \infty$  in two dimensions and  $\mathcal{O}(k + h^{\frac{4}{3}})$  in three dimensions, respectively. If in addition  $\|z_k(\bar{q}_k)\|_{L^2(I, W^{1,\infty}(\Omega))}$  is bounded, then we have in both cases the order of convergence  $\mathcal{O}(k + h^{\frac{3}{2}})$ .

*Remark 5.9.* The above result relies on Assumption 1. This assumption is valid in the majority of practical cases; cf. Remark 5.4. In the absence of this assumption a weaker result for the behavior of the spatial error can be shown, i.e.,

$$\lim_{h \rightarrow 0} \frac{1}{h} \|\bar{q}_k - \bar{q}_\sigma\|_I = 0.$$

The proofs in this section can simply be adapted to this situation. For the corresponding result for elliptic optimal control problems, we refer to [4].

**5.3. Variational approach.** In this subsection we prove an estimate for the error  $\|\bar{q} - \bar{q}_\sigma\|_I$  in the case of no control discretization; see section 3.3.3. In this case we choose  $Q_d = Q$ , and thus  $Q_{d,\text{ad}} = Q_{\text{ad}}$ . This implies  $\bar{q}_\sigma = \bar{q}_{kh}$ .

**THEOREM 5.10.** *Let  $\bar{q} \in Q_{\text{ad}}$  be the solution of optimization problem (2.2) and  $\bar{q}_{kh} \in Q_{\text{ad}}$  be the solution of the discretized problem (3.11). Then the following estimate holds:*

$$\|\bar{q} - \bar{q}_{kh}\|_I \leq \frac{1}{\alpha} \|z(\bar{q}) - z_{kh}(\bar{q})\|_I.$$

*Proof.* The proof is similar to the proof of Theorem 5.1. The optimality conditions (2.4) and (3.12) lead to

$$-j'_{kh}(\bar{q}_{kh})(\bar{q} - \bar{q}_{kh}) \leq 0 \leq -j'(\bar{q})(\bar{q} - \bar{q}_{kh}).$$

Using (3.15) we have with any  $p \in Q$ ,

$$\begin{aligned} \alpha \|\bar{q} - \bar{q}_{kh}\|_I^2 &\leq j''_{kh}(p)(\bar{q} - \bar{q}_{kh}, \bar{q} - \bar{q}_{kh}) \\ &= j'_{kh}(\bar{q})(\bar{q} - \bar{q}_{kh}) - j'_{kh}(\bar{q}_{kh})(\bar{q} - \bar{q}_{kh}) \\ &\leq j'_{kh}(\bar{q})(\bar{q} - \bar{q}_{kh}) - j'(\bar{q})(\bar{q} - \bar{q}_{kh}) \\ &= (z(\bar{q}) - z_{kh}(\bar{q}), \bar{q} - \bar{q}_{kh})_I. \end{aligned}$$

The desired assertion follows by Cauchy's inequality.  $\square$

This approach provides the optimal order of convergence stated in the following corollary.

**COROLLARY 5.11.** *Let the conditions of Theorem 5.10 be fulfilled. Then there holds*

$$\begin{aligned} \|\bar{q} - \bar{q}_{kh}\|_I &\leq \frac{C}{\alpha} k \{ \|\partial_t u(\bar{q})\|_I + \|\partial_t z(\bar{q})\|_I \} \\ &\quad + \frac{C}{\alpha} h^2 \{ \|\nabla^2 u_k(\bar{q})\|_I + \|\nabla^2 z_k(\bar{q})\|_I \} = \mathcal{O}(k + h^2). \end{aligned}$$

*Proof.* The proof follows directly from Theorem 5.10 and Propositions 4.3 and 4.4.  $\square$

**5.4. Postprocessing strategy.** In this section, we extend the postprocessing techniques initially proposed in [21] to the parabolic case. As described in section 3.3.4 we discretize the control by piecewise constants in time and space. To improve the quality of the approximation, we additionally employ the postprocessing step (3.18).

In what follows we will use the operator  $R_d$  defined for functions  $g \in C(\bar{\Omega})$  cellwise by

$$R_d g|_K = g(S_K), \quad K \in \mathcal{T}_h,$$

where  $S_K$  denotes the barycenter of the cell  $K$ . This operator allows for the following interpolation estimates.

LEMMA 5.12. *Let  $K \in \mathcal{T}_h$  be a given cell. Then we have that*

- *for  $g \in H^2(K)$ ,*

$$\left| \int_K (g(x) - (R_d g)(x)) dx \right| \leq Ch^2 |K|^{\frac{1}{2}} \|\nabla^2 g\|_{L^2(K)};$$

- *for  $g \in W^{1,p}(K)$  with  $n < p \leq \infty$ ,*

$$\|g - R_d g\|_{L^p(K)} \leq Ch \|\nabla g\|_{L^p(K)}.$$

*Proof.* The proof is done by standard arguments using the Bramble–Hilbert lemma; see [21] for details.  $\square$

The operator  $R_d$  will also be used for time-dependent functions  $g$  by setting  $(R_d g)(t) = R_d g(t)$ . There holds the following lemma.

LEMMA 5.13. *For a function  $g_k \in X_k^0 \cap L^2(I, H^2(\Omega))$  and a cellwise constant function  $p_d \in Q_d$ , the estimate*

$$(p_d, g_k - R_d g_k)_I \leq Ch^2 \|p_d\|_I \|\nabla^2 g_k\|_I$$

*holds.*

*Proof.* Using Lemma 5.12 we obtain

$$\begin{aligned} (p_d, g_k - R_d g_k)_I &= \sum_{m=1}^M \int_{I_m} (p_d(t), g_k(t) - R_d g_k(t)) dt \\ &= \sum_{m=1}^M k_m (p_d(t_m), g_k(t_m) - R_d g_k(t_m)) \\ &= \sum_{m=1}^M k_m \sum_{K \in \mathcal{T}_h} p_d(t_m, S_K) \int_K (g_k(t_m, x) - (R_d g_k)(t_m, x)) dx \\ &\leq Ch^2 \sum_{m=1}^M k_m \sum_{K \in \mathcal{T}_h} |p_d(t_m, S_K)| |K|^{\frac{1}{2}} \|\nabla^2 g_k(t_m)\|_{L^2(K)}. \end{aligned}$$

We complete the proof by Cauchy's inequality.  $\square$

LEMMA 5.14. *Let  $\bar{q}_k \in Q_{ad}$  be the solution of the semidiscrete optimization problem (3.4) and  $\bar{q}_\sigma \in Q_{d,ad}$  be the solution of the discrete problem (3.16), where the cellwise constant control discretization is employed. Then the following relation holds:*

$$(\alpha R_d \bar{q}_k + R_d z_k(\bar{q}_k), \bar{q}_\sigma - R_d \bar{q}_k)_I \geq 0.$$

*Proof.* From the optimality condition (3.5) for  $\bar{q}_k$ , we obtain

$$(\alpha \bar{q}_k(t_m, x) + z_k(\bar{q}_k)(t_m, x)) \cdot (\delta q(t_m, x) - \bar{q}_k(t_m, x)) \geq 0$$

for any  $\delta q \in Q_{d,\text{ad}}$  pointwise a.e. in  $\Omega$  and for  $m = 1, 2, \dots, M$ . For an arbitrary cell  $K \in \mathcal{T}_h$  we apply this formula for  $x = S_K$  and  $\delta q = \bar{q}_\sigma$ :

$$(\alpha \bar{q}_k(t_m, S_K) + z_k(\bar{q}_k)(t_m, S_K)) \cdot (\bar{q}_\sigma(t_m, S_K) - \bar{q}_k(t_m, S_K)) \geq 0.$$

This can be done because of the spatial continuity of  $z_k(\bar{q}_k)$ ,  $\bar{q}_k$ , and  $\bar{q}_\sigma$ . Due to the definition of  $R_d$ , this is equivalent to

$$(\alpha R_d \bar{q}_k(t_m, S_K) + R_d z_k(\bar{q}_k)(t_m, S_K)) \cdot (\bar{q}_\sigma(t_m, S_K) - R_d \bar{q}_k(t_m, S_K)) \geq 0.$$

Then, integration over  $K$  and  $I_m$ , summation over all  $K \in \mathcal{T}_h$ , and  $m = 1, 2, \dots, M$  lead to the proposed relation.  $\square$

LEMMA 5.15. *Let  $\bar{q}_k \in Q_{\text{ad}}$  be the solution of the semidiscrete optimization problem (3.4) and let  $\psi_{kh} \in X_{k,h}^{0,1}$ . Moreover, let Assumption 1 be fulfilled and  $n < p \leq \infty$ . Then, it holds that*

$$\begin{aligned} (\psi_{kh}, \bar{q}_k - R_d \bar{q}_k)_I &\leq \frac{C}{\alpha} h^2 \{ \|\nabla \psi_{kh}\|_I \|\nabla z_k(\bar{q}_k)\|_I + \|\psi_{kh}\|_{L^2(I, L^\infty(\Omega))} \|\nabla^2 z_k(\bar{q}_k)\|_I \} \\ &\quad + \frac{C}{\alpha} h^{2-\frac{1}{p}} \|\psi_{kh}\|_{L^2(I, L^\infty(\Omega))} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))}, \end{aligned}$$

provided that  $z_k(\bar{q}_k) \in L^2(I, W^{1,p}(\Omega))$ .

*Proof.* By means of the  $L^2$ -projection  $\pi_d: Q \rightarrow Q_d$ , we split

$$(\psi_{kh}, \bar{q}_k - R_d \bar{q}_k)_I = (\psi_{kh}, \bar{q}_k - \pi_d \bar{q}_k)_I + (\psi_{kh}, \pi_d \bar{q}_k - R_d \bar{q}_k)_I.$$

Using the optimality condition (3.9) and property (2.10) of the projection operator  $P_{Q_{\text{ad}}}$ , we have for the first term

$$\begin{aligned} (\psi_{kh}, \bar{q}_k - \pi_d \bar{q}_k)_I &= (\psi_{kh} - \pi_d \psi_{kh}, \bar{q}_k - \pi_d \bar{q}_k)_I \leq C h^2 \|\nabla \psi_{kh}\|_I \|\nabla \bar{q}_k\|_I \\ (5.12) \quad &\leq \frac{C}{\alpha} h^2 \|\nabla \psi_{kh}\|_I \|\nabla z_k(\bar{q}_k)\|_I. \end{aligned}$$

For the second term we obtain

$$\begin{aligned} (\psi_{kh}, \pi_d \bar{q}_k - R_d \bar{q}_k)_I &= \sum_{m=1}^M \int_{I_m} (\psi_{kh}(t), \pi_d \bar{q}_k(t) - R_d \bar{q}_k(t)) dt \\ &= \sum_{m=1}^M k_m (\psi_{kh}(t_m), \pi_d \bar{q}_k(t_m) - R_d \bar{q}_k(t_m)). \end{aligned}$$

Utilizing the fact that  $\pi_d \bar{q}_k(t_m)$  as well as  $R_d \bar{q}_k(t_m)$  are constant on each cell  $K$ , we

proceed with

$$\begin{aligned}
 (5.13) \quad & (\psi_{kh}(t_m), \pi_d \bar{q}_k(t_m) - R_d \bar{q}_k(t_m)) \\
 &= \sum_{K \in \mathcal{T}_h} \int_K \psi_{kh}(t_m, x) (\pi_d \bar{q}_k(t_m, x) - (R_d \bar{q}_k)(t_m, x)) dx \\
 &= \sum_{K \in \mathcal{T}_h} \frac{1}{|K|} \int_K \psi_{kh}(t_m, x) dx \int_K (\pi_d \bar{q}_k(t_m, x) - (R_d \bar{q}_k)(t_m, x)) dx \\
 &\leq \|\psi_{kh}(t_m)\|_{L^\infty(\Omega)} \sum_{K \in \mathcal{T}_h} \left| \int_K (\bar{q}_k(t_m, x) - (R_d \bar{q}_k)(t_m, x)) dx \right|.
 \end{aligned}$$

As in section 5.2, we split the last sum using the separation  $\mathcal{T}_h = \mathcal{T}_{h,m}^1 \cup \mathcal{T}_{h,m}^2 \cup \mathcal{T}_{h,m}^3$  for  $m = 1, 2, \dots, M$ . For the sum over  $\mathcal{T}_{h,m}^1 \cup \mathcal{T}_{h,m}^2$  we obtain by means of Lemma 5.12 and the fact that  $\bar{q}_k(t_m)$  equals either  $q_a$ ,  $q_b$ , or  $-\frac{1}{\alpha} z_k(\bar{q}_k)(t_m)$ :

$$\begin{aligned}
 (5.14) \quad & \sum_{K \in \mathcal{T}_{h,m}^1 \cup \mathcal{T}_{h,m}^2} \left| \int_K (\bar{q}_k(t_m, x) - R_d \bar{q}_k(t_m, x)) dx \right| \\
 &\leq Ch^2 \sum_{K \in \mathcal{T}_{h,m}^1 \cup \mathcal{T}_{h,m}^2} |K|^{\frac{1}{2}} \|\nabla^2 \bar{q}_k(t_m)\|_{L^2(K)} \\
 &\leq \frac{C}{\alpha} h^2 \|\nabla^2 z_k(\bar{q}_k)(t_m)\|.
 \end{aligned}$$

For the part of the sum over  $\mathcal{T}_{h,m}^3$ , the estimate of Lemma 5.12, Assumption 1, the optimality condition (3.9), and property (2.10) lead to

$$\begin{aligned}
 (5.15) \quad & \sum_{K \in \mathcal{T}_{h,m}^3} \left| \int_K (\bar{q}_k(t_m, x) - R_d \bar{q}_k(t_m, x)) dx \right| \leq \sum_{K \in \mathcal{T}_{h,m}^3} |K|^{1-\frac{1}{p}} \|\bar{q}_k(t_m) - R_d \bar{q}_k(t_m)\|_{L^p(K)} \\
 &\leq Ch \sum_{K \in \mathcal{T}_{h,m}^3} |K|^{1-\frac{1}{p}} \|\nabla \bar{q}_k(t_m)\|_{L^p(K)} \\
 &\leq \frac{C}{\alpha} h^{2-\frac{1}{p}} \|\nabla z_k(\bar{q}_k(t_m))\|_{L^p(\Omega)}.
 \end{aligned}$$

Inserting (5.14) and (5.15) into (5.13) and collecting the estimates (5.12) and (5.13) completes the proof.  $\square$

The following theorem provides a supercloseness result on the difference  $R_d \bar{q}_k - \bar{q}_\sigma$ .

**THEOREM 5.16.** *Let  $\bar{q}_k \in Q_{ad}$  be the solution of the semidiscretized optimization problem (3.4) and  $\bar{q}_\sigma \in Q_{d,ad}$  be the solution of the discrete problem (3.16), where the cellwise constant discretization for the control variable is employed. Moreover, let*

Assumption 1 be fulfilled and  $n < p \leq \infty$ . Then, it holds that

$$\begin{aligned} \|R_d \bar{q}_k - \bar{q}_\sigma\|_I &\leq \frac{C}{\alpha} h^2 \left\{ \|\nabla^2 u_k(\bar{q}_k)\|_I + \frac{1}{\alpha} \|\nabla z_k(\bar{q}_k)\|_I + \left(1 + \frac{1}{\alpha}\right) \|\nabla^2 z_k(\bar{q}_k)\|_I \right\} \\ &\quad + \frac{C}{\alpha^2} h^{2-\frac{1}{p}} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))}, \end{aligned}$$

provided that  $z_k(\bar{q}_k) \in L^2(I, W^{1,p}(\Omega))$ .

*Proof.* As before, we proceed with an arbitrary  $p \in Q$ ,

$$\begin{aligned} \alpha \|R_d \bar{q}_k - \bar{q}_\sigma\|_I^2 &\leq j''_{kh}(p)(R_d \bar{q}_k - \bar{q}_\sigma, R_d \bar{q}_k - \bar{q}_\sigma) \\ &= j'_{kh}(R_d \bar{q}_k)(R_d \bar{q}_k - \bar{q}_\sigma) - j'_{kh}(\bar{q}_\sigma)(R_d \bar{q}_k - \bar{q}_\sigma). \end{aligned}$$

By means of the inequality

$$-j'_{kh}(\bar{q}_\sigma)(R_d \bar{q}_k - \bar{q}_\sigma) \leq 0 \leq -(\alpha R_d \bar{q}_k + R_d z_k(\bar{q}_k), R_d \bar{q}_k - \bar{q}_\sigma)_I,$$

which is implied by the optimality of  $\bar{q}_\sigma$  and Lemma 5.14, and by means of the explicit representation of  $j'_{kh}$  from (3.13), we obtain

$$\begin{aligned} \alpha \|R_d \bar{q}_k - \bar{q}_\sigma\|_I^2 &\leq (z_{kh}(R_d \bar{q}_k) - R_d z_k(\bar{q}_k), R_d \bar{q}_k - \bar{q}_\sigma)_I \\ (5.16) \quad &\leq (z_{kh}(R_d \bar{q}_k) - z_k(\bar{q}_k), R_d \bar{q}_k - \bar{q}_\sigma)_I \\ &\quad + (z_k(\bar{q}_k) - R_d z_k(\bar{q}_k), R_d \bar{q}_k - \bar{q}_\sigma)_I. \end{aligned}$$

For the first term on the right-hand side of (5.16), we have by Cauchy's inequality,

$$(z_{kh}(R_d \bar{q}_k) - z_k(\bar{q}_k), R_d \bar{q}_k - \bar{q}_\sigma)_I \leq \|z_{kh}(R_d \bar{q}_k) - z_k(\bar{q}_k)\|_I \|R_d \bar{q}_k - \bar{q}_\sigma\|_I.$$

By insertion of  $z_{kh}(\bar{q}_k)$ , the term  $\|z_{kh}(R_d \bar{q}_k) - z_k(\bar{q}_k)\|_I$  is further estimated as

$$(5.17) \quad \|z_{kh}(R_d \bar{q}_k) - z_k(\bar{q}_k)\|_I \leq \|z_{kh}(R_d \bar{q}_k) - z_{kh}(\bar{q}_k)\|_I + \|z_{kh}(\bar{q}_k) - z_k(\bar{q}_k)\|_I.$$

Due to the stability estimate of the fully discrete adjoint solution (see Proposition 4.2), the first term is bounded by

$$(5.18) \quad \|z_{kh}(R_d \bar{q}_k) - z_{kh}(\bar{q}_k)\|_I \leq C \|u_{kh}(R_d \bar{q}_k) - u_{kh}(\bar{q}_k)\|_I.$$

Further, we have by means of the discrete state equation (3.10) and the discrete adjoint equation (3.14),

$$\|u_{kh}(R_d \bar{q}_k) - u_{kh}(\bar{q}_k)\|_I^2 = (z_{kh}(\bar{q}_k) - z_{kh}(R_d \bar{q}_k), \bar{q}_k - R_d \bar{q}_k)_I.$$

With  $\psi_{kh} = z_{kh}(\bar{q}_k) - z_{kh}(R_d \bar{q}_k)$  in Lemma 5.15, we have

$$\begin{aligned} \|u_{kh}(R_d \bar{q}_k) - u_{kh}(\bar{q}_k)\|_I^2 &\leq \frac{C}{\alpha} h^2 \left\{ \|\nabla(z_{kh}(\bar{q}_k) - z_{kh}(R_d \bar{q}_k))\|_I \|\nabla z_k(\bar{q}_k)\|_I \right. \\ &\quad \left. + \|z_{kh}(\bar{q}_k) - z_{kh}(R_d \bar{q}_k)\|_{L^2(I, L^\infty(\Omega))} \|\nabla^2 z_k(\bar{q}_k)\|_I \right\} \\ &\quad + \frac{C}{\alpha} h^{2-\frac{1}{p}} \|z_{kh}(\bar{q}_k) - z_{kh}(R_d \bar{q}_k)\|_{L^2(I, L^\infty(\Omega))} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))}, \end{aligned}$$

and the stability estimates from Proposition 4.2 and Lemma 4.5,

$$\begin{aligned}\|\nabla(z_{kh}(q_k) - z_{kh}(R_d q_k))\|_I &\leq C\|u_{kh}(R_d q_k) - u_{kh}(q_k)\|_I, \\ \|z_{kh}(q_k) - z_{kh}(R_d q_k)\|_{L^2(I, L^\infty(\Omega))} &\leq C\|u_{kh}(R_d q_k) - u_{kh}(q_k)\|_I,\end{aligned}$$

yield the following intermediary result:

$$\begin{aligned}\|u_{kh}(R_d \bar{q}_k) - u_{kh}(\bar{q}_k)\|_I &\leq \frac{C}{\alpha} h^2 \{ \|\nabla z_k(\bar{q}_k)\|_I + \|\nabla^2 z_k(\bar{q}_k)\|_I \} \\ &\quad + \frac{C}{\alpha} h^{2-\frac{1}{p}} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))}.\end{aligned}$$

We proceed by inserting this in (5.18) and in (5.17). Together with an estimate for the second term on the right-hand side of (5.17) from Proposition 4.4, this leads to

$$\begin{aligned}(5.19) \quad \|z_{kh}(R_d \bar{q}_k) - z_k(\bar{q}_k)\|_I &\leq C h^2 \left\{ \|\nabla^2 u_k(\bar{q}_k)\|_I + \frac{1}{\alpha} \|\nabla z_k(\bar{q}_k)\|_I \right. \\ &\quad \left. + \left(1 + \frac{1}{\alpha}\right) \|\nabla^2 z_k(\bar{q}_k)\|_I \right\} + \frac{C}{\alpha} h^{2-\frac{1}{p}} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))}.\end{aligned}$$

By applying Lemma 5.13 with  $p_d = R_d \bar{q}_k - \bar{q}_\sigma$  to the second term on the right-hand side of (5.16), we get

$$(z_k(\bar{q}_k) - R_d z_k(\bar{q}_k), R_d \bar{q}_k - \bar{q}_\sigma)_I \leq C h^2 \|R_d \bar{q}_k - \bar{q}_\sigma\|_I \|\nabla^2 z_k(\bar{q}_k)\|_I.$$

The asserted result is obtained by insertion of the last two estimates into (5.16).  $\square$

Based on this theorem, we state the main result of this section concerning the order of convergence of the error between  $\bar{q}$  and  $\tilde{q}_\sigma$ , where  $\tilde{q}_\sigma$  is defined using the postprocessing step (3.18).

**COROLLARY 5.17.** *Let the conditions of Theorem 5.16 be fulfilled. Then, there holds*

$$\begin{aligned}\|\bar{q} - \tilde{q}_\sigma\|_I &\leq \frac{C}{\alpha} \left(1 + \frac{1}{\alpha}\right) k \{ \|\partial_t u(\bar{q})\|_I + \|\partial_t z(\bar{q})\|_I \} \\ &\quad + \frac{C}{\alpha} \left(1 + \frac{1}{\alpha}\right) h^2 \left\{ \|\nabla^2 u_k(\bar{q}_k)\|_I + \frac{1}{\alpha} \|\nabla z_k(\bar{q}_k)\|_I + \left(1 + \frac{1}{\alpha}\right) \|\nabla^2 z_k(\bar{q}_k)\|_I \right\} \\ &\quad + \frac{C}{\alpha^2} \left(1 + \frac{1}{\alpha}\right) h^{2-\frac{1}{p}} \|\nabla z_k(\bar{q}_k)\|_{L^2(I, L^p(\Omega))} = \mathcal{O}(k + h^{2-\frac{1}{p}}).\end{aligned}$$

*Proof.* From the optimality condition (2.9) and the definition (3.18) of  $\tilde{q}_\sigma$  we have the representation

$$\|\bar{q} - \tilde{q}_\sigma\|_I = \left\| P_{Q_{\text{ad}}} \left( -\frac{1}{\alpha} z(\bar{q}) \right) - P_{Q_{\text{ad}}} \left( -\frac{1}{\alpha} z_{kh}(\bar{q}_\sigma) \right) \right\|_I.$$

By means of the Lipschitz continuity of  $P_{Q_{\text{ad}}}$  on  $L^2(I, L^2(\Omega))$ , this leads to

$$(5.20) \quad \alpha \|\bar{q} - \tilde{q}_\sigma\|_I \leq \|z(\bar{q}) - z_{kh}(\bar{q}_\sigma)\|_I \leq \|z(\bar{q}) - z_k(\bar{q}_k)\|_I + \|z_k(\bar{q}_k) - z_{kh}(\bar{q}_\sigma)\|_I.$$

The first term is controlled by means of Proposition 4.1, Theorem 5.1, and Proposition 4.3 as

$$\begin{aligned}
 \|z(\bar{q}) - z_k(\bar{q}_k)\|_I &\leq \|z(\bar{q}) - z_k(\bar{q})\|_I + \|z_k(\bar{q}) - z_k(\bar{q}_k)\|_I \\
 &\leq \|z(\bar{q}) - z_k(\bar{q})\|_I + C\|u_k(\bar{q}) - u_k(\bar{q}_k)\|_I \\
 &\leq \|z(\bar{q}) - z_k(\bar{q})\|_I + C\|\bar{q} - \bar{q}_k\|_I \\
 &\leq \left(1 + \frac{C}{\alpha}\right) \|z(\bar{q}) - z_k(\bar{q})\|_I \\
 &\leq C\left(1 + \frac{1}{\alpha}\right) k\{\|\partial_t u(\bar{q})\|_I + \|\partial_t z(\bar{q})\|_I\}.
 \end{aligned}$$

The second term can be estimated by means of the stability result of Proposition 4.2 as

$$\begin{aligned}
 \|z_k(\bar{q}_k) - z_{kh}(\bar{q}_\sigma)\|_I &\leq \|z_k(\bar{q}_k) - z_{kh}(R_d \bar{q}_k)\|_I + \|z_{kh}(R_d \bar{q}_k) - z_{kh}(\bar{q}_\sigma)\|_I \\
 &\leq \|z_k(\bar{q}_k) - z_{kh}(R_d \bar{q}_k)\|_I + C\|u_{kh}(R_d \bar{q}_k) - u_{kh}(\bar{q}_\sigma)\|_I \\
 &\leq \|z_k(\bar{q}_k) - z_{kh}(R_d \bar{q}_k)\|_I + C\|R_d \bar{q}_k - \bar{q}_\sigma\|_I.
 \end{aligned}$$

Inserting the two last inequalities into (5.20) and applying the estimates from (5.19) and Theorem 5.16 yield the stated assertion.  $\square$

The choice of  $p$  in Corollary 5.17 follows the description in section 5.2 requiring  $z_k(\bar{q}_k) \in L^2(I, W^{1,p}(\Omega))$ . Due to the fact that  $\|z_k(\bar{q}_k)\|_{L^2(I, H^2(\Omega))}$  is bounded independently of  $k$ , the result in Corollary 5.17 holds for any  $n < p < \infty$  in the two dimensional case, leading to the order of convergence  $\mathcal{O}(k + h^{2-\frac{1}{p}})$ . In the three dimensional case we obtain  $p = 6$  and therefore  $\mathcal{O}(k + h^{\frac{11}{6}})$ . If in addition  $\|z_k(\bar{q}_k)\|_{L^2(I, W^{1,\infty}(\Omega))}$  is bounded, then we have in both cases the order of convergence  $\mathcal{O}(k + h^2)$ .

**6. Numerical results.** In this section, we are going to validate the a priori error estimates for the error in the control, state, and adjoint state numerically. To this end, we consider the following concretion of the optimal control problem (2.2) with known exact solution on  $\Omega \times I = (0, 1)^2 \times (0, 0.1)$  and homogeneous Dirichlet boundary conditions. According to the first part of this article [20], the right-hand side  $f$ , the desired state  $\hat{u}$ , and the initial condition  $u_0$  are given in terms of the eigenfunctions

$$w_a(t, x_1, x_2) := \exp(a\pi^2 t) \sin(\pi x_1) \sin(\pi x_2), \quad a \in \mathbb{R},$$

of the operator  $\pm \partial_t - \Delta$  as

$$\begin{aligned}
 f(t, x_1, x_2) &:= -\pi^4 w_a(t, x_1, x_2) - P_{Q_{\text{ad}}}(-\pi^4 \{w_a(t, x_1, x_2) - w_a(T, x_1, x_2)\}), \\
 \hat{u}(t, x_1, x_2) &:= \frac{a^2 - 5}{2 + a} \pi^2 w_a(t, x_1, x_2) + 2\pi^2 w_a(T, x_1, x_2), \\
 u_0(x_1, x_2) &:= \frac{-1}{2 + a} \pi^2 w_a(0, x_1, x_2),
 \end{aligned}$$

with  $P_{Q_{\text{ad}}}$  given by (2.8) with  $q_a = -70$  and  $q_b = -1$ . For this choice of data and with the regularization parameter  $\alpha$  chosen as  $\alpha = \pi^{-4}$ , the optimal solution triple

$(\bar{q}, \bar{u}, \bar{z})$  of the optimal control problem (2.2) is given by

$$\bar{q}(t, x_1, x_2) := P_{Q_{\text{ad}}}(-\pi^4\{w_a(t, x_1, x_2) - w_a(T, x_1, x_2)\}),$$

$$\bar{u}(t, x_1, x_2) := \frac{-1}{2+a}\pi^2 w_a(t, x_1, x_2),$$

$$\bar{z}(t, x_1, x_2) := w_a(t, x_1, x_2) - w_a(T, x_1, x_2).$$

We are going to validate the estimates developed in the previous section by separating the discretization errors. That is, we consider at first the behavior of the error for a sequence of discretizations with decreasing size of the time steps and a fixed spatial triangulation with  $N = 1089$  nodes. Second, we examine the behavior of the error under refinement of the spatial triangulation for  $M = 2048$  time steps.

The state discretization is chosen as cG(1)dG(0), i.e.,  $r = 0, s = 1$ . For the control discretization we use the same temporal and spatial meshes as for the state variable and present results for two choices of the discrete control space  $Q_a$ : cG(1)dG(0) and dG(0)dG(0). For the following computations, we choose the free parameter  $a$  to be  $-\sqrt{5}$ .

The optimal control problems are solved by the optimization library RoDoBo [22] and the finite element toolkit GASCOIGNE [11] using a primal-dual active set strategy (cf. [3, 14]) in combination with a conjugate gradient method applied to the reduced problem (3.16).

Figure 6.1(a) depicts the development of the error under refinement of the temporal step size  $k$ . Up to the spatial discretization error it exhibits the proven convergence order  $\mathcal{O}(k)$  for both kinds of spatial discretization of the control space.

(a) Refinement of the time steps for  $N = 1089$  spatial nodes.

(b) Refinement of the spatial triangulation for  $M = 2048$  time steps.

FIG. 6.1. Discretization error  $\|\bar{q} - \bar{q}_\sigma\|_I$ .

FIG. 6.2. Discretization error  $\|\bar{u} - \bar{u}_\sigma\|_I$ .FIG. 6.3. Discretization error  $\|\bar{z} - \bar{z}_\sigma\|_I$ .

For piecewise constant control (dG(0)dG(0) discretization), the discretization error is already reached at 128 time steps, whereas in the case of bilinear control (cG(1)dG(0) discretization), the number of time steps could be increased up to  $M = 1024$  until reaching the spatial accuracy. This illustrates the convergence results from sections 5.1 and 5.2 with respect to the *temporal* discretization.

In Figure 6.1(b) the development of the error in the control variable under spatial refinement is shown. The expected order  $\mathcal{O}(h)$  for piecewise constant control (dG(0)dG(0) discretization) and  $\mathcal{O}(h^{\frac{3}{2}})$  for bilinear control (cG(1)dG(0) discretization) are observed. This illustrates the convergence results from sections 5.1 and 5.2 with respect to the *spatial* discretization.

Figures 6.2 and 6.3 show the errors in the state and in the adjoint variables,  $\|\bar{u} - \bar{u}_\sigma\|_I$  and  $\|\bar{z} - \bar{z}_\sigma\|_I$ , for separate refinement of the time and space discretization. Thereby, we observe convergence of order  $\mathcal{O}(k + h^2)$  regardless of the type of spatial discretization used for the controls. This is consistent with the results proved in the previous section. Since the postprocessing strategy presented in section 5.4 relies essentially on the convergence properties of the adjoint variable, Figure 6.3 confirms the proven order of convergence of the error  $\|\bar{q} - \bar{q}_\sigma\|_I$ .

## OPTIMAL TRANSPORTATION WITH TRAFFIC CONGESTION AND WARDROP EQUILIBRIA\*

G. CARLIER<sup>†</sup>, C. JIMENEZ<sup>†</sup>, AND F. SANTAMBROGIO<sup>‡</sup>

**Abstract.** In the classical Monge–Kantorovich problem, the transportation cost depends only on the amount of mass sent from sources to destinations and not on the paths followed by this mass. Thus, it does not allow for congestion effects. Using the notion of traffic intensity, we propose a variant, taking into account congestion. This variant is a continuous version of a well-known traffic problem on networks that is studied both in economics and in operational research. The interest of this problem is in its relations with traffic equilibria of Wardrop type. What we prove in the paper is exactly the existence and the variational characterization of equilibria in a continuous space setting.

**Key words.** optimal transportation, traffic congestion, Wardrop equilibria

**AMS subject classifications.** 90C46, 91A13

**DOI.** 10.1137/060672832

**1. Introduction.** Researchers in the field of applied traffic modeling have long emphasized the role of congestion in networks. In the early 1950s, Wardrop (see [14]) considered the situation where a large number of vehicles have to go from one location to another, connected by a finite number of different roads. Each vehicle has to choose one road (or a probability on the set of possible roads) to minimize some transportation cost which depends not only on the road chosen but also on the total flow of vehicles on this road. Some roads may be better than others, for instance, because they are shorter or wider, but they are all affected by congestion effects: the “cost” (in terms of time, say) for a vehicle of following a road depends increasingly on the total number of vehicles that choose to use it. Wardrop gave a minimal stability requirement for transportation strategies: the cost of every actually used road should be less than or equal to that which would be experienced by a single vehicle on any other road. In particular, there is an equilibrium concept (all actually used roads have the same cost, i.e., they compensate in terms of congestion for their differences given by length and other conditions) and a minimality concept as well (those roads are minimal among all the possible ones). This natural equilibrium concept has been very popular since its introduction because of its applications to networks, of course, but also due to the development of noncooperative game theory. To the best of our knowledge, the study of Wardrop equilibria has mainly been restricted to the case where admissible roads are given by a finite graph. In the present paper our main goal is to introduce Wardrop’s concepts in a continuous state setting, to prove the existence of such equilibria, and to relate it to the optimal transportation problem with congestion (Theorem 4.2).

The key point of the discrete theory about Wardrop equilibria is the fact that such an equilibrium problem may be linked to a variational one (see, for instance, [2] and the references therein). Suppose the cost for a road  $\sigma$  is given by  $\int_{\sigma} g(i)$ ,

---

where  $i$  denotes the traffic intensity along the road (it can be nonconstant, since at branching points of different roads, the traffic splits according to Kirchhoff's law) where  $g \geq 0$  is an increasing function modeling congestion effects. We may say that  $g(i)$  is the cost per unit length for a road where the traffic intensity is  $i$ . It is known that looking for an equilibrium is equivalent to solving a minimization problem with total congestion cost  $\int_N H(i)$ , where  $N$  represents the whole network and  $H$  is another increasing function which is linked to  $g$ . The relation which is necessary to ensure that minima of the variational problem coincide with solutions of the equilibrium one is  $H' = g$ . Notice that solving this problem does not amount, in general, to finding the configuration which minimizes the total cost paid by vehicles, since this quantity is represented instead by the integral  $\int_N ig(i)$ . The two functions  $H(i)$  and  $ig(i)$  are the same up to multiplicative constants in the case of power functions, but otherwise they give rise to different optimization problems.

The unknown, both in the equilibrium and in the optimization problems, is the distribution of vehicles along the possible paths. In a continuous-setting language, this is a measure on the set of paths. The constraints on such a measure are given by the data: usually the total amount of vehicles commuting from a point  $x$  to a point  $y$  of the network is prescribed for every pair  $(x, y)$ . This corresponds to fixing a measure  $\gamma$  on the set of sources-destinations pairs. As a possible alternative, one could prescribe the total quantity of vehicles leaving  $x$  and the total quantity reaching  $y$ , and look at all possible couplings between these "boundary data." In this case, the fixed data are two measures  $\mu_0$  and  $\mu_1$  modeling the distribution of sources and destinations separately. Also the coupling or *transport plan*  $\gamma$  (i.e., a measure on the sources-destinations space whose projections on the two coordinates are  $\mu_0$  and  $\mu_1$ ) is part of the unknowns.

In the present paper, we introduce a variational problem in a continuous setting, i.e., when the data on sources and destinations are arbitrary probability measures on a domain  $\Omega \subset \mathbb{R}^2$  and the allowed paths are all possible Lipschitz curves connecting points of  $\Omega$ . In this problem, the functional is built as a total cost arising from the congested transport problem. This means that we start from a congestion function  $g$  and we look at a minimization problem involving the function  $i \mapsto H(i) = ig(i)$ . Obviously, the concept of traffic intensity associated to a probability measure on a suitable set of paths has to be carefully defined in the continuous framework, which we do in section 2.2. The definition of traffic intensity we provide is the path-dependent analogue of the well-known notion of *transport density* in Monge's problem (see Bouchitté, Buttazzo, and Seppecher [4], Bouchitté and Buttazzo [3], Caffarelli, Feldman, and McCann [7]).

After defining the cost and the constraint, we may forget about the origin of the function  $H$  and, as in the discrete case, look at the minimization problem: we are concerned with existence, finiteness of the minimum value, and optimality conditions. Interestingly, in the continuous case, this variational problem takes the form of a *path-dependent* optimal transportation problem.

We show, under some extra assumptions on  $H$ , that solutions of the variational problem exist and are characterized by two optimality conditions. One of them is nothing but the continuous counterpart of Wardrop equilibria: the quantity  $H'(i) \geq 0$  defines a metric on  $\Omega$  and the paths that are actually used must be geodesics for this metric. The other optimality condition is peculiar to the case of nonfixed couplings and is much more linked to Monge–Kantorovich optimal transport theory (which can be traced back to Monge [12]; see [1], [5], and [13] for a modern account of the theory). In fact, once a solution is found, we can call  $c(x, y)$  the minimal cost for commuting

from  $x$  to  $y$ , according to the previously mentioned metric  $H'(i)$ . It turns out that, for an optimal solution,  $\gamma$  solves the optimal transport problem between  $\mu_0$  and  $\mu_1$  with respect to the cost  $c$ . The case of a nonfixed transport plan is the one which is developed in this paper because it is the richest case from a mathematical point of view. Moreover, it allows for a direct comparison with optimal transport problems à la Monge and Kantorovich. A variant of the problem we study is the case where, instead of allowing any transport plan between  $\mu_0$  and  $\mu_1$ , we prescribe a given convex and compact subset of couplings compatible with the data. All of the results of this paper can be extended to such a variant, which includes the case of a single prescribed transport plan.

In the minimization problem we study, the functional is linked to a Monge transport cost, in the case of a nonuniform metric. It corresponds to a cost  $\int d(x, y) d\gamma(x, y)$ , where  $d$  is a distance which in this case is unknown as it depends on the traffic intensity itself. Other transportation costs, for instance, squared distances, are very important for the applications of the Monge–Kantorovich theory but are not directly linked to this equilibrium problem. Notice, however, that, from an individual point of view (i.e., the viewpoint of the equilibrium issue), minimizing the displacement cost or its square is the same.

The presentation of the model, the construction of the functional, and its links with the Monge–Kantorovich theory follow the discrete case in its generality. Yet, most of the results require some additional assumptions on the function  $H$ . In particular,  $H$  is required to behave like a power  $H(i) = i^q$  with  $1 < q < 2$ . This is needed both for technical and feasibility reasons. First, it ensures the validity of some crucial estimates giving continuity results, providing well-defined transport costs  $c(x, y)$ . Second, it turns out that if  $\gamma$  is discrete (i.e., any path is allowed but the set of sources and destinations is finite), then the condition for having a finite minimal cost is exactly  $q < 2$ . Moreover, if we come back to the congestion function  $g$ , then this condition on  $H$  corresponds to  $g$  behaving like a concave power  $i^{q-1}$ , which is very natural from an economic point of view.

## 2. Optimal transportation with congestion.

**2.1. Notation.** Given a Polish (i.e., metrizable, separable, and complete) space  $X$ , we will denote, respectively, by  $\mathcal{M}_+(X)$  and  $\mathcal{M}_+^1(X)$  the set of positive and finite Radon measures on  $X$  and the set of Radon probability measures on  $X$ . If  $X$  and  $Y$  are Polish spaces,  $\mu \in \mathcal{M}_+^1(X)$ , and  $f : X \rightarrow Y$  is a Borel map, we shall denote by  $f\#\mu$  the push forward of  $\mu$  through  $f$ , i.e., the element of  $\mathcal{M}_+^1(Y)$  defined by  $f\#\mu(B) = \mu(f^{-1}(B))$  for every Borel subset  $B$  of  $Y$ .

In what follows,  $\mathcal{L}^d$  denotes the  $d$ -dimensional Lebesgue measure. If  $\mu$  and  $\nu$  are in  $\mathcal{M}_+^1(\mathbb{R}^d)$ , then  $\frac{d\mu}{d\nu}$  denotes the Radon–Nikodym derivative of  $\mu$  with respect to  $\nu$ . We shall write  $\mu \ll \nu$  to express that  $\mu$  is absolutely continuous with respect to  $\nu$ , in which case, slightly abusing notation, we will identify  $\mu$  with the Radon–Nikodym derivative  $\frac{d\mu}{d\nu}$ .

The data of our problem are  $\Omega$  (its closure  $\overline{\Omega}$  modeling the city, say), which is some open bounded convex subset of  $\mathbb{R}^2$ , and two probability measures  $\mu_0$  and  $\mu_1$  in  $\mathcal{M}_+^1(\overline{\Omega})$  giving, respectively, the distribution of residents and services in the city  $\overline{\Omega}$ . The set of transportation plans associated to  $\mu_0$  and  $\mu_1$  will be denoted  $\Pi(\mu_0, \mu_1)$  and consists of the probability measures on  $\overline{\Omega} \times \overline{\Omega}$  having  $\mu_0$  and  $\mu_1$  as marginals:

$$(2.1) \quad \Pi(\mu_0, \mu_1) := \{\gamma \in \mathcal{M}_+^1(\overline{\Omega} \times \overline{\Omega}) : \pi_0\#\gamma = \mu_0, \pi_1\#\gamma = \mu_1\},$$

where  $(\pi_0(x, y), \pi_1(x, y)) := (x, y)$  stand for the canonical projections ( $x$  and  $y$  in  $\overline{\Omega}$ ).

Introducing congestion naturally leads us to consider spaces of paths, lengths of such paths, and sets of probability measures on sets of paths. From now on, we shall denote the following:

- $C := W^{1,\infty}([0, 1], \overline{\Omega})$ , viewed as a subset of  $C^0([0, 1], \mathbb{R}^2)$ , i.e., equipped with the uniform topology;
- $C^{x,y} := \{\sigma \in C : \sigma(0) = x, \sigma(1) = y\}$  ( $x, y$  in  $\overline{\Omega}$ );
- $l(\sigma) := \int_0^1 |\dot{\sigma}(t)| dt$ , the length of  $\sigma \in C$ ;
- for  $\sigma \in C$ ,  $\tilde{\sigma}$  denotes the constant speed reparameterization of  $\sigma$  belonging to  $C$ , and hence  $|\dot{\tilde{\sigma}}(t)| = l(\sigma) = l(\tilde{\sigma})$  for a.e.  $t \in [0, 1]$ ;
- $\tilde{C} := \{\sigma \in C : |\dot{\sigma}| \text{ is constant}\} = \{\tilde{\sigma}, \sigma \in C\}$ ;
- slightly abusing notation, we will denote  $Q \in \mathcal{M}_+^1(C)$ , whenever  $Q \in \mathcal{M}_+^1(C^0([0, 1], \mathbb{R}^2))$  and  $Q(C) = 1$ ;
- for  $Q \in \mathcal{M}_+^1(C)$ , we define  $\tilde{Q} \in \mathcal{M}_+^1(\tilde{C})$  as the push forward of  $Q$  through the map  $\sigma \mapsto \tilde{\sigma}$ ;
- for  $\varphi \in C^0(\overline{\Omega}, \mathbb{R})$  and  $\sigma \in C$ , we define

$$L_\varphi(\sigma) := \int_0^1 \varphi(\sigma(t)) |\dot{\sigma}(t)| dt = l(\sigma) \int_0^1 \varphi(\tilde{\sigma}(t)) dt;$$

- $e_0(\sigma) := \sigma(0)$ ,  $e_1(\sigma) := \sigma(1)$  for all  $\sigma \in C^0([0, 1], \mathbb{R}^2)$ .

**2.2. Traffic congestion modeling.** The classical Monge–Kantorovich optimal transportation problem for a given cost function  $c \in C^0(\overline{\Omega} \times \overline{\Omega}, \mathbb{R})$  is

$$(2.2) \quad \inf \left\{ \int_{\overline{\Omega} \times \overline{\Omega}} c(x, y) d\gamma(x, y) : \gamma \in \Pi(\mu_0, \mu_1) \right\}.$$

Note that, in the linear problem (2.2), the cost of transporting one unit of mass from  $x$  to  $y$ ,  $c(x, y)$ , is given and does not depend on the path(s) followed by the mass from  $x$  to  $y$ . In order to take into account congestion effects, we explicitly introduce probabilities over  $C^{x,y}$  as part of the optimization problem. More precisely, the overall transportation cost will depend not only on the transportation plan  $\gamma \in \Pi(\mu_0, \mu_1)$  but also on the way travelers commuting from  $x$  to  $y$  use the different possible paths  $\sigma \in C^{x,y}$ . In what follows, the way commuters from  $x$  to  $y$  are split according to the different paths will be given by a probability measure  $p^{x,y}$  on  $C^{x,y}$ . Put differently,  $p^{x,y}(\Sigma)$  is the proportion of travelers from  $x$  to  $y$  using a path  $\sigma \in \Sigma \subset C^{x,y}$ . This naturally leads to the following definition.

**DEFINITION 2.1.** A transportation strategy consists of a pair  $(\gamma, p)$  with  $\gamma \in \Pi(\mu_0, \mu_1)$  and where  $p = (p^{x,y})_{(x,y) \in \overline{\Omega} \times \overline{\Omega}}$  is a Borel family of probability measures on  $C$  (i.e.,  $(x, y) \rightarrow \int_C F(\sigma) dp^{x,y}(\sigma)$  is Borel for every bounded Borel function  $F: C \rightarrow \mathbb{R}$ ) such that  $p^{x,y}(C^{x,y}) = 1$  for  $\gamma$ -a.e.  $(x, y) \in \overline{\Omega} \times \overline{\Omega}$ .

Thanks to Lemma 2.7 proved below, for every  $\varphi \in C^0(\overline{\Omega}, \mathbb{R}_+)$ , the map  $\sigma \rightarrow L_\varphi(\sigma)$  is l.s.c., and hence Borel on  $C$  (equipped with the uniform topology). For  $Q \in \mathcal{M}_+^1(C)$  one can therefore define  $\int_C L_\varphi(\sigma) dQ(\sigma)$  and this integral is finite for every  $\varphi \in C^0(\overline{\Omega}, \mathbb{R}_+)$  whenever  $\int_C l(\sigma) dQ(\sigma) < +\infty$ , i.e., the average for the probability  $Q$  length is finite. Hence, there results, from the use of a transportation strategy  $(\gamma, p)$ ,

an overall *traffic intensity*  $I_{\gamma,p} \in \mathcal{M}_+(\overline{\Omega})$  defined by

$$\begin{aligned} \int_{\overline{\Omega}} \varphi(x) dI_{\gamma,p}(x) &:= \int_{\overline{\Omega} \times \overline{\Omega}} \left( \int_{C^{x,y}} \left( \int_0^1 \varphi(\sigma(t)) |\dot{\sigma}(t)| dt \right) dp^{x,y}(\sigma) \right) d\gamma(x, y) \\ &= \int_{\overline{\Omega} \times \overline{\Omega}} \left( \int_{C^{x,y}} L_{\varphi}(\sigma) dp^{x,y}(\sigma) \right) d\gamma(x, y) \quad \forall \varphi \in C^0(\overline{\Omega}, \mathbb{R}_+) \end{aligned} \quad (2.3)$$

and an overall probability over paths  $Q_{\gamma,p} \in \mathcal{M}_+^1(C)$  given by  $Q_{\gamma,p} = p^{x,y} \otimes \gamma$ , i.e.,

$$(2.4) \quad \int_C F(\sigma) dQ_{\gamma,p}(\sigma) = \int_{\overline{\Omega} \times \overline{\Omega}} \left( \int_{C^{x,y}} F(\sigma) dp^{x,y}(\sigma) \right) d\gamma(x, y) \quad \forall F \in C^0(C, \mathbb{R}).$$

One could consider the probability  $Q_{\gamma,p}$  as if it represented the total number of travelers that use a path  $\sigma \in \Sigma$  given the global transportation strategy  $(\gamma, p)$ .

Let us remark that if we set  $Q := Q_{\gamma,p} \in \mathcal{M}_+^1(C)$ , then  $I_{\gamma,p}$  depends only on  $Q$  and can be written as  $I_{\gamma,p} = i_Q \in \mathcal{M}_+(\overline{\Omega})$ , where  $i_Q$  is defined for every  $Q \in \mathcal{M}_+^1(C)$  by

$$(2.5) \quad \int_{\overline{\Omega}} \varphi(x) di_Q(x) = \int_C L_{\varphi}(\sigma) dQ(\sigma) \quad \forall \varphi \in C^0(\overline{\Omega}, \mathbb{R}_+).$$

Let us also remark that since  $L_{\varphi}(\sigma) = L_{\varphi}(\tilde{\sigma})$ , one has  $i_Q = i_{\tilde{Q}}$ , for all  $Q \in \mathcal{M}_+^1(C)$ . Finally, let us note that the total mass of  $i_Q$  is the average length with respect to  $Q$ :

$$(2.6) \quad i_Q(\overline{\Omega}) = \int_C l(\sigma) dQ(\sigma).$$

If the probability  $Q$  is concentrated on injective curves, one can also express the measure  $i_Q$  through  $\mathcal{H}^1$ -integrals as explained in the next remark.

*Remark 2.2.* If a curve  $\sigma$  is injective, then one could also write  $l(\sigma) = \mathcal{H}^1(\sigma([0, 1]))$  and  $L_{\varphi}(\sigma) = \int_{\sigma([0,1])} \varphi d\mathcal{H}^1$ . Moreover, if for  $\gamma$ -a.e.  $(x, y)$  the probability  $p^{x,y}$  is concentrated on the set of injective curves from  $x$  to  $y$ , one could also define the measure  $I_{\gamma,p}$  by replacing the integral with respect to  $|\dot{\sigma}(t)|dt$  in (2.3) with an integral in  $d\mathcal{H}^1$ . Notice, moreover, that for every Borel subset  $A \subset \overline{\Omega}$  one would have

$$I_{\gamma,p}(A) = \int_{\overline{\Omega} \times \overline{\Omega}} \left( \int_{C^{x,y}} \mathcal{H}^1(A \cap \sigma) dp^{x,y}(\sigma) \right) d\gamma(x, y) = \int_C \mathcal{H}^1(A \cap \sigma) dQ_{\gamma,p}(\sigma).$$

If we imagine that, for each  $\sigma \in C^{x,y}$ , the mass of travelers commuting on  $\sigma$  is uniformly distributed on  $\sigma$ , this means that  $I_{\gamma,p}(A)$  represents the cumulative traffic through the region  $A$ . The same formula remains true, under no injectivity assumption, if we replace  $\mathcal{H}^1(A \cap \sigma)$  with  $L_{\mathbf{1}_A}(\sigma)$ , and in this case the cumulative traffic takes into account the number of times a path  $\sigma$  passes through the points of  $A$ .

In what follows, it will be convenient to formulate our optimization problem in terms of  $Q = Q_{\gamma,p}$  rather than in the transportation strategy  $(\gamma, p)$ . To that end, we shall use the following.

LEMMA 2.3. *Let us define*

$$\mathcal{Q}(\mu_0, \mu_1) := \{Q_{\gamma,p} : (\gamma, p) \text{ transportation strategy}\};$$

*then one has*

$$\mathcal{Q}(\mu_0, \mu_1) = \{Q \in \mathcal{M}_+^1(C) : e_0 \# Q = \mu_0, e_1 \# Q = \mu_1\}.$$

*Proof.* If  $(\gamma, p)$  is a transportation strategy, then  $e_0\#Q_{\gamma,p} = \pi_0\#\gamma = \mu_0$  and  $e_1\#Q_{\gamma,p} = \pi_1\#\gamma = \mu_1$ . Now let  $Q \in \mathcal{M}_+^1(C)$  be such that  $e_0\#Q = \mu_0$ ,  $e_1\#Q = \mu_1$ . If we define  $\gamma := (e_0, e_1)\#Q$ , we have  $\gamma \in \Pi(\mu_0, \mu_1)$ . It then follows from the disintegration theorem (see [9]) that there exists  $p = (p^{x,y})_{(x,y) \in \bar{\Omega} \times \bar{\Omega}}$ , a Borel family of probability measures on  $C$ , such that  $p^{x,y}(C^{x,y}) = 1$  for  $\gamma$ -a.e.  $(x, y) \in \bar{\Omega} \times \bar{\Omega}$  and  $Q = p^{x,y} \otimes \gamma$ . Hence  $Q = Q_{\gamma,p}$  for a transportation strategy  $(\gamma, p)$ .  $\square$

At this point, a natural way to model traffic congestion is, for a given transportation strategy  $(\gamma, p)$ , to consider that the transportation cost per unit of mass between  $x$  and  $y$  is given by

$$(2.7) \quad c_{\gamma,p}(x, y) = \int_{C^{x,y}} L_{G_{I_{\gamma,p}}}(\sigma) dp^{x,y}(\sigma),$$

where  $G_{I_{\gamma,p}}$  is a nonnegative function which depends (in a way that will be specified later) on the traffic intensity  $I_{\gamma,p}$ . The optimal transportation with traffic congestion then takes the form (to be compared with the usual Monge–Kantorovich problem (2.2))

$$(2.8) \quad \inf \left\{ \int_{\bar{\Omega} \times \bar{\Omega}} c_{\gamma,p}(x, y) d\gamma(x, y) : (\gamma, p) \text{ transportation strategy} \right\}.$$

Setting  $Q = Q_{\gamma,p}$  and using formally (2.5), we see that the total transportation cost in (2.8) can be rewritten as

$$\int_{\bar{\Omega} \times \bar{\Omega}} c_{\gamma,p}(x, y) d\gamma(x, y) = \int_C L_{G_{i_Q}}(\sigma) dQ(\sigma) = \int_{\bar{\Omega}} G_{i_Q}(x) di_Q(x).$$

Hence using Lemma 2.3, we can reformulate (2.8) in terms of  $Q$  only:

$$(2.9) \quad \inf \left\{ \int_{\bar{\Omega}} G_{i_Q}(x) di_Q(x) : Q \in \mathcal{Q}(\mu_0, \mu_1) \right\}.$$

Note that in the definition (2.7), it is required that  $G_{I_{\gamma,p}}$  is continuous (or at least l.s.c.), whereas the form (2.9) allows for more general forms of congestion through  $i \mapsto G_i$ . From now on, we assume that  $G$  has the following local form:

$$(2.10) \quad G_i(x) = g \left( \frac{di}{d\mathcal{L}^2}(x) \right),$$

where  $\frac{di}{d\mathcal{L}^2}$  is the Radon–Nikodym derivative of  $i$  with respect to the Lebesgue measure and  $g$  is a nondecreasing function  $\mathbb{R}_+ \rightarrow \mathbb{R}_+$  such that the function  $H$  defined by  $H(z) = zg(z)$  for all  $z \in \mathbb{R}_+$  is convex and superlinear (i.e.,  $\lim_{z \rightarrow +\infty} g(z) = +\infty$ ).

The optimization problem we shall study now then reads as

$$(2.11) \quad \inf_{Q \in \mathcal{Q}(\mu_0, \mu_1)} \mathcal{H}(i_Q), \text{ where } \mathcal{H}(i) = \begin{cases} \int_{\bar{\Omega}} H(i(x)) dx & \text{if } i \ll \mathcal{L}^2, \\ +\infty & \text{otherwise.} \end{cases}$$

In what follows, we shall say that a transportation strategy  $(\gamma, p)$  is optimal if  $Q_{\gamma,p}$  solves (2.11).

*Remark 2.4.* It will be clear in what follows that the probability  $Q_{\gamma,p}$  associated to an optimal transportation strategy  $(\gamma, p)$  will be concentrated on injective curves, so that the interpretation in terms of  $\mathcal{H}^1$ -integrals (see Remark 2.2) may apply.

**2.3. Existence of minimizers.** From now on, we make the following assumptions:

- $H$  is convex and nondecreasing on  $\mathbb{R}_+$  with  $H(0) = 0$ ;
- there exists  $q > 1$ , and positive constants  $a$  and  $b$  such that  $az^q \leq H(z) \leq b(z^q + 1)$  for all  $z \in \mathbb{R}_+$ ;
- $H$  is differentiable on  $\mathbb{R}_+$ , and there exists a positive constant  $c$  such that  $0 \leq H'(z) \leq c(z^{q-1} + 1)$ , for all  $z \in \mathbb{R}_+$ ;
- the set

$$(2.12) \quad \mathcal{Q}^q(\mu_0, \mu_1) := \{Q \in \mathcal{Q}(\mu_0, \mu_1) : i_Q \in L^q\}$$

is nonempty (in the definition of  $\mathcal{Q}^q(\mu_0, \mu_1)$ , we intend, of course, both  $i_Q \ll \mathcal{L}^2$  and  $\frac{di_Q}{d\mathcal{L}^2} \in L^q$ ).

These assumptions enable us to simply rewrite (2.11) as

$$(2.13) \quad \inf_{Q \in \mathcal{Q}^q(\mu_0, \mu_1)} \int_{\Omega} H(i_Q(x)) dx.$$

*Remark 2.5.* Let us discuss the assumption that  $\mathcal{Q}^q(\mu_0, \mu_1) \neq \emptyset$  which, at first glance, may seem difficult to check. In order to have the existence of a  $Q \in \mathcal{Q}(\mu_0, \mu_1)$  such that  $i_Q \in L^q$  it is sufficient that  $\mu_0$  and  $\mu_1$  are in  $L^q$ . This result, which is not obvious, follows from the regularity results of De Pascale and Pratelli (see [10] and [11]) who proved that  $L^q$  regularity of  $\mu_0$  and  $\mu_1$  implies that for  $\gamma$  solving the Monge–Kantorovich problem (2.2) with  $c(x, y) = |x - y|$  and  $p^{x,y} = \delta_{[x,y]}$  (the Dirac mass at the segment  $[x, y]$ ) for every  $x$  and  $y$  the corresponding traffic density  $I_{\gamma,p}$  is  $L^q$ .

*Remark 2.6.* It is not necessary, however, that  $\mu_0$  and  $\mu_1$  are absolutely continuous for the assumption to be satisfied. Indeed, in the discrete case, i.e., when  $\mu_0$  and  $\mu_1$  have finite support, one can easily prove that  $\mathcal{Q}^q(\mu_0, \mu_1) \neq \emptyset$  for every  $q \in (1, 2)$ . Finally, let us consider, for instance, the case where  $\overline{\Omega} = [0, 1]^2$  and  $\mu_0$  and  $\mu_1$  are, respectively, the one-dimensional Hausdorff measures of the segments  $[(0, 0), (0, 1)]$  and  $[(1, 0), (1, 1)]$ . If we define  $\gamma := (\text{id}, \text{id} + (1, 0))\# \mu_0$  and  $p^{x,y} = \delta_{[x,y]}$ , then a straightforward computation shows that  $I_{\gamma,p}$  is uniform on  $[0, 1]^2$ .

Under the assumptions above, we are going to prove that (2.13) admits a solution. The proof of existence involves some preliminary lemmas.

**LEMMA 2.7.** *For any  $\varphi \in C^0(\overline{\Omega}, \mathbb{R}_+)$ ,  $L_\varphi$  is l.s.c. on  $C$  for the uniform topology; indeed, for any  $\sigma \in C$ , one has*

$$(2.14) \quad L_\varphi(\sigma) = \sup \left\{ \sum_{i=1}^n \left( \inf_{[t_i, t_{i+1}]} (\varphi \circ \sigma) \right) |\sigma(t_{i+1}) - \sigma(t_i)| : \right. \\ \left. ([t_i, t_{i+1}])_i \text{ is a subdivision of } [0, 1] \right\}.$$

*Proof.* For any subdivision  $([t_i, t_{i+1}])_{i=1, \dots, n}$ , we have

$$\begin{aligned} L_\varphi(\sigma) &= \sum_{i=1}^n \int_{t_i}^{t_{i+1}} \varphi(\sigma(t)) |\dot{\sigma}(t)| \, dt \\ &\geq \sum_{i=1}^n \inf_{[t_i, t_{i+1}]} (\varphi \circ \sigma) \int_{t_i}^{t_{i+1}} |\dot{\sigma}(t)| \, dt \\ &\geq \sum_{i=1}^n \inf_{[t_i, t_{i+1}]} (\varphi \circ \sigma) |\sigma(t_{i+1}) - \sigma(t_i)|. \end{aligned}$$

Taking the supremum over all such divisions, we get

$$L_\varphi(\sigma) \geq \sup \left\{ \sum_{i=1}^n \inf_{[t_i, t_{i+1}]} (\varphi \circ \sigma) |\sigma(t_{i+1}) - \sigma(t_i)| : ([t_i, t_{i+1}])_i \text{ is a subdivision of } [0, 1] \right\}.$$

Let us prove the converse inequality. Let  $\varepsilon > 0$ ; since  $\varphi \circ \sigma$  is uniformly continuous, there is a  $\delta > 0$  such that

$$\forall t, t' \in [0, 1]^2, \quad (|t - t'| \leq \delta \Rightarrow |\varphi(\sigma(t)) - \varphi(\sigma(t'))| \leq \varepsilon).$$

For any subdivision  $([t_i, t_{i+1}])_{i=1, \dots, n}$  such that  $|t_i - t_{i+1}| \leq \delta$  for all  $i$ , we have

$$\begin{aligned} L_\varphi(\sigma) &\leq \sum_{i=1}^n \left( \inf_{[t_i, t_{i+1}]} (\varphi \circ \sigma) + \varepsilon \right) \int_{t_i}^{t_{i+1}} |\dot{\sigma}(t)| \, dt \\ &= \sum_{i=1}^n \left( \inf_{[t_i, t_{i+1}]} (\varphi \circ \sigma) + \varepsilon \right) \sup \left\{ \sum_j |\sigma(\tau_j) - \sigma(\tau_{j+1})| : \right. \\ &\quad \left. ([\tau_j, \tau_{j+1}])_j \text{ is a subdivision of } [t_i, t_{i+1}] \right\} \\ &\leq \sup \left\{ \sum_i \sum_j \left( \inf_{[\tau_j, \tau_{j+1}]} (\varphi \circ \sigma) + \varepsilon \right) |\sigma(\tau_j) - \sigma(\tau_{j+1})| : \right. \\ &\quad \left. ([\tau_j, \tau_{j+1}])_j \text{ is a subdivision of } [t_i, t_{i+1}] \right\} \\ &= \sup \left\{ \sum_{i=1}^n \left( \inf_{t \in [t_i, t_{i+1}]} (\varphi \circ \sigma) + \varepsilon \right) |\sigma(t_{i+1}) - \sigma(t_i)| : \right. \\ &\quad \left. ([t_i, t_{i+1}])_i \text{ is a subdivision of } [0, 1] \right\}. \end{aligned}$$

As this last inequality is true for any  $\varepsilon > 0$ , we get (2.14). The lower semicontinuity is then obvious since, by (2.14),  $L_\varphi$  is the supremum of the family of l.s.c. functions on  $C^0([0, 1], \bar{\Omega})$ .  $\square$

**LEMMA 2.8.** *Let  $(Q_n)_n \in \mathcal{M}_+^1(C^0([0, 1], \mathbb{R}^2))^{\mathbb{N}}$  such that  $Q_n(C) = 1$  for all  $n$ , and let there exist a constant  $M > 0$  such that*

$$\sup_n \int_C l(\sigma) \, dQ_n(\sigma) \leq M.$$

Then the sequence  $(\tilde{Q}_n)_n$  is tight and admits a subsequence that converges weakly\* to a probability  $Q$  such that  $Q(C) = 1$ .

*Proof.* The tightness of  $(\tilde{Q}_n)_n$  easily follows from the inequality

$$\begin{aligned} \tilde{Q}_n \left( \{ \sigma \in \tilde{C} : |\dot{\sigma}| > K \} \right) &= Q_n \left( \{ \sigma \in C : l(\sigma) > K \} \right) \\ (2.15) \qquad \qquad \qquad &\leq \frac{1}{K} \int_C l(\sigma) dQ_n(\sigma). \end{aligned}$$

By the Prokhorov theorem, we may therefore assume, passing to a subsequence if necessary, that  $(\tilde{Q}_n)_n$  converges weakly\* to  $Q \in \mathcal{M}_+^1(C^0([0, 1], \mathbb{R}^2))$ . It remains to show that  $Q(C) = 1$ . For  $K > 0$  let us define  $C_K := \{ \sigma \in C : |\dot{\sigma}| \leq K \}$ ; then inequality (2.15) and the fact that the measures  $\tilde{Q}_n$  are concentrated on  $\tilde{C}$  yield

$$\sup_n \tilde{Q}_n \frac{C}{C_K} = \sup_n \tilde{Q}_n \frac{\tilde{C}}{C_K} \leq \frac{M}{K},$$

for every  $K > 0$ , which implies

$$\begin{aligned} 1 = \limsup_n \tilde{Q}_n(C) &\leq \limsup_n \tilde{Q}_n(C_K) + \limsup_n \tilde{Q}_n \frac{C}{C_K} \\ &\leq Q(C_K) + \frac{M}{K}. \end{aligned}$$

Letting  $K$  tend to  $\infty$ , we then get  $Q(C) = \sup_K Q(C_K) = 1$ .  $\square$

LEMMA 2.9. *Let  $(Q_n)_n$  be a sequence in  $\mathcal{M}_+^1(C)$  that converges weakly\* to some  $Q \in \mathcal{M}_+^1(C)$ . If there exists  $i \in M_+(\bar{\Omega})$  such that  $i_{Q_n}$  converges weakly\* to  $i$  in  $\mathcal{M}_+(\bar{\Omega})$ , then we have  $i_Q \leq i$ .*

*Proof.* Let  $\varphi \in C^0(\bar{\Omega}, \mathbb{R}_+)$ . We first have

$$\int_{\bar{\Omega}} \varphi di = \lim_n \int_{\bar{\Omega}} \varphi di_{Q_n} = \lim_n \int_C L_\varphi dQ_n;$$

it easily follows from Lemma 2.7 that  $Q \mapsto \int_C L_\varphi dQ$  is l.s.c. for the weak\* topology of  $\mathcal{M}_+^1(C)$ . We then have

$$\int_{\bar{\Omega}} \varphi di \geq \int_C L_\varphi dQ = \int_{\bar{\Omega}} \varphi di_Q. \quad \square$$

Now, we are in position to prove the following.

THEOREM 2.10. *The minimization problem (2.13) admits a solution.*

*Proof.* Our assumptions imply that the value of (2.13) is finite. Let  $(Q_n)_n$  be some minimizing sequence of (2.13). From the identity  $i_Q = i_{\tilde{Q}}$ , we may assume  $Q_n = \tilde{Q}_n$  for all  $n$ . We deduce from our growth condition on  $H$  that  $(i_{Q_n})_n$  is bounded in  $L^q$ . On the one hand, extracting a subsequence if necessary, we may therefore assume that  $(i_{Q_n})_n$  converges weakly in  $L^q$  to some  $i$ . On the other hand, since  $i_{Q_n}$  is bounded in  $L^q$  and hence in  $L^1$ , we have

$$\sup_n \int_C l(\sigma) dQ_n(\sigma) = \sup_n \int_{\Omega} i_{Q_n} < +\infty.$$

Moreover,  $Q_n = \tilde{Q}_n$  and we deduce from Lemma 2.8 that (up to some subsequence)  $(Q_n)_n$  weakly\* converges to some  $Q$  in  $\mathcal{M}_+^1(C)$ . Since  $Q(\mu_0, \mu_1)$  is obviously weakly\*

closed, we have  $Q \in \mathcal{Q}(\mu_0, \mu_1)$ , and Lemma 2.9 implies that  $i_Q \leq i$  (consequently, to this inequality  $i_Q$  is absolutely continuous). From the monotonicity and convexity of  $H$  we then have

$$\int_{\Omega} H(i_Q(x)) dx \leq \int_{\Omega} H(i(x)) dx \leq \liminf_n \int_{\Omega} H(i_{Q_n}(x)) dx,$$

which proves that  $Q$  solves (2.13).  $\square$

Let us remark that if  $H$  is furthermore assumed to be strictly convex, then if  $Q_1$  and  $Q_2$  solve (2.13), then  $i_{Q_1} = i_{Q_2}$  so that the optimal traffic intensity is unique (of course, this does not imply, in general, that  $Q_1 = Q_2$  or that the corresponding optimal transportation strategy is unique).

**3. Characterization of the minimizers.** In what follows, we shall denote by  $q^*$  the conjugate exponent of  $q$ , given by  $q^* = q/(q-1)$ .

**3.1. Optimality conditions.** The variational inequalities characterizing solutions of the convex problem (2.13) can be expressed as follows.

PROPOSITION 3.1.  $\bar{Q} \in \mathcal{Q}^q(\mu_0, \mu_1)$  solves (2.13) if and only if

$$(3.1) \quad \int_{\Omega} \bar{\xi} i_{\bar{Q}} = \inf \left\{ \int_{\Omega} \bar{\xi} i_Q : Q \in \mathcal{Q}^q(\mu_0, \mu_1) \right\} \text{ with } \bar{\xi} := H'(i_{\bar{Q}}) \in L^{q^*}.$$

*Proof.* Assume that  $\bar{Q}$  solves (2.13); then for every  $Q \in \mathcal{Q}^q(\mu_0, \mu_1)$ , one has

$$\begin{aligned} 0 &\leq \lim_{\varepsilon \rightarrow 0^+} \frac{1}{\varepsilon} [\mathcal{H}(i_{\bar{Q} + \varepsilon(Q - \bar{Q})}) - \mathcal{H}(i_{\bar{Q}})] = \lim_{\varepsilon \rightarrow 0^+} \frac{1}{\varepsilon} [\mathcal{H}(i_{\bar{Q}} + \varepsilon(i_Q - i_{\bar{Q}})) - \mathcal{H}(i_{\bar{Q}})] \\ &= \int_{\Omega} H'(i_{\bar{Q}})(i_Q - i_{\bar{Q}}) = \int_{\Omega} \bar{\xi}(i_Q - i_{\bar{Q}}), \end{aligned}$$

which proves (3.1). Conversely, if  $\bar{Q} \in \mathcal{Q}^q(\mu_0, \mu_1)$  satisfies (3.1), then by convexity of  $H$ , for every  $Q \in \mathcal{Q}^q(\mu_0, \mu_1)$ , one has

$$\mathcal{H}(i_Q) - \mathcal{H}(i_{\bar{Q}}) \geq \int_{\Omega} \bar{\xi}(i_Q - i_{\bar{Q}}) \geq 0. \quad \square$$

Sections 3.2 and 3.3 will be devoted to investigating the precise meaning of (3.1). Before going further, let us do some formal manipulations to give a formal interpretation of (3.1) in terms of optimal transportation strategy. Let us assume that  $\bar{Q}$  solves (2.13) and let us write  $\bar{Q} = Q_{\bar{\gamma}, \bar{p}}$  for some (optimal) transportation strategy  $(\bar{\gamma}, \bar{p})$  and define  $\bar{\xi} := H'(i_{\bar{Q}})$ ; then (3.1) formally can be rewritten as

$$\begin{aligned} \int_{\Omega} \bar{\xi} i_{\bar{Q}} &= \int_C L_{\bar{\xi}}(\sigma) d\bar{Q}(\sigma) \\ &= \int_{\bar{\Omega} \times \bar{\Omega}} \left( \int_{C^{x,y}} L_{\bar{\xi}}(\sigma) d\bar{p}^{x,y}(\sigma) \right) d\bar{\gamma}(x, y) \\ &= \inf_{(\gamma, p) \text{ transp. strategy}} \int_{\bar{\Omega} \times \bar{\Omega}} \left( \int_{C^{x,y}} L_{\bar{\xi}}(\sigma) dp^{x,y}(\sigma) \right) d\gamma(x, y) \\ &= \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \left( \inf_{p \in \mathcal{M}_+^1(C^{x,y})} \int_{C^{x,y}} L_{\bar{\xi}}(\sigma) dp(\sigma) \right) d\gamma(x, y) \\ &= \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \left( \inf_{\sigma \in C^{x,y}} L_{\bar{\xi}}(\sigma) \right) d\gamma(x, y), \end{aligned}$$

defining (again formally) the transportation cost

$$c_{\bar{\xi}}(x, y) = \inf_{\sigma \in C^{x, y}} L_{\bar{\xi}}(\sigma).$$

We then first have

$$\int_{\bar{\Omega} \times \bar{\Omega}} c_{\bar{\xi}}(x, y) d\bar{\gamma}(x, y) \leq \int_C L_{\bar{\xi}} d\bar{Q} = \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} c_{\bar{\xi}}(x, y) d\gamma(x, y)$$

so that  $\bar{\gamma}$  solves the Monge–Kantorovich problem:

$$\inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} c_{\bar{\xi}}(x, y) d\gamma(x, y).$$

Second,

$$\begin{aligned} \int_C L_{\bar{\xi}}(\sigma) d\bar{Q}(\sigma) &= \int_{\bar{\Omega} \times \bar{\Omega}} c_{\bar{\xi}}(x, y) d\bar{\gamma}(x, y) \\ &= \int_C c_{\bar{\xi}}(\sigma(0), \sigma(1)) d\bar{Q}(\sigma), \end{aligned}$$

and since  $L_{\bar{\xi}}(\sigma) \geq c_{\bar{\xi}}(\sigma(0), \sigma(1))$ , we get

$$L_{\bar{\xi}}(\sigma) = c_{\bar{\xi}}(\sigma(0), \sigma(1)) \quad \text{for } \bar{Q}\text{-a.e. } \sigma,$$

or, in an equivalent way, for  $\bar{\gamma}$ -a.e.  $(x, y)$  one has

$$L_{\bar{\xi}}(\sigma) = c_{\bar{\xi}}(x, y) \quad \text{for } \bar{p}^{x, y}\text{-a.e. } \sigma.$$

Since  $\bar{\xi}$  is only  $L^{q^*}$ ,  $L_{\bar{\xi}}$  and  $c_{\bar{\xi}}$  are not well defined and the previous arguments are purely formal. In section 3.2, we will extend the definition of  $c_{\xi}$  to the case where  $\xi$  is only  $L^{q^*}$  under the additional assumption  $q < 2$ . This will enable us to make the formal argument above rigorous and to characterize optimal transportation strategies in section 3.3.

**3.2. The transportation cost  $\bar{c}_{\xi}$  when  $\xi$  is  $L^{q^*}$ .** For a nonnegative function  $\xi \in C^0(\bar{\Omega}, \mathbb{R}_+)$  we define

$$c_{\xi}(x, y) = \inf\{L_{\xi}(\sigma) : \sigma \in C^{x, y}\}.$$

**PROPOSITION 3.2.** *Assume that  $q < 2$  and define  $\alpha := 1 - 2/q^*$ ; then there exists a nonnegative constant  $C$  such that for every  $\xi \in C^0(\bar{\Omega}, \mathbb{R}_+)$  and every  $(x_1, y_1, x_2, y_2) \in \Omega^4$ , one has*

$$(3.2) \quad |c_{\xi}(x_1, y_1) - c_{\xi}(x_2, y_2)| \leq C \|\xi\|_{L^{q^*}(\Omega)} (|x_1 - x_2|^{\alpha} + |y_1 - y_2|^{\alpha}).$$

Consequently, if  $(\xi_n)_n \in C^0(\bar{\Omega}, \mathbb{R}_+)^{\mathbb{N}}$  is bounded in  $L^{q^*}$ , then  $(c_{\xi_n})_n$  admits a subsequence that converges in  $C^0(\bar{\Omega} \times \bar{\Omega}, \mathbb{R}_+)$ .

*Proof.* Let  $\xi \in C^0(\bar{\Omega}, \mathbb{R}_+)$  and  $x, y \in \Omega^2$ . For  $k > 0$  let  $\sigma_k \in C^{x, y}$  be such that

$$\int_0^1 \xi(\sigma_k(t)) |\dot{\sigma}_k(t)| dt \leq c_{\xi}(x, y) + \frac{1}{k}.$$

Then for all  $\varepsilon > 0$  and  $z$  such that  $y + \varepsilon z \in \Omega$  and  $t_0 \in (0, 1)$  we consider the following element of  $C^{x, y + \varepsilon z}$ :

$$\sigma_{k, t_0}(t) := \begin{cases} \sigma_k\left(\frac{t}{t_0}\right) & \text{if } t \in [0, t_0], \\ y + \left(\frac{t - t_0}{1 - t_0}\right) \varepsilon z & \text{if } t \in [t_0, 1]. \end{cases}$$

We then have, for all  $k > 0$ ,

$$\begin{aligned} c_\xi(x, y + \varepsilon z) &\leq \int_0^1 \xi(\sigma_{k, t_0}(t)) |\dot{\sigma}_{k, t_0}(t)| dt \\ &= \int_0^1 \xi(\sigma_k(t)) |\dot{\sigma}_k(t)| dt + \int_0^1 \xi(y + t\varepsilon z) \varepsilon |z| dt \\ &\leq c_\xi(x, y) + \varepsilon |z| \int_0^1 \xi(y + t\varepsilon z) dt + \frac{1}{k}. \end{aligned}$$

Now we let  $k$  tend to  $\infty$  and we get

$$\frac{c_\xi(x, y + \varepsilon z) - c_\xi(x, y)}{\varepsilon} \leq |z| \int_0^1 \xi(y + t\varepsilon z) dt,$$

and by a similar argument,

$$\frac{c_\xi(x, y) - c_\xi(x, y + \varepsilon z)}{\varepsilon} \leq |z| \int_0^1 \xi(y + (1 - t)\varepsilon z) dt.$$

This implies that  $c_\xi(x, \cdot) \in W^{1, \infty}$  and

$$(3.3) \quad |\nabla_y c_\xi(x, \cdot)| \leq |\xi(\cdot)| \quad \forall x.$$

By symmetry we also have

$$(3.4) \quad |\nabla_x c_\xi(\cdot, y)| \leq |\xi(\cdot)| \quad \forall y.$$

Since  $q^* > 2$ , we deduce from (3.3), (3.4), and Morrey's theorem (see [6, Chapter IX]), that there is a constant  $C$  such that

$$\begin{aligned} |c_\xi(x, y_1) - c_\xi(x, y_2)| &\leq C \|\xi\|_{L^{q^*}} |y_1 - y_2|^\alpha \quad \forall x, y_1, y_2 \text{ in } \Omega, \\ |c_\xi(x_1, y) - c_\xi(x_2, y)| &\leq C \|\xi\|_{L^{q^*}} |x_1 - x_2|^\alpha \quad \forall x_1, x_2, y \text{ in } \Omega. \end{aligned}$$

This proves (3.2). The second claim in the proposition then follows from (3.2), the identity  $c_{\xi_n}(x, x) = 0$ , and Ascoli's theorem.  $\square$

From now on, we further assume that  $q < 2$ . For a nonnegative function  $\xi \in L^{q^*}(\Omega)$  we then define

$$\bar{c}_\xi(x, y) = \sup \{c(x, y) : c \in \mathcal{A}(\xi)\},$$

where

$$\mathcal{A}(\xi) = \left\{ \lim_n c_{\xi_n} \text{ in } C^0(\bar{\Omega} \times \bar{\Omega}) : (\xi_n)_n \in C^0(\bar{\Omega}), \xi_n \geq 0, \xi_n \rightarrow \xi \text{ in } L^{q^*} \right\}.$$

*Remark 3.3.* The definition of  $\bar{c}_\xi$  is unchanged if one replaces  $\xi_n \rightarrow \xi$  in  $L^{q^*}$  by  $\xi_n \rightharpoonup \xi$  in  $L^{q^*}$  in the definition of  $\mathcal{A}(\xi)$ . Indeed, if we do so, we obviously obtain a

function which is larger than  $\bar{c}_\xi$ . Now, let us assume that  $\xi_n \rightarrow \xi$  in  $L^q$ , and  $c_{\xi_n}$  converges to  $c$  in  $C^0(\bar{\Omega} \times \bar{\Omega})$ ; using Mazur's lemma there exists a sequence  $\eta_n$  which converges strongly to  $\xi$  and such that each  $\eta_n$  is in the convex hull of  $\{\xi_k, k \geq n\}$ . It is clear that for fixed  $x, y$ ,  $\xi \rightarrow c_\xi(x, y)$  is concave, and hence  $c(x, y) = \lim c_{\xi_n}(x, y) \leq \limsup c_{\eta_n}(x, y) \leq \bar{c}_\xi(x, y)$ .

When  $\xi$  is continuous, one has the following.

LEMMA 3.4. *If  $\xi$  is continuous and nonnegative, then  $\bar{c}_\xi = c_\xi$ .*

*Proof.* The inequality  $\bar{c}_\xi \geq c_\xi$  is obvious, as one can always choose the constant sequence  $\xi_n = \xi$  in the definition of  $\bar{c}_\xi$ . Let us show now the opposite inequality. Take  $x, y \in \Omega$ ,  $\varepsilon > 0$ , and  $\sigma \in C^{x,y}$  such that  $L_\xi(\sigma) < c_\xi(x, y) + 1/k$ . We can choose  $\sigma$  so that it is piecewise linear by density of this kind of curve and using the continuity of  $\xi$ . Let  $(S_i)_{i=0,\dots,m-1}$  be the segments which compose  $\sigma$  with  $S_i = x_i x_{i+1}$ ,  $x_0 = x$ , and  $x_m = y$ . Let us fix, moreover, a sequence  $\xi_n \rightarrow \xi$  such that  $c_{\xi_n} \rightarrow c$ . Now, we want to prove  $c \leq c_\xi$ . Fix a small number  $\delta > 0$ , and for any  $\alpha \in [0, \delta]$  let us define a curve  $\sigma^\alpha$  in the following way: let  $R$  be the clockwise  $90^\circ$  rotation in the plane; let  $x'_i(\alpha)$  and  $x''_i(\alpha)$  be the only points such that  $x_i x'_i(\alpha) = \alpha R e_i$  and  $x_{i+1} x''_i(\alpha) = \alpha R e_i$ , where  $e_i$  is the tangent unit vector to  $\sigma$  in the  $S_i$  part; define  $\sigma^\alpha$  by linking any point  $x'_i(\alpha)$  to  $x''_i(\alpha)$  by some segments  $S'_i(\alpha)$  and  $x''_i(\alpha)$  to  $x'_{i+1}(\alpha)$  by some arcs  $A_{i+1}(\alpha)$  with center  $x_{i+1}$  and radius  $\alpha$ . In this way we have  $\sigma^\alpha \in C^{x_\alpha, y_\alpha}$ , where  $x_\alpha = x'_0(\alpha)$  and  $y_\alpha = x''_m(\alpha)$ . Let  $R_i(\delta)$  be the rectangle whose vertices are the points  $x_i$ ,  $x'_i(\delta)$ ,  $x''_i(\delta)$ , and  $x_{i+1}$  and let  $B_i(\delta)$  be the circular sector centered at  $x_i$  and whose vertices are  $x''_{i-1}(\delta)$  and  $x'_i(\delta)$ .

If we compute  $\int_0^\delta L_{\xi_n}(\sigma_\alpha) d\alpha$ , it is not difficult to see that we get

$$\int_0^\delta L_{\xi_n}(\sigma_\alpha) d\alpha = \sum_{i=0}^{m-1} \left( \int_{R_i(\delta)} \xi_n d\mathcal{L}^2 \right) + \sum_{i=1}^{m-1} \left( \int_{B_i(\delta)} \xi_n d\mathcal{L}^2 \right).$$

Moreover, it holds that  $c_{\xi_n}(x^\alpha, y^\alpha) \leq L_{\xi_n}(\sigma^\alpha)$ , and hence we get

$$\int_0^\delta c_{\xi_n}(x^\alpha, y^\alpha) d\alpha \leq \sum_{i=0}^{m-1} \left( \int_{R_i(\delta)} \xi_n d\mathcal{L}^2 \right) + \sum_{i=1}^{m-1} \left( \int_{B_i(\delta)} \xi_n d\mathcal{L}^2 \right).$$

If we pass to the limit as  $n \rightarrow \infty$ , then by using the uniform convergence of  $c_{\xi_n}$  to  $c$  on the left-hand side and the  $L^q$  convergence of  $\xi_n$  to  $\xi$  on the right-hand side, we get

$$\int_0^\delta c(x^\alpha, y^\alpha) d\alpha \leq \sum_{i=0}^{m-1} \left( \int_{R_i(\delta)} \xi d\mathcal{L}^2 \right) + \sum_{i=1}^{m-1} \left( \int_{B_i(\delta)} \xi d\mathcal{L}^2 \right).$$

Then we divide by  $\delta$  and pass to the limit as  $\delta \rightarrow 0$ . Using the fact that  $c$  is continuous, we have

$$\lim_{\delta \rightarrow 0} \frac{1}{\delta} \int_0^\delta c(x^\alpha, y^\alpha) d\alpha = c(x, y).$$

On the other hand, we may notice that the areas of the sectors  $B_i(\delta)$  may be estimated by  $C\delta^2$ , and hence we have, for  $\delta \rightarrow 0$ ,

$$\frac{1}{\delta} \sum_{i=1}^{m-1} \left( \int_{B_i(\delta)} \xi d\mathcal{L}^2 \right) \leq mC|\xi|\delta \rightarrow 0.$$

On the contrary the integrals over  $R_i(\delta)$ , when divided by  $\delta$ , converge on the integrals on the segments  $S_i$ , which give exactly the integral over the curve  $\sigma$ , i.e.,  $L_\xi(\sigma)$ . We have, consequently,

$$\lim_{\delta \rightarrow 0} \frac{1}{\delta} \left( \sum_{i=0}^{m-1} \left( \int_{R_i(\delta)} \xi d\mathcal{L}^2 \right) + \sum_{i=1}^{m-1} \left( \int_{B_i(\delta)} \xi d\mathcal{L}^2 \right) \right) = L_\xi(\sigma) < c_\xi(x, y) + \frac{1}{k}.$$

This gives

$$c(x, y) < c_\xi(x, y) + \frac{1}{k},$$

and,  $k$  being arbitrary, we also get  $c \leq c_\xi$  and the thesis.  $\square$

LEMMA 3.5. *Let us assume that  $q < 2$  and let  $\xi$  be a nonnegative function belonging to  $L^{q^*}$ ; then there exists a sequence  $(\xi_n)_n \in C^0(\Omega)$ ,  $\xi_n \geq 0$ ,  $\xi_n \rightarrow \xi$  in  $L^{q^*}$ , such that  $c_{\xi_n}$  converges uniformly to  $\bar{c}_\xi$  on  $\Omega \times \Omega$ .*

*Proof.* It is easy to see that for every  $(x, y) \in \Omega^2$  there exists a sequence of nonnegative continuous functions  $(\xi_n)_n$  converging to  $\xi$  in  $L^{q^*}(\Omega)$  such that  $c_{\xi_n}$  converges in  $C^0$  and  $\bar{c}_\xi(x, y) = \lim_n c_{\xi_n}(x, y)$ . Let  $I$  be a finite set,  $(x_i, y_i) \in \Omega^2$  for all  $i \in I$ , and for every  $i$ , let  $(\xi_n^i)$  be a sequence of nonnegative continuous functions converging to  $\xi$  in  $L^{q^*}(\Omega)$  such that  $\bar{c}_\xi(x_i, y_i) = \lim_n c_{\xi_n^i}(x_i, y_i)$ . Let us set  $\xi_n := \max_{i \in I} \xi_n^i$ . We then have  $(\xi_n)_n$  converging to  $\xi$  in  $L^{q^*}(\Omega)$ , and

$$\bar{c}_\xi(x_i, y_i) \leq \liminf_n c_{\xi_n}(x_i, y_i) \leq \limsup_n c_{\xi_n}(x_i, y_i) \leq \bar{c}_\xi(x_i, y_i).$$

We thus have  $\bar{c}_\xi(x_i, y_i) = \lim_n c_{\xi_n}(x_i, y_i)$  for every  $i \in I$ . Now, let  $(x_i, y_i)_{i \in \mathbb{N}}$  be a dense sequence of points of  $\Omega^2$ . From what precedes, for every  $n$ , there exists a continuous nonnegative  $\xi_n$  such that

$$\|\xi_n - \xi\|_{L^{q^*}} \leq \frac{1}{n}, \quad |\bar{c}_\xi(x_k, y_k) - c_{\xi_n}(x_k, y_k)| \leq \frac{1}{n} \quad \forall k \leq n.$$

By the Hölder estimate of Proposition 3.2 and Ascoli's theorem, passing to a subsequence, if necessary, we may assume that  $c_{\xi_n}$  converges in  $C^0$  to some  $c$ . Since obviously  $c(x_k, y_k) = \bar{c}_\xi(x_k, y_k)$  for all  $k$ , we deduce  $c = \bar{c}_\xi$ , and the desired result follows.  $\square$

The next lemma enables us to extend  $L_\xi$  in some sense when  $\xi \geq 0$  is only  $L^{q^*}$ .

LEMMA 3.6. *Let us assume that  $q < 2$ . Let  $Q \in \mathcal{Q}^q(\mu_0, \mu_1)$ ,  $\xi$  be a nonnegative element of  $L^{q^*}$ , and  $(\xi_n)_n$  be a sequence of nonnegative continuous functions that converges to  $\xi$  in  $L^{q^*}$ . Then we have the following:*

- (i)  $(L_{\xi_n})_n$  converges strongly in  $L^1(C, Q)$  to some limit which is independent of the approximating sequence  $(\xi_n)_n$  and which will again be denoted  $L_\xi$ .
- (ii) The following equality holds:

$$(3.5) \quad \int_{\Omega} \xi(x) i_Q(x) \, dx = \int_C L_\xi(\sigma) \, dQ(\sigma).$$

- (iii) The following inequality holds for  $Q$ -a.e.  $\sigma \in C$ :

$$(3.6) \quad L_\xi(\sigma) \geq \bar{c}_\xi(\sigma(0), \sigma(1)).$$

*Proof.* For all  $n$  and  $m$  in  $\mathbb{N}$ , we have

$$\begin{aligned} \int_C |L_{\xi_n}(\sigma) - L_{\xi_m}(\sigma)| \, dQ(\sigma) &= \int_C \left| \int_0^1 (\xi_n(\sigma(t)) - \xi_m(\sigma(t))) |\dot{\sigma}(t)| \, dt \right| \, dQ(\sigma) \\ &\leq \int_{\Omega} |\xi_n(x) - \xi_m(x)| i_Q(x) \, dx \\ &\leq \|\xi_n - \xi_m\|_{L^{q^*}} \|i_Q\|_{L^q}. \end{aligned}$$

This implies that  $(L_{\xi_n})_n$  is a Cauchy sequence in  $L^1(C, Q)$ , and it is obvious from the previous inequality that its  $L^1(C, Q)$  limit does not depend on the approximating sequence  $(\xi_n)_n$ .

The proof of (ii) follows from (i):

$$\begin{aligned} \int_{\Omega} \xi(x) i_Q(x) \, dx &= \lim_n \int_{\Omega} \xi_n(x) i_Q(x) \, dx \\ &= \lim_n \int_C L_{\xi_n}(\sigma) \, dQ(\sigma) \\ &= \int_C L_{\xi}(\sigma) \, dQ(\sigma). \end{aligned}$$

To prove (iii) we choose an approximating sequence  $(\xi_n)_n$  as in Lemma 3.5 and pass to the limit in

$$L_{\xi_n}(\sigma) \geq c_{\xi_n}(\sigma(0), \sigma(1)). \quad \square$$

*Remark 3.7.* The condition  $q < 2$  may seem restrictive; however, if, for instance,  $\mu_0$  and  $\mu_1$  are discrete (and  $\mu_0 \neq \mu_1$ ), this condition is in fact sharp. Indeed, in this case, it can easily be proved that  $\mathcal{Q}^q(\mu_0, \mu_1) \neq \emptyset$  for  $q \in (1, 2)$  but  $\mathcal{Q}^2(\mu_0, \mu_1) = \emptyset$ . To see that  $\mathcal{Q}^2(\mu_0, \mu_1) = \emptyset$ , assume on the contrary that there is a  $Q \in \mathcal{Q}(\mu_0, \mu_1)$  such that  $i_Q \in L^2$ , and define the vector measure  $\vec{i}_Q$  by

$$\int_{\Omega} X(x) d\vec{i}_Q(x) = \int_C \left( \int_0^1 X(\sigma(t)) \cdot \dot{\sigma}(t) dt \right) dQ(\sigma) \quad \forall X \in C^0(\overline{\Omega}, \mathbb{R}^2).$$

It is easy to check that

$$\operatorname{div}(\vec{i}_Q) = \mu_0 - \mu_1 \quad \text{and} \quad \|\vec{i}_Q\|_{L^2} \leq \|i_Q\|_{L^2} < +\infty.$$

But, since  $\mu_0 - \mu_1 \notin H^{-1}(\Omega)$ , we get the desired contradiction (and in fact we have proved that  $\mathcal{Q}^2(\mu_0, \mu_1) = \emptyset$  as soon as  $\mu_0 - \mu_1 \notin H^{-1}(\Omega)$ ). In other words, if  $q \geq 2$ , the congestion effect is so strong that the total congested cost in (2.13) is always  $+\infty$  as soon as  $\mu_0 - \mu_1 \notin H^{-1}(\Omega)$ .

*Remark 3.8.* We have assumed throughout the paper that the ambient dimension is 2, and we have seen in this case that one can extend the definitions of  $c_{\xi}$  and  $L_{\xi}$  to the case  $\xi \in L^{q^*}$ ,  $\xi \geq 0$ , provided  $q < 2$ . In dimension  $d \geq 2$ , it is easy to see that the Hölder estimate of Proposition 3.2 still holds for  $q^* > d$ , i.e.,  $q < d/(d-1)$ . All the results of the paper in fact extend to this more general case.

**3.3. Characterization of optimal transport strategies.** In this section, our goal is to make the formal arguments of section 3.1 rigorous in order to characterize optimal transport strategies. This can be done under the additional assumption that

$H$  is strictly convex. First, we relate the optimality condition (3.1) to the Monge–Kantorovich problem with cost  $\bar{c}_{\bar{\xi}}$  as follows.

PROPOSITION 3.9. *Let us assume that  $q < 2$  and that  $H$  is strictly convex. If  $\bar{Q}$  solves (2.13) and  $\bar{\xi} := H'(i_{\bar{Q}})$ , then we have*

$$(3.7) \quad \int_{\Omega} \bar{\xi} i_{\bar{Q}} = \inf_{Q \in \mathcal{Q}^q(\mu_0, \mu_1)} \int_{\Omega} \bar{\xi} i_Q = \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\bar{\xi}}(x, y) d\gamma(x, y).$$

*Proof.* Let us recall that from Proposition 3.1, we have

$$(3.8) \quad \int_{\Omega} \bar{\xi} i_{\bar{Q}} = \inf_{Q \in \mathcal{Q}^q(\mu_0, \mu_1)} \int_{\Omega} \bar{\xi} i_Q.$$

Let  $\xi$  be a nonnegative element of  $L^{q^*}$  and let  $Q \in \mathcal{Q}^q(\mu_0, \mu_1)$ . Using Lemma 3.6 and the definition of  $\mathcal{Q}^q(\mu_0, \mu_1)$  yields

$$\begin{aligned} \int_{\Omega} \xi i_Q &= \int_C L_{\xi} dQ \geq \int_C \bar{c}_{\xi}(\sigma(0), \sigma(1)) dQ(\sigma) \\ &\geq \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\xi}(x, y) d\gamma(x, y). \end{aligned}$$

We then have, for all  $\xi \in L^{q^*}$ ,  $\xi \geq 0$ ,

$$(3.9) \quad \inf_{Q \in \mathcal{Q}^q(\mu_0, \mu_1)} \int_{\Omega} \xi i_Q \geq \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\xi}(x, y) d\gamma(x, y).$$

By a similar argument and using Lemma 3.4, we also have, for all  $\xi \in C^0(\bar{\Omega}, \mathbb{R}_+)$ ,

$$(3.10) \quad \inf_{Q \in \mathcal{Q}(\mu_0, \mu_1)} \int_{\bar{\Omega}} \xi di_Q \geq \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\xi}(x, y) d\gamma(x, y).$$

Let  $\xi \in C^0(\bar{\Omega}, \mathbb{R}_+)$  and  $\varepsilon > 0$ . For every  $x$  and  $y$  in  $\bar{\Omega}$ , there exists  $\sigma_{\varepsilon}^{x,y} \in C^{x,y}$  such that  $(x, y) \mapsto \sigma_{\varepsilon}^{x,y}$  is measurable (see, for instance, [8]), and by Lemma 3.4,

$$(3.11) \quad L_{\xi}(\sigma_{\varepsilon}^{x,y}) \leq c_{\xi}(x, y) + \varepsilon = \bar{c}_{\xi}(x, y) + \varepsilon.$$

Let  $\gamma \in \Pi(\mu_0, \mu_1)$  and let us define the element of  $\mathcal{Q}(\mu_0, \mu_1)$ :  $Q_{\varepsilon} := \delta_{\sigma_{\varepsilon}^{x,y}} \otimes \gamma$ . We then have

$$\int_{\bar{\Omega}} \xi di_{Q_{\varepsilon}} = \int_{\bar{\Omega} \times \bar{\Omega}} L_{\xi}(\sigma_{\varepsilon}^{x,y}) d\gamma(x, y) \leq \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\xi}(x, y) d\gamma(x, y) + \varepsilon.$$

Since  $\gamma$  and  $\varepsilon$  are arbitrary, using (3.10) we obtain

$$(3.12) \quad \inf_{Q \in \mathcal{Q}(\mu_0, \mu_1)} \int_{\bar{\Omega}} \xi di_Q = \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\xi}(x, y) d\gamma(x, y) \quad \forall \xi \in C^0(\bar{\Omega}, \mathbb{R}_+).$$

In what follows, for every  $\mu \in \mathcal{M}_+(\bar{\Omega})$ , we extend  $\mu$  by 0 outside  $\bar{\Omega}$ . Let  $(\rho_n)_n$  be a standard mollifying sequence. For  $n \in \mathbb{N}^*$  let us consider the regularized problem

$$(3.13) \quad \inf_{Q \in \mathcal{Q}(\mu_0, \mu_1)} \int_{\mathbb{R}^2} H(\rho_n \star i_Q).$$

The existence of a solution  $\overline{Q}_n$  of (3.13) can be obtained by similar arguments as in Theorem 2.10 (using Lemma 2.8 and the fact that the  $L^1$  norm of  $\rho_n \star i_Q$  equals the total mass of  $i_Q$ ). Proceeding as in Proposition 3.1 and defining  $j_n := \rho_n \star i_{\overline{Q}_n}$ ,  $\xi_n := H'(j_n)$ ,  $\eta_n := \rho_n \star \xi_n$ , we have

$$(3.14) \quad \int_{\mathbb{R}^2} H'(\rho_n \star i_{\overline{Q}_n})(\rho_n \star i_{\overline{Q}_n}) = \int_{\mathbb{R}^2} \xi_n j_n = \int_{\mathbb{R}^2} \eta_n d i_{\overline{Q}_n} = \inf_{Q \in \mathcal{Q}(\mu_0, \mu_1)} \int_{\mathbb{R}^2} \eta_n d i_Q.$$

With (3.12), we then get

$$(3.15) \quad \int_{\mathbb{R}^2} \eta_n d i_{\overline{Q}_n} = \int_{\mathbb{R}^2} \xi_n j_n = \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\overline{\Omega} \times \overline{\Omega}} \bar{c}_{\eta_n}(x, y) d\gamma(x, y).$$

By convexity of  $H$ , we also have

$$(3.16) \quad \int_{\mathbb{R}^2} H(j_n) \leq \int_{\mathbb{R}^2} H(\rho_n \star i_{\overline{Q}}) \leq \int_{\mathbb{R}^2} \rho_n \star H(i_{\overline{Q}}),$$

which implies that  $j_n$  is bounded in  $L^q$ . Passing to subsequences, we may therefore assume

$$(3.17) \quad j_n \rightharpoonup j \text{ in } L^q, \quad \xi_n \rightharpoonup \xi \text{ in } L^{q^*}, \quad \eta_n \rightharpoonup \xi \text{ in } L^{q^*}.$$

Since the total mass of  $i_{\overline{Q}_n}$  is the same as that of  $j_n$ , and  $j_n$  is bounded in  $L^q$  (and hence in  $L^1$ ), we get a bound on  $i_{\overline{Q}_n}(\Omega)$  and, from Lemma 2.8, we may also assume

$$(3.18) \quad \overline{Q}_n \xrightarrow{*} Q \text{ in } \mathcal{M}_+(C), \quad i_{\overline{Q}_n} \xrightarrow{*} i \text{ in } \mathcal{M}_+(\overline{\Omega}).$$

It is obvious that  $i = j$  and that Lemma 2.9 implies  $j \geq i_Q$ . With (3.16) and the monotonicity of  $H$ , we then get

$$(3.19) \quad \int_{\Omega} H(i_Q) \leq \int_{\Omega} H(j) \leq \liminf_n \int_{\mathbb{R}^2} H(j_n) \leq \int_{\Omega} H(i_{\overline{Q}}).$$

With the strict convexity of  $H$  and the optimality of  $\overline{Q}$ , this also yields

$$(3.20) \quad i_{\overline{Q}} = i_Q = j \in L^q \text{ and } \liminf_n \int_{\mathbb{R}^2} H(j_n) = \int_{\mathbb{R}^2} H(i_{\overline{Q}}).$$

Up to some subsequence (as  $\bar{\xi} = H'(i_{\overline{Q}}) \in L^{q^*}$ ), this also implies

$$H(j_n) - H(i_{\overline{Q}}) - \bar{\xi}(j_n - i_{\overline{Q}}) \rightarrow 0 \text{ a.e. and in } L^1,$$

and using the strict convexity of  $H$ , we deduce that  $j_n$  converges a.e. to  $i_{\overline{Q}}$ . This implies that  $\xi_n$  converges a.e. to  $\bar{\xi} = H'(i_{\overline{Q}})$  and that  $\xi = \bar{\xi}$ . With Fatou's lemma and (3.15), we therefore obtain

$$\begin{aligned} \int_{\Omega} \bar{\xi} i_{\overline{Q}} &= \int_{\mathbb{R}^2} H'(i_{\overline{Q}}) i_{\overline{Q}} \\ &\leq \liminf_n \int_{\mathbb{R}^2} \xi_n j_n \\ &= \liminf_n \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\overline{\Omega} \times \overline{\Omega}} \bar{c}_{\eta_n}(x, y) d\gamma(x, y). \end{aligned}$$

Using  $\eta_n \rightarrow \bar{\xi}$  and Remark 3.3, from the uniform convergence of  $c_{\eta_n}$  to a cost  $c \leq c_{\bar{\xi}}$  we get

$$\int_{\Omega} \bar{\xi} i_{\bar{Q}} \leq \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\bar{\xi}}(x, y) d\gamma(x, y).$$

Together with (3.8) and (3.9), this completes the proof.  $\square$

The characterization of optimal transport strategies then reads as follows.

**THEOREM 3.10.** *Let us assume that  $q < 2$  and that  $H$  is strictly convex. A transportation strategy  $(\bar{\gamma}, \bar{p})$  is optimal if and only if, setting  $\bar{Q} := Q_{\bar{\gamma}, \bar{p}}$  and  $\bar{\xi} := H'(i_{\bar{Q}})$ , one has that*

1.  $\bar{\gamma}$  solves the Monge–Kantorovich problem

$$(3.21) \quad \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\bar{\xi}}(x, y) d\gamma(x, y);$$

2. for  $\bar{Q}$ -a.e.  $\sigma \in C$ , one has

$$(3.22) \quad L_{\bar{\xi}}(\sigma) = \bar{c}_{\bar{\xi}}(\sigma(0), \sigma(1)).$$

*Proof.* Let us assume first that the transportation strategy  $(\bar{\gamma}, \bar{p})$  is optimal and set  $\bar{Q} := Q_{\bar{\gamma}, \bar{p}}$  and  $\bar{\xi} := H'(i_{\bar{Q}})$ . From Proposition 3.9 and Lemma 3.6, we get

$$\begin{aligned} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\bar{\xi}}(x, y) d\bar{\gamma}(x, y) &= \int_C \bar{c}_{\bar{\xi}}(\sigma(0), \sigma(1)) d\bar{Q}(\sigma) \\ &\leq \int_C L_{\bar{\xi}} d\bar{Q} = \int_{\Omega} \bar{\xi} i_{\bar{Q}} \\ &= \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\bar{\xi}}(x, y) d\gamma(x, y). \end{aligned}$$

This proves that  $\bar{\gamma}$  solves (3.21) and implies that the inequalities above are equalities. We therefore deduce (3.22) from the inequality  $\bar{c}_{\bar{\xi}}(\sigma(0), \sigma(1)) \leq L_{\bar{\xi}}(\sigma)$ .

Conversely, assume that the transportation strategy  $(\bar{\gamma}, \bar{p})$  satisfies the two conditions of the theorem. Condition (3.22) first yields

$$\int_{\Omega} \bar{\xi} i_{\bar{Q}} = \int_C L_{\bar{\xi}} d\bar{Q} = \int_C \bar{c}_{\bar{\xi}}(\sigma(0), \sigma(1)) d\bar{Q}(\sigma) = \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\bar{\xi}}(x, y) d\bar{\gamma}(x, y).$$

Second, if  $Q = Q_{\gamma, p} \in \mathcal{Q}^q(\mu_0, \mu_1)$ , one has

$$\int_{\Omega} \bar{\xi} i_Q = \int_C L_{\bar{\xi}} dQ \geq \int_C \bar{c}_{\bar{\xi}}(\sigma(0), \sigma(1)) dQ(\sigma) = \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\bar{\xi}}(x, y) d\gamma(x, y),$$

and since  $\bar{\gamma}$  solves (3.21), we finally have

$$\int_{\Omega} \bar{\xi} i_{\bar{Q}} \leq \int_{\Omega} \bar{\xi} i_Q \quad \forall Q \in \mathcal{Q}^q(\mu_0, \mu_1),$$

which, with Proposition 3.1, proves that  $(\bar{\gamma}, \bar{p})$  is optimal.  $\square$

Let us see, through an easy example, an application of Theorem 3.10.

**Example 3.11.** Suppose that  $\bar{\Omega}$  contains the two segments  $A = \{0\} \times [0, 1]$  and  $B = \{1\} \times [0, 1]$  and the square  $S = [0, 1] \times [0, 1]$ , which is their convex hull. Set

$\mu_1 = \mathcal{H}^1 \llcorner A$  and  $\mu_2 = \mathcal{H}^1 \llcorner B$  and denote by  $T : A \rightarrow C$  the map that associates to every point  $(0, x) \in A$  the curve  $T(x)$  given by  $T(x)(t) = (t, x)$ , i.e., the horizontal segment from  $A$  to  $B$  starting from  $x$ . Set  $Q = T\# \mu_1$ . It is clear that  $Q$  comes from an admissible transportation strategy linking  $\mu_1$  to  $\mu_2$ , and it is not difficult to see that the traffic intensity  $i_Q$  has constant density 1 on  $S$  and 0 elsewhere. We consider only two particular cases: we claim that  $Q$  is optimal if  $\Omega = ]0, 1[ \times ]0, 1[$ , while it is not if  $S$  is compactly contained in  $\Omega$ . Indeed, if  $\bar{\Omega} = S$ , the metric induced by  $i_Q$  is the Euclidean metric, the paths  $T(x)$  are geodesic, and the transport plan induced by  $Q$  is optimal according to this metric. On the other hand, if  $\Omega$  is larger than  $S$ , then all the segments  $T(x)$  that are very close to the upper or lower boundary of  $S$  are not geodesic according to this metric, because they could be improved by nonstraight line paths which arrive up to zone  $\Omega \setminus S$ , where  $i_Q = 0$  and the transportation is cheaper. In the former case, consequently, the sufficient optimality conditions are satisfied, while in the latter the geodesic conditions on the paths (Wardrop condition; see the next section) is not and prevents optimality.

*Remark 3.12.* Let us remark that  $\bar{\xi} = H'(i_{\bar{Q}})$  (with  $\bar{Q}$  solving (2.13)) solves the following (dual of (2.13)) problem:

$$(3.23) \quad \sup_{\xi \in L^{q^*}, \xi \geq 0} W(\xi) - \int_{\Omega} H^*(\xi(x)) dx,$$

where  $H^*$  is the Fenchel transform of  $H$ , and

$$W(\xi) := \inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\xi}(x, y) d\gamma(x, y).$$

Indeed, it follows from Proposition 3.9 and  $\bar{\xi} = H'(i_{\bar{Q}})$  that

$$W(\bar{\xi}) - \int_{\Omega} H^*(\bar{\xi}(x)) dx = \int_{\Omega} (\bar{\xi} i_{\bar{Q}} - H^*(\bar{\xi})) = \int_{\Omega} H(i_{\bar{Q}}).$$

If  $\xi \in L^{q^*}$  is nonnegative, we deduce from (3.9) and Young's inequality,

$$W(\xi) \leq \int_{\Omega} \xi i_{\bar{Q}} \leq \int_{\Omega} H(i_{\bar{Q}}) + \int_{\Omega} H^*(\xi),$$

which proves that  $\bar{\xi}$  solves (3.23).

*Remark 3.13.* It is very natural to investigate numerical schemes for the primal problem (2.13). We believe that the dual problem (3.23) offers a tractable and convenient way to address this numerical issue. We are not developing this point further here and leave the numerical approximation of (2.13) and (3.23) for future research.

**4. Application to equilibria of Wardrop type.** In this final section, we relate the results of the previous sections to some concepts of equilibria of Wardrop type. Modeling congestion as in section 2.2 enables us to extend the concept of Wardrop equilibrium to a continuous setting.

Let us consider a congestion function  $g : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ , which is continuous increasing and satisfies  $az^{q-1} \leq g(z) \leq b(z^{q-1} + 1)$  for all  $z \in \mathbb{R}_+$  and some  $q \in (1, 2)$  and nonnegative constants  $a$  and  $b$ . Then for any transportation strategy  $(\gamma, p)$  such that  $I_{\gamma, p}$  (defined by (2.3)) belongs to  $L^q$ , the transportation cost function resulting from the strategy  $(\gamma, p)$  is  $\bar{c}_{\xi}$  for  $\xi := g \circ I_{\gamma, p} \in L^{q^*}$ . Roughly speaking, an equilibrium is then a transportation strategy  $(\gamma, p)$  that satisfies the Wardrop stability condition

(i.e.,  $Q_{\gamma,p}$  gives full mass to the set of geodesics for the metric  $\xi = g \circ I_{\gamma,p}$ ) and the additional requirement that  $\gamma$  is an optimal transportation plan between  $\mu_0$  and  $\mu_1$  for the cost resulting from  $(\gamma, p)$ . This leads to the following.

DEFINITION 4.1. *A transportation strategy  $(\bar{\gamma}, \bar{p})$  is said to be an equilibrium if  $I_{\bar{\gamma}, \bar{p}} \in L^q$  and, setting  $\bar{\xi} := g \circ I_{\bar{\gamma}, \bar{p}}$ , one has*

1.  $L_{\bar{\xi}}(\sigma) = \bar{c}_{\bar{\xi}}(\sigma(0), \sigma(1))$  for  $Q_{\bar{\gamma}, \bar{p}}$ -a.e.  $\sigma \in C$ ;
2.  $\bar{\gamma}$  solves the Monge–Kantorovich problem

$$\inf_{\gamma \in \Pi(\mu_0, \mu_1)} \int_{\bar{\Omega} \times \bar{\Omega}} \bar{c}_{\bar{\xi}}(x, y) d\gamma(x, y).$$

Only the first condition above is linked to Wardrop's original equilibrium concept. Imagine that some social planner chooses the transportation plan  $\gamma$ ; then the second equilibrium condition expresses that  $\gamma$  is optimal for the transportation cost resulting from  $\gamma$  itself and the traveler's individual behavior. Our notion of equilibrium can therefore be viewed either as a refinement of the Wardrop equilibrium or as its generalization to the case where the transportation plan is not given a priori.

Defining the function  $H_g : \mathbb{R}_+ \rightarrow \mathbb{R}$  by

$$(4.1) \quad H'_g(z) = g(z) \quad \forall z \in \mathbb{R}_+, \quad H_g(0) = 0,$$

a direct application of Theorems 2.10 and 3.10 then gives the existence of equilibria together with a variational characterization as follows.

THEOREM 4.2. *If  $Q^q(\mu_0, \mu_1) \neq \emptyset$ , there exists an equilibrium. Moreover,  $(\bar{\gamma}, \bar{p})$  is an equilibrium if and only if  $\bar{Q} := Q_{\bar{\gamma}, \bar{p}}$  solves the minimization problem*

$$(4.2) \quad \inf_{Q \in Q^q(\mu_0, \mu_1)} \int_{\Omega} H_g(i_Q(x)) dx,$$

where  $H_g$  is defined by (4.1).

REMARK 4.3. We have always assumed that the congestion function  $g$  depends only on the intensity  $z$ . It is, of course, straightforward to extend all our results to the case of a congestion function  $(x, z) \rightarrow g(x, z)$  that also depends on  $x$ . In this case, one finds equilibria by solving

$$\inf_{Q \in Q^q(\mu_0, \mu_1)} \int_{\Omega} H_g(x, i_Q(x)) dx,$$

where  $H_g$  is defined by  $H_g(x, 0) = 0$  and  $\partial_z H_g(x, z) = g(x, z)$ .

REMARK 4.4. A slightly different situation, which can be relevant in some applications, occurs when not only the marginals  $\mu_0$  and  $\mu_1$  are fixed but also when the transportation plan  $\bar{\gamma} \in \Pi(\mu_0, \mu_1)$  is fixed. In this case, one defines equilibria as the set of  $\bar{p}$ 's such that  $(\bar{\gamma}, \bar{p})$  satisfies the first condition (Wardrop) of Definition 4.1. If the set

$$Q^q(\bar{\gamma}) := \{Q \in \mathcal{M}_+^1(C) : (e_0, e_1) \# Q = \bar{\gamma}, i_Q \in L^q\}$$

is nonempty, then by slightly adapting our arguments we have existence of equilibria, and  $\bar{p}$  is an equilibrium if and only if  $\bar{Q} := Q_{\bar{\gamma}, \bar{p}}$  solves the minimization problem

$$\inf_{Q \in Q^q(\bar{\gamma})} \int_{\Omega} H_g(i_Q(x)) dx.$$

## CONTROLLABILITY AND OBSERVABILITY OF SECOND ORDER DESCRIPTOR SYSTEMS\*

PHILIP LOSSE<sup>†</sup> AND VOLKER MEHRMANN<sup>‡</sup>

**Abstract.** We analyze controllability and observability conditions for second order descriptor systems and show how the classical conditions for first order systems can be generalized to this case. We show that performing a classical transformation to first order form may destroy some controllability and observability properties. As an example, we demonstrate that the loss of impulse controllability in constrained multibody systems is due to the representation as a first order system. To avoid this problem, we will derive a canonical form and new first order formulations that do not destroy the controllability and observability properties.

**Key words.** descriptor system, impulse controllability, impulse observability, second order system, order reduction, index reduction, complete controllability, strong controllability, complete observability, strong observability

**1. Introduction.** We study linear second order constant coefficient descriptor control problems of the form

$$(1.1) \quad M\ddot{x} + G\dot{x} + Kx = Bu,$$

$$(1.2) \quad y = Cx,$$

$$(1.3) \quad x(0) = x_0, \quad \dot{x}(0) = \dot{x}_0$$

with coefficients  $M, G, K \in \mathbb{R}^{n,n}$ ,  $C \in \mathbb{R}^{p,n}$ , and  $B \in \mathbb{R}^{n,m}$ . Here  $\mathbb{R}^{n,\ell}$  denotes the vector space of  $n \times \ell$  real matrices,  $x$  is the state,  $u$  is the input or control, and  $y$  is the output of the system. In particular, we study descriptor systems, where the matrix  $M$  is singular, and, despite the fact that formally  $\ddot{x}$  and  $\dot{x}$  occur in (1.1), we require that  $\ddot{x}$  only has to exist outside the kernel of  $M$  and that  $\dot{x}$  has to exist outside the kernel of  $G$ .

All of the results in this paper also carry over to the complex case, and they can also be easily extended to systems of higher than second order, but, for ease of notation and because this is the most important case in practice, we restrict ourselves to the real second order case.

In the following we denote by  $I$  or  $I_n$  the identity matrix of size  $n \times n$  and by  $A^T$  the transpose of a matrix  $A$ . We denote a matrix with orthonormal columns spanning the right null space of the matrix  $M$  by  $S_\infty(M)$  and a matrix with orthonormal columns spanning the left null space of  $M$  by  $T_\infty(M)$ . These matrices are not uniquely determined, although the corresponding spaces are. Nevertheless, for simplicity, we speak of these matrices as the corresponding spaces.

Second order descriptor systems arise in the control of constrained mechanical systems (see, e.g., [14, 19, 23, 36, 38, 39, 40]) in the control of electrical and electromechanical systems [2, 3], and in particular in heterogeneous systems, where different models are coupled together [37].

Usually, in the classical theory of ordinary differential equations and *classical state space systems* (i.e., descriptor systems where the leading coefficient is the identity), second order systems are turned into first order systems by introducing new variables for the first derivative. This gives rise to linear first order *descriptor* (or *generalized state space*) systems of the form

$$(1.4) \quad E\dot{\xi} = A\xi + B_1 u,$$

$$(1.5) \quad y = C_1 \xi,$$

$$(1.6) \quad \xi(0) = \xi_0.$$

Let us briefly recall some results for first order descriptor systems; see, e.g., [4, 9, 12, 44]. In contrast to classical state space systems, where  $E = I$ , the response of a descriptor system can consist of step functions or can be discussed only in a distributional setting [10, 18, 43], if the input function  $u$  is not sufficiently smooth. But here we are interested only in classical solutions in the sense that  $M\ddot{x}$  and  $G\dot{x}$  exist, and we explicitly want to avoid impulsive terms in the solution; thus, we do not use this formulation.

The response of system (1.4) can be described in terms of the eigenstructure of the matrix pencil  $\alpha E - \beta A$ . The pencil and the corresponding system (1.4)–(1.5) are said to be *regular* if  $\det(\alpha E - \beta A) \neq 0$  for some  $(\alpha, \beta) \in \mathbb{C}^2$ . Regular systems are *solvable* in the sense that (1.4) admits a classical solution  $\xi : \mathbb{R} \rightarrow \mathbb{R}^n$ , with  $\xi$  differentiable in the image of  $E$  for all sufficiently smooth controls  $u$  and consistent initial conditions  $\xi_0$  [9, 12, 44].

For regular pencils, *generalized eigenvalues* are the pairs  $(\alpha, \beta) \in \mathbb{C}^2 \setminus \{(0, 0)\}$  for which  $\det(\alpha E - \beta A) = 0$ . If  $\beta \neq 0$ , then the pair represents the finite eigenvalue  $\lambda = \alpha/\beta$ . If  $\beta = 0$ , then  $(\alpha, \beta)$  represents an “infinite” eigenvalue. In the following, for simplicity, we use the notation with  $\lambda$ .

The solution and many properties of the *free descriptor system* (with  $u = 0$ ) can be characterized in terms of the Weierstraß canonical form (WCF) for regular matrix pencils.

**THEOREM 1.1** (see [16]). *If  $\lambda E - A$  is a regular pencil, then there exist nonsingular matrices  $X = \begin{bmatrix} X_r & X_\infty \end{bmatrix} \in \mathbb{R}^{n,n}$  and  $Y = \begin{bmatrix} Y_r & Y_\infty \end{bmatrix} \in \mathbb{R}^{n,n}$  for which*

$$(1.7) \quad Y^T E X = \begin{bmatrix} Y_r^T \\ Y_\infty^T \end{bmatrix} E \begin{bmatrix} X_r & X_\infty \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix}$$

and

$$(1.8) \quad Y^T A X = \begin{bmatrix} Y_r^T \\ Y_\infty^T \end{bmatrix} A \begin{bmatrix} X_r & X_\infty \end{bmatrix} = \begin{bmatrix} J & 0 \\ 0 & I \end{bmatrix},$$

where  $J$  is a matrix in real Jordan canonical form whose eigenvalues are the finite eigenvalues of the pencil and  $N$  is a nilpotent matrix, also in Jordan form.  $J$  and  $N$  are unique up to permutation of Jordan blocks.

Usually, the index of nilpotency  $\nu$  of the nilpotent matrix  $N$  in (1.7) is called the *differentiation index* or *index* of the system, and if  $E$  is nonsingular, then the pencil is said to be of index zero. In recent years the theory of descriptor systems has

been extended to rectangular, time-varying, and even nonlinear systems, and different index concepts, in particular the *strangeness index*, have been introduced; see [30] for a recent textbook. The strangeness index generalizes the index of a linear descriptor system to over- and underdetermined linear and nonlinear systems, and it uses a slightly different counting; i.e., systems of the form (1.4) with an index of at most one have a strangeness index of zero and are called *strangeness-free*. For all other systems where the differentiation index is defined, it is the strangeness index plus 1. Since we restrict ourselves to square systems, we will use only the differentiation index  $\nu$  and call it the *index of the system*.

For first order systems (1.4) the index describes the degree of differentiability of the input function that is needed to achieve a continuous solution with the property that  $Ex$  is continuously differentiable. In analogy we define the *index of the second order system* (1.1) to be the degree of differentiability of the input function that is needed to achieve a continuous solution with the property that  $Mx$  is twice and  $Gx$  is once continuously differentiable.

In the notation of (1.7)–(1.8), classical solutions of (1.4) take the form

$$\xi(t) = X_r z_1(t) + X_\infty z_2(t),$$

where

$$(1.9) \quad \begin{aligned} \dot{z}_1 &= Jz_1 + Y_r^T B_1 u, \\ N\dot{z}_2 &= z_2 + Y_\infty^T B_1 u. \end{aligned}$$

This system admits the explicit solution

$$(1.10) \quad \begin{aligned} z_1(t) &= e^{tJ} z_1(t_0) + \int_{t_0}^t e^{(t-s)J} Y_r^T B_1 u(s) ds, \\ z_2(t) &= - \sum_{i=0}^{\nu-1} \frac{d^i}{dt^i} (N^i Y_\infty^T B_1 u(t)), \end{aligned}$$

where  $\nu$  is the index of the system. Equation (1.10) shows that, for regular systems that are not of index at most one, in order to have classical, continuous solutions, the input  $u$  has to be sufficiently smooth, and, to ensure a smooth response for every continuous input  $u$ , the system must be regular and of index at most one. Under certain further requirements that we discuss below, this property may, however, be achieved by feedback. If this is the case, then the system is said to be *regularizable*.

Equation (1.10) also shows that the initial condition  $\xi_0$  is restricted. For a given input function  $u$ , the set of *consistent* initial conditions is given by

$$(1.11) \quad \mathcal{S} = \left\{ X_r z_1 + X_\infty z_2 \mid z_1 \in \mathbb{R}^r, z_2 = - \sum_{i=0}^{\nu-1} \left( \frac{d^i}{dt^i} (N^i Y_\infty^T B_1 u)(0) \right) \right\}.$$

The set  $\mathcal{R}$  of *reachable* states or *reachable set* of (1.4) from the set  $\mathcal{S}$  of consistent initial conditions is  $\mathcal{S}$  itself [44].

Coming back to second order descriptor systems and their first order representations, one should note first that there is no unique way of performing this transformation to first order; see [33] for large vector spaces of first order formulations in the context of eigenvalue problems. As a consequence, the solution space and the set of admissible controls may be different for different first order formulations.

This has recently been shown in the context of the numerical solution of higher order differential-algebraic systems [35, 41]. There, it also has been demonstrated that the classical first order formulations may even lead to false results if certain smoothness conditions are not met or if the initial conditions are not chosen properly.

Let us illustrate these difficulties with the well-known example of mechanical multibody systems.

*Example 1.2.* Consider a simplified, linearized model of a two-dimensional, three-link mobile manipulator [22]. The Lagrangian equations of motion in its linearized form are given by a linear second order system

$$\begin{aligned} M_0 \ddot{z} + G_0 \dot{z} + K_0 z &= B_0 u - H_0^T \phi, \\ H_0 z &= 0, \end{aligned}$$

where  $M_0$  represents the nonsingular mass matrix,  $G_0$  the coefficient matrix associated with damping, centrifugal, gravity, and Coriolis forces,  $K_0$  the stiffness matrix, and  $H_0$  the constraint, whereas  $\phi$  is a vector of Lagrange multipliers.

By setting  $x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} z \\ \phi \end{bmatrix}$ , and adding an output equation

$$y = Cz = \begin{bmatrix} C_0 & 0 \end{bmatrix} x,$$

we obtain a descriptor system of the form (1.1)–(1.2) given by

$$\begin{aligned} \begin{bmatrix} M_0 & 0 \\ 0 & 0 \end{bmatrix} \ddot{x} + \begin{bmatrix} G_0 & 0 \\ 0 & 0 \end{bmatrix} \dot{x} + \begin{bmatrix} K_0 & H_0^T \\ H_0 & 0 \end{bmatrix} x &= \begin{bmatrix} B_0 \\ 0 \end{bmatrix} u, \\ y &= \begin{bmatrix} C_0 & 0 \end{bmatrix} x. \end{aligned}$$

If one would follow the usual approach for ordinary differential equations, then one would introduce a new state vector, often called a *descriptor vector*,

$$\xi = \begin{bmatrix} \dot{x} \\ x \end{bmatrix} = \begin{bmatrix} \dot{z} \\ \dot{\phi} \\ z \\ \phi \end{bmatrix}.$$

Under the usual assumptions that  $M_0$  is invertible and that  $H_0$  has full row rank, it is easy to check that the resulting descriptor system has blocks of size 4 in the Weierstraß form associated with the eigenvalue  $\infty$  and thus an index  $\nu = 4$ . It follows that the input functions have to be at least three times continuously differentiable to obtain a continuous solution.

As a simple example, consider the system

$$(1.12) \quad \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \ddot{x} + \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \dot{x} + \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} x = \begin{bmatrix} 1 \\ 0 \end{bmatrix} u,$$

which has the structure of a constrained and damped mechanical system. The classical first order version yields

$$E = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad A = \begin{bmatrix} 1 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}.$$

A transformation  $(\hat{E}, \hat{A}) = P(E, A)Q$ , with

$$P = \begin{bmatrix} 0 & 0 & 0 & -1 \\ -1 & 1 & -1 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}, \quad Q = \begin{bmatrix} 0 & 0 & -1 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & -1 & 0 & 0 \end{bmatrix},$$

yields the Weierstraß canonical form

$$(\hat{E}, \hat{A}) = \left( \left[ \begin{array}{cc|cc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ \hline 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{array} \right], \left[ \begin{array}{cc|cc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array} \right] \right),$$

which consists only of one block associated with the eigenvalue  $\infty$  of size 4.

This classical approach, however, is usually not taken in practice, since on one hand it would introduce the unnecessary derivative of the Lagrange multiplier  $\phi$ , which may not be differentiable, and also this approach would require extra initial values associated with  $\dot{\phi}(t_0)$  which usually are not available. In practice, one therefore uses the knowledge about the structure of the system and introduces the reduced descriptor vector

$$\xi = \begin{bmatrix} \xi_1 \\ \xi_2 \\ \xi_3 \end{bmatrix} = \begin{bmatrix} \dot{z} \\ z \\ \phi \end{bmatrix}.$$

In this way one obtains a first order descriptor system of the form

$$\begin{aligned} \begin{bmatrix} M_0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & I & 0 \end{bmatrix} \dot{\xi} &= \begin{bmatrix} -G_0 & -K_0 & -H_0^T \\ 0 & -H_0 & 0 \\ I & 0 & 0 \end{bmatrix} \xi + \begin{bmatrix} B_0 \\ 0 \\ 0 \end{bmatrix} u, \\ (1.13) \quad y &= \begin{bmatrix} 0 & C_0 & 0 \end{bmatrix} \xi, \end{aligned}$$

which has index  $\nu = 3$ .

For the simple system (1.12) the first order formulation (1.13) has

$$E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} -1 & -1 & -1 \\ 0 & -1 & 0 \\ 1 & 0 & 0 \end{bmatrix}.$$

If we use the transformation  $(\hat{E}, \hat{A}) = P(E, A)Q$ , with

$$P = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}, \quad Q = \begin{bmatrix} 0 & -1 & 0 \\ 0 & 0 & -1 \\ 1 & 1 & 1 \end{bmatrix},$$

then we obtain the Weierstraß canonical form

$$(\hat{E}, \hat{A}) = \left( \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right),$$

which has only one block of size 3.

From this example we see that different first order formulations lead to different indexes and therefore to different differentiability requirements for the input functions  $u$  which we assume to be at least piecewise continuous functions.

But there is a second difficulty which both first order formulations in Example 1.2 share that is connected to the controllability and observability of the descriptor system and its first order formulations.

To describe this second difficulty we return again to our review of results for first order descriptor systems (1.4)–(1.5). Typically one or more of the following conditions is essential for most classical control design aims:

$$\begin{aligned}
 \mathbf{C0}: \quad & \text{rank}[\alpha E - \beta A, B_1] = n \text{ for all } (\alpha, \beta) \in \mathbb{C}^2 \setminus \{(0, 0)\}; \\
 \mathbf{C1}: \quad & \text{rank}[\lambda E - A, B_1] = n \text{ for all } \lambda \in \mathbb{C}; \\
 (1.14) \quad \mathbf{C2}: \quad & \text{rank}[E, AS_\infty(E), B_1] = n.
 \end{aligned}$$

A regular first order descriptor system is called *completely controllable* or *C-controllable* if **C0** holds [44] and *controllable in the reachable set* or  *$\mathcal{R}$ -controllable* if condition **C1** holds. The system is called *strongly controllable* or *S-controllable* if **C1** and **C2** hold [5]. C-controllability ensures that for any given initial and final states  $\xi_0, \xi_f$  there exists a piecewise continuous control  $u$  that transfers the system from  $\xi_0$  to  $\xi_f$  in finite time [44], while S-controllability ensures the same for any given initial and final states in the reachable set, i.e.,  $\xi_0, \xi_f \in \mathcal{R}$ . Systems that satisfy condition **C2** are called *controllable at infinity*, *impulse-controllable*, or *I-controllable* [11, 27, 43]. For these systems, impulsive modes that arise from a high index of  $(E, A)$  can be avoided by a suitable linear feedback; see [4, 5]. It has been shown in [12] that a first order descriptor system is C-controllable if and only if it is  $\mathcal{R}$ -controllable and  $\text{rank} \begin{bmatrix} E & B_1 \end{bmatrix} = n$ . To have S-controllability, however, the condition that  $\text{rank} \begin{bmatrix} E & B_1 \end{bmatrix} = n$  is not needed; see [4, 5].

Observability for descriptor systems is the dual of controllability. Consider the following conditions:

$$\begin{aligned}
 \mathbf{O0}: \quad & \text{rank} \begin{bmatrix} \alpha E - \beta A \\ C_1 \end{bmatrix} = n \text{ for all } (\alpha, \beta) \in \mathbb{C}^2 \setminus \{(0, 0)\}; \\
 \mathbf{O1}: \quad & \text{rank} \begin{bmatrix} \lambda E - A \\ C_1 \end{bmatrix} = n \text{ for all } \lambda \in \mathbb{C}; \\
 (1.15) \quad \mathbf{O2}: \quad & \text{rank} \begin{bmatrix} E \\ T_\infty^T(E)A \\ C_1 \end{bmatrix} = n.
 \end{aligned}$$

A regular descriptor system is called *completely observable* or *C-observable* if condition **O0** holds, *observable in the reachable set* or  *$\mathcal{R}$ -observable* if condition **O2** holds, and *strongly observable* or *S-observable* if conditions **O1** and **O2** hold. A system that satisfies condition **O2** is called *observable at infinity*, *impulse-observable*, or *I-observable*. Analogous to the controllable case, a system is C-observable if and only if it is  $\mathcal{R}$ -observable and  $\text{rank} \begin{bmatrix} E \\ C_1 \end{bmatrix} = n$ ; see [12].

Note that the conditions (1.14) are preserved under equivalence transformations of the system and under state and output feedback. Analogous properties hold for (1.15).

Classical design approaches in control require the system to be at least S-controllable and S-observable; see [12, 30, 34]. But it is well known that in many practical examples, e.g., in the context of constrained mechanical systems, the resulting system

in neither of the first order formulations as described in Example 1.2 is I-controllable and I-observable.

*Example 1.3.* Consider the first order formulation (1.13) in Example 1.2 with

$$E = \begin{bmatrix} M_0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & I & 0 \end{bmatrix}, \quad A = \begin{bmatrix} -G_0 & -K_0 & -H_0^T \\ 0 & -H_0 & 0 \\ I & 0 & 0 \end{bmatrix},$$

$$B_1 = \begin{bmatrix} B_0 \\ 0 \\ 0 \end{bmatrix}, \quad C_1 = [0 \quad C_0 \quad 0].$$

Here we immediately see that

$$\begin{bmatrix} E & AS_\infty(E) & B_1 \end{bmatrix} = \begin{bmatrix} M_0 & 0 & 0 & -H_0^T & B_0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \end{bmatrix}$$

does not have full row rank if constraints are present, and hence the system is not I-controllable. Similarly,

$$\begin{bmatrix} E \\ T_\infty^T(E)A \\ C_1 \end{bmatrix} = \begin{bmatrix} M_0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & I & 0 \\ 0 & -H_0 & 0 \\ 0 & C_0 & 0 \end{bmatrix}$$

does not have full column rank either; i.e., the system is not I-observable. Furthermore, neither  $[E \quad B_1]$  has full row rank, nor  $\begin{bmatrix} E \\ C_1 \end{bmatrix}$  has full column rank, and hence the system is neither C-controllable nor C-observable.

It should be noted that a first order system that is regular and of index at most one is always I-controllable, since already  $\text{rank}[E, AS_\infty(E)]$  is full, which follows directly from the Weierstraß canonical form.

Since the conditions of I-controllability and I-observability are so important, it has been discussed, for the first order case in [6] for linear systems with constant coefficients and in [7, 26, 29, 31] for linear variable coefficient and nonlinear systems (see also [30]), how systems that are not I-controllable can be modified by a combination of index reduction and feedback to have this property. It has also been argued in [6] that if the system is not I-observable, then the modeling of the system should be reconsidered, since this means that the solution can be formulated only with the help of distributions, but these impulsive parts are not observed.

In view of all of these difficulties it is a natural question to ask whether the choice of the first order formulation may be the reason for the described difficulties with the I-controllability and I-observability. To analyze this question is the topic of the present paper which is organized as follows.

In section 2 we derive normal forms that allow us to check the controllability and observability conditions and the construction of adequate first order formulations. In sections 3 and 4 we then derive the controllability and observability conditions for second order systems analogous to **C0**, **C1**, **C2** and **O1**, **O2**, **O3**. We demonstrate that we can always find first order formulations which are guaranteed to be I-controllable and I-observable, so that the described difficulties can be avoided. We finish with some conclusions.

**2. Normal forms.** In this section we will discuss partial normal forms for matrix triples. The general results for matrix tuples can be found in [35].

DEFINITION 2.1. *Two second order descriptor systems of the form (1.1) with system matrices  $(M, G, K, B)$ , and  $(\hat{M}, \hat{G}, \hat{K}, \hat{B})$  are called strongly equivalent if there exist nonsingular matrices  $P \in \mathbb{R}^{n,n}$ ,  $Q \in \mathbb{R}^{n,n}$ , and  $V \in \mathbb{R}^{m,m}$  such that*

$$(2.1) \quad \hat{M} = PMQ, \quad \hat{G} = PGQ, \quad \hat{K} = PKQ, \quad \hat{B} = PBV.$$

We write  $(M, G, K, B) \sim (\hat{M}, \hat{G}, \hat{K}, \hat{B})$ .

Canonical forms under strong equivalence are known only for the case of matrix pairs, giving the Weierstraß and Kronecker canonical forms [15, 16]. For matrix triples or larger tuples, such canonical forms are not known. Condensed forms which present partial information about the invariants associated with the eigenvalue  $\infty$  and the singular chains have recently been given in [35]. We will recall and extend these results below.

Another class of equivalence transformations that is studied in matrix polynomials is unimodular transformations such as adding the  $\lambda a$  multiple of one row to another (or the same for columns) without increasing the degree of the polynomial. The analogue of these transformations in the context of descriptor systems is well studied [30] and has been discussed in the context of higher order systems in [35]. We reformulate these transformations by using the concept of differential polynomials; see, e.g., [25]. Let  $\mathbb{R}[D_i]$  be the set of *ith order differential polynomials with coefficients in  $\mathbb{R}$* , i.e.,

$$\mathbb{R}[D_i] := \left\{ a_0 + a_1 \frac{d}{dt} + a_2 \frac{d^2}{dt^2} + \dots + a_i \frac{d^i}{dt^i} \mid a_k \in \mathbb{R}, k = 0, 1, \dots, i \right\}.$$

Since we do not want to increase the order of the polynomial, we consider only the following restricted transformations.

DEFINITION 2.2. *Systems  $M\ddot{x} + G\dot{x} + Kx = Bu$  and  $\hat{M}\ddot{x} + \hat{G}\dot{x} + \hat{K}x = \hat{B}u$ , with  $M, G, K, \hat{M}, \hat{G}, \hat{K} \in \mathbb{R}^{n,n}$ ,  $B, \hat{B} \in \mathbb{R}^{n,m}$ , are called order-preserving unimodularly equivalent, or opu-equivalent, if there exists  $P \in \mathbb{R}[D_2]^{n,n}$  with a constant nonzero determinant such that*

$$P(M\ddot{x} + G\dot{x} + Kx - Bu) = \hat{M}\ddot{x} + \hat{G}\dot{x} + \hat{K}x - \hat{B}u.$$

The concept of opu-equivalence requires that the order of differentiation in  $x, u$  does not increase. In section 4 we will make use of analogous transformations which do not increase the order of differentiation in  $x$  but allow derivatives of the input function  $u$  to be introduced. To distinguish these two types of transformations we call the latter ones *state order-preserving unimodularly equivalences, or sopu-equivalences*.

Note that the set of consistent initial conditions is not altered by opu- and sopu-equivalence transformations, since the solution set is not altered.

In the following we will show that, as in the first order case, regularization and index reduction can be obtained via a combination of unimodular equivalence transformations and appropriate feedback transformations.

DEFINITION 2.3. *Systems  $M\ddot{x} + G\dot{x} + Kx = Bu$  and  $M\ddot{x} + \hat{G}\dot{x} + \hat{K}x = B\hat{u}$  are called equivalent under proportional feedback if there exists a matrix  $F_0$  of appropriate dimension such that  $\hat{K} = K + BF_0$ .*

*They are called equivalent under first order derivative feedback if there exists a matrix  $F_1$  of appropriate dimension such that  $\hat{G} = G + BF_1$ .*

After introducing the definitions, we now describe a condensed form under strong equivalence.

THEOREM 2.4. Consider the system (1.1). Then there exist nonsingular matrices  $P, Q \in \mathbb{R}^{n,n}$  such that the coefficients in the transformed system

$$(2.2) \quad \hat{M}\ddot{\hat{x}} + \hat{G}\dot{\hat{x}} + \hat{K}\hat{x} - \hat{B}u = PMQ\ddot{\hat{x}} + PGQ\dot{\hat{x}} + PKQ\hat{x} - PBu$$

that are obtained by setting  $x = Q\hat{x}$  have the following form:

$$(2.3) \quad \begin{pmatrix} \begin{bmatrix} I_{s^{(0,1,2)}} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & I_{s^{(1,2)}} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & I_{s^{(0,2)}} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I_{d^{(2)}} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \\ \begin{bmatrix} 0 & 0 & * & * & 0 & 0 & * & * \\ 0 & 0 & * & * & 0 & 0 & * & * \\ 0 & 0 & * & * & 0 & 0 & * & * \\ 0 & 0 & * & * & 0 & 0 & * & * \\ 0 & 0 & 0 & * & I_{s^{(0,1)}} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & I_{d^{(1)}} & 0 & 0 \\ I_{s^{(0,1,2)}} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & I_{s^{(1,2)}} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \\ \begin{bmatrix} 0 & * & 0 & * & 0 & * & 0 & * \\ 0 & * & 0 & * & 0 & * & 0 & * \\ 0 & * & 0 & * & 0 & * & 0 & * \\ 0 & * & 0 & * & 0 & * & 0 & * \\ 0 & * & 0 & * & 0 & * & 0 & * \\ 0 & * & 0 & * & 0 & * & 0 & * \\ 0 & * & 0 & * & 0 & * & 0 & * \\ 0 & * & 0 & * & 0 & * & 0 & * \\ 0 & 0 & 0 & 0 & 0 & 0 & I_a & 0 \\ 0 & 0 & 0 & 0 & I_{s^{(0,1)}} & 0 & 0 & 0 \\ 0 & 0 & I_{s^{(0,2)}} & 0 & 0 & 0 & 0 & 0 \\ I_{s^{(0,1,2)}} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} \hat{B}_1 \\ \hat{B}_2 \\ \hat{B}_3 \\ \hat{B}_4 \\ \hat{B}_5 \\ \hat{B}_6 \\ \hat{B}_7 \\ \hat{B}_8 \\ \hat{B}_9 \\ \hat{B}_{10} \\ \hat{B}_{11} \\ \hat{B}_{12} \\ \hat{B}_{13} \end{bmatrix} \end{pmatrix},$$

where  $s^{(0,1,2)}, s^{(1,2)}, s^{(0,2)}, s^{(0,1)}, d^{(2)}, d^{(1)}, a$ , and  $v$  are nonnegative integers and the blocks denoted by  $*$  are not specified.

*Proof.* This result follows directly from Theorem 12 in [35] with  $f = Bu$ .  $\square$

Based on Theorem 2.4 we can then show the following result.

THEOREM 2.5. *Consider system (1.1)–(1.2). Then there exists a sequence of strong and opu-equivalence transformations such that the transformed system*

$$\hat{M}\ddot{\hat{x}} + \hat{G}\dot{\hat{x}} + \hat{K}\hat{x} = \hat{B}\hat{u}$$

*has the form*

$$\begin{aligned} & \begin{bmatrix} I & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \ddot{\hat{x}} + \begin{bmatrix} \hat{G}_{11} & 0 & \hat{G}_{13} & 0 \\ 0 & I & 0 & 0 \\ \hat{G}_{31} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \dot{\hat{x}} + \begin{bmatrix} \hat{K}_{11} & \hat{K}_{12} & \hat{K}_{13} & 0 \\ \hat{K}_{21} & \hat{K}_{22} & \hat{K}_{23} & 0 \\ \hat{K}_{31} & \hat{K}_{32} & \hat{K}_{33} & 0 \\ \hat{K}_{41} & \hat{K}_{42} & \hat{K}_{43} & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I \end{bmatrix} \hat{x} \\ &= \begin{bmatrix} \hat{B}_1 \\ \hat{B}_2 \\ \hat{B}_3 \\ \hat{B}_4 \\ \hat{B}_5 \\ 0 \end{bmatrix} \hat{u}, \\ & y = [\hat{C}_1 \quad \hat{C}_2 \quad \hat{C}_3 \quad \hat{C}_4] \hat{x}, \end{aligned}$$

where

$$\hat{x} = [\hat{x}_1^T \quad \hat{x}_2^T \quad \hat{x}_3^T \quad \hat{x}_4^T]^T,$$

and, furthermore,  $\hat{B}_3, \hat{B}_4$ , and  $\hat{B}_5$  have full row rank.

*Proof.* A detailed constructive proof is given in Appendix A of [32].  $\square$

THEOREM 2.6. *Consider system (1.1)–(1.2). Then there exists a sequence of strong and opu-equivalence transformations, as well as proportional feedbacks and first order derivative feedbacks such that the transformed system*

$$\hat{M}\ddot{\hat{x}} + \hat{G}\dot{\hat{x}} + \hat{K}\hat{x} = \hat{B}\hat{u}$$

*has the form*

$$\begin{aligned} & \begin{bmatrix} I & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \ddot{\hat{x}} + \begin{bmatrix} \hat{G}_{11} & 0 & \hat{G}_{13} & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \dot{\hat{x}} + \begin{bmatrix} \hat{K}_{11} & \hat{K}_{12} & \hat{K}_{13} & 0 \\ \hat{K}_{21} & \hat{K}_{22} & \hat{K}_{23} & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I \end{bmatrix} \hat{x} \\ &= \begin{bmatrix} \hat{B}_1 \\ \hat{B}_2 \\ \hat{B}_3 \\ 0 \end{bmatrix} \hat{u}, \\ (2.4) \quad y &= [\hat{C}_1 \quad \hat{C}_2 \quad \hat{C}_3 \quad \hat{C}_4] \hat{x}, \end{aligned}$$

where

$$\hat{x} = [\hat{x}_1^T \quad \hat{x}_2^T \quad \hat{x}_3^T \quad \hat{x}_4^T]^T,$$

and  $\hat{B}_3$  has full row rank.

*Proof.* A detailed constructive proof is given in Appendix B of [32].  $\square$

*Remark 2.7.* It is important to note that, in general, a combination of all of the described types of transformations in Theorem 2.6 is needed to achieve the condensed form (2.4). Furthermore, even though the proofs to Theorems 2.5 and 2.6 as well as that of the condensed form (2.3) are constructive (see [32, 35]), in general they cannot be implemented in a numerically reliable way. As an alternative way, for matrix pencils, staircase algorithms have been constructed that determine the structural information in the condensed forms via orthogonal transformations; see, e.g., [13, 42].

We can use the normal form (2.4) to derive a first order formulation which, as we will show later, avoids the difficulties of other first order formulations.

**COROLLARY 2.8.** *Consider system (1.1)–(1.2). Then there exists a bijective map between the solutions of (1.1) and the components  $\xi_2, \dots, \xi_5$  of the first order system  $\hat{E}\dot{\xi} = \hat{A}\xi + \hat{B}_1\hat{u}$  given by*

$$(2.5) \quad \begin{bmatrix} I & \hat{G}_{11} & 0 & \hat{G}_{13} & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \end{bmatrix} \dot{\xi} = \begin{bmatrix} 0 & -\hat{K}_{11} & -\hat{K}_{12} & -\hat{K}_{13} & 0 \\ 0 & -\hat{K}_{21} & -\hat{K}_{22} & -\hat{K}_{23} & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -I \\ I & 0 & 0 & 0 & 0 \end{bmatrix} \xi + \begin{bmatrix} \hat{B}_1 \\ \hat{B}_2 \\ \hat{B}_3 \\ 0 \\ 0 \end{bmatrix} \hat{u},$$

$$(2.5) \quad y = \begin{bmatrix} 0 & \hat{C}_1 & \hat{C}_2 & \hat{C}_3 & \hat{C}_4 \end{bmatrix} \xi,$$

where  $\hat{B}_3$  has full row rank,

$$\xi = \begin{bmatrix} \xi_1^T & \xi_2^T & \xi_3^T & \xi_4^T & \xi_5^T \end{bmatrix}^T = \begin{bmatrix} \hat{x}_1^T & \hat{x}_1^T & \hat{x}_2^T & \hat{x}_3^T & \hat{x}_4^T \end{bmatrix}^T,$$

and  $\hat{x} = [\hat{x}_1^T \ \hat{x}_2^T \ \hat{x}_3^T \ \hat{x}_4^T]^T$  is a solution of (2.4).

Furthermore, the first order system (2.5) is I-controllable.

*Proof.* By solving for  $\xi_1$  in the last block row of (2.5) we obtain (2.4), which is equivalent to (1.1)–(1.2).

The I-controllability of (2.5) follows immediately from the definition, since in this case

$$[E, AS_\infty(E), B] = \left[ \begin{array}{ccccc|cc|c} I & \hat{G}_{11} & 0 & \hat{G}_{13} & 0 & -\hat{K}_{13} & 0 & \hat{B}_1 \\ 0 & 0 & I & 0 & 0 & -\hat{K}_{23} & 0 & \hat{B}_2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_3 \\ 0 & 0 & 0 & 0 & 0 & 0 & -I & 0 \\ 0 & I & 0 & 0 & 0 & -\hat{G}_{13} & 0 & 0 \end{array} \right]$$

has full rank.  $\square$

*Remark 2.9.* The bijectivity of the map in Corollary 2.8 follows from the fact that strong equivalence transformations form a bijection and that the linear combination of derivatives of equations that do contain the output (opu-equivalence) does not change the solution sets of classical solutions. Note that the relationship between  $u$  and  $\hat{u}$  is just a change of basis.

If the system is considered in the distributional setting, then one has to be careful with opu-equivalences, since then the impulse order may change but the smooth parts of the solution are still mapped in a bijective way. See [17, 30] for a detailed discussion of this issue.

Let us illustrate these results with some examples.

*Example 2.10.* Consider the artificial second order descriptor system (1.1) with

$$M = 0, \quad G = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad K = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 1 \\ 0 \end{bmatrix}.$$

Since this is in fact a first order system, we can check its I-controllability using condition **C2** with  $E = G$ ,  $A = -K$ ,  $B_1 = B$  and see that

$$\text{rank} \begin{bmatrix} E & AS_\infty(E) & B \end{bmatrix} = \text{rank} \left[ \begin{array}{cc|c} 0 & 1 & 0 \\ 0 & 0 & -1 \end{array} \right] = 2.$$

But if we perform the classical transformation to first order, then we obtain

$$\tilde{E} = \left[ \begin{array}{cc|cc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array} \right], \quad \tilde{A} = \left[ \begin{array}{cc|cc} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ \hline 0 & 0 & 0 & -1 \\ -1 & 0 & 0 & 0 \end{array} \right], \quad \tilde{B} = \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}.$$

In this case

$$\begin{bmatrix} \tilde{E} & \tilde{A}S_\infty(\tilde{E}) & \tilde{B} \end{bmatrix} = \left[ \begin{array}{cccc|cc|c} 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array} \right]$$

does not have full row rank, and hence the system is not I-controllable.

In this system we can easily reduce the classical first order formulation to one which is I-controllable by carrying out an index reduction procedure on the first order formulation.

The previous example seems artificial, but a similar phenomenon arises for constrained mechanical systems.

*Example 2.11.* Consider again the system (1.12). The first order version (1.13) yields

$$E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} -1 & -1 & -1 \\ 0 & -1 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix},$$

which is obviously not I-controllable.

If, however, we use the construction to the normal form (2.4), then we obtain a system with

$$\hat{M} = 0, \quad \hat{G} = 0, \quad \hat{K} = K, \quad \hat{B} = B,$$

and this system is I-controllable.

We see from these examples that the choice of the first order formulation is important. While the classical first order formulation of the system may not be I-controllable, the normal form (2.4) allows one to obtain a first order formulation that is I-controllable.

*Remark 2.12.* A natural question that arises is whether we could not just formally first introduce a first order formulation and then perform index reduction via transformation to normal form, including opu-equivalence transformations. This is indeed possible if the original triple is regular, i.e.,  $\det(\lambda^2 M + \lambda G + K) \neq 0$ , since

it is then known that the length of chains associated with the eigenvalue  $\infty$  is kept invariant under the classical companion formulation [20]. This is not true any longer if  $\det(\lambda^2 M + \lambda G + K)$  vanishes identically as the following example of [8] shows. For the singular matrix polynomial

$$P(\lambda) = \begin{bmatrix} \lambda^2 + \lambda & 0 \\ 1 & 0 \end{bmatrix},$$

the right null space is  $x(\lambda) = e_2$ , which creates a chain of length 1, and the left null space is  $y(\lambda) = [-1 \quad \lambda^2 + \lambda]$ , which gives  $y_0 = -e_1$ ,  $y_1 = e_2$ , and  $y_2 = e_2$ , and thus the chain has length 3.

By considering the first companion linearization, we get

$$L(\lambda) = \lambda \left[ \begin{array}{cc|cc} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array} \right] + \left[ \begin{array}{cc|cc} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ \hline -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{array} \right].$$

The right and left null space vector polynomials are

$$x(\lambda) = \begin{bmatrix} 0 \\ \lambda \\ 0 \\ 1 \end{bmatrix}, \quad y(\lambda) = \begin{bmatrix} 1 \\ -\lambda^2 - \lambda \\ \lambda + 1 \\ 0 \end{bmatrix},$$

and clearly the right chain does not have the same length as in the original matrix polynomial.

Furthermore, performing a first order formulation first may substantially change the sensitivity of the problem, in particular when computing the index reduction; see [35] for an illustrative example.

Thus it is generally preferable to perform index reductions and reformulations on the original data which is the second order pencil.

In the next section we will show how we can use the condensed forms of this section to check the different controllability and observability conditions directly for second order systems and how to derive first order formulations that preserve these conditions.

**3. Controllability for second order systems.** For a descriptor system (1.1)–(1.3), the following definitions extend the concepts of C-controllability and C-observability to second order descriptor systems.

**DEFINITION 3.1.** Consider a system as in (1.1)–(1.3). A set  $\mathcal{R} \subseteq \mathbb{R}^n$  is called reachable from  $x_0, \dot{x}_0$  if for every  $x_f \in \mathcal{R}$  there exists a piecewise continuous input function  $u$  that transfers the system in finite time from  $x(t_0) = x_0$  to  $x_f$ .

A set  $\mathcal{R} \subseteq \mathbb{R}^n \times \mathbb{R}^n$  is called  $\mathcal{R}2$ -reachable from  $x_0, \dot{x}_0$  if for every  $x_f, \dot{x}_f \in \mathcal{R}$  there exists a piecewise continuous input function  $u$  that transfers the system in finite time from  $x(t_0) = x_0, \dot{x}(t_0) = \dot{x}_0$  to  $x_f, \dot{x}_f$ . The system is called

- (i) C-controllable if for any  $x_0$  and  $\dot{x}_0$  and any  $x_f \in \mathbb{R}^n$  there exist a time  $t_f$  and a piecewise continuous input function  $u : [t_0, t_f] \rightarrow \mathbb{R}^m$  such that  $x(t_f) = x_f$ ;
- (ii) strongly C2-controllable if for any  $x_0, \dot{x}_0$  and any  $x_f, \dot{x}_f \in \mathbb{R}^n$  there exist a time  $t_f$  and a piecewise continuous input function  $u : [t_0, t_f] \rightarrow \mathbb{R}^m$  such that  $x(t_f) = x_f, \dot{x}(t_f) = \dot{x}_f$ ;

- (iii)  $\mathcal{R}$ -controllable if any state  $x_f$  in the reachable set  $\mathcal{R}$  can be reached from any admissible  $x_0, \dot{x}_0$  in finite time;
- (iv)  $\mathcal{R}2$ -controllable if any state and derivative  $(x_f, \dot{x}_f)$  in the  $\mathcal{R}2$ -reachable set can be reached from any admissible  $x_0, \dot{x}_0$  in finite time.

By using the normal form (2.4) we get a variation of C2-controllability, which is better adapted to the problem.

**DEFINITION 3.2.** *A system in normal form (2.4) is called C2-controllable if for any  $\hat{x}(0), \dot{\hat{x}}_1(0)$  and any  $\hat{x}_f \in \mathbb{R}^n, \hat{x}_{1,f} \in \mathbb{R}^{\dim(\hat{x}_1)}$  there exists a time  $t_f$  and a piecewise continuous input function  $u : [t_0, t_f] \rightarrow \mathbb{R}^m$  such that  $\hat{x}(t_f) = \hat{x}_f, \dot{\hat{x}}(t_f) = \dot{\hat{x}}_{1,f}$ .*

We immediately see that a strongly C2-controllable second order descriptor system is also C2-controllable, that a C2-controllable second order descriptor system is also C-controllable, and that an  $\mathcal{R}2$ -controllable second order descriptor system is also  $\mathcal{R}$ -controllable.

For the analysis of controllability conditions let us first discuss the case that  $M$  is invertible; i.e., we have an implicitly defined second order ordinary differential equation. Then it is known that C-controllability is equivalent to C2-, strong C2-,  $\mathcal{R}2$ -, and  $\mathcal{R}$ -controllability, and all five are characterized by the Hautus criterion [1, 24],

$$(3.1) \quad \text{rank} \begin{bmatrix} \lambda^2 M + \lambda G + K & B \end{bmatrix} = n \text{ for all } \lambda \in \sigma(M, G, K),$$

where  $\sigma(M, G, K)$  denotes the spectrum of the matrix polynomial  $P(\lambda) = \lambda^2 M + \lambda G + K$ , i.e., the roots of  $\det P(\lambda)$ .

Strong C2-controllability and  $\mathcal{R}2$ -controllability is trivially characterized via the classical (companion) first order form.

**COROLLARY 3.3.** *Consider a second order descriptor system (1.1) and its classical (companion) first order form*

$$(3.2) \quad \begin{bmatrix} M & 0 \\ 0 & I \end{bmatrix} \dot{z} = \begin{bmatrix} -G & -K \\ I & 0 \end{bmatrix} z + \begin{bmatrix} B \\ 0 \end{bmatrix} u.$$

- (i) *System (1.1) is strongly C2-controllable if and only if (3.2) is C-controllable.*
- (ii) *System (1.1) is  $\mathcal{R}2$ -controllable if and only if (3.2) is  $\mathcal{R}$ -controllable.*

To characterize the other controllability conditions for second order descriptor systems, we make use of the condensed forms of section 2. From (2.4) we see that, for a consistent initial condition in the variables that occurs only in first order, we can prescribe only initial values and not initial derivatives. This immediately implies the following corollary.

**COROLLARY 3.4.**

- (i) *A second order system in normal form (2.4) is C2-controllable if and only if the associated first order system (2.5) is C-controllable.*
- (ii) *A second order system in normal form (2.4) is  $\mathcal{R}2$ -controllable if and only if the associated first order system (2.5) is  $\mathcal{R}$ -controllable.*

We can illustrate the difference between strong C2-controllability and C2-controllability by the following example.

**Example 3.5.** Consider the following C2-controllable second order system in normal form (2.4):

$$\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \ddot{x} + \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} \dot{x} + \begin{bmatrix} 0 & 0 \\ -1 & 0 \end{bmatrix} x = \begin{bmatrix} 1 \\ 0 \end{bmatrix} u.$$

The first order formulation given in Corollary 2.8 is given by

$$\left[ \begin{array}{c|cc} 1 & 0 & 0 \\ 0 & 0 & 1 \\ \hline 0 & 1 & 0 \end{array} \right] \dot{\xi} = \left[ \begin{array}{c|cc} 0 & 0 & 0 \\ 0 & 1 & 0 \\ \hline 1 & 0 & 0 \end{array} \right] \xi + \left[ \begin{array}{c} 1 \\ 0 \\ 0 \end{array} \right] u.$$

This system is C-controllable, since

$$\text{rank} \left[ \begin{array}{cc|c} \alpha E - \beta A & B_1 \end{array} \right] = \left[ \begin{array}{ccc|c} \alpha & 0 & 0 & 1 \\ 0 & -\beta & \alpha & 0 \\ -\beta & \alpha & 0 & 0 \end{array} \right] = 3 \text{ for all } (\alpha, \beta) \in \mathbb{C}^2 \setminus \{(0, 0)\}.$$

But the classical first order formulation

$$\left[ \begin{array}{cc|cc} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array} \right] \dot{z} = \left[ \begin{array}{cc|cc} 0 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 \\ \hline -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{array} \right] z + \left[ \begin{array}{c} 1 \\ 0 \\ 0 \\ 0 \end{array} \right] u$$

is not C-controllable, since

$$\text{rank} \left[ \begin{array}{cc|ccc} \alpha & 0 & 0 & 0 & 1 \\ 0 & -\beta & \beta & 0 & 0 \\ \beta & 0 & \alpha & 0 & 0 \\ 0 & \beta & 0 & \alpha & 0 \end{array} \right] \neq 4 \text{ for } \beta = 0,$$

and hence the original system is not strongly C2-controllable. It is easily checked that both first order formulations are  $\mathcal{R}$ -controllable.

In order to study I-controllability we will make use of different types of feedback. DEFINITION 3.6. Consider a second order descriptor system (1.1)–(1.2).

- (i) The system is called proportionally I-controllable if there exists a state feedback  $u = \hat{u} - F_0 x$  such that the resulting system with coefficients  $(M, G, K + BF_0)$  is regular and of index at most one.
- (ii) The system is called differentially I-controllable if there exists a first order derivative feedback  $u = \hat{u} - F_1 \dot{x}$  such that the resulting system with coefficients  $(M, G + BF_1, K)$  is regular and of index at most one.
- (iii) The system is called proportionally and differentially I-controllable or just I-controllable if there exist a proportional and a first order derivative feedback  $u = \hat{u} - F_0 x - F_1 \dot{x}$  such that the resulting system given by  $(M, G + BF_1, K + BF_0)$  is regular and of index at most one.

It is straightforward to show that strong equivalence transformations preserve all types of controllability for second order descriptor systems.

The same is true for proportional and first order derivative feedback. On the other hand, opu-equivalence transformations preserve C-, C2-, and strong C2-controllability as well as  $\mathcal{R}$ - and  $\mathcal{R}2$ -controllability but may turn a system that is not I-controllable into one that is I-controllable.

Example 3.7. Consider the first order descriptor system (1.4) given by

$$\left[ \begin{array}{ccc} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{array} \right] \dot{\xi} + \left[ \begin{array}{ccc} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{array} \right] \xi = \left[ \begin{array}{c} 1 \\ 1 \\ 0 \end{array} \right] u.$$

The system is not I-controllable, since

$$\text{rank} \begin{bmatrix} E & AS_\infty(E) & B_1 \end{bmatrix} = \text{rank} \left[ \begin{array}{ccc|ccc} 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{array} \right] = 2,$$

but if we apply the opu-equivalence transformation of multiplying by

$$P = \begin{bmatrix} 1 & 0 & -\frac{d}{dt} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

from the left, then we obtain the I-controllable system

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \dot{\xi} + \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix} \xi = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} u.$$

As we will see below, a combination of opu-equivalence transformations and proportional and first order derivative feedbacks together always allows one to make a second order system regular and of index at most one, which then implies I-controllability. See also [30, 31] for similar results in the first order case.

In the following we derive algebraic characterizations for the different controllability conditions. We begin with systems in normal form (2.4).

**THEOREM 3.8.** *Consider a second order descriptor system (1.1) in normal form (2.4), and let (2.5) be the first order system derived from this normal form.*

- (i) *The first order system (2.5) is  $\mathcal{R}$ -controllable if the system matrices of the normal form (2.4) satisfy (3.1).*
- (ii) *System (2.5) is I-controllable.*
- (iii) *System (2.5) is C-controllable if and only if it is  $\mathcal{R}$ -controllable and the 4th row in (2.4) is void.*

*Proof.* Let  $n_1$  be the size of the component  $\xi_1$ . To see that (i) holds, we observe that (2.5) is  $\mathcal{R}$ -controllable if and only if

$$\text{rank} \begin{bmatrix} \lambda I & \lambda \hat{G}_{11} - \hat{K}_{11} & -\hat{K}_{12} & \lambda \hat{G}_{13} - \hat{K}_{13} & 0 & \hat{B}_1 \\ 0 & -\hat{K}_{21} & \lambda I - \hat{K}_{22} & -\hat{K}_{23} & 0 & \hat{B}_2 \\ 0 & 0 & 0 & 0 & 0 & \hat{B}_3 \\ 0 & 0 & 0 & 0 & -I & 0 \\ -I & -\lambda I & 0 & 0 & 0 & 0 \end{bmatrix} = n + n_1,$$

and this is the case if and only if

$$\text{rank} \begin{bmatrix} 0 & -\lambda^2 I + \lambda \hat{G}_{11} - \hat{K}_{11} & -\hat{K}_{12} & \lambda \hat{G}_{13} - \hat{K}_{13} & 0 & \hat{B}_1 \\ 0 & -\hat{K}_{21} & \lambda I - \hat{K}_{22} & -\hat{K}_{23} & 0 & \hat{B}_2 \\ 0 & 0 & 0 & 0 & 0 & \hat{B}_3 \\ 0 & 0 & 0 & 0 & -I & 0 \\ I & 0 & 0 & 0 & 0 & 0 \end{bmatrix} = n + n_1,$$

which holds if and only if

$$\text{rank} \begin{bmatrix} -\lambda^2 I + \lambda \hat{G}_{11} - \hat{K}_{11} & -\hat{K}_{12} & \lambda \hat{G}_{13} - \hat{K}_{13} & 0 & \hat{B}_1 \\ -\hat{K}_{21} & \lambda I - \hat{K}_{22} & -\hat{K}_{23} & 0 & \hat{B}_2 \\ 0 & 0 & 0 & 0 & \hat{B}_3 \\ 0 & 0 & 0 & -I & 0 \end{bmatrix} = n.$$

By comparison with (2.4) we see that this holds if and only if  $\text{rank}[-\lambda^2 M + \lambda G - K B] = n$  for all  $\lambda \in \mathbb{C}$ , which proves the assertion.

(ii) We first carry out a strong equivalence transformation by a change of basis that eliminates  $\hat{G}_{11}$ ,  $\hat{G}_{13}$  and turn (2.5) to the form

$$\begin{bmatrix} I & 0 & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & -I & 0 & 0 & 0 \end{bmatrix} \dot{\hat{\xi}} + \begin{bmatrix} 0 & \hat{K}_{11} & \hat{K}_{12} & \hat{K}_{13} & 0 \\ 0 & \hat{K}_{21} & \hat{K}_{22} & \hat{K}_{23} & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & I \\ I & \hat{G}_{11} & 0 & \hat{G}_{13} & 0 \end{bmatrix} \hat{\xi} = \begin{bmatrix} \hat{B}_1 \\ \hat{B}_2 \\ \hat{B}_3 \\ 0 \\ 0 \end{bmatrix} \hat{u}.$$

This system is I-controllable if the matrix

$$\begin{bmatrix} I & 0 & 0 & 0 & 0 & \hat{K}_{13} & 0 & \hat{B}_1 \\ 0 & 0 & I & 0 & 0 & \hat{K}_{23} & 0 & \hat{B}_2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_3 \\ 0 & 0 & 0 & 0 & 0 & 0 & I & 0 \\ 0 & -I & 0 & 0 & 0 & \hat{G}_{13} & 0 & 0 \end{bmatrix}$$

has full row rank. But this follows since  $\hat{B}_3$  has full row rank.

(iii) Since (see, e.g., [4]) a first order descriptor system is C-controllable if it is  $\mathcal{R}$ -controllable and  $[E \ B_1]$  has full row rank, we can just check this rank condition. In the given case this matrix has the form

$$\begin{bmatrix} I & \hat{G}_{11} & 0 & \hat{G}_{13} & 0 & \hat{B}_1 \\ 0 & 0 & I & 0 & 0 & \hat{B}_2 \\ 0 & 0 & 0 & 0 & 0 & \hat{B}_3 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -I & 0 & 0 & 0 & 0 \end{bmatrix},$$

and since  $\hat{B}_3$  has full row rank, this matrix has full row rank if and only if the 4th block row is void. By considering system (2.5), we see that this holds if and only if the part  $\xi_5$  is void. But  $\xi_5 = \hat{x}_4$ , and thus we have finished the proof.  $\square$

**THEOREM 3.9.** *Consider a second order descriptor system (1.1) in normal form (2.4). Then the 4th component  $\hat{x}_4$  in (2.4) is void if and only if  $\text{rank}[M \ G \ B] = n$ .*

*Proof.* From the proof of Theorem 2.6 we see that the component  $\hat{x}_4$  is void if and only if there is no rank deficit in  $[\hat{B}_9^T \ \hat{B}_{10}^T \ \hat{B}_{11}^T \ \hat{B}_{12}^T \ \hat{B}_{13}^T]^T$ , with  $\hat{B}_9, \dots, \hat{B}_{13}$  as in (2.3).

It remains to show that this is equivalent to  $\text{rank}[M \ G \ B] = n$ . Since this rank is invariant under strong equivalence transformations, it remains to show that  $\text{rank}[\hat{M} \ \hat{G} \ \hat{B}] = n$  in (2.3) if and only if  $[\hat{B}_9^T \ \hat{B}_{10}^T \ \hat{B}_{11}^T \ \hat{B}_{12}^T \ \hat{B}_{13}^T]^T$  has full row

rank. But

$$\begin{aligned} & \text{rank} \begin{bmatrix} \hat{M} & \hat{G} & \hat{B} \end{bmatrix} \\ &= \text{rank} \begin{bmatrix} I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & * & * & \hat{B}_1 \\ 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & * & * & \hat{B}_2 \\ 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & * & * & \hat{B}_3 \\ 0 & 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & 0 & * & * & \hat{B}_4 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & I & 0 & 0 & 0 & \hat{B}_5 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & I & 0 & 0 & \hat{B}_6 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_7 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_8 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_9 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{10} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{11} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{12} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{13} \end{bmatrix} \\ &= \text{rank} \begin{bmatrix} I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & I & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & I & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_9 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{10} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{11} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{12} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{13} \end{bmatrix}, \end{aligned}$$

and hence the assertion follows.  $\square$

**THEOREM 3.10.** *Consider a second order descriptor system (1.1) and the corresponding classical (companion) first order form (3.2). Then (3.2) is C-controllable if and only if (1.1) is  $\mathcal{R}2$ -controllable and  $\text{rank}[M, B] = n$ .*

*Proof.* System (3.2) is C-controllable if and only if

$$\text{rank} \begin{bmatrix} \alpha M - \beta G & -\beta K & B \\ \beta I & \alpha I & 0 \end{bmatrix} = 2n.$$

Setting  $\beta = 0$  gives  $\text{rank}[M, B] = n$ , and  $\beta \neq 0$  gives the  $\mathcal{R}2$ -controllability condition.  $\square$

Obviously, for a second order descriptor system (1.1),  $\text{rank}[\lambda^2 M + \lambda G + K \quad B]$  is invariant under strong equivalence transformations, proportional and first order derivative feedback, and opu-equivalence transformations. Thus, we can combine these results with Corollaries 3.3 and 3.4.

**COROLLARY 3.11.** *A second order descriptor system of the form (1.1) is*

(i)  $\mathcal{R}2$ -controllable if and only if

$$\text{rank} \begin{bmatrix} \lambda^2 M + \lambda G + K & B \end{bmatrix} = n \quad \text{for all } \lambda \in \mathbb{C};$$

(ii)  $\mathcal{C}2$ -controllable if and only if it is  $\mathcal{R}2$ -controllable and

$$\text{rank} \begin{bmatrix} M & G & B \end{bmatrix} = n;$$

(iii) *strongly C2-controllable if and only if it is R2-controllable and*

$$\text{rank} \begin{bmatrix} M & B \end{bmatrix} = n.$$

Let us illustrate this result with an example.

*Example 3.12.* By continuing with the data of Example 2.11, we obtain

$$\text{rank} \begin{bmatrix} \lambda^2 M + \lambda G + K & B \end{bmatrix} = \text{rank} \begin{bmatrix} \lambda^2 + \lambda + 1 & 1 & 1 \\ 1 & 0 & 0 \end{bmatrix} = 2 \text{ for all } \lambda \in \mathbb{C}.$$

Hence, the system is R2-controllable, while

$$\text{rank} \begin{bmatrix} M & G & B \end{bmatrix} = \text{rank} \begin{bmatrix} 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} = 1,$$

and thus the system is not C2-controllable.

To characterize I-controllability we use the condensed form (2.3) which can be obtained by using only strong equivalence transformations.

**THEOREM 3.13.** *Consider a second order descriptor system (1.1) in condensed form (2.3). The system is*

- (i) *proportionally I-controllable if and only if in (2.3) the 7th and 8th block rows are void and the matrix  $[\hat{B}_{10}^T \dots \hat{B}_{13}^T]^T$  has full row rank;*
- (ii) *first order derivative I-controllable if and only if in (2.3) the 10th to 12th block rows are void and the matrix  $[\hat{B}_7^T \hat{B}_8^T \hat{B}_{13}^T]^T$  has full row rank;*
- (iii) *proportional and first order derivative I-controllable if and only if in (2.3) the matrix  $[\hat{B}_7^T \hat{B}_8^T \hat{B}_{10}^T \dots \hat{B}_{13}^T]^T$  has full row rank.*

*Proof.* From the proof of Theorem 2.6 we observe the following:

(a) If in (2.3) the 7th and 8th block rows are void, then we do not need a first order derivative feedback to make the system regular and of index at most one. If these are not void, then proportional feedback is not enough to achieve this.

(b) Similarly, if in (2.3) the 10th to 12th block rows are void, then we do not need a proportional feedback to make the system regular and of index at most one. If these are not void, then first order derivative feedback is not enough to achieve this.

(c) If in (2.3) the matrix

$$\begin{bmatrix} \hat{B}_7^T & \hat{B}_8^T & \hat{B}_{10}^T & \dots & \hat{B}_{13}^T \end{bmatrix}^T$$

has full row rank, then we do not need opu-equivalence transformations to make the system regular and of index at most one. If there is a rank deficit, then proportional and first order derivative feedback is not sufficient to make the system regular and of index at most one.

Then with (c) we obtain (iii), with (a) and (c) we obtain (i), and with (b) and (c) we get (ii).  $\square$

Theorem 3.13 shows that the condensed form (2.3) and the canonical form (2.4) allow one to check the different controllability properties for second order descriptor systems. For mathematical elegance and a simpler description it would also be nice to have a coordinate-free algebraic characterization. This is given in the following theorem.

**THEOREM 3.14.** *Consider a second order descriptor system (1.1) and its condensed form (2.3), and let  $s^{(0,1,2)}$ ,  $s^{(0,2)}$ ,  $s^{(0,1)}$ , and  $s^{(1,2)}$  be the integer quantities defined in Theorem 2.4. Then the system is*

(i) *proportionally and first order derivative I-controllable if and only if*

$$(3.3) \quad \text{rank} \begin{bmatrix} M & GS_\infty^1 & KS_\infty^2 & B \end{bmatrix} = n,$$

where the columns of the matrix  $S_\infty^1$  form a basis of  $\ker M$ , the columns of  $S_\infty^2$  form a basis of

$$\ker \begin{bmatrix} M \\ Z_1^T G \end{bmatrix} \setminus \ker \begin{bmatrix} M \\ Z_3^T G \\ Z_3^T K \end{bmatrix},$$

the columns of  $Z_1$  form a basis of  $\ker M^T$ , and those of  $Z_3$  form a basis of  $\ker \begin{bmatrix} M^T \\ G^T \end{bmatrix}$ ;

(ii) *proportionally I-controllable if and only if it satisfies (i) and  $s^{(0,1,2)} = s^{(1,2)} = 0$ ;*

(iii) *first order derivative I-controllable if and only if it satisfies (i) and  $s^{(0,1,2)} = s^{(0,2)} = s^{(0,1)} = 0$ .*

*Proof.* (i) In the condensed form (2.3) we have

$$\begin{bmatrix} M & GS_\infty^1 & KS_\infty^2 & B \end{bmatrix} = \left[ \begin{array}{cccccccc|cccc|c|c} I_{s^{(0,1,2)}} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & \hat{B}_1 \\ 0 & I_{s^{(1,2)}} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & \hat{B}_2 \\ 0 & 0 & I_{s^{(0,2)}} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & \hat{B}_3 \\ 0 & 0 & 0 & I_{d^{(2)}} & 0 & 0 & 0 & 0 & 0 & 0 & * & * & 0 & \hat{B}_4 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & I_{s^{(0,1)}} & 0 & 0 & 0 & 0 & \hat{B}_5 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & I_{d^{(1)}} & 0 & 0 & 0 & \hat{B}_6 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_7 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_8 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & I_a & \hat{B}_9 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{10} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{11} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{12} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \hat{B}_{13} \end{array} \right].$$

Thus,  $\text{rank}[M \ GS_\infty^1 \ KS_\infty^2 \ B] = n$  if and only if the matrix  $\text{sfif}[\hat{B}_7^T \ \hat{B}_8^T \ \hat{B}_{10}^T \ \dots \ \hat{B}_{13}^T]^T$  has full row rank. Then by Theorem 3.13(iii) the system is proportionally and first order derivative I-controllable.

It remains to show that  $\text{rank} \begin{bmatrix} M & GS_\infty^1 & KS_\infty^2 & B \end{bmatrix}$  is invariant under strong equivalence. For this let

$$\tilde{M} = PMQ, \quad \tilde{G} = PGQ, \quad \tilde{K} = PKQ, \quad \tilde{B} = PBV,$$

and let  $\tilde{Z}_1, \tilde{Z}_3, \tilde{S}_\infty^1, \tilde{S}_\infty^2$  be the corresponding subspaces. Since  $\tilde{M}v = 0$  if and only if  $PMQv = 0$  if and only if  $MQv = 0$ , we obtain  $Q\tilde{S}_\infty^1 = S_\infty^1$  and analogously in Theorem  $P^T\tilde{Z}_1 = Z_1$  and  $P^T\tilde{Z}_3 = Z_3$ . Since, furthermore,

$$\begin{bmatrix} \tilde{M} \\ \tilde{Z}_1^T \tilde{G} \end{bmatrix} v = 0 \Leftrightarrow \begin{bmatrix} PMQ \\ Z_1^T P^{-1} PGQ \end{bmatrix} v = 0 \Leftrightarrow \begin{bmatrix} M \\ Z_1^T G \end{bmatrix} Qv = 0$$

and

$$\begin{bmatrix} \tilde{M} \\ \tilde{Z}_1^T \tilde{G} \\ \tilde{Z}_3^T \tilde{K} \end{bmatrix} v = 0 \Leftrightarrow \begin{bmatrix} PMQ \\ Z_1^T P^{-1} PGQ \\ Z_3^T P^{-1} PKQ \end{bmatrix} v = 0 \Leftrightarrow \begin{bmatrix} M \\ Z_1^T G \\ Z_3^T K \end{bmatrix} Qv = 0,$$

we have  $Q\tilde{S}_\infty^2 = S_\infty^2$ . Thus, altogether we have

$$\begin{aligned} \text{rank}[\tilde{M}, \tilde{G}\tilde{S}_\infty^1, \tilde{K}\tilde{S}_\infty^2, \tilde{B}] \\ = \text{rank}[PMQ, PGQQ^{-1}S_\infty^1, PKQQ^{-1}S_\infty^2, PBV] \\ = \text{rank}[M, GS_\infty^1, KS_\infty^2, B]. \end{aligned}$$

This finishes the proof of (i). Parts (ii) and (iii) then follow from Theorem 3.13.  $\square$

*Remark 3.15.* If in Theorem 3.14 we have  $M = 0$ , then  $S_\infty^1 = I$ ,  $Z_1 = I$ ,  $Z_3$  is a basis of  $\text{kernel } G^T$ , and  $S_\infty^2$  is a basis of

$$\text{kernel } G \setminus \text{kernel} \begin{bmatrix} G \\ Z_3 K \end{bmatrix}.$$

Thus,  $\text{rank}[M \quad GS_\infty^1 \quad KS_\infty^2 \quad B] = \text{rank}[G \quad KS_\infty^2 \quad B]$ . In this case, the condensed form is

$$\left( 0, \begin{bmatrix} I_{s^{(0,1)}} & 0 & 0 & 0 \\ 0 & I_{d^{(1)}} & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & * & 0 & * \\ 0 & * & 0 & * \\ 0 & 0 & I_a & 0 \\ I_{s^{(0,1)}} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} \hat{B}_5 \\ \hat{B}_6 \\ \hat{B}_9 \\ \hat{B}_{10} \\ \hat{B}_{13} \end{bmatrix} \right),$$

and thus

$$\begin{aligned} \text{rank} \begin{bmatrix} G & KS_\infty^2 & B \end{bmatrix} &= \text{rank} \left[ \begin{array}{cccc|c} I_{s^{(0,1)}} & 0 & 0 & 0 & 0 \\ 0 & I_{d^{(1)}} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & I_a \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array} \begin{array}{c} \hat{B}_5 \\ \hat{B}_6 \\ \hat{B}_9 \\ \hat{B}_{10} \\ \hat{B}_{13} \end{array} \right] \\ &= \text{rank} \begin{bmatrix} G & KS_\infty(G) & B \end{bmatrix}. \end{aligned}$$

This shows that Theorem 3.14 is a direct generalization of the I-controllability results for first order systems.

*Example 3.16.* By continuing with Example 2.10, we obtain that the system is proportionally and first order derivative I-controllable if and only if  $\text{rank}[G \quad KS_\infty(G) \quad B] = n$ , which we have seen already. Since  $M = 0$  we have  $s^{(0,1,2)} = s^{(1,2)} = s^{(0,2)} = 0$ , and, thus, the system is proportionally I-controllable as well as first order derivative I-controllable.

This example also demonstrates that condition (3.3) in Theorem 3.14(i) is not equivalent to condition **C2** in (1.14), since the classical first order companion form does not satisfy **C2** but (3.3). Other examples with  $M \neq 0$  are easily constructed.

*Example 3.17.* In Example 1.2 we have

$$GS_\infty^1 = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad Z_1^T G = \begin{bmatrix} 0 & 0 \end{bmatrix}, \quad Z_3^T K = \begin{bmatrix} H_1 & 0 \end{bmatrix},$$

and

$$\text{kernel} \begin{bmatrix} M \\ Z_1^T G \end{bmatrix} \setminus \text{kernel} \begin{bmatrix} M \\ Z_1^T G \\ Z_3^T K \end{bmatrix} = \emptyset.$$

Then  $\text{rank}[M \quad GS_\infty^1 \quad KS_\infty^2 \quad B] = 3 < n = 5$ ; i.e., the system is not I-controllable.

We also have similar  $\mathcal{R}$ -controllability.

**THEOREM 3.18.** *Consider a second order descriptor system (1.1) and its first order formulation (2.5). Let  $\mathcal{R}$  be the reachable set of (2.5), and let*

$$E_0 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix}$$

be partitioned as  $\hat{E}$  in (2.5). Then the following are equivalent:

- (i) The system is  $\mathcal{C}$ -controllable.
- (ii) In the first order formulation (2.5) for  $\xi_2(t_0), \dots, \xi_5(t_0)$  and  $\xi_{2f}, \dots, \xi_{5f}$ , there exist  $t_f$  and an input function  $u : [t_0, t_f] \rightarrow \mathbb{R}^m$  such that  $\xi_2(t_f) = \xi_{2f}, \dots, \xi_5(t_f) = \xi_{5f}$ .
- (iii) The system is  $\mathcal{R}$ -controllable and  $\text{Im}(E_0) \subset \mathcal{R}$ .
- (iv) The system is  $\mathcal{R}$ -controllable and  $\text{rank} \begin{bmatrix} M & G & B \end{bmatrix} = n$ .

*Proof.* The equivalence of (i) and (ii) is obvious. To prove the other equivalences, consider the first order system (2.5). By carrying out a strong equivalence transformation with

$$P = \begin{bmatrix} I & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -I \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & I & 0 \end{bmatrix}, \quad Q = \begin{bmatrix} I & -\hat{G}_{11} & 0 & -\hat{G}_{13} & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & I & 0 \end{bmatrix}$$

from left and right, respectively, we obtain the system

$$\begin{bmatrix} I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \dot{\hat{\xi}} + \begin{bmatrix} 0 & \hat{K}_{11} & \hat{K}_{12} & \hat{K}_{13} & 0 \\ -I & \hat{G}_{11} & 0 & \hat{G}_{13} & 0 \\ 0 & \hat{K}_{21} & \hat{K}_{22} & \hat{K}_{23} & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix} \hat{\xi} = \begin{bmatrix} \hat{B}_1 \\ 0 \\ \hat{B}_2 \\ \hat{B}_3 \\ 0 \end{bmatrix} \hat{u},$$

where  $\xi = Q\hat{\xi}$ . Since  $\hat{B}_3$  has full row rank, we can compress its columns and eliminate with the full-rank part upwards. This gives the system

$$\begin{bmatrix} I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \dot{\hat{\xi}} + \begin{bmatrix} 0 & \hat{K}_{11} & \hat{K}_{12} & \hat{K}_{13} & 0 \\ -I & \hat{G}_{11} & 0 & \hat{G}_{13} & 0 \\ 0 & \hat{K}_{21} & \hat{K}_{22} & \hat{K}_{23} & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix} \hat{\xi} = \begin{bmatrix} 0 & \tilde{B}_1 \\ 0 & 0 \\ 0 & \tilde{B}_2 \\ I & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}.$$

By choosing a proportional feedback  $u_1 = v_1 - \hat{\xi}_4$ ,  $u_2 = v_2$ , which does not change the  $\mathcal{R}$ -controllability or the reachable set  $\mathcal{R}$ , we obtain a closed loop system  $E\dot{\hat{\xi}} + A\hat{\xi} = Bv$  of the form

$$\begin{bmatrix} I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \dot{\hat{\xi}} + \begin{bmatrix} 0 & \hat{K}_{11} & \hat{K}_{12} & \hat{K}_{13} & 0 \\ -I & \hat{G}_{11} & 0 & \hat{G}_{13} & 0 \\ 0 & \hat{K}_{21} & \hat{K}_{22} & \hat{K}_{23} & 0 \\ 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix} \hat{\xi} = \begin{bmatrix} 0 & \tilde{B}_1 \\ 0 & 0 \\ 0 & \tilde{B}_2 \\ I & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix}.$$

By eliminating further in the second coefficient matrix, we get

$$\left[ \begin{array}{ccc|ccc} I & 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{array} \right] \dot{\hat{\xi}} + \left[ \begin{array}{ccc|cc} 0 & \hat{K}_{11} & \hat{K}_{12} & 0 & 0 \\ -I & \hat{G}_{11} & 0 & 0 & 0 \\ 0 & \hat{K}_{21} & \hat{K}_{22} & 0 & 0 \\ \hline 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & I \end{array} \right] \hat{\xi} = \left[ \begin{array}{cc} -\hat{K}_{13} & \tilde{B}_1 \\ -\hat{G}_{13} & 0 \\ -\hat{K}_{23} & \tilde{B}_2 \\ \hline I & 0 \\ 0 & 0 \end{array} \right] \begin{bmatrix} v_1 \\ v_2 \end{bmatrix}.$$

This system has the form

$$(3.4) \quad \begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix} \dot{\hat{\xi}} + \begin{bmatrix} A_1 & 0 \\ 0 & I \end{bmatrix} \hat{\xi} = \begin{bmatrix} \bar{B}_1 \\ \bar{B}_2 \end{bmatrix} v.$$

By following [12], we can determine the reachable set as

$$\mathcal{R} = \mathbb{R}^{n_1} \oplus \mathcal{K}(N, \bar{B}_2),$$

where  $n_1 = \text{rank}(E)$ ,  $n_2 = n - n_1$  and

$$\mathcal{K}(N, \bar{B}_2) = \text{Im}[\bar{B}_2, N\bar{B}_2, N^2\bar{B}_2, \dots, N^{n_2-1}\bar{B}_2].$$

Since  $N = 0$  we obtain

$$\mathcal{R} = \text{Im} \left[ \begin{array}{c|c} I & 0 \\ \hline 0 & \bar{B}_2 \end{array} \right] = \text{Im} \left[ \begin{array}{ccc|cc} I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ \hline 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array} \right].$$

By incorporating the change of variables in the beginning, it remains to show that

$$(3.5) \quad \text{Im} \left[ \begin{array}{cccc} 0 & 0 & 0 & 0 \\ I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{array} \right] \subset \text{Im} \left[ \begin{array}{cccc} I & -\hat{G}_{11} & 0 & -\hat{G}_{13} \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \\ 0 & 0 & 0 & 0 \end{array} \right]$$

if and only if  $\text{rank}[M \ G \ B] = n$ . But (3.5) holds if and only if the last row is void, which is by Theorem 3.9 the case if and only if  $\text{rank} \begin{bmatrix} M & G & B \end{bmatrix} = n$ .  $\square$

**THEOREM 3.19.** *The second order descriptor system (1.1) is  $\mathcal{R}$ -controllable if and only if for the corresponding first order system (3.4) the matrix*

$$\begin{bmatrix} 0 & I & 0 \\ 0 & 0 & I \end{bmatrix} [\bar{B}_1, A_1 \bar{B}_1, A_1^2 \bar{B}_1, \dots, A_1^{n_1-1} \bar{B}_1]$$

*has full row rank.*

*Proof.* From [12] it is known that for a first order system in the form (3.4) the reachable set is  $\mathcal{R} = \mathbb{R}^{n_1} \oplus \text{Im}(\mathcal{K}(N, \bar{B}_2))$  and the reachable set from  $\xi_0 = 0$  is  $\mathcal{R}(0) = \text{Im}(\mathcal{K}(A_1, \bar{B}_1)) \oplus \text{Im}(\mathcal{K}(N, \bar{B}_2))$ . Thus, the first order system is  $\mathcal{R}$ -controllable if and only if  $\text{Im}(\mathcal{K}(A_1, \bar{B}_1)) = \mathbb{R}^{n_1}$ . The second order descriptor system has in its state only the variables  $\xi_2, \dots, \xi_4$ ; the other variables come from the transformation to first order and are not relevant. Hence the proof follows.  $\square$

We conclude this section with a summary of the obtained results. We have shown that natural extensions of the rank conditions **C0**, **C1**, **C2** allow one to characterize C-, C2-, strong C2-  $\mathcal{R}$ -,  $\mathcal{R}2$ -, and I-controllability for second order systems but that the common transformations to first order form may destroy the I-controllability. This implies two possible routes for second order descriptor systems. Either one works directly with the second order form and avoids the transformation to first order, or one performs a transformation to first order that preserves the I-controllability. The latter approach would require the computation of the normal form (2.4). If a first order formulation is desirable, then, however, it is essential to first regularize the system and to reduce the index to at most one.

**4. Observability of second order descriptor systems.** In this section we derive the corresponding observability conditions for second order descriptor systems and analyze, in particular, the duality between controllability and observability. For this we will need the subspace spanned by the right eigenvectors and principal vectors corresponding to the finite eigenvalues of  $\lambda^2 M + \lambda G + K$ ; see [21]. We call this space the *right finite eigenspace* of  $\lambda^2 M + \lambda G + K$  and denote by  $P_{r,2}$  the projection onto this space.

DEFINITION 4.1. *Consider a system as in (1.1)–(1.2). The system is called*

- (i) C-observable *if from an output  $y = 0$  for the input  $u = 0$  it already follows that the system has only the trivial solution  $x = 0$ ;*
- (ii)  $\mathcal{R}$ -observable *if from an output  $y = 0$  for the input  $u = 0$  it already follows that the solution  $x$  satisfies  $P_{r,2}x = 0$ ;*
- (iii) I-observable *if the impulsive behavior of the solution is uniquely determined by the impulsive behavior of the output  $y$  and the jump behavior of the input  $u$ .*

Remark 4.2. Since for the trivial solution also its derivative vanishes, it makes no sense to define a concept like C2-observability.

Because the transformation from (2.4) to (2.5) leaves input and output unchanged and the impulsive behavior of the newly introduced variables is uniquely determined by the impulsive behavior of the old variables, I-observability of second order systems is a direct generalization of I-observability for first order systems. Thus, it follows immediately that a system (2.4) is I-observable if and only if the corresponding first order system (2.5) is I-observable.

THEOREM 4.3. *Consider a second order descriptor system (1.1)–(1.2), in normal form (2.4), and let (2.5) be the first order system derived from this normal form. Then the system (2.4) is  $\mathcal{R}$ -observable if and only if the first order system (2.5) is  $\mathcal{R}$ -observable.*

*Proof.* Let  $\hat{P}_{r,2}$  be the projection onto the right finite eigenspace of  $\lambda^2 \hat{M} + \lambda \hat{G} + \hat{K}$ , with  $\hat{M}$ ,  $\hat{G}$ ,  $\hat{K}$  as in (2.4), and let  $\hat{P}_{r,1}$  be the projection onto the right finite eigenspace of  $\lambda \hat{E} + \hat{A}$ , with  $\hat{E}$ ,  $\hat{A}$  as in (2.5). If we choose the partitioning as in (2.4), then

$$\hat{P}_{r,2} = \begin{bmatrix} I & 0 \\ 0 & I \\ 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

So, if (2.4) is  $\mathcal{R}$ -observable and if we set  $u = 0$  and  $y = 0$ , then it follows that  $\hat{x}_1 = 0$  and thus also  $\hat{\dot{x}}_1 = 0$ . From the fifth block row of (2.5) it then follows that

$\xi_1 = \dot{x}_1 = 0$ . Accordingly  $\xi$  has the form  $\xi = [0, \hat{x}^T]^T$ . Because

$$(4.1) \quad \hat{P}_{r,1} = \begin{bmatrix} I & 0 \\ 0 & \hat{P}_{r,2} \end{bmatrix},$$

it follows that  $\hat{P}_{r,1}\xi = 0$ , and so (2.5) is  $\mathcal{R}$ -observable. For the converse, observe that the solution  $\xi$  of (2.5) has the form  $\xi = [\xi_1]$ , where  $\hat{x}$  is the solution of (2.4). From  $\hat{P}_{r,1}\xi = 0$  and (4.1) it then follows immediately that  $\hat{P}_{r,2}\hat{x} = 0$ .  $\square$

It is again straightforward to show that strong equivalence preserves all types of observability for second order descriptor systems. The same is true for opu-equivalence transformations. Proportional or first order derivative feedback, on the other hand, may change the observability properties.

*Example 4.4.* The second order descriptor system  $M\ddot{x} + G\dot{x} + Kx = Bu$ ,  $y = Cx$ , with

$$M = \begin{bmatrix} 1 & & \\ & 0 & \\ & & 0 \end{bmatrix}, \quad G = \begin{bmatrix} 0 & & \\ & 1 & \\ & & 0 \end{bmatrix}, \quad K = \begin{bmatrix} 0 & & \\ & 0 & \\ & & 1 \end{bmatrix},$$

$$B = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix},$$

is clearly C-observable, because from  $u = 0$  one obtains  $x_3 = 0$  and from  $y = 0$  one gets  $x_1 = x_2 = 0$ . For the proportional feedback  $u = v + x_3$  and the closed loop system with input  $v$ , we obtain

$$\hat{M} = \begin{bmatrix} 1 & & \\ & 0 & \\ & & 0 \end{bmatrix}, \quad \hat{G} = \begin{bmatrix} 0 & & \\ & 1 & \\ & & 0 \end{bmatrix}, \quad \hat{K} = \begin{bmatrix} 0 & & \\ & 0 & \\ & & 0 \end{bmatrix},$$

$$\hat{B} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad \hat{C} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}.$$

Here we can no longer make any statement about  $x_3$ . Similar examples can be constructed by using first order derivative feedback. Analogously one can also show that  $\mathcal{R}$ -observability is not invariant.

To see the noninvariance of I-observability, consider a modification of system (1.12)

$$(4.2) \quad \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \ddot{x} + \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \dot{x} + \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} x = \begin{bmatrix} 0 \\ 1 \end{bmatrix} u, \quad y = \begin{bmatrix} 1 & 0 \end{bmatrix} x.$$

By using as input the Heaviside function  $H(t)$ , which is 0 for  $t < 0$  and 1 for  $t \geq 0$ , the solution is  $x_1 = H(t)$  and  $x_2 = -H(t) - \dot{H} - \ddot{H}$ , but this impulsive solution is not observed in the output  $y = x_1$ . By choosing the proportional feedback  $u = -x_2 + x_1 + v$ , we obtain  $x_2 = v$  and  $x_1$  solves the second order differential equation  $\ddot{x}_1 + \dot{x}_1 + x_1 + x_2 = 0$ . A jump in the input  $v$  will be integrated, and hence the output cannot contain impulsive parts if the input is piecewise continuous; i.e., all potential impulsive parts of the solution (of which there are none) are observed in the output.

The noninvariance under proportional or first order derivative feedback poses a problem insofar as we cannot use Theorem 2.6 to construct a system that can be

correctly transformed to first order. For this reason we proceed in a different way and make use of Theorem 14 in [35], which implies the following result.

**THEOREM 4.5.** *Consider a second order descriptor system (1.1)–(1.2) with differentiation index  $\nu$ , and suppose that  $Bu$  is  $\nu-1$  times continuously differentiable. Then there exists a sequence of strong equivalence transformations and sopu-equivalence transformations such that the transformed system has the coefficients*

$$(\hat{M}, \hat{G}, \hat{K}, \hat{B}) = \left( \begin{bmatrix} I_{d^2} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} \tilde{G}_{1,1} & 0 & 0 & \tilde{G}_{1,4} \\ 0 & I_{d^1} & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} \tilde{K}_{1,1} & \tilde{K}_{1,2} & 0 & \tilde{K}_{1,4} \\ \tilde{K}_{2,1} & \tilde{K}_{2,2} & 0 & \tilde{K}_{2,4} \\ 0 & 0 & I_a & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} \hat{B}_1 \\ \hat{B}_2 \\ \hat{B}_3 \\ \hat{B}_4 \end{bmatrix} \right),$$

where  $\hat{M}, \hat{G}, \hat{K} \in \mathbb{R}^{n \times n}$  and  $\hat{B} \in \mathbb{R}[D_\mu]^{n \times m}$ .

Note here that we allow sopu-equivalences, which do not increase the differentiation order of  $x$  but may introduce derivatives of  $u$ .

*Remark 4.6.* In contrast to Theorem 2.6, the transformed system with coefficients as in Theorem 4.5 requires derivatives of  $u$ . But since we consider  $u = 0$  only to check  $\mathcal{R}$ - and  $\mathcal{C}$ -observability, this is not a problem.

Now that we have a transformation to normal form that preserves  $\mathcal{R}$ -,  $\mathcal{C}$ -, and  $\mathcal{I}$ -observability, we immediately observe that the first order duality of controllability and observability [12, 28] also holds in the second order case if the particular output  $y = Cx$  is used, since transposing and changing the roles of  $B$  and  $C^T$  can be carried out also in the specific reduction order given by (2.5). Thus we have the following immediate consequences for the dual system to (1.1) given by

$$(4.3) \quad M^T \ddot{x} + G^T \dot{x} + K^T x = C^T u.$$

**THEOREM 4.7.** *Consider a second order descriptor system (1.1)–(1.2). The system is  $\mathcal{C}$ -observable if and only if the dual system (4.3) is  $\mathcal{C}2$ -controllable.*

*Proof.* Let (1.1)–(1.2) be in normal form (2.4). The system is  $\mathcal{C}$ -observable if and only if the corresponding first order system (2.5) is  $\mathcal{C}$ -observable. This, however, is the case if and only if the dual first order system is  $\mathcal{C}$ -controllable; see, e.g., [12]. But the dual first order system is  $\mathcal{C}$ -controllable if and only if the dual second order system is  $\mathcal{C}2$ -controllable.  $\square$

The result for  $\mathcal{R}$ -observability is analogous.

**THEOREM 4.8.** *Consider a second order descriptor system (1.1)–(1.2). The system is  $\mathcal{R}$ -observable if and only if the dual system (4.3) is  $\mathcal{R}2$ -controllable.*

*Proof.* By using Theorem 4.3 the proof is analogous to that of Theorem 4.7.  $\square$

**THEOREM 4.9.** *Consider a second order descriptor system (1.1)–(1.2). The system is  $\mathcal{I}$ -observable if and only if the dual system (4.3) is proportionally and first order derivative  $\mathcal{I}$ -controllable.*

*Proof.* The proof is analogous to that of Theorem 4.7.  $\square$

For completeness we will also present coordinate-free algebraic conditions that can be immediately derived from the duality between controllability and observability.

**COROLLARY 4.10.** *A second order descriptor system (1.1)–(1.2) is*

(i)  $\mathcal{R}$ -observable if and only if

$$\text{rank} \begin{bmatrix} \lambda^2 M + \lambda G + K \\ C \end{bmatrix} = n;$$

(ii)  $\mathcal{C}$ -observable if and only if it is  $\mathcal{R}$ -observable and

$$\text{rank} \begin{bmatrix} M \\ G \\ C \end{bmatrix} = n;$$

(iii)  $\mathcal{I}$ -observable if and only if

$$\text{rank} \begin{bmatrix} M \\ T_\infty^1 G \\ T_\infty^2 K \\ C \end{bmatrix} = n,$$

where the rows of the matrix  $T_\infty^1$  form a basis of cokernel  $M$  and the rows of  $T_\infty^2$  form a basis of

$$\text{cokernel} \begin{bmatrix} M & GZ_2 \end{bmatrix} \setminus \text{cokernel} \begin{bmatrix} M & GZ_2 & KZ_5 \end{bmatrix},$$

the columns of  $Z_2$  form a basis of kernel  $M$ , and those of  $Z_5$  form a basis of kernel  $\begin{bmatrix} M \\ G \end{bmatrix}$ .

*Remark 4.11.* In the output equation (1.2) we could have also considered a term  $C_1 \dot{x}$ . If such a term is present, then we can still transform to the form (2.4) and investigate the observability. In this case, however, the duality may be lost if derivatives of  $\hat{x}_2, \dots, \hat{x}_5$  occur.

**5. Conclusion.** We have shown how to extend the analysis of controllability and observability conditions to second order descriptor systems. We have demonstrated that the straightforward idea of using a classical first order formulation and then applying the first order results does not work, because in particular  $\mathcal{I}$ -controllability and  $\mathcal{I}$ -observability are not invariant under this transformation to first order. We have derived normal forms which can be used to check the controllability and observability conditions and from which we can obtain new first order formulations which preserve  $\mathcal{I}$ -controllability and  $\mathcal{I}$ -observability.

All of the presented results can be extended to nonreal, rectangular, and also higher order descriptor systems.

**Acknowledgment.** We thank three anonymous referees for several comments and suggestions which helped to improve the paper.

## A POST-TREATMENT OF THE HOMOGENIZATION METHOD FOR SHAPE OPTIMIZATION\*

O. PANTZ<sup>†</sup> AND K. TRABELSI<sup>‡</sup>

**Abstract.** We propose an alternative to the classical post-treatment of the homogenization method for shape optimization. Rather than penalize the material density once the optimal composite shape is obtained (by the homogenization method) in order to produce a workable shape close to the optimal one, we macroscopically project the microstructure of the former through an appropriate procedure that roughly consists in laying the material along the directions of lamination of the composite. We have tested our approach in the framework of compliance minimization in two-dimensional elasticity. Numerical results are provided.

**1. Introduction.** Shape optimization consists in finding the optimal shape (represented by an open set) that minimizes a given cost-function (a mapping from the set of open sets into  $\mathbb{R}$ ). The homogenization method in shape optimization extends the space of admissible shapes to composite shapes, that is, shapes containing microholes. This approach is motivated by theoretical as well as practical considerations and is now well established (see the books [1], [6], [8], and [10]). Theoretically, the problem does not, in general, admit solutions in a classical sense if the shape is not submitted to conditions; it is often useful to nucleate a multitude of tiny holes. Practically, optimization by the homogenization method allows the substitution of a nonstandard admissible space (the space of open sets) by a vector space (the parameters of the composite material). Solving the relaxed problem then leads to the obtention of a composite optimal shape.

However, more than an optimal shape, we are looking for a workable shape, i.e., a sufficiently smooth open set. A commonly used procedure consists in continuing the optimization, by the homogenization method, of the optimal composite solution obtained, albeit simultaneously penalizing the intermediate material densities. The main drawback of this method lies in the difficulty of controlling the level of detail with respect to the qualitative loss of optimality of the shape. Moreover, only the material density of the composite shape is explicitly used in the penalization procedure. The pattern of its microstructure is not directly exploited when the latter holds important information that can be turned into profit. In this paper, we propose an alternative method that consists in reconstituting a shape close to the optimal by straightforwardly reproducing the underlying microstructure at a macroscopic scale. A parameter allows us to control the desired degree of detail.

Let us mention that our work was prompted by another algorithm, which we have proposed in [13], that automatically combined the homogenization method with the boundary variation, and a topological criterion for nucleating holes. Indeed, we had

noticed that following the nucleation of a hole, the algorithm tended to produce areas of low density around the hole that were reminiscent of the underlying microstructure. Finally, note that our method is not a visual post-treatment intended to display the local microstructure of the optimal composite shape (see, for instance, [11]).

We first recall some classical results from the homogenization theory in elasticity. At this point, we present two important classes of composite materials: the periodic materials and the laminates. We have tested our procedure on the compliance minimization problem for an elastic structure in dimension two. It is a paradigm of the shape optimization problem, since it has the nonnegligible advantage of possessing an explicit relaxed formulation. The optimal shape can be attained in the special class of composite shapes made of laminates. This allows the numerical computation of (at least almost) optimal composite shapes. The compliance minimization problem as well as its relaxed version are presented in section 3. Lastly, in section 4, we introduce a new method that builds a sequence of shapes close to the optimal solution of the compliance minimization problem obtained through the homogenization method. This is illustrated by some numerical examples.

**2. Preliminaries. The theory of homogenization.** This section is a brief review of classical homogenization results in linear elasticity. We refer the reader to the monograph of Allaire [1] for more details on this topic (see also [6], [8], and [10]).

As stated in the introduction, the majority of problems arising in shape optimization are ill posed. The minimizing sequences do not converge to a classical shape. In effect, the nucleation of microscopic holes turns out to be profitable more often than not. The sequence of open sets thus obtained does not “converge” in the space of open sets. However, we can still define a notion of convergence for which these sequences are compact. The limits that may be attained in this fashion constitute the set of composite bodies. For simplicity, instead of considering bodies made of a mixture of material and void, we shall study composite bodies, occupying a fixed domain, made of two distinct materials. The theory of homogenization is actually better understood in this context. Numerically, void shall be approximated by a material of weak resistance, also called soft material.

**2.1. Composite materials: Homogenization in elasticity.** All the results presented in this section are classical. Their proofs can be found, for instance, in [1]. Let  $\Omega$  be an open set in  $\mathbb{R}^N$ . An elastic body occupying the domain  $\Omega$  is characterized in every point  $x$  of the domain  $\Omega$  by its Hooke law  $A(x)$ , a fourth-order tensor operating on  $N \times N$  symmetric matrices. Let  $\alpha$  and  $\beta$  be two positive real numbers. We introduce the following subsets of Hooke laws:

$$\mathcal{M}_{\alpha,\beta} := \{A \in \mathcal{M}_N^4 : A\xi : \xi \geq \alpha|\xi|^2 \text{ and } A^{-1}\xi : \xi \geq \beta|\xi|^2 \text{ for all } \xi \in \mathcal{M}_N^s\},$$

where  $\mathcal{M}_N^4$  denotes the space of fourth-order tensors operating on symmetric matrices and  $\mathcal{M}_N^s$  is the space of  $N \times N$  symmetric matrices. We assume the body  $\Omega$  to be clamped on its boundary, submitted to dead loads  $f \in L^2(\Omega; \mathbb{R}^N)$ . The elasticity system consists in determining the displacement  $u$  of the structure, i.e., the unique solution to the boundary value problem:

$$\begin{cases} -\operatorname{div}(Ae(u)) = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where  $e(u)$  is the linearized metric tensor associated with the displacement  $u$ :

$$e(u) = \frac{1}{2}(\nabla u + \nabla u^T).$$

Consider a sequence of Hooke laws  $A^\varepsilon \in L^\infty(\Omega; \mathcal{M}_{\alpha,\beta})$ . The sequence  $A^\varepsilon$  is said to H-converge to  $A^* \in L^\infty(\Omega; \mathcal{M}_{\alpha,\beta})$  if and only if, for all  $f \in L^2(\Omega; \mathbb{R}^N)$ , the sequence of displacements  $u_\varepsilon$  of the boundary value problems:

$$\begin{cases} -\operatorname{div}(A^\varepsilon e(u_\varepsilon)) = f & \text{in } \Omega, \\ u_\varepsilon = 0 & \text{on } \partial\Omega, \end{cases}$$

converges in  $L^2(\Omega; \mathbb{R}^N)$  to the solution  $u$  of the boundary value problem:

$$\begin{cases} -\operatorname{div}(A^* e(u)) = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

A remarkable property of H-convergence is that every sequence in  $L^\infty(\Omega; \mathcal{M}_{\alpha,\beta})$  admits a convergent subsequence.

*Remark 1.* If a sequence  $A^\varepsilon$  H-converges to  $A^*$ , the convergence result extends to elasticity problems with mixed boundary conditions.

Consider two elastic materials of Hooke laws  $A$  and  $B$ . A composite body made of these materials is a linear elastic body whose Hooke law may be obtained as an H-limit of a sequence of elements  $A^\varepsilon$  such that for all  $x \in \Omega$ ,  $A^\varepsilon(x)$  is equal to either  $A$  or  $B$ . For all mapping  $\theta \in L^\infty(\Omega; [0, 1])$ , we call  $\mathcal{G}_\theta$  the set of Hooke laws  $A^* \in L^\infty(\Omega; \mathcal{M}_{\alpha,\beta})$  derived using the materials  $A$  and  $B$  with respective local proportions  $\theta(x)$  and  $1 - \theta(x)$ . In other words,

$$\mathcal{G}_\theta := \left\{ A^* \in L^\infty(\Omega; \mathcal{M}_{\alpha,\beta}) : \exists \chi^\varepsilon \in L^\infty(\Omega; \{0, 1\}) \right. \\ \left. \text{such that } A^\varepsilon = \chi^\varepsilon A + (1 - \chi^\varepsilon)B \xrightarrow{H} A^* \text{ and } \chi^\varepsilon \xrightarrow{L^\infty-*} \theta \right\}.$$

Another noteworthy property of H-convergence is that the set of Hooke laws  $A(x)$  achieved at a point depends only on the value of  $\theta(x)$ . Hence, for all real  $\theta \in [0, 1]$ , there exists a closed subspace  $G_\theta$  of  $\mathcal{M}_{\alpha,\beta}$  satisfying

$$\mathcal{G}_\theta = \left\{ A^* \in L^\infty(\Omega; \mathcal{M}_{\alpha,\beta}) : A^*(x) \in G_{\theta(x)} \right\}.$$

In particular, this allows us to be content with the study of homogeneous composite solids in order to determine the properties of composite materials.

**2.2. Periodic composites.** A special family of composites is obtained by arranging periodically the two types of material  $A$  and  $B$ , as shown in Figure 1. Let  $Y = ]0, 1[^N$ . Let  $\chi \in L^\infty(\mathbb{R}^N; \{0, 1\})$  be a  $Y$ -periodic function, i.e.,  $\chi(x + f_i) = \chi(x)$  for all  $x \in \mathbb{R}^N$  and all vector  $f_i$  ( $i = 1, \dots, N$ ) of the canonical basis of  $\mathbb{R}^N$ . For all real  $\varepsilon > 0$ , we denote by  $A^\varepsilon$  the element of  $L^\infty(\Omega; \mathcal{M}_{\alpha,\beta})$  defined for all  $x \in \Omega$  by

$$A^\varepsilon(x) = \chi(x/\varepsilon)A + (1 - \chi(x/\varepsilon))B.$$

The sequence  $A^\varepsilon$  H-converges to a constant element  $A^* \in L^\infty(\Omega; \mathcal{M}_{\alpha,\beta})$  defined for all symmetric matrices of  $N$ th order by

$$A^* \sigma \cdot \sigma = \min_{\substack{\tau \in L^2_\#(Y; \mathcal{M}_N^s) \\ \int_Y \tau dx = \sigma \\ \operatorname{div}(\tau) = 0}} \int_Y (\chi(x)A + (1 - \chi(x))B)^{-1} \tau \cdot \tau dx,$$

where  $L^2_\#(Y; \mathcal{M}_N^s)$  is the set of  $Y$ -periodic  $L^2$  functions with values in  $\mathcal{L}_N^s$ . We call  $P_\theta$  the set of periodic composites obtained using  $A$  and  $B$  with respective proportions  $\theta$  and  $1 - \theta$ . Yet another remarkable property is the fact that  $\overline{P}_\theta = G_\theta$ ; i.e., any composite may be approximated by a periodic material.

FIG. 1. *Periodic composite.*

FIG. 2. *Rank-2 laminate.*

**2.3. Sequential laminates.** A rank-1 sequential laminate is obtained by successively layering the materials  $A$  and  $B$ . Higher-rank laminates are obtained recursively by repeating the procedure with the lower-rank laminate and  $A$  (or  $B$ ). Figure 2 shows a rank-2 laminate. The significant property of laminates consists in the fact that, unlike periodic composites, which necessitate solving variational problems, there are explicit formulas that enable us to compute the associated homogenized Hooke laws. In what follows, we shall consider only rank-2 laminates. Let us consider the limit case  $B = 0$ . A laminate is determined by several parameters: the density  $\theta$  of the material used, the successive directions of lamination  $e_i$ , and the proportions of lamination  $m_i$ , which represent the fraction of material with respect to the total quantity of material  $\theta$  used at each step of the manufacture of the laminate. In particular,  $\sum_i m_i = 1$ . The Hooke law  $A^*$  associated with such a composite is

$$A^{*-1} = A^{-1} + \frac{1 - \theta}{\theta} \left( \sum_{i=1}^N m_i f_A^c(e_i) \right)^{-1},$$

where for all unit vectors  $e$  of  $\mathbb{R}^2$ ,  $f_A^c(e)$  is the fourth-order tensor defined for all symmetric matrix  $\xi$  by the quadratic form

$$f_A^c(e)\xi \cdot \xi = A\xi \cdot \xi - \frac{1}{\mu} |A\xi|^2 + \frac{\mu + \lambda}{\mu(2\mu + \lambda)} ((A\xi)e \cdot e)^2.$$

For all densities  $\theta \in [0, 1]$ , we call  $L_{\theta,p}$  the set of all the Hooke laws generated by rank- $p$  laminates.

**3. Compliance optimization.** We restrict our analysis henceforth to the two-dimensional case,  $N = 2$ . Let  $\Omega$ , a connected open set of  $\mathbb{R}^2$ , be the reference configuration of a homogeneous and isotropic linearly elastic body. Assume that the boundary

of  $\Omega$  consists of three parts: the portion  $\Gamma_D$  along which the body is clamped, the portion  $\Gamma_F$  which is left free, and the last portion  $\Gamma_N$  which is submitted to surface loads  $g$ . The displacement of the structure  $u$  is the unique element,

$$u \in V := \{v \in H^1(\Omega) : u = 0 \text{ a.e. on } \Gamma_D\},$$

where for all  $v \in V$ , we have

$$\int_{\Omega} Ae(u) \cdot e(v) \, dx = \int_{\Gamma_N} g \cdot v \, dx.$$

In the above,  $A$  is the used material's Hooke law defined for all symmetric tensors  $\xi$  by

$$A\xi = 2\mu\xi + \lambda \operatorname{tr} \xi \operatorname{Id},$$

where  $\lambda$  and  $\mu$  are the Lamé coefficients of the constitutive material of the solid  $\Omega$ , and  $e(v)$  is the linearized metric tensor of  $v$ :

$$e(v) = \frac{1}{2}(\nabla v + \nabla v^T).$$

The compliance associated with the shape  $\Omega$  is defined as the work of exterior forces exerted on the solid, that is,

$$J(\Omega) = \int_{\Gamma_N} g \cdot u \, dx = \int_{\Omega} 2\mu|e(u)|^2 + \lambda(\operatorname{div} u)^2 \, dx.$$

The weaker the compliance, the more rigid the structure. Since we neglect the weight of the body, it is always advantageous to add material in order to strengthen the structure and reduce its compliance. We consider the compliance minimization problem that consists in determining  $\Omega^* \in \mathcal{U}_{ad}$  satisfying

$$(3.1) \quad J(\Omega^*) = \min_{\Omega \in \mathcal{U}_{ad}} J(\Omega),$$

where  $\mathcal{U}_{ad}$  denotes the set of open sets whose boundaries contain  $\Gamma_N$  and  $\Gamma_D$ , and whose volumes do not exceed a given maximal volume  $V$ :

$$\mathcal{U}_{ad} = \{\Omega \text{ open set in } \mathbb{R}^2 \text{ such that } \Gamma_N \cup \Gamma_D \subset \partial\Omega \text{ and } |\Omega| \leq V\}.$$

**3.1. Relaxation by the homogenization method.** Problem (3.1) is ill posed: it does not have an optimal solution. Minimizing sequences of  $J$  consist of shapes  $\Omega$  having an increasing number of holes, and do not *converge* to an element of  $\mathcal{U}_{ad}$ . In order to solve this problem, it is necessary to enlarge the space of admissible designs by allowing for composite shapes. Such a structure is determined through the local density of the used material  $\theta(x)$ , and through its effective Hooke law  $A^*(x)$  corresponding to its microstructure. In the particular case we are concerned with, an optimal solution may be obtained thanks to the particular class of composite materials that consists of the rank-2 sequential laminates. Should we impose upon the shape to be contained in a fixed box  $D$ , the relaxed minimization problem associated with the compliance minimization problem consists in solving the following minimization problem:

$$\min_{\substack{0 \leq \theta \leq 1 \\ A^* \in L_{\theta,2} \\ \int_D \theta dx \leq V}} J(\theta, A^*),$$

with

$$J(\theta, A^*) = \int_{\Gamma_N} g \cdot u \, dx,$$

where

$$u \in W := \{v \in H^1(D)^2 : v = 0 \text{ a.e. on } \Gamma_D\},$$

and the displacement of the structure satisfies for all  $v \in W$ ,

$$\int_D A^* e(u) \cdot e(v) \, dx = \int_{\Gamma_N} g \cdot v \, dx.$$

To conclude, let us recall that the above problem may be rewritten, using the dual (or complementary) energy principle, as the minimization of a functional that does not directly involve the solution of a variational problem. More precisely, we have

$$(3.2) \quad J(\theta, A^*) = \min_{\substack{\sigma \in L^2(D; \mathcal{M}_2^s) \\ \operatorname{div} \sigma = 0 \text{ in } \bar{D} \\ \sigma n = g \text{ on } \Gamma_N}} \int_D A^{*-1} \sigma \cdot \sigma \, dx.$$

The asset of such a formulation is that it enables swapping the different steps of minimization. Now, for a given  $\theta$  and  $\sigma$ , we may explicitly determine the tensor  $A^*$  of  $L_{\theta,2}$  that minimizes  $A^* \sigma \cdot \sigma$ . In addition, we infer that the directions of lamination coincide with the eigenvectors of the matrix  $\sigma$  (in particular, they are orthogonal) and that the respective proportions of lamination are

$$m_1 = \frac{|\sigma_2|}{|\sigma_1| + |\sigma_2|} \quad \text{and} \quad m_2 = \frac{|\sigma_1|}{|\sigma_1| + |\sigma_2|}.$$

Lastly, we have

$$\min_{A^* \in L_{\theta,2}} A^{*-1} \sigma \cdot \sigma = A^{-1} \sigma \cdot \sigma + \frac{1-\theta}{\theta} g^*(\sigma),$$

with

$$g^*(\sigma) = \frac{\kappa + \mu}{2\mu\kappa} (|\sigma_1| + |\sigma_2|)^2.$$

The relaxed problem (3.2) is classically solved by successive minimizations with respect to  $(\theta, A^*)$  and  $\sigma$ ; minimizing with respect to  $\sigma$  requires, at each iteration, solving a variational problem.

**4. Projection of a composite shape.** In the previous section, we have recalled how the optimal solution to the compliance minimization problem is determined. Unfortunately, the solution obtained is a composite shape that is not workable in practice. To make up for this problem, it is natural to try to build up a sequence of shapes  $\Omega^\varepsilon$  that reproduce at a macroscopic scale the underlying microstructure of the optimal composite. This sequence shall be built so that its limit behavior is that of the optimal composite shape. However, this construction is difficult to achieve because of the different scales the construction of the shape involves: the size of the structure  $L$ , and the two scales of the microstructure. Indeed, the principal microstructure (of

FIG. 3. *Three scales for one shape ( $L \gg \varepsilon_1 \gg \varepsilon_2$ ).*

characteristic scale  $\varepsilon_1$ ) itself contains a composite material (a micro-microstructure in a certain sense), namely, a rank-1 laminate (of characteristic scale  $\varepsilon_2$ ); see Figure 3. We may consider proceeding in two steps. First, reproduce a microstructure (at the macroscopic level) composed of a mixture of material, and a rank-1 laminate. Next, apply once again this procedure in order to end up with a noncomposite shape. Seemingly, three different scales have to be introduced. From a practical viewpoint, the smallest scale  $\varepsilon_2$  is bounded from below by the size of the smallest workable detail. The other magnitude scale  $\varepsilon_1$  is submitted to two contradictory constraints: it has to be small compared with the size of the structure  $L$ , and it has to be large with respect to the former scale  $\varepsilon_2$ , i.e., the smallest details allowed for; see Figure 3. Details must therefore be of a size order twice as small as the structure. Since the size of the smallest details, as well as the scale of the structure, are both parameters of the problem, they do not necessarily agree with this constraint. Moreover, the relationship between the Hooke law and the microstructure is not univocal. The same Hooke law may be achieved by different microstructures. Hence, the choice of reproducing the microstructure of a rank-2 laminate at a macroscopic scale proves to be somewhat arbitrary, all the more so as, even in this subclass of composite materials, different microstructures lead to the same Hooke law. For instance, changing the order of lamination ( $e_1$  with  $e_2$ , and  $m_1$  with  $m_2$ ) produces different microstructures without changing the Hooke law. These observations have induced us into opting for a slightly different approach that consists in reproducing, at a macroscopic level, a locally periodic shape whose associated constitutive law remains close (without being identical, however) to that of a rank-2 laminate. Such a shape has (locally) only one scale parameter, that is, the period.

**4.1. Construction of locally periodic elastic bodies.** As stated in section 2, in the nondegenerate case ( $A$  and  $B \in \mathcal{M}_{\alpha,\beta}$ ), every solid, whose Hooke law is that of a homogeneous composite solid pointwise (i.e., belonging to  $G_\theta$ ), may be obtained as the limit of solid bodies with Hooke laws taking their values in  $\{A, B\}$ . However, we do not have at our disposal a similar result in the general case (in particular, if  $B = 0$ ). Therefore, it is not obvious that we shall manage to build up a sequence of shapes  $\Omega^\varepsilon$  whose limit behavior converges to an optimal composite solid belonging to  $\mathcal{G}_\theta$ . Since we are not able to identify the set of composite solids that can be obtained with a unique elastic material  $A$  (combined with void), we set out to exhibit some of them. This shall enable us to project the optimal composite on an element of this subclass and accordingly build up a sequence of *real* shapes that converges to this element.

The constructions of homogeneous periodic solids and homogeneous sequential

 FIG. 4. Construction of  $\Omega_\varphi^\varepsilon$ .

laminates proposed in section 2 extend to the case  $B = 0$ . Homogeneous periodic solids are obtained as limits of the open sets:

$$\Omega^\varepsilon = D \cap \omega^\varepsilon,$$

where

$$\omega^\varepsilon = \{x \in \mathbb{R}^2 : \varepsilon^{-1}x \in \omega\},$$

and  $\omega$  is a  $Y$ -periodic open set, i.e.,

$$x \in \omega \Leftrightarrow x + f_1 \in \omega \Leftrightarrow x + f_2 \in \omega,$$

where  $(f_1, f_2)$  is the canonical basis of  $\mathbb{R}^2$ . It is easy to modify this definition in order to produce nonhomogeneous solids by allowing the open set  $\omega$  to depend on the considered point  $x$ . Let  $\omega$  be a smooth enough mapping from  $D$  into the space of  $Y$ -periodic open sets of  $\mathbb{R}^2$ . The sequence of open sets

$$\Omega^\varepsilon = \{x \in D : \varepsilon^{-1}x \in \omega(x)\}$$

converges to a composite solid whose Hooke law at every point  $x$  is that of a homogeneous periodic solid associated with  $\omega(x)$ . The set of composite solids that we may build up, in this fashion, remains limited after all. In particular, all the cells of periodicity are square (when we may likewise use rectangular cells) and identically oriented. Let  $\varphi$  be a smooth mapping of  $D$  into  $\mathbb{R}^2$ ; the sequence of open sets

$$(4.1) \quad \Omega_\varphi^\varepsilon = \{x \in D : \varepsilon^{-1}x \in \varphi^{-1}(\omega(x))\}$$

FIG. 5. Open set  $\omega_{\theta,m}$ .

converges to a composite solid whose Hooke law  $A^*$  is, at every point  $x$ , that of a periodic homogeneous body of period  $D\varphi^{-1}(x)Y$ , associated with the open set  $D\varphi^{-1}(x)\omega(x)$ ; see Figure 4. It should be mentioned that Briane [9] proposes a different construction that is also based on the deformation of a periodic network.

**4.2. An alternate composite material.** We substitute the optimal composite shape by a composite whose behavior is close and that may be obtained by the construction (4.1) described in the previous section.

At each point  $x$  of the domain  $D$ , the optimal laminate is determined by the orthogonal directions of lamination  $e_1$  and  $e_2$ , the density of the material  $\theta$ , and the proportions of lamination  $m_1$  and  $m_2$ . First of all, with all parameters  $m_1$ ,  $m_2$ , and  $\theta$ , we associate the  $Y$ -periodic open set  $\omega_{\theta,m}$  defined by

$$\omega_{\theta,m} \cap Y = \{x \in Y : 2|x_1 - 1/2| > p_1 \text{ and } 2|x_1 - 1/2| > p_2\},$$

where  $p_1$  and  $p_2$  are positive reals that satisfy

$$1 - p_1 p_2 = \theta \quad \text{and} \quad (1 - p_1)m_2 = (1 - p_2)m_1.$$

We assume that the directions of lamination  $e = (e_1, e_2)$  of the optimal shape constitute a regular field and that  $D$  is simply connected. Furthermore, we introduce the set  $\mathcal{F}_e$  of functions from  $D$  into  $\mathbb{R}^2$  defined by

$$(4.2) \quad \mathcal{F}_e = \left\{ \varphi : D \rightarrow \mathbb{R}^2 : \det(D_x \varphi) \neq 0, \right. \\ \left. D_x \varphi(e_1) \wedge f_1(x) = 0 \text{ and } D_x \varphi(e_2) \wedge f_2(x) = 0 \right\}.$$

The following lemma ensures that  $\mathcal{F}_e$  is not empty.

**LEMMA 4.1.** *Let  $D$  be a smooth connected bounded open set, and let  $e_1 \in C^1(\overline{D}; \mathbb{R}^2)$  be a vector field of unit norm defined in a neighborhood of  $\Omega$ ; then the set  $\mathcal{F}_e$  defined by (4.2) is not empty.*

This result is standard. However, it is not easy to find in the literature under the current formulation. For the reader's convenience, a proof is given in the appendix.

*Remark 2.* Should the directions of lamination reveal pointwise singularities or should  $D$  be not simply connected,  $\mathcal{F}_e$  may be empty.

For all elements  $\varphi \in \mathcal{F}_e$ , we call  $\Omega_\varphi^\varepsilon$  the sequence of open sets produced by the previous construction applied to  $\varphi$  and  $\omega = \omega_{\theta,m}$ ,

$$\Omega_\varphi^\varepsilon = \left\{ x \in D : \varepsilon^{-1}x \in \varphi^{-1}(\omega_{\theta,m}(x)) \right\}.$$

The sequence of open sets  $\Omega_\varphi^\varepsilon$  converges to a locally periodic composite whose density is that of the optimal laminate. Conditions  $D_x\varphi(e_i) \wedge f_i(x) = 0$  ( $i = 1, 2$ ) ensure that periodicity cells are oriented along the directions of lamination.

*Remark 3.* The limit behavior of the sequence of open sets  $\Omega_\varphi^\varepsilon$  is a locally periodic body whose periodicity cells are of the form  $R\omega_{\theta,m}$ , where  $R$  is a linear mapping (more precisely,  $R = D\varphi^{-1}$ ). Instead of solving the compliance minimization problem over rank-2 laminates, it is possible to perform only a partial relaxation by restricting the minimization to this class of composites. This approach was developed by Bendsøe and Kikuchi [7] for periodicity cells of the form above, where  $R$  is a rotation.

**5. Numerical applications.** It remains to determine an element  $\varphi$  of  $\mathcal{F}_e$  in order to infer the sequence of open sets  $\Omega_\varphi^\varepsilon$ . We choose to determine the element  $\varphi$  of  $\mathcal{F}_e$  that minimizes

$$I(\varphi) = \frac{1}{2} \int_D |\nabla\varphi_1 - e_1|^2 + |\nabla\varphi_2 - e_2|^2 dx.$$

The shape  $\Omega_\varphi^\varepsilon$  is then defined by

$$\Omega_\varphi^\varepsilon = \left\{ x \in D : \cos(\varphi_1(x)/\varepsilon) > \cos(\pi(1 - p_1)), \right. \\ \left. \text{and } \cos(\varphi_2(x)/\varepsilon) > \cos(\pi(1 - p_2)) \right\}.$$

The choice made is somewhat arbitrary, but it entails a linear system that is easily solved. Other choices are conceivable. The selection of the element  $\varphi$  of  $\mathcal{F}_e$  has an influence on the relative size of the nucleated holes and on their (more or less elongated) shape. We may consider selecting  $\varphi$  in order to minimize the error when substituting the optimal composite shape by the limit composite of the sequence  $\Omega_\varphi^\varepsilon$ . However, an explicit formula expressing a periodic material's Hooke law is not available, so this seems to be quite delicate to carry out.

**5.1. Orientation of eigenvectors.** The procedure described here requires the orientation of eigenvalues in a consistent fashion. Nevertheless, we can avoid such a computation. Assume that such an orientation has been established. We introduce vectors  $v_1$  and  $v_2$  defined by  $v_1 = \varphi_1 e_1$  and  $v_2 = \varphi_2 e_2$ . In this case, for  $i = 1, 2$  and  $j = 1, 2$ , we have

$$\nabla\varphi_i \cdot e_j = (\nabla v_i \cdot e_i) \cdot e_j.$$

Hence, minimizers of  $I(\varphi)$  also minimize the functional

$$I(v) = \frac{1}{2} \int_D |(\nabla v_1 \cdot e_1) \cdot e_1 - 1|^2 + |(\nabla v_2 \cdot e_2) \cdot e_2 - 1|^2 dx$$

on the set of vectors  $v = (v_1, v_2) : D \rightarrow \mathbb{R}^2 \times \mathbb{R}^2$  that satisfy

$$(5.1) \quad v_1 \wedge e_1 = 0, v_2 \wedge e_2 = 0, (\nabla v_1 \cdot e_2) \cdot e_1 = 0, \text{ and } (\nabla v_2 \cdot e_1) \cdot e_2 = 0.$$

Moreover, we have  $|\varphi_1| = \|v_1\|$  and  $|\varphi_2| = \|v_2\|$ . Now, the definition of  $\Omega_\varphi^\varepsilon$  depends only on the moduli of  $\varphi_1$  and  $\varphi_2$ . Therefore, in order to fully determine  $\Omega_\varphi^\varepsilon$ , it suffices to minimize  $I$  under the constraints (5.1), which is independent from the orientation of the eigenvectors  $e_1$  and  $e_2$ .

**5.2. Computing a minimizer of  $I$ .** Note that the computations of  $v_1$  and  $v_2$  are disconnected so that they can be carried out separately. To compute  $v_1$ , we introduce the Lagrangian

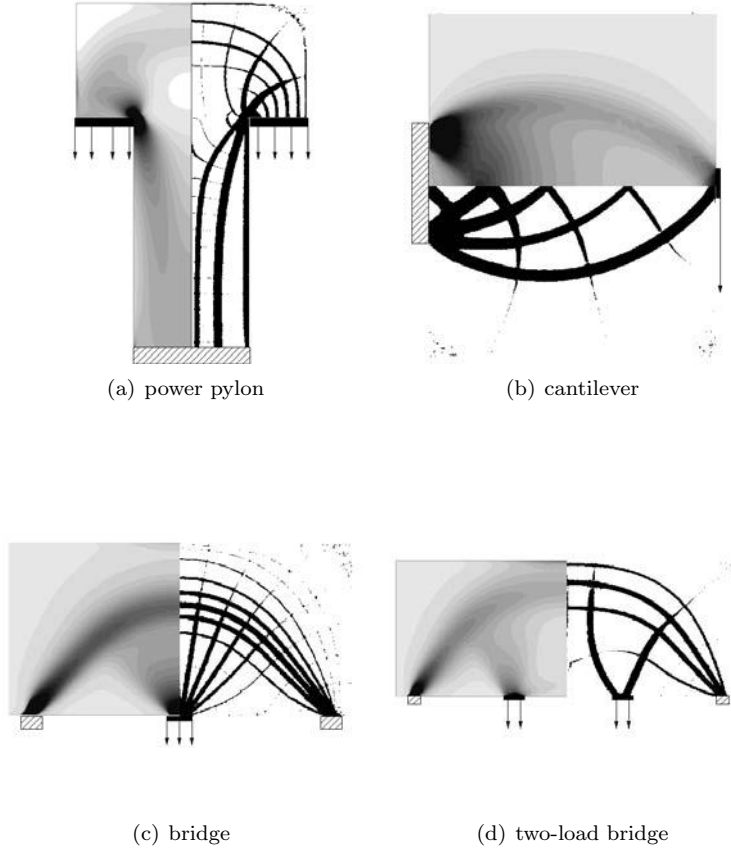

$$\begin{aligned} \mathcal{L}(v_1, p, P) = & \frac{1}{2} \int_D |(\nabla v_1 \cdot e_1) \cdot e_1 - 1|^2 + |\nabla(v_1 \cdot e_2)|^2 + |(\nabla v_1 \cdot e_2) \cdot e_1|^2 \\ & + \left| \frac{\sigma v_1 - \lambda v_1}{\lambda_1 - \lambda_2} \right|^2 + |v_1 \cdot (\nabla e_1 \cdot e_1)|^2 - |P \wedge e_1|^2 dx \\ & + \int_D (\nabla v_1 \cdot e_2) \cdot e_1 p + \frac{\sigma v_1 - \lambda_1 v_1}{\lambda_1 - \lambda_2} \cdot P dx, \end{aligned}$$

where the functions  $p$  and  $P$  are valued in  $\mathbb{R}$  and  $\mathbb{R}^2$ , respectively. Minimizers of  $I$  are saddle points of the Lagrangian. In order to determine a stationary point of the Lagrangian, we have used Lagrange finite elements  $P_1$  for all unknowns. An easy, but somewhat tedious, computation allows us to explicitly specify the different terms that appear in the Lagrangian  $\mathcal{L}$  in terms of  $v_1$  and  $\sigma$ . In particular,

$$(\nabla v_1 \cdot e_1) \cdot e_1 = \delta^{-1} \left( (\lambda_1 - \sigma_{22}) \frac{\partial v_1^1}{\partial x_1} + \sigma_{12} \left( \frac{\partial v_1^2}{\partial x_1} + \frac{\partial v_1^1}{\partial x_2} \right) + (\lambda_1 - \sigma_{11}) \frac{\partial v_1^2}{\partial x_2} \right),$$

$$\begin{aligned} \nabla(v_1 \cdot e_2) \cdot e_2 = & \delta^{-1} \left( \sigma_{12} \left( \frac{\partial v_1^1}{\partial x_1} - \frac{\partial v_1^2}{\partial x_2} \right) + (\lambda_1 - \sigma_{11}) \frac{\partial v_1^2}{\partial x_1} - (\lambda_1 - \sigma_{22}) \frac{\partial v_1^1}{\partial x_2} \right) \\ & - \delta^{-3} \left[ \left( \sigma_{12}(\lambda_1 - \sigma_{11}) \frac{\partial \sigma_{22} - \sigma_{11}}{\partial x_1} - \sigma_{12}^2 \frac{\partial \sigma_{22} - \sigma_{11}}{\partial x_2} \right. \right. \\ & \quad \left. \left. - (\sigma_{22} - \sigma_{11})(\lambda_1 - \sigma_{11}) \frac{\partial \sigma_{12}}{\partial x_1} + \sigma_{12}(\sigma_{22} - \sigma_{11}) \frac{\partial \sigma_{12}}{\partial x_2} \right) v_1^1 \right. \\ & \quad \left. - \left( \sigma_{12}^2 \frac{\partial \sigma_{22} - \sigma_{11}}{\partial x_1} - \sigma_{12}(\lambda_1 - \sigma_{22}) \frac{\partial \sigma_{22} - \sigma_{11}}{\partial x_2} \right. \right. \\ & \quad \left. \left. - (\sigma_{22} - \sigma_{11}) \sigma_{12} \frac{\partial \sigma_{12}}{\partial x_1} + (\sigma_{22} - \sigma_{11})(\lambda_1 - \sigma_{22}) \frac{\partial \sigma_{12}}{\partial x_2} \right) v_1^2 \right], \end{aligned}$$

$$\begin{aligned} \nabla(v_1 \cdot e_2) \cdot e_1 = & \delta^{-1} \left( \sigma_{12} \left( \frac{\partial v_1^2}{\partial x_1} + \frac{\partial v_1^1}{\partial x_2} \right) - (\lambda_1 - \sigma_{22}) \frac{\partial v_1^1}{\partial x_1} + (\lambda_1 - \sigma_{11}) \frac{\partial v_1^2}{\partial x_2} \right) \\ & - \delta^{-3} \left[ \left( -\sigma_{12}^2 \frac{\partial \sigma_{22} - \sigma_{11}}{\partial x_1} - \sigma_{12}(\lambda_1 - \sigma_{11}) \frac{\partial \sigma_{22} - \sigma_{11}}{\partial x_2} \right. \right. \\ & \quad \left. \left. + (\sigma_{22} - \sigma_{11}) \sigma_{12} \frac{\partial \sigma_{12}}{\partial x_1} + (\sigma_{22} - \sigma_{11})(\lambda_1 - \sigma_{11}) \frac{\partial \sigma_{12}}{\partial x_2} \right) v_1^1 \right. \\ & \quad \left. + \left( \sigma_{12}(\lambda_1 - \sigma_{22}) \frac{\partial \sigma_{22} - \sigma_{11}}{\partial x_1} + \sigma_{12}^2 \frac{\partial \sigma_{22} - \sigma_{11}}{\partial x_2} \right. \right. \\ & \quad \left. \left. - (\sigma_{22} - \sigma_{11})(\lambda_1 - \sigma_{22}) \frac{\partial \sigma_{12}}{\partial x_1} - \sigma_{12}(\sigma_{22} - \sigma_{11}) \frac{\partial \sigma_{12}}{\partial x_2} \right) v_1^2 \right], \end{aligned}$$

FIG. 6. *Optimal composite shapes and their projections.*

and

$$(\nabla v_1 \cdot e_2) \cdot e_1 = \delta^{-1} \left( \sigma_{12} \left( \frac{\partial v_1^2}{\partial x_2} - \frac{\partial v_1^1}{\partial x_1} \right) + (\lambda_1 - \sigma_{22}) \frac{\partial v_1^1}{\partial x_2} - (\lambda_1 - \sigma_{11}) \frac{\partial v_1^2}{\partial x_1} \right),$$

where

$$\lambda_1 = \frac{1}{2} (\sigma_{11} + \sigma_{22} + \delta),$$

is the greatest eigenvalue with  $\delta = \sqrt{(\sigma_{11} - \sigma_{22})^2 + 4\sigma_{12}^2}$  and  $v_1 = (v_1^1, v_1^2)$ . We have tested our approach for the compliance minimization of various structures: a power pylon, a cantilever, and several bridges. The results obtained are displayed in Figure 6. For each configuration, we show, on the one hand, the density of the optimal composite produced by the homogenization method, and, on the other, the projected shape  $\Omega_\varphi^\varepsilon$  derived by our method. Each structure is clamped on a part of its boundary (represented by a hatched block) and submitted to dead surface loads on another part of it (applied forces are represented by arrows). The weight of the structures was not taken into account. Finally, let us mention that the optimization may be naturally pursued by a geometric optimization method. To this end, a level set method (see [5], [3], [4], [2], [14], [15], [12]) seems quite appropriate. Figure 7 displays the shapes  $\Omega_\varphi^\varepsilon$

FIG. 7. Cantilever  $\Omega_\varphi^\varepsilon$  for different values of  $\varepsilon$ .

obtained for different values of  $\varepsilon$ . In the case at hand, the compliance of the optimal composite is 16.28. We notice that the compliance decreases proportionally with the parameter  $\varepsilon$ .

**5.3. Singularity of the field of eigenvectors.** The proposed method does not allow for the projection of laminates whose directions of lamination (i.e., the eigenvectors of the stress tensor  $\sigma$  of the optimal composite) show singularities. Generically, the singularities of the eigenvector field are made of a finite set of points for which  $\sigma$  is proportional to the identity. In such an instance, the eigenvector field is not orientable: it performs u-turns around singularities. Two different kinds of singularities are likely to occur according to the direction of rotation of the eigenvector field around the singularity. A singularity is said to be positive if along a small circle around it the eigenvector field has the standard trigonometric orientation; otherwise, it is said to be negative. Such a singularity typically appears in the case of a bridge with two loads as displayed in Figure 6(d). Figure 8 shows the (nonorientable) eigenvector field of the constraint  $\sigma$  of the optimal composite associated with the greatest eigenvalue  $\lambda_1$  around the singularity (located between the two loads, slightly above the platform of the bridge). We have also plotted the *level sets* orthogonal to the eigenvector fields  $e_1$  and  $e_2$ . We notice that the network thus obtained is not diffeomorphic to a square

FIG. 8. *Nonorientable eigenvector field.*

FIG. 9. *Negative singularity of the eigenvector field.*

network. It has a defect; i.e., the cell containing the singularity has five *right angles*. The trick, introduced earlier, that consists in bringing in the vectors  $v_1$  and  $v_2$  allows us to circumvent the problem in the case of a single singularity. Actually, the set of vector fields  $v_1$  of zero gradient and satisfying the constraints (5.1) is not empty, contrary to  $\mathcal{F}_e$ . Figures 9 and 10 display the eigenvector field  $e_1$  associated with, respectively, a negative and a positive singularity, as well as the projection plotted for different values of the parameter  $\varepsilon$  (with  $\theta = 1/2$  and  $m_1 = m_2 = 1/2$ ).

FIG. 10. *Positive singularity of the eigenvector field.*

In the case of several singularities, the set of vector fields  $v_1$  of zero gradient meeting the constraints (5.1) may be empty, and our algorithm is no longer adapted. Figures 11 and 12 display the eigenvector field  $e_1$  associated with, respectively, negative and positive singularities, as well as the projection plotted for several values of the parameter  $\varepsilon$  (with  $\theta = 1/2$  and  $m_1 = m_2 = 1/2$ ). The result of the projection is not satisfactory. In particular, it is different from the shape produced by symmetrizing shapes obtained for isolated singularities.

Our method cannot be applied as is if such a combination of singularities occurs. We may always consider partitioning the domain in order to isolate each singularity, apply our method to each part, then glue back the pieces. Yet, such a procedure is difficult to automate.

**6. Conclusion.** The post-treatment of the homogenization method presented here provides, in the framework of compliance minimization, quite interesting results compared to the classical penalization method. The main advantage is that it enables a sharp control of the size of the details of the final shape. Furthermore, the computational time it demands is negligible with respect to the homogenization procedure, whereas the material density penalization requires as much time as the latter. Several issues deserve to be investigated. First of all, this method should be coupled with a level set algorithm in order to sharpen the final shape. Besides, the suggested post-treatment of the homogenization method applies to the case where the directions of lamination exhibit at most one singularity. This is a strong limitation if we wanted to extend it to more general objective functions and/or complex geometries. In both

FIG. 11. *Two negative singularities of the eigenvector field.*

cases, the directions of lamination of the solutions computed by the homogenization method are likely to have more than one singularity. In the three-dimensional case, even more tricky situations may arise as lines (and not points) of singularities will have to be handled. Therefore, one needs to break free from this limitation. To conclude, this method potentially offers the prospect of an alternative to the classical topological gradient method by allowing us to nucleate a multitude of holes (or bars) in one iteration.

**Appendix A. Proof of Lemma 4.1.** We set out to exhibit an element of  $\mathcal{F}_e$ . First of all, we note that a function  $\varphi = (\varphi_1, \varphi_2)$  belongs to  $\mathcal{F}_e$  if and only if

$$(A.1) \quad \nabla \varphi_1 \neq 0, \quad \nabla \varphi_1 \cdot e_2 = 0$$

and

$$(A.2) \quad \nabla \varphi_2 \neq 0, \quad \nabla \varphi_2 \cdot e_1 = 0.$$

The conditions, to which  $\varphi_1$  and  $\varphi_2$  are submitted, are independent of one another. Therefore, it suffices to build a function  $\varphi_1$  satisfying hypotheses (A.1), since the function  $\varphi_2$  is produced by a similar procedure.

If  $\varphi_1$  satisfies (A.1), the level sets are smooth curves tangent to  $e_2$ . For all elements  $x$  in  $D$ , we denote by  $X_2(x, t)$  the solution of the following equation:

$$\begin{cases} X_2(x, 0) = x, \\ \frac{\partial X_2}{\partial t}(x, t) = e_2(X(x, t)). \end{cases}$$

FIG. 12. Two positive singularities of the eigenvector field.

FIG. 13. Alteration of the vector fields in  $G_y$ .

Likewise, we define  $X_1(x, t)$  (by changing  $e_2$  into  $e_1$ ). By the Cauchy–Lipschitz theorem, there exists a unique maximal solution to this equation, since  $e_2$  is Lipschitzian. We call  $T_x^- \in \mathbb{R} \cup \{-\infty\}$  and  $T_x^+ \in \mathbb{R} \cup \{+\infty\}$  the lower and upper bounds of the time interval in which the maximal solution is defined, and we call  $S_x$  the set of points spanned by  $X(x, t)$ :

$$S_x = \{y = X(x, t)\}.$$

Note that there exists  $T_x > 0$  for which the mapping  $G_x$  from  $] -T_x, T_x[$  into  $\Omega$  that maps  $(t_1, t_2)$  onto  $X_2(X_1(x, t_2), t_1)$  is defined. Moreover, for  $T_x > 0$  small enough,  $G_x$  is a diffeomorphism, since  $D(G_x)(x) = (e_1, (x), e_2(x))$ . Now,  $\overline{D}$  is a compact set included in the image of functions  $G_x$ , so there exists a finite subset  $\mathcal{X}$  of elements of  $\overline{D}$  such that  $\overline{D} \subset \cup_{x \in \mathcal{X}} \text{Im}(G_x)$ . We set  $\omega = \cup_{x \in \mathcal{X}} \text{Im}(G_x)$ . Should we replace  $\Omega$  by

$\omega$ , we may assume that  $\Omega = \omega$ . We shall prove, on the one hand, that  $S_x$  cannot be a closed curve (it necessarily has endpoints), and, on the other hand, that it is of finite length, that is,  $T_x^-$  and  $T_x^+$  are finite. Assume that this is not true; every component of the preimage of  $G_y$  (for an element  $y \in \mathcal{X}$ ) by the map  $]T_x^-, T_x^+[\rightarrow \Omega, t \mapsto X_2(x, t)$  has its diameter bounded from below (by  $2 \max_{z \in \mathcal{X}} T_z$ ). Thus, if the interval  $]T_x^-, T_x^+[[$  is not bounded, there exists an element  $y \in \mathcal{X}$  such that  $X_2(x, \cdot)^{-1}(G_y)$  has an infinity of connected components. As we shall show, this is impossible. If this were the case, there would exist  $t_1$  and  $t_2$  in  $]T_x^-, T_x^+[[$  such that  $t_2 > t_1$ ,

$$X_2(x, t_1) = G_y(T_y, h_1), \quad \text{and} \quad X_2(x, t_2) = G_y(-T_y, h_2).$$

Without loss of generality, we may assume that  $t_1 = 0$ .

In addition, should we alter the field  $e_1$  as it is illustrated in Figure 13, we may assume that  $h_1 = h_2$ , and so  $S_x$  is diffeomorphic to a circle. However, all injections of the circle into  $\mathbb{R}^2$  are isotopic either to the canonical injection, or to the latter composed with a central symmetry. Therefrom, we infer the existence of a diffeomorphism  $F$  from the unit disc  $D^1$  onto the open set  $U$  included in  $D$ , and satisfying  $F(S^1) = S_x$ . Let  $f \in \mathcal{C}^0(D^1; S^1)$  be defined by  $f(x) = DF^{-1}(e_1(F(x)))/|DF^{-1}(e_1(F(x)))|$ . For all elements  $s \in S^1$ ,  $f(s)$  is nothing but  $s$  rotated by  $\pi/2$ . Now, according to Brouwer's theorem, such a field cannot be extended into a continuous field defined on the whole circle, which is exactly what  $f$  achieves. We have come to a contradiction, our initial hypothesis is accordingly false, and  $R_x$  is an open curve of finite length.

For all elements  $x$  in  $D$ , we denote by  $H_x$  the mapping defined in a neighborhood of the origin of  $\mathbb{R}^2$  by  $H_x(t, h) = X_2(X_1(x, h), t)$ . The restriction of  $H_x(t, h)$  to the axis  $h = 0$  is nothing but the injection  $t \mapsto X_2(x, t)$  of image  $S_x$ . Furthermore, the map  $H_x$  is differentiable, and

$$\frac{\partial H_x}{\partial t} = \dot{X}_2(X_1(x, h), t) = e_2(X_2(X_1(x, h)), t),$$

$$\frac{\partial H_x}{\partial h} = D_{X_1((x, h), t)} X_2 e_1(X_1(x, h)).$$

Wherefrom, we deduce, in particular, that

$$\frac{\partial}{\partial t} D_{h, t} H_x = D_{X_2(X_1(x, h), t)} e_2 D_{h, t} H_x$$

and that

$$\det(D_{(h, t)} H) = \text{Tr}(D_{X_2(X_1(x, h), t)} e_2) \det(D_{(h, t)} H).$$

However,  $D_{h=0, t=0} H_x = (e_1, e_2)$ , so that  $\det(D_{(h=0, t)} H) > 0$  for all  $t$ . Let  $\delta_x > 0$  be small enough for the endpoints of  $X_2(x, ]T_x^- + \delta_x, T_x^+ - \delta_x[)$  to belong to  $\omega \setminus \overline{D}$ . According to the local inversion theorem, for  $h_x > 0$  small enough, the map  $]T_x^- + \delta_x, T_x^+ - \delta_x[ \times ]-h_x, h_x[ \rightarrow \omega, (t, h) \mapsto H_x(t, h) = X_2(X_1(x, h), t)$  is a diffeomorphism onto its image, called  $V_x$ .

Once this tubular neighborhood is built, it is somewhat easy to build a function  $\varphi_x$  having the aforementioned properties in a neighborhood of  $S_x \cap \overline{D}$ . To do so, we first remark that  $D \setminus S_x$  consists of two distinct connected components (since  $\omega$  is simply connected). We call  $D_x^+$  the connected component of  $D \setminus S_x$  that contains  $H_x(t = 0, h_x)$ , and  $D_x^-$  the one that contains  $H_x(t = 0, -h_x)$ . We denote by  $\pi_2$

the projection of  $\mathbb{R}^2$  on the second coordinate. Let  $T$  be an infinitely differentiable increasing mapping satisfying  $T(x) = x$  in  $] -1/2, 1/2[$ , and  $T(x)$  is constant if  $|x| > 1$ . We define the mapping  $\varphi_x : \overline{D} \rightarrow \mathbb{R}$  by  $\varphi_x(y) = T(\pi_2 \circ H_x^{-1}(y)/h_x)$  for all  $y \in V_x \cap D$ ,  $\varphi(y) = T(1)$  for all  $y \in \overline{D}_x^+ \setminus V_x$ , and  $\varphi(y) = T(-1)$  for all  $y \in \overline{D}_x^- \setminus V_x$ . The map  $\varphi_x$  is  $C^1$  and satisfies  $\nabla \varphi_x \cdot e_2 = 0$ ,  $\nabla \varphi_x \cdot e_1 \geq 0$ . Finally,  $\nabla \varphi_x \cdot e_1 > 0$  in a neighborhood  $W_x$  of  $\overline{D} \cap S_x$  in  $\overline{D}$ . Now,  $\overline{D}$  is compact, which implies the existence of a finite family  $\tau$  of elements  $x \in D$  such that  $\overline{D} = \cup_{x \in \tau} W_x$ . The function  $\varphi_1 = \sum_{x \in \tau} \varphi_x$  satisfies (A.1); thus  $\mathcal{F}_e$  is not empty as claimed.

## REDUCTION FOR CONSTRAINED VARIATIONAL PROBLEMS ON 3-DIMENSIONAL NULL CURVES\*

EMILIO MUSSO<sup>†</sup> AND LORENZO NICOLODI<sup>‡</sup>

**Abstract.** We consider the optimal control problem for null curves in de Sitter 3-space defined by a functional which is linear in the curvature of the trajectory. We show how techniques based on the method of moving frames and exterior differential systems, coupled with the reduction procedure for systems with a Lie group of symmetries, lead to the integration by quadratures of the extremals. Explicit solutions are found in terms of elliptic functions and integrals.

**Key words.** null curves, invariant variational problems, extremal trajectories, optimal control systems, moving frames, Lax formulation, Marsden–Weinstein reduction

**AMS subject classifications.** 49F05, 58E10, 58A17

**DOI.** 10.1137/070686470

**1. Introduction.** Let  $M^3$  be a 3-dimensional Lorentz space form and  $\gamma \subset M^3$  a null curve parametrized by the natural (pseudo-arc) parameter  $s$  which normalizes the derivative of its tangent vector field. It is known that, in general,  $\gamma$  admits a curvature  $k_\gamma(s)$  that is a Lorentz invariant and that uniquely determines  $\gamma$  up to Lorentz transformations. We consider the variational problem on null curves defined by the Lorentz invariant functional

$$(1.1) \quad \mathcal{L}(\gamma) = \int_\gamma (m + k_\gamma) ds, \quad m \in \mathbb{R},$$

and ask how to determine the explicit form for the extremal trajectories. Motivations are provided by optimal control theory and recent work on relativistic particle models associated with action functionals of the type above (cf. [19], [18], [17], [7], and references therein).

From the Euler–Lagrange equation of the action it follows that the curvature of an extremal trajectory either is constant or is an elliptic function (possibly degenerate) of the natural parameter. In the first case, the extremals are orbits of 1-parameter subgroups of the group of Lorentz transformations and can be described in terms of elementary functions [6]. In the second case, we are led to a linear system of ODEs whose coefficients are doubly periodic functions. By the Fuchsian theory of ODEs, and in particular the results of Picard [20], the trajectories are then expressible in terms of the Weierstrass elliptic functions  $\wp$ ,  $\sigma$ , and  $\zeta$ . Alternatively, we follow a general scheme for the reduction of constrained variational problems on homogeneous spaces. We will use techniques from optimal control theory based on the method of moving frames and on Cartan’s exterior differential systems [4], [11], [8], [9], coupled with the reduction procedure for systems admitting a Lie group of symmetries extended to

this setting [2]. For other applications of this general scheme of integration we refer to [10], [15], [16].

In this article, we determine the explicit form of the extremal curves when the target manifold is de Sitter 3-space. In this case, the functional (1.1) is invariant under the group  $\mathrm{SL}(2, \mathbb{C})$ , which doubly covers the identity component of the isometry group of de Sitter 3-space. The starting point of our study is the replacement of the original variational problem on null curves in de Sitter 3-space by an  $\mathrm{SL}(2, \mathbb{C})$ -invariant variational problem for integral curves of a control system on  $M \cong \mathrm{SL}(2, \mathbb{C}) \times \mathbb{R}$  defined by a suitable Pfaffian differential ideal  $(\mathcal{I}, \omega)$  with an independence condition. This is accomplished by proving the existence of a preferred  $\mathrm{SL}(2, \mathbb{C})$ -invariant frame along null curves without flex points (cf. section 2). We then follow a general construction due to Griffiths [11] and carry out a calculation to associate to the variational problem a Pfaffian differential system  $\mathcal{J}$ , the *Euler–Lagrange system*, whose integral curves are stationary for the associated functional. The Euler–Lagrange system is defined on the *momentum space*  $Y \cong \mathrm{SL}(2, \mathbb{C}) \times \mathbb{R}^3$ , which turns out to carry a contact structure, whose characteristic curves coincide with the integral curves of  $\mathcal{J}$ . As a matter of fact, in the case at hand all extremal trajectories arise as projections of integral curves of the Euler–Lagrange system. The theoretical reason for this is that all the derived systems of  $(\mathcal{I}, \omega)$  have constant rank (cf. [1]). Further, we show that the characteristic flow factors over a flow in an affine 3-dimensional subspace of  $\mathfrak{sl}(2, \mathbb{C})$  and find a Lax formulation of its defining differential equation. This implies that the momentum map induced by the Hamiltonian action of  $\mathrm{SL}(2, \mathbb{C})$  on  $Y$  is constant on solution curves of the Euler–Lagrange system, which leads to the integration by quadratures of the extremals (cf. section 4).

The paper is organized as follows. Section 2 gives the details of the construction of the canonical frame along null curves with no flex points by the method of moving frames, and defines the Pfaffian differential system of such frames. Section 3 studies the action functional (1.1), introduces the corresponding Euler–Lagrange system, and proves the constancy of the momentum map on its integral curves. Section 4 focuses on the integration procedure. It first outlines some facts from the theory of elliptic functions and then carries out the explicit integration of the extremals in terms of elliptic functions and elliptic integrals of the third kind.

## 2. Preliminaries.

**2.1. The geometry of de Sitter 3-space.** Let  $\mathrm{Herm}(2)$  be the 4-dimensional space of  $2 \times 2$  Hermitian complex matrices endowed with the Lorentz metric given by the quadratic form  $\langle X, X \rangle = -\det X$  for all  $X \in \mathrm{Herm}(2)$ . De Sitter 3-space,  $\mathbb{S}_1^3$ , can be viewed as the set of  $2 \times 2$  Hermitian matrices of determinant  $-1$ ,

$$(2.1) \quad \mathbb{S}_1^3 = \{X \in \mathrm{Herm}(2) \mid \det X = -1\},$$

with the induced metric  $g$ . The special linear group  $\mathrm{SL}(2, \mathbb{C})$  acts transitively by isometries on  $\mathbb{S}_1^3$  via the action

$$A \cdot X = AXA^*,$$

where  $A^*$  stands for the conjugate transpose of  $A$ . The stability subgroup at

$$J = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$$

is the group  $\mathrm{SL}(2, \mathbb{R})$ , and  $\mathbb{S}_1^3$  may be described as a Lorentzian symmetric space

$$\mathbb{S}_1^3 \cong \mathrm{SL}(2, \mathbb{C}) / \mathrm{SL}(2, \mathbb{R}).$$

The projection

$$\pi : \mathrm{SL}(2, \mathbb{C}) \ni A \mapsto AJA^* \in \mathbb{S}_1^3$$

makes  $\mathrm{SL}(2, \mathbb{C})$  into a principal bundle with structure group  $\mathrm{SL}(2, \mathbb{R})$ .

Let  $\Omega = \alpha + i\beta$  be the Maurer–Cartan form of  $\mathrm{SL}(2, \mathbb{C})$ , where

$$(2.2) \quad \alpha = \begin{pmatrix} \alpha_1^1 & \alpha_2^1 \\ \alpha_1^2 & -\alpha_1^1 \end{pmatrix}, \quad \beta = \begin{pmatrix} \beta_1^1 & \beta_2^1 \\ \beta_1^2 & -\beta_1^1 \end{pmatrix}.$$

Note that the matrix of 1-forms  $\beta$  is semibasic<sup>1</sup> for the projection  $\pi$ , and that the Lorentz metric  $g$  on  $\mathbb{S}_1^3$  is given by

$$g = (\beta_1^1)^2 - \beta_1^2 \beta_2^1.$$

The matrix  $\alpha$  amounts to the Levi–Civita (spinor) connection of  $g$ . The Maurer–Cartan equations of  $\mathrm{SL}(2, \mathbb{C})$ , or the structure equations, are given by

$$\begin{cases} d\alpha_1^1 = -\alpha_2^1 \wedge \alpha_1^2 + \beta_2^1 \wedge \beta_1^2, \\ d\alpha_1^2 = 2\alpha_1^1 \wedge \alpha_1^2 - 2\beta_1^1 \wedge \beta_1^2, \\ d\alpha_2^1 = -2\alpha_1^1 \wedge \alpha_2^1 + 2\beta_1^1 \wedge \beta_2^1, \\ \\ d\beta_1^1 = -\beta_2^1 \wedge \alpha_1^2 + \beta_1^2 \wedge \alpha_2^1, \\ d\beta_1^2 = 2\beta_1^1 \wedge \alpha_1^2 - 2\beta_1^2 \wedge \alpha_1^1, \\ d\beta_2^1 = -2\beta_1^1 \wedge \alpha_2^1 + 2\beta_2^1 \wedge \alpha_1^1. \end{cases}$$

**2.2. The canonical frame along a null curve.** A smooth parametrized curve

$$\gamma : I \rightarrow \mathbb{S}_1^3,$$

where  $I$  denotes any open interval of real numbers, is *null* (or *light-like*) if the velocity vector field  $\gamma'$  is null along  $\gamma$ , i.e.,  $g(\gamma'(t), \gamma'(t)) = 0$ , for each  $t \in I$ . We will assume throughout that  $\gamma$  has no flex points, i.e.,  $\gamma'(t)$  and  $\gamma''(t)$  are linearly independent, for each  $t \in I$ , where  $\gamma''$  denotes the covariant derivative of  $\gamma'$  along the curve.

A frame field along  $\gamma$  is a smooth map  $\Gamma : I \rightarrow \mathrm{SL}(2, \mathbb{C})$  such that  $\gamma = \pi \circ \Gamma$ . For any such frame, let  $\Theta = \Gamma^* \Omega$  denote the pullback of the Maurer–Cartan form of  $\mathrm{SL}(2, \mathbb{C})$  and write  $\Theta = \phi + i\theta$ . Given a frame field along  $\gamma$ , any other is given by

$$\tilde{\Gamma} = \Gamma X,$$

where  $X : I \rightarrow \mathrm{SL}(2, \mathbb{R})$  is a smooth map. If  $\tilde{\Theta} = \tilde{\Gamma}^* \Omega = \tilde{\phi} + i\tilde{\theta}$ , then

$$(2.3) \quad \tilde{\Theta} = X^{-1} \Theta X + X^{-1} dX.$$

<sup>1</sup>We recall that a differential form  $\varphi$  on the total space of a fiber bundle  $\pi : P \rightarrow B$  is said to be *semibasic* if its contraction with any vector field tangent to the fibers of  $\pi$  vanishes, or equivalently, if its value at each point  $p \in P$  is the pullback via  $\pi_p^*$  of some form at  $\pi(p) \in B$ . Some authors call such a form *horizontal*. A stronger condition is that  $\varphi$  is *basic*, meaning that it is locally the pullback via  $\pi^*$  of a form on the base  $B$ .

A frame field  $\Gamma : I \rightarrow \mathrm{SL}(2, \mathbb{C})$  along  $\gamma$  is said to be of *first order* if

$$(2.4) \quad \theta_1^1 = \theta_2^1 = 0, \quad \theta_1^2 \neq 0.$$

It is easily seen that first-order frame fields exist locally. If  $\Gamma : I \rightarrow \mathrm{SL}(2, \mathbb{C})$  is a first-order frame along  $\gamma$ , then any other is given by  $\tilde{\Gamma} = \Gamma X$ , where  $X : I \rightarrow G_1 \subset \mathrm{SL}(2, \mathbb{R})$  is a smooth map, and

$$G_1 = \left\{ \begin{pmatrix} a & 0 \\ c & a^{-1} \end{pmatrix} : a \neq 0, c \in \mathbb{R} \right\}.$$

According to (2.3), one computes

$$(2.5) \quad \tilde{\phi}_2^1 = a^2 \phi_2^1, \quad \tilde{\theta}_1^2 = \frac{1}{a^2} \theta_1^2.$$

Moreover, for first-order frames the form  $\phi_2^1$  is semibasic. If the curve  $\gamma$  has no flex points, then  $\phi_2^1 \neq 0$ . We say that the curve has *positive* or *negative spin* according to whether  $\phi_2^1$  is a positive or negative multiple of  $\theta_1^2$ .

Under our assumption, it follows from the transformation formula (2.3) that there always exist local first-order frames along  $\gamma$  such that

$$(2.6) \quad \phi_2^1 = \varepsilon \theta_1^2,$$

where  $\varepsilon = \pm 1$ , according to whether  $\gamma$  has positive or negative spin. A first-order frame field is said to be of *second order* if it satisfies (2.6) on  $I$ .

A second-order frame field along  $\gamma$  is said to be a *canonical* frame if

$$(2.7) \quad \phi_1^1 = 0.$$

Note that canonical frame fields exist on  $I$ , and that if  $\Gamma$  is a canonical frame, then any other is given by  $\pm \Gamma$ .

Summarizing, we have proved the following.

**PROPOSITION 2.1.** *Let  $\gamma : I \subset \mathbb{R} \rightarrow \mathbb{S}_1^3$  be a null curve with no flex points. Then there exists a frame along  $\gamma$ , the canonical frame,*

$$\Gamma : I \rightarrow \mathrm{SL}(2, \mathbb{C}),$$

*such that*

$$(2.8) \quad \Gamma^{-1} d\Gamma = \begin{pmatrix} 0 & \varepsilon \\ k+i & 0 \end{pmatrix} \omega,$$

*where  $\varepsilon = \pm 1$ ,  $\omega$  is a nowhere vanishing 1-form, the canonical pseudo-arc element, and  $k : I \rightarrow \mathbb{R}$  is a smooth function, the curvature of  $\gamma$ . Moreover, if  $\Gamma$  is a canonical frame field along  $\gamma$ , then any other canonical frame field is given by  $\pm \Gamma$ .*

*Remark 1.* Henceforth, we abuse the terminology and refer to the  $\mathbb{Z}_2$ -class  $[\Gamma] = \{\pm \Gamma\}$  as the canonical frame  $\Gamma$  of a null curve  $\gamma$ .

*Remark 2.* Conversely, for a smooth function  $k : I \rightarrow \mathbb{R}$ , let  $H(k) : I \rightarrow \mathfrak{sl}(2, \mathbb{C})$  be

$$(2.9) \quad H(k) = \begin{pmatrix} 0 & \varepsilon \\ k+i & 0 \end{pmatrix}.$$

Then by solving a linear system of ODEs, we see that there exists a unique (up to left multiplication)

$$\Gamma : I \rightarrow \mathrm{SL}(2, \mathbb{C})$$

such that

$$(2.10) \quad \Gamma^{-1}\Gamma' = H(k).$$

In particular,  $\gamma = \Gamma J\Gamma^* : I \rightarrow \mathbb{S}_1^3$  is a null curve without flex points and with curvature  $k$ .

*Remark 3* (null helices). The simplest examples are null helices, that is, null curves with constant curvature. Such curves are orbits of 1-parameter subgroups of  $\mathrm{SL}(2, \mathbb{C})$  (cf. Remark 9) and have been described by elementary functions in [6].

**2.3. The Pfaffian system of canonical frames.** Let  $(\mathcal{I}, \omega)$  be the Pfaffian differential system on  $M := \mathrm{SL}(2, \mathbb{C}) \times \mathbb{R}$  defined by the differential ideal  $\mathcal{I}$  generated by the linearly independent 1-forms

$$\begin{cases} \eta^1 = \beta_1^1, & \eta^2 = \beta_2^1, & \eta^3 = \alpha_1^1 - \varepsilon\omega, \\ \eta^4 = \alpha_1^1, & \eta^5 = \alpha_1^2 - k\omega, \end{cases}$$

where

$$\omega := \beta_1^2$$

gives the independence condition  $\omega \neq 0$ .

Now, let  $\gamma : I \rightarrow \mathbb{S}_1^3$  be a null curve without flex points. Then, by Proposition 2.1, the curve  $g = (\Gamma_\gamma, k_\gamma) : I \rightarrow M$ , whose components are, respectively, the canonical frame field along  $\gamma$  and the curvature of  $\gamma$ , is an integral curve of the Pfaffian system  $(\mathcal{I}, \omega)$ . Conversely, if  $g = (\Gamma, k) : I \rightarrow M$  is an integral curve of the Pfaffian system  $(\mathcal{I}, \omega)$ , then  $\gamma = \Gamma J\Gamma^* : I \rightarrow \mathbb{S}_1^3$  defines a null curve with no flex points,  $\Gamma$  is the canonical frame field along  $\gamma$ , and  $k$  is the curvature of  $\gamma$ . For this reason, null curves without flex points in  $\mathbb{S}_1^3$  can be identified with the integral curves of the Pfaffian system  $(\mathcal{I}, \omega)$ .

**DEFINITION 2.2.** *The Pfaffian differential system  $(\mathcal{I}, \omega)$  will be referred to as the canonical system.*

*Remark 4.* A smooth curve  $g = (\Gamma, k) : I \rightarrow M$  is an integral curve of the canonical system if and only if  $\Gamma : I \rightarrow \mathrm{SL}(2, \mathbb{C})$  is a solution of the linear system

$$\Gamma^{-1}(t)\Gamma'(t) = H(k(t)).$$

The function  $k$  plays the role of a control. Note that if we assign a smooth map  $k : I \rightarrow \mathbb{R}$  and a point  $A_0 \in \mathrm{SL}(2, \mathbb{C})$ , then there exists a unique integral curve  $g = (\Gamma, k)$  of the control system satisfying the initial condition  $\Gamma(t_0) = A_0$  for  $t_0 \in I$ .

Exterior differentiation and use of the Maurer–Cartan equations give, modulo the algebraic ideal generated by  $\eta^1, \dots, \eta^5$ , the *quadratic equations* of  $(\mathcal{I}, \omega)$ :

$$(2.11) \quad \begin{cases} d\omega \equiv 2(k\eta^1 + \eta^4) \wedge \omega, \\ d\eta^1 \equiv -(k\eta^2 + \eta^3) \wedge \omega, \\ d\eta^2 \equiv -2\varepsilon\eta^1 \wedge \omega, \\ d\eta^3 \equiv -2\varepsilon(k\eta^1 + 2\eta^4) \wedge \omega, \\ d\eta^4 \equiv (\eta^2 - k\eta^3 + \varepsilon\eta^5) \wedge \omega, \\ d\eta^5 \equiv -(dk + 2(1 + k^2)\eta^1) \wedge \omega. \end{cases}$$

### 3. The variational problem and the Euler–Lagrange system.

**3.1. The constrained variational problem.** Let  $\mathcal{N}$  be the space of null curves in  $\mathbb{S}_1^3$  without flex points. We consider the action functional

$$(3.1) \quad \mathcal{L}_m : \gamma \in \mathcal{N} \mapsto \int_{I_\gamma} (m + k_\gamma) \omega_\gamma, \quad m \in \mathbb{R},$$

where  $I_\gamma$  is the domain of definition of the curve,  $k_\gamma$  is its curvature, and  $\omega_\gamma$  the canonical pseudo-arc element (cf. section 2). We refer to [18], [19], [17], [7], and the references therein for a discussion on the particle model associated with this action functional.

**DEFINITION 3.1.** *A curve  $\gamma \in \mathcal{N}$  is said to be an extremal trajectory (or simply a trajectory) in  $\mathbb{S}_1^3$  if it is a critical point of the action functional  $\mathcal{L}_m$  when one considers compactly supported variations. The constant  $m$  is called the Lagrange multiplier of the trajectory.*

*Remark 5.* As usual, by a compactly supported variation of  $\gamma \in \mathcal{N}$  we mean a mapping  $V : I \times (-\epsilon, \epsilon) \rightarrow \mathbb{S}_1^3$  such that (1) for all  $u \in (-\epsilon, \epsilon)$ , the map  $\gamma_u := V(t, u) : I \rightarrow \mathbb{S}_1^3$  is a null curve without flex points; (2)  $\gamma_0 = \gamma(t)$  for all  $t \in I$ ; and (3) there exists a closed interval  $[a, b] \subset I$  such that

$$(3.2) \quad V(t, u) = \gamma(t) \quad \forall t \in I \setminus [a, b], \forall u \in (-\epsilon, \epsilon).$$

Accordingly, a curve  $\gamma \in \mathcal{N}$  is an extremal trajectory if, for every compactly supported variation  $V$ , we have that

$$\left. \frac{d}{du} \left( \int_{a_V}^{b_V} (m + k_{\gamma_u}) ds_u \right) \right|_{u=0} = 0,$$

where  $[a_V, b_V]$  is the support of the variation, i.e., the smallest closed interval for which (3.2) holds, and  $ds_u$  is the canonical pseudo-arc element of the curve  $\gamma_u$ .

In [7], the authors derive the Euler–Lagrange equation associated with (3.1) for null curves with prescribed endpoints and the same canonical frame at each end.

By the preceding discussion (cf. Proposition 2.1 and section 2.3), a curve  $\gamma \in \mathcal{N}$  is an extremal trajectory if and only if the pair  $g = (\Gamma_\gamma, k_\gamma)$  of its canonical frame field and curvature function is a critical point of the variational problem on the space  $\mathcal{V}(\mathcal{I}, \omega)$  of all integral curves of  $(\mathcal{I}, \omega)$  defined by the functional,

$$(3.3) \quad \widehat{\mathcal{L}} : g \in \mathcal{V}(\mathcal{I}, \omega) \mapsto \int_{I_g} g^*((m + k)\omega),$$

when one considers compactly supported variations through integral curves of  $(\mathcal{I}, \omega)$ .

*Remark 6.* The replacement of the original functional by the functional (3.3) is the starting point in the application of the Griffiths formalism. This approach to constrained variational problems with one independent variable provides conditions for criticality in terms of Pfaffian differential systems and is particularly well suited when one considers compactly supported variations among constrained curves. More importantly, it furnishes the appropriate setting for the explicit integration of the extremals (cf. [11], [1], [2], [12], and below).

**3.2. The Euler–Lagrange system.** Associated to the functional  $\widehat{\mathcal{L}}$  we will introduce, following Griffiths [11], the Euler–Lagrange system  $(\mathcal{J}, \omega)$  on a new manifold  $Y$ , which will be made explicit below.

For this, let  $Z \subset T^*M$  be the affine subbundle defined by

$$Z = (m + k)\omega + I \subset T^*M,$$

where  $I$  is the subbundle of  $T^*M$  associated to the differential ideal  $\mathcal{I}$ . The 1-forms  $(\eta^1, \dots, \eta^5, \omega)$  induce a global affine trivialization of  $Z$ , which may be identified with  $M \times \mathbb{R}^5$  by setting

$$M \times \mathbb{R}^5 \ni ((\Gamma, k); x_1, \dots, x_5) \mapsto \omega|_{(\Gamma, k)} + x_j \eta^j|_{(\Gamma, k)} \in Z$$

(throughout we use summation convention). Thus, the Liouville (canonical) 1-form of  $T^*M$  restricted to  $Z$  is given by

$$\mu = (m + k)\omega + x_j \eta^j.$$

Exterior differentiation and use of the quadratic equations (2.11) give

$$\begin{aligned} d\mu \equiv & dk \wedge \omega + 2(m + k)(k\eta^1 + \eta^4) \wedge \omega + dx_j \wedge \eta^j \\ & - x_1(k\eta^2 + \eta^3) \wedge \omega - 2\varepsilon x_2 \eta^1 \wedge \omega \\ & - 2\varepsilon x_3(k\eta^1 + 2\eta^4) \wedge \omega + x_4(\eta^2 - k\eta^3 + \varepsilon\eta^5) \wedge \omega \\ & - x_5(dk + 2(1 + k^2)\eta^1) \wedge \omega \quad \text{mod } \{\eta^i \wedge \eta^j\}. \end{aligned}$$

Next, we compute the Cartan system  $\mathcal{C}(d\mu) \subset T^*Z$  determined by the 2-form  $d\mu$ , i.e., the Pfaffian system generated by the 1-forms

$$\{i_\xi d\mu \mid \xi \in \mathfrak{X}(Z)\} \subset \Omega^1(Z).$$

Contracting  $d\mu$  with the vector fields of the tangent frame

$$\left( \frac{\partial}{\partial \omega}, \frac{\partial}{\partial k}, \frac{\partial}{\partial \eta^1}, \dots, \frac{\partial}{\partial \eta^5}, \frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_5} \right)$$

on  $Z$ , dual to the coframe

$$(\omega, dk, \eta^1, \dots, \eta^5, dx_1, \dots, dx_5),$$

we find the 1-forms

$$(3.4) \quad \eta^1, \dots, \eta^5,$$

$$(3.5) \quad \pi_1 = (x_5 - 1)dk,$$

$$(3.6) \quad \pi_2 = (1 - x_5)\omega,$$

$$(3.7) \quad \beta_1 = dx_1 - 2\{km + k^2 - \varepsilon x_2 - \varepsilon kx_3 - x_5(1 + k^2)\}\omega,$$

$$(3.8) \quad \beta_2 = dx_2 + (kx_1 - x_4)\omega,$$

$$(3.9) \quad \beta_3 = dx_3 + (x_1 + kx_4)\omega,$$

$$(3.10) \quad \beta_4 = dx_4 - \{2(m + k) - 4\varepsilon x_3\}\omega,$$

$$(3.11) \quad \beta_5 = dx_5 - \varepsilon x_4\omega.$$

We have proven the following.

LEMMA 3.2. *The Cartan system  $(\mathcal{C}(d\mu), \omega)$  associated to  $(I, \omega)$  is the differential ideal on  $Z \cong M \times \mathbb{R}^5$  generated by*

$$\{\eta^1, \dots, \eta^5, \pi_1, \pi_2, \beta_1, \dots, \beta_5\}$$

*and with independence condition  $\omega$ .*

DEFINITION 3.3. *The involutive prolongation of  $(\mathcal{C}(d\mu), \omega)$  on  $Z$  gives rise to a Pfaffian differential system  $(\mathcal{J}, \omega)$  on a submanifold  $Y \subset Z$ , which is called the Euler–Lagrange differential system associated to the variational problem. The submanifold  $Y$  is called the momentum space. We refer the reader to the book of Griffiths [11] for a discussion of how this system is derived and for more details on Pfaffian systems.*

LEMMA 3.4. *The momentum space  $Y$  is the 9-dimensional submanifold of  $Z$  defined by the equations*

$$x_5 = 1, \quad x_4 = 0, \quad x_3 = \frac{\varepsilon}{2}(m + k).$$

*The Euler–Lagrange system  $(\mathcal{J}, \omega)$  is the Pfaffian differential system on  $Y$  with independence condition  $\omega$  generated by the 1-forms*

$$\begin{cases} \eta^1|_Y, \dots, \eta^5|_Y, \\ \sigma_1 = dx_1 + (k^2 - mk + 2\varepsilon x_2 + 2)\omega, \\ \sigma_2 = dx_2 + kx_1\omega, \\ \sigma_3 = dk + 2\varepsilon x_1\omega. \end{cases}$$

Moreover,

$$\begin{aligned} \mu|_Y = & \frac{1}{2}(m - k)\beta_1^2 - \frac{\varepsilon}{2}k'\beta_1^1 + \frac{1}{2}\left(\frac{k''}{2} - \varepsilon k(k - m) - 2\varepsilon\right)\beta_2^1 \\ & + \frac{\varepsilon}{2}(m + k)\alpha_2^1 + \alpha_1^2. \end{aligned}$$

*Proof.* Let  $V_1(d\mu) \hookrightarrow \mathbb{P}[T(Z)] \rightarrow Z$  be the totality of 1-dimensional integral elements of  $\mathcal{C}(d\mu)$ . In view of (3.5) and (3.6), we find that

$$V_1(d\mu)|_{((\Gamma, k); x)} \neq \emptyset \iff x_5 = 1.$$

Thus, the first involutive prolongation of  $(\mathcal{C}(d\mu), \omega)$ , i.e., the image  $Z_1 \subset Z$  of  $V_1(d\mu)$  with respect to the natural projection  $V_1(d\mu) \rightarrow Z$ , is given by

$$Z_1 = \{((\Gamma, k); x) \in Z : x_5 = 1\}.$$

Next, the restriction of  $\beta_5$  to  $Z_1$  takes the form  $-\varepsilon x_4\omega$ . Thus, the second involutive prolongation  $Z_2$  is characterized by the equations

$$x_5 = 1, \quad x_4 = 0.$$

Considering then the restriction of  $\beta_4$  to  $Z_2$  yields the equations

$$x_5 = 1, \quad x_4 = 0, \quad x_3 = \frac{\varepsilon}{2}(m + k),$$

which define the third involutive prolongation  $Z_3$ . Now, the restriction  $\mathcal{C}_3(d\mu)$  to  $Z_3$  of  $\mathcal{C}(d\mu)$  is generated by the 1-forms  $\eta^1, \dots, \eta^5$  and

$$\begin{aligned} \sigma_1 &= dx_1 + (k^2 - mk + 2\varepsilon x_2 + 2)\omega, \\ \sigma_2 &= dx_2 + kx_1\omega, \\ \sigma_3 &= dk + 2\varepsilon x_1\omega. \end{aligned}$$

This implies that there exists an integral element of  $V_1(d\mu)$  over each point of  $Z_3$ , i.e.,  $V_1(d\mu)_p \neq \emptyset$ , for each  $p \in Z_3$ . Hence  $Y := Z_3$  and  $(\mathcal{J}, \omega) := (\mathcal{C}_3(d\mu), \omega)$  is the involutive prolongation of the Cartan system  $(\mathcal{C}(d\mu), \omega)$ .  $\square$

*Remark 7.* The importance of this construction is that the natural projection  $\pi_Y : Y \rightarrow M$  maps integral curves of the Euler–Lagrange system to extremals of the variational problem associated to  $(M, \mathcal{I})$ . The converse is not true in general. However, it is known to be true if all the derived systems of  $(\mathcal{I}, \omega)$  are of constant rank (cf. [1], [12]). In our case, one can easily check, using (2.11), that all the derived systems of  $(\mathcal{I}, \omega)$  have indeed constant rank, so that all the extremals do arise as projections of integral curves of the Euler–Lagrange system (see also section 3.3).

*Remark 8.* A direct calculation shows that

$$(3.12) \quad \mu|_Y \wedge (d\mu|_Y)^4 \neq 0$$

on  $Y$ , i.e., the variational problem is nondegenerate.<sup>2</sup> This implies that  $\mu|_Y$  is a contact form and that there exists a unique vector field  $\zeta \in \mathfrak{X}(Y)$ , the *characteristic vector field* of the contact structure, such that  $\mu|_Y(\zeta) = 1$  and  $i_\zeta d\mu|_Y = 0$ . In particular, the integral curves of the Euler–Lagrange system coincide with the characteristic curves of  $\zeta$ .

**3.3. The natural equation of integral curves.** Let  $\mathcal{V}(\mathcal{J}, \omega)$  be the set of integral curves of the Euler–Lagrange Pfaffian system  $(\mathcal{J}, \omega)$ . If  $y = ((\Gamma, k); x_1, x_2) : I \rightarrow Y$  is in  $\mathcal{V}(\mathcal{J}, \omega)$ , then equations

$$\eta^1 = \eta^2 = \cdots = \eta^5 = 0$$

and the independence condition  $\omega \neq 0$  tell us that  $\Gamma$  defines a canonical frame along the null curve  $\gamma = \Gamma J\Gamma^*$  and that  $k$  is the curvature of  $\gamma$ .

Next, for the smooth function  $k : I \rightarrow \mathbb{R}$ , let  $k'$ ,  $k''$ , and  $k'''$  be defined by

$$dk = k'\omega, \quad dk' = k''\omega, \quad dk'' = k'''\omega.$$

Equation  $\sigma_3 = 0$  implies

$$x_1 = -\frac{\varepsilon}{2}k'.$$

Further,  $\sigma_1 = 0$  gives

$$x_2 = \frac{1}{4}k'' - \frac{\varepsilon}{2}(k^2 - mk + 2).$$

Finally,  $\sigma_2 = 0$  yields

$$(3.13) \quad k''' - 6\varepsilon k k' + 2\varepsilon m k' = 0.$$

<sup>2</sup>A variational problem is said to be *nondegenerate* in the case when

$$\dim Y = 2m + 1 \quad \text{and} \quad \mu|_Y \wedge (d\mu|_Y)^m \neq 0.$$

Let  $V(\mathcal{J}, \omega)$  and  $V(\mathcal{C}(d\mu|_Y), \omega)$  denote the set of integral elements of the Euler–Lagrange system and of the Cartan system. For nondegenerate problems we have  $V(\mathcal{J}, \omega) = V(\mathcal{C}(d\mu|_Y), \omega)$ , whereas in general we have only inclusion  $V(\mathcal{J}, \omega) \subset V(\mathcal{C}(d\mu|_Y), \omega)$  (cf. [11, p. 84]). For a discussion on the relation between the classical Legendre transform and the construction of the Euler–Lagrange system on the momentum space, with special attention to the nondegeneracy condition, we refer the reader to [11, Chapter I, section e]).

This is the Euler–Lagrange equation of the extremals of (3.1). It has been computed, for example, in [7]. Thus, an integral curve of the Euler–Lagrange system projects to an extremal trajectory in  $\mathbb{S}_1^3$ .

Conversely, let  $\gamma : I \rightarrow \mathbb{S}_1^3$  be a null curve without flex points,  $\Gamma_\gamma$  its canonical frame, and  $k_\gamma$  its curvature. Define the lift  $y_\gamma : I \rightarrow Y$  of  $\gamma$  to the momentum space  $Y$  by

$$y_\gamma(t) = \left( (\Gamma_\gamma, k_\gamma); -\frac{\varepsilon}{2}k'_\gamma, \frac{1}{4}k''_\gamma - \frac{\varepsilon}{2}(k_\gamma^2 - mk + 2) \right).$$

Then,  $y_\gamma$  is an integral curve of the Euler–Lagrange system if and only if  $k_\gamma$  satisfies (3.13) if and only if  $\gamma$  is an extremal trajectory. Thus, the integral curves of the Euler–Lagrange system arise as lifts of trajectories in  $\mathbb{S}_1^3$ .

**3.4. The Lax formulation.** Introduce the *reduced curvature*

$$h := \frac{\varepsilon}{2} \left( k - \frac{m}{3} \right)$$

and identify  $Y \cong \mathrm{SL}(2, \mathbb{C}) \times \mathbb{R}^3$ , where  $\mathbb{R}^3$  has coordinates  $(h, h', h'')$ . Then, the Pfaffian equations defining the Euler–Lagrange system  $\mathcal{J}$  are given by

$$(3.14) \quad \begin{cases} \eta^j = 0, & (j = 1, \dots, 5), \\ dh = h'\omega, \\ dh' = h''\omega, \\ dh'' = 12hh'\omega, \end{cases}$$

where  $\omega \neq 0$  is the independence condition. Equation (3.13) becomes

$$(3.15) \quad h''' - 12hh' = 0,$$

$$(3.16) \quad H(h) = \begin{pmatrix} 0 & \varepsilon \\ 2\varepsilon h + \frac{m}{3} + i & 0 \end{pmatrix}$$

and we also have

$$\begin{aligned} \mu = & -\left(\varepsilon h - \frac{m}{3}\right)\beta_1^2 - h'\beta_1^1 + \frac{\varepsilon}{2}\left(h'' - 4h^2 + \frac{2}{3}\varepsilon mh + \frac{2}{9}m^2 - 2\right)\beta_2^1 \\ & + \left(h + \frac{2}{3}\varepsilon m\right)\alpha_2^1 + \alpha_1^2. \end{aligned}$$

Next, define the *momentum* associated with  $h$ ,  $U(h) \in \mathfrak{sl}(2, \mathbb{C})$ , by

$$(3.17) \quad \begin{pmatrix} ih' & 2i\varepsilon\left(h - \varepsilon\left(\frac{m}{3} + i\right)\right) \\ 2\left(h + \frac{2\varepsilon m}{3}\right) - i\varepsilon\left(h'' - 4h^2 + \frac{2\varepsilon mh}{3} + \frac{2m^2}{9} - 2\right) & -ih' \end{pmatrix}.$$

A direct computation shows that (3.15) is equivalent to

$$U(h)' = [U(h), H(h)].$$

The above discussion yields the following result.

**PROPOSITION 3.5.** *A map  $(A; h, h', h'') : I \subset \mathbb{R} \rightarrow Y$  is an integral curve of the Euler–Lagrange system  $(\mathcal{J}, \omega)$  if and only if*

$$(3.18) \quad \begin{cases} A^{-1}A' = H(h), \\ U(h)' = [U(h), H(h)]. \end{cases}$$

As a consequence, we have the following.

**COROLLARY 3.6.** *The momentum map*

$$\Phi : Y \rightarrow \mathfrak{sl}(2, \mathbb{C}), \quad (A; h, h', h'') \mapsto AU(h)A^{-1}$$

*is constant on integral curves of the Euler–Lagrange system.*

*Remark 9.* The momentum space  $Y$  may be identified with  $\mathrm{SL}(2, \mathbb{C}) \times \mathfrak{a}$ , where  $\mathfrak{a} = \mathrm{span}\{U(h)\}$  is an affine subspace of  $\mathfrak{sl}(2, \mathbb{C})$ . The group  $\mathrm{SL}(2, \mathbb{C})$  acts on  $(Y, \mu)$  by

$$g \cdot (A; U(h)) = (gA; U(h)), \quad \text{for each } g \in \mathrm{SL}(2, \mathbb{C}), U(h) \in \mathfrak{a},$$

in a Hamiltonian way. Using the isomorphism of  $\mathfrak{sl}(2, \mathbb{C})$  with its dual Lie algebra induced by the Killing form, one sees that the momentum map associated with this action is given by  $\Phi$ . Moreover, if  $y = (A(t), U(h)(t))$  is an integral curve of the characteristic vector field  $\zeta$ , then  $U(h)(t)$  is an integral curve of the vector field

$$X_\zeta : U(h) \mapsto [U(h), H(h)]$$

and  $\zeta$  can be written

$$\zeta|_y = H(h)|_A + X_\zeta(U(h)),$$

for all  $y = (A, U(h)) \in Y$ . If  $\mathfrak{a}_s$  denotes the singular set of  $X_\zeta$ , then the integral curves through  $(A, U(h)) \in \mathrm{SL}(2, \mathbb{C}) \times \mathfrak{a}_s$  are orbits of the 1-parameter subgroups generated by  $H(h)$ . By (3.17), these project to curves with constant curvature (null helices). Next, consider  $\Phi : \mathrm{SL}(2, \mathbb{C}) \times \mathfrak{a}_r \rightarrow \mathfrak{sl}(2, \mathbb{C})$ , where  $\mathfrak{a}_r$  denotes the complement of  $\mathfrak{a}_s$  in  $\mathfrak{a}$ . For each regular value  $\ell \in \mathfrak{sl}(2, \mathbb{C})$  of  $\Phi$ , the isotropy subgroup at  $\ell$ ,  $\mathrm{SL}(2, \mathbb{C})_\ell$ , is abelian and  $\dim \mathrm{SL}(2, \mathbb{C})_\ell = \mathrm{rank} \mathrm{SL}(2, \mathbb{C})_\ell = 2$ . The reduced space  $Y_\ell = \Phi^{-1}(\ell)/\mathrm{SL}(2, \mathbb{C})_\ell$  is then 1-dimensional. This implies that an integral curve  $y$  with momentum  $\ell$  (i.e.,  $\Phi \circ y = \ell$ ) can be found by quadratures. Any other integral curve with momentum  $\ell$  is given by  $b \cdot y$  for some  $b \in \mathrm{SL}(2, \mathbb{C})_\ell$ .

Note that when the action of the symmetry group on the momentum space is co-isotropic (as in the present case), the equation governing the flow of  $X_\zeta$  can always be written in Lax form. See, for instance, [10].

#### 4. Integration of the trajectories.

**4.1. Preparatory material.** From (3.15), it follows that the reduced curvature  $h$  satisfies

$$(4.1) \quad (h')^2 = 4h^3 - g_2h - g_3$$

for real constants  $g_2$  and  $g_3$ . Hence  $h$  is expressed by the real values of either a Weierstrass  $\wp$ -function with invariants  $g_2, g_3$ , or one of its degenerate forms.

We call a solution to (4.1) a *potential* with analytic invariants  $g_2, g_3$ . Two potentials are considered equivalent if they differ by a reparametrization of the form  $s \mapsto s + c$ , where  $c$  is a constant.<sup>3</sup> For real  $g_2$  and  $g_3$ , let  $\Delta(g_2, g_3) = 27g_3^2 - g_2^3$  be the discriminant of the cubic polynomial

$$P(t; g_2, g_3) = 4t^3 - g_2t - g_3.$$

<sup>3</sup>When invariants  $g_2$  and  $g_3$  are given, such that  $27g_3^2 \neq g_2^3$ , the general solution of the differential equation  $(\frac{dy}{dz})^2 = 4y^3 - g_2y - g_3$  can be written in the form  $\wp(z + \alpha; g_2, g_3)$ , where  $\alpha$  is a constant of integration.

The study of the real values of the Weierstrass  $\wp$ -function with real invariants  $g_2, g_3$  (and its degenerate forms) leads to primitive half-periods  $\omega_1, \omega_3$  such that (see for instance [14])

- $\Delta(g_2, g_3) < 0$ :  $\omega_1 > 0, \omega_3 = i\nu\omega_1, \nu > 0$ .
- $\Delta(g_2, g_3) > 0$ :  $\omega_1 > 0, \omega_3 = \frac{1}{2}(1 + i\nu)\omega_1, \nu > 0$ .
- $\Delta(g_2, g_3) = 0$  and  $g_3 > 0$ :  $\omega_1 > 0, \omega_3 = +i\infty$ .
- $\Delta(g_2, g_3) = 0$  and  $g_3 < 0$ :  $\omega_1 = +\infty, -i\omega_3 > 0$ .
- $g_2 = g_3 = 0$ :  $\omega_1 = +\infty, \omega_3 = +i\infty$ .

Accordingly, denoting by  $\mathcal{D}(g_2, g_3)$  the fundamental period-parallelogram spanned by  $2\omega_1$  and  $2\omega_3$ , the only possible cases for the potential function  $h : I \rightarrow \mathbb{R}$  are

- $\Delta < 0$ :  $h(s) = \wp(s; g_2, g_3), I = (0, 2\omega_1)$ .
- $\Delta < 0$ :  $h(s) = \wp_3(s; g_2, g_3) = \wp(s + \omega_3; g_2, g_3), I = \mathbb{R}$ .
- $\Delta > 0$ :  $h(s) = \wp(s; g_2, g_3), I = (0, 2\omega_1)$ .
- $\Delta = 0, g_3 = -8a^3 > 0$ :

$$h(s) = -3a \tan^2(\sqrt{-3a}s) - 2a, \quad I = \left(-\frac{\pi}{\sqrt{-12a}}, \frac{\pi}{\sqrt{-12a}}\right).$$

- $\Delta = 0, g_3 = -8a^3 < 0$ :

$$h(s) = 3a \tanh^2(\sqrt{3a}s) - 2a, \quad I = \mathbb{R}.$$

- $g_2 = g_3 = 0$ :  $h(s) = s^{-2}, I = (-\infty, 0)$ , or  $I = (0, +\infty)$ .

Let  $h$  be a Weierstrass potential with real invariants  $g_2, g_3$ , and let  $U(h)$  be the corresponding momentum as given by (3.17). Then

$$\begin{aligned} \det U(h) &= \left(\frac{4}{27}m^3 - 4m - \frac{m}{3}g_2 - \varepsilon g_3\right) + i\varepsilon \left(\frac{4}{3}m^2 - g_2 - 4\right) \\ &= P\left(\varepsilon \left(\frac{m}{3} + i\right); g_2, g_3\right). \end{aligned}$$

Let

$$\nu(m, h) := \sqrt{P\left(\varepsilon \left(\frac{m}{3} + i\right); g_2, g_3\right)},$$

chosen once for all. Then  $\pm\nu(m, h)$  are the eigenvalues of the momentum  $U(h)$ .

Next, define

$$(4.2) \quad \phi(m, h) := \begin{cases} \int \frac{\nu(m, h)}{h - \varepsilon \left(\frac{m}{3} + i\right)} ds, & \nu(m, h) \neq 0, \\ \int \frac{1}{h - \varepsilon \left(\frac{m}{3} + i\right)} ds, & \nu(m, h) = 0. \end{cases}$$

These are elliptic integrals of the third kind. Let  $w(m, h)$  be the unique point in the period-parallelogram  $\mathcal{D}(g_2, g_3)$  such that

$$h(w) = \varepsilon \left(\frac{m}{3} + i\right) \quad \text{and} \quad h'(w) = \nu(m, h).$$

Denote by  $\sigma_h$  and  $\zeta_h$ , respectively, the sigma and zeta Weierstrassian functions corresponding to the potential  $h$ , i.e., the unique analytic odd functions whose meromorphic

extensions satisfy  $\zeta'_h = -h$  and  $\sigma'_h/\sigma_h = \zeta_h$ . Under the above assumptions, we now compute the elliptic integrals (4.2). Three cases are considered.

*Case I.*  $\nu(m, h) \neq 0$ . In this case,

$$\phi(m, h) = \int \frac{h'(w)}{h(s) - h(w)} ds = \log \frac{\sigma_h(s - w)}{\sigma_h(s + w)} + 2s\zeta_h(w) + \text{const.}$$

*Case II.*  $\nu(m, h) = 0$  and  $g_2^2 + g_3^2 \neq 0$ . In this case,  $h(w) = \varepsilon \left( \frac{m}{3} + i \right)$  is a root of the cubic polynomial  $P$ , say  $e_3$ . If  $e_1, e_2$  denote the other two roots, we have

$$\begin{aligned} \phi(m, h) &= \int \frac{ds}{h(s) - e_3} = \int \frac{h(s + w) - e_3}{(e_3 - e_1)(e_3 - e_2)} ds \\ &= \frac{1}{\frac{g_2}{4} - 3 \left( \frac{m}{3} + i \right)^2} \left\{ \zeta_h(s + w) + \varepsilon \left( \frac{m}{3} + i \right) s \right\} + \text{const.} \end{aligned}$$

*Case III.*  $\nu(m, h) = 0$  and  $g_2 = g_3 = 0$ . In this case,

$$\phi(m, h) = \frac{1}{3}s^3 + \text{const.}$$

**4.2. Explicit integration.** We are now in a position to explicitly integrate the extremal trajectories. This amounts to integrating by quadratures the reduced system associated to the Hamiltonian action of  $\text{SL}(2, \mathbb{C})$  on  $Y$  (cf. Remark 9). The key to explicit integration is the conservation of the momentum map along integral curves of the Euler–Lagrange system.

**THEOREM 4.1.** *Let  $\gamma : I \rightarrow \mathbb{S}_1^3$  be an extremal trajectory with Lagrange multiplier  $m$  and reduced curvature  $h$  with real invariants  $g_2, g_3$ . Let  $U_\gamma(h)$  be the momentum of  $h$  given by (3.17), and assume that  $\gamma$  is parametrized by the canonical parameter  $s$ , i.e.,  $\omega = ds$ . According to whether  $\det U_\gamma(h)$  is zero or different from zero, we distinguish two cases.*

*Case I.* If  $\det U(h) \neq 0$ , then the canonical frame field  $\Gamma : I \rightarrow \text{SL}(2, \mathbb{C})$  along  $\gamma$  is given by

$$\Gamma(s) = A \cdot M(s),$$

where  $A \in \text{SL}(2, \mathbb{C})$  and  $M(s)$  takes the form

$$\frac{1}{\sqrt{-4i\varepsilon\nu}} \begin{pmatrix} e^{\phi(m, h)} & 0 \\ 0 & e^{-\phi(m, h)} \end{pmatrix} \begin{pmatrix} \frac{ih' + \nu}{\sqrt{h - \varepsilon \left( \frac{m}{3} + i \right)}} & 2i\varepsilon\sqrt{h - \varepsilon \left( \frac{m}{3} + i \right)} \\ \frac{-ih' + \nu}{\sqrt{h - \varepsilon \left( \frac{m}{3} + i \right)}} & -2i\varepsilon\sqrt{h - \varepsilon \left( \frac{m}{3} + i \right)} \end{pmatrix}$$

*Case II.* If  $\det U(h) = 0$ , then the canonical frame field  $\Gamma : I \rightarrow \text{SL}(2, \mathbb{C})$  along  $\gamma$  is given by

$$\Gamma(s) = A \cdot M(s),$$

where  $A \in \text{SL}(2, \mathbb{C})$  and  $M(s)$  takes the form

$$\frac{1}{\sqrt{-2i\varepsilon}} \begin{pmatrix} 1 & -\phi(m, h) \\ \sqrt{h - \varepsilon \left( \frac{m}{3} + i \right)} & 2i \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -ih' & -2i\varepsilon\sqrt{h - \varepsilon \left( \frac{m}{3} + i \right)} \\ \sqrt{h - \varepsilon \left( \frac{m}{3} + i \right)} & 1 \end{pmatrix}$$

*Proof of Case I.* Let  $\Gamma = (C_1, C_2) : I \rightarrow \mathrm{SL}(2, \mathbb{C})$  be a canonical frame along  $\gamma$  and  $U_\gamma(h)$  be the momentum of  $\gamma$  given by (3.17). Consider the eigenvalues  $\pm\nu(m, h)$  of  $U_\gamma(h)$  and denote by  $\mathbf{L}_\pm$  the corresponding eigenspaces. From the definition of  $U_\gamma(h)$ , it follows that

$$\begin{aligned} L_+ &= -2i\varepsilon \left( h - \varepsilon \left( \frac{m}{3} + i \right) \right) C_1 + (ih' - \nu(m, h)) C_2 : I \rightarrow \mathbf{L}_+, \\ L_- &= -2i\varepsilon \left( h - \varepsilon \left( \frac{m}{3} + i \right) \right) C_1 + (ih' + \nu(m, h)) C_2 : I \rightarrow \mathbf{L}_- \end{aligned}$$

are eigenvectors of  $U_\gamma(h)$  corresponding to  $\nu(m, h)$  and  $-\nu(m, h)$ , respectively. Thus, we must have

$$L'_+ = \rho_1 L_+, \quad L'_- = \rho_2 L_-$$

for analytic functions  $\rho_1, \rho_2$ . Using the Maurer–Cartan equation  $\Gamma' = \Gamma H(m, h)$ , we compute

$$L'_+ = \frac{h' + \nu(m, h)}{2(h - \varepsilon(\frac{m}{3} + i))} L_+, \quad L'_- = \frac{h' - \nu(m, h)}{2(h - \varepsilon(\frac{m}{3} + i))} L_-.$$

We thus see that the two vectors

$$\begin{aligned} \Lambda_1 &:= \exp \left( - \int \frac{h' + \nu(m, h)}{2(h - \varepsilon(\frac{m}{3} + i))} ds \right) L_+, \\ \Lambda_2 &:= \exp \left( - \int \frac{h' - \nu(m, h)}{2(h - \varepsilon(\frac{m}{3} + i))} ds \right) L_- \end{aligned}$$

are constant along  $\gamma$ . By (4.2), they become

$$\Lambda_1 = \frac{\exp(-\phi(m, h))}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} L_+, \quad \Lambda_2 = \frac{\exp(\phi(m, h))}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} L_-.$$

Hence

$$\Gamma \cdot R(m, h) \cdot S(m, h) = \Lambda = (\Lambda_1, \Lambda_2),$$

where

$$R(m, h) = \begin{pmatrix} -2i\varepsilon(h - \varepsilon(\frac{m}{3} + i)) & -2i\varepsilon(h - \varepsilon(\frac{m}{3} + i)) \\ ih' - \nu(m, h) & ih' + \nu(m, h) \end{pmatrix}$$

and

$$S(m, h) = \begin{pmatrix} \frac{1}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} & 0 \\ 0 & \frac{1}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} \end{pmatrix} \begin{pmatrix} \exp(-\phi(m, h)) & 0 \\ 0 & \exp(\phi(m, h)) \end{pmatrix}.$$

From this, we obtain

$$\Gamma \begin{pmatrix} -2i\varepsilon\sqrt{h - \varepsilon(\frac{m}{3} + i)} & -2i\varepsilon\sqrt{h - \varepsilon(\frac{m}{3} + i)} \\ \frac{ih' - \nu}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} & \frac{ih' + \nu}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} \end{pmatrix} \begin{pmatrix} e^{-\phi(m, h)} & 0 \\ 0 & e^{\phi(m, h)} \end{pmatrix} = \Lambda,$$

and hence

$$\Gamma = \tilde{\Lambda} \begin{pmatrix} e^{\phi(m,h)} & 0 \\ 0 & e^{-\phi(m,h)} \end{pmatrix} \begin{pmatrix} \frac{ih' + \nu}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} & 2i\varepsilon\sqrt{h - \varepsilon(\frac{m}{3} + i)} \\ \frac{-ih' + \nu}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} & -2i\varepsilon\sqrt{h - \varepsilon(\frac{m}{3} + i)} \end{pmatrix}. \quad \square$$

*Proof of Case II.* Again, let  $\Gamma = (C_1, C_2) : I \rightarrow \mathrm{SL}(2, \mathbb{C})$  be a canonical frame along  $\gamma$  and  $U_\gamma(h)$  be the momentum of  $\gamma$ . If  $\nu(m, h) = 0$ , then

$$L_1 = -2i\varepsilon \left( h - \varepsilon \left( \frac{m}{3} + i \right) \right) C_1 + ih' C_2$$

belongs to the kernel of  $U_\gamma(h)$ , and proceeding as in Case I, we see that the vector

$$(4.3) \quad \Lambda_1 = \frac{1}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} L_1$$

is a first integral. In order to find another first integral, we look for analytic functions  $f$  and  $g$  such that

$$(4.4) \quad \Lambda_2 := gC_2 + fL_1$$

is a constant vector. Differentiating and using the Maurer–Cartan equation  $\Gamma' = \Gamma H(m, h)$ , we obtain

$$g'C_2 + g\varepsilon C_1 + f'L_1 = 0,$$

from which we compute

$$g = \frac{1}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}}, \quad f = \frac{1}{2i} \int \frac{ds}{h - \varepsilon(\frac{m}{3} + i)} = \frac{1}{2i} \phi(m, h).$$

Now, from (4.3) and (4.4), we obtain

$$\Gamma \begin{pmatrix} -2i\varepsilon\sqrt{h - \varepsilon(\frac{m}{3} + i)} & 0 \\ \frac{ih'}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} & 1 \end{pmatrix} \begin{pmatrix} 1 & \frac{1}{2i}\phi(m, h) \\ 0 & \frac{1}{\sqrt{h - \varepsilon(\frac{m}{3} + i)}} \end{pmatrix} = \Lambda = (\Lambda_1, \Lambda_2),$$

and hence the required result.  $\square$

# ON THE BOUNDEDNESS OF THE SPECTRAL FACTORIZATION MAPPING ON DECOMPOSING BANACH ALGEBRAS\*

HOLGER BOCHE<sup>†</sup> AND VOLKER POHL<sup>‡</sup>

**Abstract.** In [SIAM J. Control Optim., 40 (2001), pp. 88–106], Jacob and Partington studied the continuity and boundedness of the spectral factorization mapping on decomposing Banach algebras. Many function spaces considered in systems theory are decomposing Banach algebras. The most well known example is the Wiener algebra, the space of all absolutely convergent Fourier series. Jacob and Partington showed in the above paper that the spectral factorization is locally Lipschitz continuous on all decomposing algebras, but unbounded on the most important examples of decomposing algebras. Our paper gives an extension of this result and shows that the spectral factorization mapping is unbounded on every decomposing algebra.

**1. Introduction.** Let  $f$  be a real valued function given on the unit circle. Then the spectral factorization of  $f$  is the process by which a function  $f_+$  is determined such that  $f$  can be written as  $f = f_+ f_+^*$ , in which the spectral factor  $f_+$  is an outer function and  $f_+^*$  its para-Hermitian conjugate. This operation arises in many different applications. In communications and signal processing, it is an important tool for filter design [6, 9, 11, 23] and spectral estimation [5, 17]. In control theory, it is closely related to  $H_\infty$  and quadratic optimal control [10, 20]. Moreover, it plays a prominent roll in the theory of stochastic processes [8, 24].

The question of whether the spectral factorization mapping  $\mathfrak{S} : f \mapsto f_+$  is continuous and bounded is of fundamental importance in practical applications since these properties are linked to the robustness of the operation with respect to disturbances of the given data and to the stability of the resulting spectral factor (see, e.g., [3, 13]). Whether the spectral factorization mapping is continuous or bounded depends crucially on the normed space on which one is working. Consequently, there exists several results [1, 2, 16] on the continuity of  $\mathfrak{S}$  on different function spaces. In [7], Clancy and Gohberg introduced a general class of Banach algebras of continuous functions, so-called decomposing Banach algebras, on which the spectral factorization exists. In [18] a slightly more restricted definition of a decomposing Banach algebra was given and used to study the problem of best approximation of analytic function. In fact, many of the most important Banach algebras used in system theory are decomposing. Examples include the Wiener algebra, the set of Hölder continuous functions, and the space of functions of vanishing mean oscillation (VMO).

The present paper was motivated by the work of Jacob and Partington [15], where the continuity and boundedness of the spectral factorization mapping on decomposing Banach algebras was investigated in depth. It was shown that the spectral factorization is locally Lipschitz continuous on all decomposing Banach algebras, but since the spectral factorization mapping is nonlinear, this continuity does not imply the boundedness of  $\mathfrak{S}$ . However, in [15] a necessary condition for the boundedness of  $\mathfrak{S}$  on decomposing Banach algebras was derived. Based on this condition, it was shown that the spectral factorization is unbounded on a large number of concrete Banach algebras. In fact, [15] contains no example of a decomposing Banach algebra on which the spectral factorization is bounded. This observation may suggest that there exists no decomposing Banach algebra at all on which the spectral factorization is bounded. This conjecture will be proved in the present paper. It will be shown that the condition for the boundedness of the spectral factorization mapping given in [15] is contradictory to the axioms of a decomposing Banach algebra.

The outline of the paper is as follows. Sections 2 and 3 briefly review the concept of decomposing Banach algebras and of the spectral factorization, respectively. Section 4 gives an extension of the boundedness condition in [15] and derives some consequences regarding Fourier series. Based on these consequences, we prove in section 5 that there exists no decomposing Banach algebra on which the spectral factorization is bounded. The paper closes with some discussions in section 6 and a conclusion in section 7.

**2. Decomposing Banach algebras.** This section introduces notation and briefly recalls the concept of decomposing Banach algebras. Moreover, it states some known results which are used frequently in this paper and gives some examples of decomposing algebras.

Throughout this paper,  $\mathbb{D} := \{z \in \mathbb{C} : |z| < 1\}$  and  $\mathbb{T} := \{z \in \mathbb{C} : |z| = 1\}$  denote the unit disc and the unit circle in the complex plane, respectively. The imaginary unit is denoted by  $i = \sqrt{-1}$ , and  $\bar{z}$  is the conjugate complex of  $z$ . The set  $\mathcal{C}(\mathbb{T})$  of all continuous functions on  $\mathbb{T}$  is a Banach space under the usual supremum norm  $\|f\|_\infty = \sup_{\zeta \in \mathbb{T}} |f(\zeta)|$ . The Banach space of  $p$ -integrable functions ( $1 < p < \infty$ ) on  $\mathbb{T}$  with the usual norm  $\|f\|_p := (\frac{1}{2\pi} \int_{\mathbb{T}} |f(\zeta)|^p d\zeta)^{1/p}$  is denoted by  $L^p(\mathbb{T})$ . Moreover,  $L^\infty(\mathbb{T})$  denotes the set of all measurable and essentially bounded functions on  $\mathbb{T}$ . For any function  $f \in L^1(\mathbb{T})$ , the *Fourier coefficients* are defined by

$$(2.1) \quad \hat{f}(k) = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(e^{i\tau}) e^{-ik\tau} d\tau, \quad k = 0, \pm 1, \pm 2, \dots$$

Let  $\mathcal{A} \subset L^1(\mathbb{T})$  be a commutative Banach algebra with unity and with norm  $\|\cdot\|_{\mathcal{A}}$ . We define the two subspaces  $\mathcal{A}_+$  and  $\mathcal{A}_-$  of  $\mathcal{A}$  by

$$\mathcal{A}_+ := \{f \in \mathcal{A} : \hat{f}(k) = 0 \text{ for all } k < 0\},$$

$$\mathcal{A}_- := \{f \in \mathcal{A} : \hat{f}(k) = 0 \text{ for all } k \geq 0\}.$$

In particular, let  $\mathcal{A} = L^p(\mathbb{T})$ ,  $1 < p \leq \infty$ ; then  $[L^p(\mathbb{T})]_+$  coincides with the *Hardy space*  $H^p(\mathbb{D})$  of functions in  $L^p(\mathbb{T})$  which are analytic in  $\mathbb{D}$ . The mapping

$$(2.2) \quad \sum_{k=-\infty}^{\infty} \hat{f}(k) z^k \mapsto \sum_{k=0}^{\infty} \hat{f}(k) z^k,$$

which assigns to every  $f \in \mathcal{A}$  with Fourier coefficients (2.1) a corresponding function in  $\mathcal{A}_+$ , will be denoted by  $\mathfrak{P}_+$  and is called the *Riesz projection*. Inserting the Fourier

coefficients (2.1) into (2.2) yields a closed form integral representation of the Riesz projection  $\mathfrak{P}_+ : \mathcal{A} \rightarrow \mathcal{A}_+$ :

$$(\mathfrak{P}_+ f)(z) = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(e^{i\tau}) \frac{e^{i\tau}}{e^{i\tau} - z} d\tau.$$

A linear functional  $h : \mathcal{A} \rightarrow \mathbb{C}$  is called a *homomorphism* (a multiplicative linear functional) on  $\mathcal{A}$  if  $h(\phi\psi) = h(\phi)h(\psi)$  for all  $\phi, \psi \in \mathcal{A}$ . The set of all homomorphisms on  $\mathcal{A}$  will be denoted by  $\Gamma(\mathcal{A})$ . Moreover,  $\mathcal{G}(\mathcal{A})$  will stand for the set of all invertible elements of  $\mathcal{A}$ . Thus  $\mathcal{G}(\mathcal{A})$  is the set of all  $f \in \mathcal{A}$  for which there exists a function  $f^{-1} \in \mathcal{A}$  such that  $f \cdot f^{-1} = \mathbf{1}$ , where  $\mathbf{1}$  denotes the unity of  $\mathcal{A}$ . Accordingly,  $\mathcal{G}(\mathcal{A}_+)$  denotes the set of all invertible elements in  $\mathcal{A}_+$ . Let  $f \in \mathcal{A}$  and define  $(\exp f)(\zeta) := \sum_{k=0}^{\infty} \frac{1}{k!} f(\zeta)^k$ . By the properties of a Banach algebra, it is clear that  $\|\exp f\|_{\mathcal{A}} \leq \exp(\|f\|_{\mathcal{A}})$ ; from what follows, that  $\exp f \in \mathcal{A}$ . Moreover, it holds that  $\exp(f) \in \mathcal{G}(\mathcal{A})$ . Another important subset of  $\mathcal{A}$  that will be needed frequently is the set

$$\mathcal{A}_{\text{pos}} = \{f \in \mathcal{A} : f(\zeta) > 0 \text{ for all } \zeta \in \mathbb{T}\}$$

of all strictly positive functions in  $\mathcal{A}$ .

Next, we recall the notion of decomposing Banach algebras and review some of their most important properties. In general, a decomposing Banach algebra is a Banach algebra  $\mathcal{A}$  with an identity which can be written as a direct sum  $\mathcal{A} = \mathcal{A}_+ \oplus \mathcal{A}_-$  of two closed subalgebras  $\mathcal{A}_+$  and  $\mathcal{A}_-$  [7]. However, as in [15], we are interested in decomposing Banach algebras  $\mathcal{B}$ , which are subspaces of  $L^2(\mathbb{T})$ . Then, a decomposing Banach algebra is defined by the following four axioms [15].

DEFINITION 2.1. *A commutative Banach algebra  $\mathcal{B} \subset L^2(\mathbb{T})$  is called a decomposing Banach algebra if the following hold:*

- (A1) *If  $f \in \mathcal{B}$ , then  $\bar{f} \in \mathcal{B}$  and  $\mathfrak{P}_+ f \in \mathcal{B}$ .*
- (A2)  *$\mathcal{B}$  is a Banach algebra with respect to pointwise multiplication.*
- (A3) *The set of all trigonometric polynomials is dense in  $\mathcal{B}$ .*
- (A4) *Every multiplicative functional on  $\mathcal{B}$  coincides with a functional  $f \mapsto f(\zeta)$  defined as the value  $f(\zeta)$  at some point  $\zeta \in \mathbb{T}$ .*

Note that this definition coincides with the definition given by Peller and Khrushchev in [18]. The following results recall some essential properties of decomposing Banach algebras.

PROPOSITION 2.2. *Let  $\mathcal{B}$  be a decomposing Banach algebra. Every  $f \in \mathcal{B}$  with  $f(\zeta) \neq 0$  for all  $\zeta \in \mathbb{T}$  belongs to  $\mathcal{G}(\mathcal{B})$ .*

*Proof.* Let  $\zeta \in \mathbb{T}$  be arbitrary; then (A2) implies that the functional  $h : \mathcal{B} \rightarrow \mathbb{C}$  defined by  $h(\phi) := \phi(\zeta)$  is a homomorphism on  $\mathcal{B}$ , and (A4) shows that all possible homomorphisms on  $\mathcal{B}$  are obtained in this way. Therefore,  $\phi(\zeta) \neq 0$  for all  $\zeta \in \mathbb{T}$  implies  $h(\phi) \neq 0$  for all  $h \in \Gamma(\mathcal{B})$ , and by the Beurling–Gelfand theorem,  $\phi \in \mathcal{B}$  is invertible in  $\mathcal{B}$  if and only if  $h(\phi) \neq 0$  for all  $h \in \Gamma(\mathcal{B})$ ; see, e.g., [19, section 11.5].  $\square$

PROPOSITION 2.3. *Every decomposing Banach algebra  $\mathcal{B}$  is continuously embedded in  $\mathcal{C}(\mathbb{T})$  with*

$$\|f\|_{\infty} \leq \|f\|_{\mathcal{B}} \quad \text{for all } f \in \mathcal{B}.$$

*Proof.* By (A2) and (A4), for every  $\zeta \in \mathbb{T}$  there exists an  $h \in \Gamma(\mathcal{B})$  such that  $h(\phi) = \phi(\zeta)$  for every  $\phi \in \mathcal{B}$ . Since each complex homomorphism of  $\mathcal{B}$  is bounded by 1 (see, e.g., [19, section 10.7]), one has  $|\phi(\zeta)| = |h(\phi)| \leq \|\phi\|_{\mathcal{B}}$ , which implies  $\|\phi\|_{\infty} \leq \|\phi\|_{\mathcal{B}}$ . By (A3), for every  $\epsilon > 0$  there exists a trigonometric polynomial  $\psi$  such that  $\|\phi - \psi\|_{\infty} \leq \|\phi - \psi\|_{\mathcal{B}} < \epsilon$ , which proves that  $\phi \in \mathcal{C}(\mathbb{T})$ .  $\square$

The next lemma, taken from [15], will be used frequently in what follows.

LEMMA 2.4. *Let  $\mathcal{B}$  be a decomposing Banach algebra. Then there exists a constant  $m_1 > 0$  such that*

$$\|\bar{f}\|_{\mathcal{B}} \leq m_1 \|f\|_{\mathcal{B}} \quad \text{for all } f \in \mathcal{B}.$$

From now on, the symbol  $\mathcal{B}$  always stands for a decomposing Banach algebra. The unity in  $\mathcal{B}$  will be denoted by  $\mathbf{1}$  is given by  $\mathbf{1}(\zeta) = 1$  for all  $\zeta \in \mathbb{T}$ .

We complete this section with some examples of decomposing and nondecomposing Banach algebras. All these examples can be found in [15] or [18] along with their corresponding proofs.

Example 2.5 (Wiener algebra). The Wiener algebra  $\mathcal{W}$  is the set of all functions of the form

$$f(e^{i\omega}) = \sum_{k=-\infty}^{\infty} a_k e^{ik\omega},$$

which are bounded with respect to the norm

$$\|f\|_{\mathcal{W}} = \sum_{k=-\infty}^{\infty} |a_k|.$$

The Wiener algebra  $\mathcal{W}$  is a decomposing Banach algebra.

Example 2.6 (Hölder continuous functions). For  $0 < \alpha < 1$ , denote by  $\Lambda_{\alpha}$  the set of all functions on  $\mathbb{T}$  for which the norm

$$\|f\|_{\alpha} = \|f\|_{\infty} + \sup_{\zeta, z \in \mathbb{T}, \zeta \neq z} \frac{|f(\zeta) - f(z)|}{|\zeta - z|^{\alpha}}$$

is bounded. The closure of all trigonometric polynomials under the norm  $\|\cdot\|_{\alpha}$  is denoted by  $\lambda_{\alpha}$ , and it can be shown that  $\lambda_{\alpha}$  is a decomposing Banach algebra.

Example 2.7 (nondecomposing Banach algebras). The set of continuous functions  $\mathcal{C}(\mathbb{T})$  on the unit circle  $\mathbb{T}$  is a Banach algebra under pointwise multiplication and satisfies also the axioms (A3) and (A4) of a decomposing Banach algebra. However, it does not satisfy the second part of property (A1) since there exist functions  $f \in \mathcal{C}(\mathbb{T})$  for which the Riesz projection  $\mathfrak{P}_+ f$  is not continuous. This follows, e.g., from the counterexample given in [21], or it can be seen from the last paragraph of the proof of Theorem 5.3. The same holds also for  $L^{\infty}(\mathbb{T})$ . It does not satisfy the second part of (A1) since there exists no bounded projection  $L^{\infty}(\mathbb{T})$  to  $H^{\infty}(\mathbb{D})$  [14, Chapter 9].

**3. Spectral factorization.** This sections briefly reviews the notation and definitions of the spectral factorization, as far as it is needed in this paper.

DEFINITION 3.1. *Let  $\mathcal{B}$  be a Banach algebra of functions on the unit circle  $\mathbb{T}$ . An element  $f \in \mathcal{B}$  possesses a spectral factorization if there exists an invertible element  $f_+ \in \mathcal{G}(\mathcal{B}_+)$  such that*

$$(3.1) \quad f(e^{i\omega}) = f_+(e^{i\omega}) \overline{f_+(e^{i\omega})} \quad \text{for all } \omega \in [-\pi, \pi].$$

The function  $f_+$  is called a spectral factor of  $f$ , and every  $f \in \mathcal{B}$  which possesses a spectral factorization is called a spectral density.

Which elements of a decomposing Banach algebra  $\mathcal{B}$  are spectral densities? The answer is given by the following proposition, which is taken from [15].

PROPOSITION 3.2. *Let  $\mathcal{B}$  be a decomposing Banach algebra. An element  $f \in \mathcal{B}$  is a spectral density if and only if  $f \in \mathcal{B}_{\text{pos}}$ . One spectral factor is given by*

$$(3.2) \quad f_+(z) = (\mathfrak{S}f)(z) = \exp \left( \frac{1}{4\pi} \int_{-\pi}^{\pi} \log f(e^{i\tau}) \frac{e^{i\tau} + z}{e^{i\tau} - z} d\tau \right), \quad z \in \mathbb{D}.$$

*This spectral factor is unique up to a constant of modulus 1.*

Remark 3.3. The above proposition holds also for some nondecomposing Banach algebras. It holds, e.g., for  $L^\infty(\mathbb{T})$ , but it does not hold for  $\mathcal{C}(\mathbb{T})$  because, as is well known [14, 21], there exist functions  $f \in \mathcal{C}(\mathbb{T})$  with  $f(\zeta) > 0$  for all  $\zeta \in \mathbb{T}$  but for which the spectral factor (3.2) is not continuous.

Remark 3.4. Note that the spectral factorization mapping (3.2) is well defined already for all functions  $f \in \mathcal{B}$  which satisfy the so-called *Paley–Wiener condition*,  $\int_{\mathbb{T}} \log f(\zeta) d\zeta > -\infty$ . However, if  $f \in \mathcal{B}$  had a zero on  $\mathbb{T}$ , then by (3.1) the function  $\mathfrak{S}f$  also would have a zero on  $\mathbb{T}$ , and because of property (A4) of a decomposing Banach algebra,  $\mathfrak{S}f$  would not be invertible in  $\mathcal{B}_+$ . By Definition 3.1 of the spectral factorization, this implies that  $\mathfrak{S}f$  is no spectral factor of  $f$  in this case.

Note that the spectral factorization mapping (3.2) can also be written in terms of the Riesz projection  $\mathfrak{P}_+$ :

$$(3.3) \quad \begin{aligned} f_+(z) &= (\mathfrak{S}f)(z) = \exp \left[ (\mathfrak{P}_+[\log f])(z) - \frac{1}{2}(\mathfrak{P}_+[\log f])(0) \right] \\ &= A(f) \exp [(\mathfrak{P}_+[\log f])(z)] \end{aligned}$$

with the constant  $A(f)$ , which is determined by the zeroth Fourier coefficient of  $\log f$ . Note also that the spectral factorization mapping is nonlinear. Therefore, for every constant  $\alpha > 0$ , it holds in particular that  $\mathfrak{S}(\alpha f) = \mathfrak{S}(\alpha) \mathfrak{S}(f) = \sqrt{\alpha} \mathfrak{S}(f)$ .

**4. Basic results.** This paper investigates the boundedness of the spectral factorization mapping on decomposing Banach algebras. The boundedness of the mapping guarantees that the norm of the spectral factor is small whenever the norm of the spectral density is small.

DEFINITION 4.1. *Let  $\mathcal{B}$  be a decomposing Banach algebra. Then the spectral factorization mapping  $\mathfrak{S} : \mathcal{B} \rightarrow \mathcal{B}_+$  is said to be bounded if there exists a constant  $C < \infty$  such that for every  $f \in \mathcal{B}_{\text{pos}}$  with  $\|f\|_{\mathcal{B}} \leq 1$ , it always holds that*

$$(4.1) \quad \|f_+\|_{\mathcal{B}} = \|\mathfrak{S}f\|_{\mathcal{B}} \leq C.$$

In [15] a simple equivalent condition for the boundedness of the spectral factorization on a decomposing Banach algebra was given as follows.

PROPOSITION 4.2. *The spectral factorization mapping is bounded on a decomposing algebra  $\mathcal{B}$  if and only if there exists a constant  $m_2 > 0$  such that*

$$(4.2) \quad m_2 \|h\|_{\mathcal{B}}^2 \leq \|h \bar{h}\|_{\mathcal{B}} \quad \text{for all } h \in \mathcal{G}(\mathcal{B}_+).$$

Thus, in order for the spectral factorization to be bounded on the decomposing Banach algebra  $\mathcal{B}$ , condition (4.2) has to be satisfied for all functions  $h \in \mathcal{G}(\mathcal{B}_+)$ . It was annotated in [15] that condition (4.2) cannot be satisfied for all elements of the decomposing algebra  $\mathcal{B}$  because this would imply that  $\mathcal{B}$  is isomorphic to  $\mathcal{C}(\mathbb{T})$ , which is not a decomposing Banach algebra. However, our paper will show that there exists no decomposing algebra on which the spectral factorization mapping is

bounded. This will be done in several steps: In the following subsection, we show that the boundedness of the spectral factorization implies that condition (4.2) holds for all  $f \in \mathcal{B}_+$ , and in section 4.2 we derive consequences of this extension with respect to Fourier series in decomposing Banach algebras in which the spectral factorization is bounded. These results are used in section 5 to show that condition (4.2) holds even for all  $f \in \mathcal{B}$ . Then, the above cited argument from [15] implies immediately that there exists no decomposing Banach algebra on which the spectral factorization is bounded.

**4.1. Extension to  $\mathcal{B}_+$ .** The result of this subsection shows that condition (4.2) for the boundedness of the spectral factorization on a decomposing Banach algebra can be extended to every  $f \in \mathcal{B}_+$ .

LEMMA 4.3. *The spectral factorization is bounded on a decomposing Banach algebra  $\mathcal{B}$  if and only if there exists a constant  $m_3 > 0$  such that*

$$(4.3) \quad m_3 \|f\|_{\mathcal{B}}^2 \leq \|f \bar{f}\|_{\mathcal{B}} \quad \text{for all } f \in \mathcal{B}_+ .$$

Remark 4.4. Lemmas 4.3 and 2.4 together give the relation

$$m_3 \|f\|_{\mathcal{B}}^2 \leq \|f \bar{f}\|_{\mathcal{B}} \leq m_1 \|f\|_{\mathcal{B}}^2 \quad \text{for all } f \in \mathcal{B}_+$$

in every decomposing Banach algebra  $\mathcal{B}$  on which the spectral factorization is bounded.

*Proof.* Since  $\mathcal{G}(\mathcal{B}_+) \subset \mathcal{B}_+$ , Proposition 4.2 implies that (4.3) is sufficient for the boundedness of the spectral factorization. The necessity of (4.3) is shown by contradiction: Assume that the spectral factorization is bounded but that there exists no constant  $m_3 > 0$  such that (4.3) holds. Then, for every  $\epsilon > 0$  there exists a  $g \in \mathcal{B}_+$  with  $\|g\|_{\mathcal{B}} = 1$  and such that  $\|g \bar{g}\|_{\mathcal{B}} \leq \epsilon^2$ . Moreover, it holds obviously that  $\|g \bar{g}\|_{\infty} = \sup_{\zeta \in \mathbb{T}} |g(\zeta)|^2 = \|g\|_{\infty}^2$ . These facts and Proposition 2.3 together give

$$(4.4) \quad \|g\|_{\infty}^2 = \|g \bar{g}\|_{\infty} \leq \|g \bar{g}\|_{\mathcal{B}} \leq \epsilon^2 .$$

Next, we consider the function  $f := g + \|g\|_{\infty} + \epsilon$ . By this definition, it is clear that  $|f(z)| \geq \epsilon$  for all  $z \in \mathbb{D}$ , i.e.,  $f \in \mathcal{G}(\mathcal{B}_+)$ . Using the triangle inequality and (4.4), one gets a lower bound and an upper bound for the norm of this function,

$$(4.5) \quad 1 - 2\epsilon \leq \|f\|_{\mathcal{B}} \leq 1 + 2\epsilon .$$

Therewith, one obtains that

$$\begin{aligned} \|f \bar{f}\|_{\mathcal{B}} &\leq \|g \bar{g}\|_{\mathcal{B}} + (\|g\|_{\infty} + \epsilon) \|g + \bar{g}\|_{\mathcal{B}} + (\|g\|_{\infty} + \epsilon)^2 \|1\|_{\mathcal{B}} \\ &\leq \epsilon^2 + 2\epsilon(1 + m_1) + 4\epsilon^2 \|1\|_{\mathcal{B}} = C_1 \epsilon^2 + C_2 \epsilon \end{aligned}$$

with the constants  $C_1 = 1 + 4\|1\|_{\mathcal{B}}$  and  $C_2 = 2(1 + m_1)$  and in which inequality (4.4) and Lemma 2.4 were used to obtain the second line. On the other hand, since it was assumed that the spectral factorization is bounded, and since  $f \in \mathcal{G}(\mathcal{B}_+)$ , one can apply Proposition 4.2. Together with (4.5) this gives the lower bound

$$\|f \bar{f}\|_{\mathcal{B}} \geq m_2 \|f\|_{\mathcal{B}}^2 \geq m_2 (1 - 2\epsilon)^2$$

with  $m_2 > 0$ . Combining the lower bound and the upper bound for  $\|f \bar{f}\|_{\mathcal{B}}$ , one obtains that

$$0 < m_2 \leq \epsilon \frac{C_1 \epsilon + C_2}{(1 - 2\epsilon)^2} .$$

The right-hand side of this expression tends to zero as  $\epsilon \rightarrow 0$ . Therefore, this last inequality gives a contradiction for sufficiently small  $\epsilon$ . This shows that if the spectral factorization is bounded on  $\mathcal{B}$ , then there exists a constant  $m_3 > 0$  such that (4.3) holds.  $\square$

This extension of the statement of Proposition 4.2 from  $\mathcal{G}(\mathcal{B}_+)$  onto the whole  $\mathcal{B}_+$  has some important consequences for decomposing Banach algebras on which the spectral factorization is bounded. Some of these consequences are discussed in the following subsection.

**4.2. Fourier series.** Recall [12, 14] that an *inner function* is a function  $\varphi \in H^\infty(\mathbb{D})$  such that  $|\varphi(\zeta)| = 1$  for almost all  $\zeta \in \mathbb{T}$ . Assume now that  $\varphi \in \mathcal{B}$  is an arbitrary inner function. Then it is clear that  $\varphi \in \mathcal{B}_+$ , and Lemma 4.3 implies that  $m_3 \|\varphi\|_{\mathcal{B}}^2 \leq \|\varphi \bar{\varphi}\|_{\mathcal{B}} = \|\mathbf{1}\|_{\mathcal{B}}$ . This shows that in every decomposing Banach algebra  $\mathcal{B}$  on which the spectral factorization is bounded, one has a universal upper bound on the norm for every inner function in  $\mathcal{B}$ ,

$$\|\varphi\|_{\mathcal{B}} \leq \sqrt{\frac{\|\mathbf{1}\|_{\mathcal{B}}}{m_3}} =: C_3,$$

which depends only on the algebra  $\mathcal{B}$ .

Next, we show that in a decomposing Banach algebra  $\mathcal{B}$  on which the spectral factorization is bounded, the Fourier series of every  $f \in \mathcal{B}$  converges uniformly. To this end, define for  $n = 0, 1, 2, \dots$  the function  $s_n(z) = z^n$ . Since the trigonometric polynomials are dense in every decomposing algebra,  $s_n \in \mathcal{B}_+$  for all  $n \in \mathbb{N}$  and every  $s_n$  is obviously an inner function. Moreover, the functions  $s_{-n} := \overline{s_n}$ ,  $n \in \mathbb{N}$ , belong to  $\mathcal{B}$ , and because of Lemmas 2.4 and 4.3, one obtains a uniform upper bound

$$(4.6) \quad \|s_n\|_{\mathcal{B}} \leq m_1 C_3 \quad \text{for all } n \in \mathbb{Z}$$

for the norms of these functions.

Let  $f \in \mathcal{B} \subset L^2(\mathbb{T})$  with Fourier series representation  $f(\zeta) = \sum_{k=-\infty}^{\infty} \hat{f}(k) \zeta^k$ . For every  $n \in \mathbb{N}$ , we consider the operators  $\mathfrak{A}_n : \mathcal{B} \rightarrow \mathcal{B}$  and  $\mathfrak{A}_{-n} : \mathcal{B} \rightarrow \mathcal{B}$  defined by

$$(4.7) \quad \begin{aligned} (\mathfrak{A}_n f)(\zeta) &= \sum_{k=-\infty}^{n-1} \hat{f}(k) \zeta^k = f(\zeta) - s_n(\zeta) [\mathfrak{P}_+(\overline{s_n} f)](\zeta), \\ (\mathfrak{A}_{-n} f)(\zeta) &= \sum_{k=-n}^{\infty} \hat{f}(k) \zeta^k = \overline{s_n}(\zeta) [\mathfrak{P}_+(s_n f)](\zeta). \end{aligned}$$

As  $n$  tends to infinity, both  $\mathfrak{A}_n f$  and  $\mathfrak{A}_{-n} f$  should converge to  $f$ . That this really happens is the statement of the following proposition.

**PROPOSITION 4.5.** *Let  $\mathcal{B}$  be a decomposing Banach algebra on which the spectral factorization is bounded. Then there exist constants  $m_4$  and  $m_5$  such that*

$$(4.8) \quad \|\mathfrak{A}_n f\|_{\mathcal{B}} \leq m_4 \|f\|_{\mathcal{B}} \quad \text{and} \quad \|\mathfrak{A}_{-n} f\|_{\mathcal{B}} \leq m_5 \|f\|_{\mathcal{B}}$$

for all  $f \in \mathcal{B}$  and all  $n \in \mathbb{N}$ . Moreover, for all  $f \in \mathcal{B}$  it holds that

$$(4.9) \quad \lim_{n \rightarrow \infty} \|f - \mathfrak{A}_n f\|_{\mathcal{B}} = 0 \quad \text{and} \quad \lim_{n \rightarrow \infty} \|f - \mathfrak{A}_{-n} f\|_{\mathcal{B}} = 0.$$

*Proof.* Since  $\mathcal{B}$  is decomposing, the Riesz projection is bounded; i.e., there exists a constant  $C_4$  such that  $\|\mathfrak{P}_+ f\|_{\mathcal{B}} \leq C_4 \|f\|_{\mathcal{B}}$  for all  $f \in \mathcal{B}$ . The uniform boundedness of  $\mathfrak{A}_n$  follows immediately from its definition (4.7) and from the properties of the Banach algebra  $\mathcal{B}$  and the shift functions  $s_n$ :

$$\|\mathfrak{A}_n f\|_{\mathcal{B}} \leq \|f\|_{\mathcal{B}} + C_4 \|s_n\|_{\mathcal{B}} \|\overline{s_n}\|_{\mathcal{B}} \|f\|_{\mathcal{B}} \leq (1 + C_4 m_1^2 C_3^2) \|f\|_{\mathcal{B}}.$$

It is clear that (4.9) holds for all polynomials in  $\mathcal{B}$ , and since the polynomials are dense in  $\mathcal{B}$ , and since the operator sequence  $\mathfrak{A}_n$  is uniformly bounded, (4.9) follows. The statements for  $\mathfrak{A}_{-n}$  are proved in exactly the same way.  $\square$

**5. Boundedness of the spectral factorization.** In this section we finally show that there exists no decomposing Banach algebra on which the spectral factorization is bounded. First, we extend the statement of Lemma 4.3 to the whole decomposing Banach algebra  $\mathcal{B}$ .

LEMMA 5.1. *Let  $\mathcal{B}$  be a decomposing Banach algebra and assume that there exists a constant  $m_3$  such that (4.3) holds. Then there exists a constant  $m_6$  such that*

$$(5.1) \quad m_6 \|f\|_{\mathcal{B}}^2 \leq \|f \bar{f}\|_{\mathcal{B}} \quad \text{for all } f \in \mathcal{B}.$$

*Proof.* Let  $f(\zeta) = \sum_{k=-\infty}^{\infty} \hat{f}(k) \zeta^k$  with  $\zeta \in \mathbb{T}$  be an arbitrary element of  $\mathcal{B}$ , and let  $s_n(\zeta) = \zeta^n$ . Note that the Fourier series of  $f$  (and all the following Fourier series in this proof) converge in the  $\mathcal{B}$ -norm by Proposition 4.5. Applying the upper bound (4.6) for the shift function  $s_n$ , one obtains for an arbitrary  $n \in \mathbb{N}$  that

$$(5.2) \quad \|f\|_{\mathcal{B}} = \|\overline{s_n} s_n f\|_{\mathcal{B}} \leq \|s_{-n}\|_{\mathcal{B}} \|s_n f\|_{\mathcal{B}} \leq m_1 C_3 \|s_n f\|_{\mathcal{B}}.$$

It is easily checked that

$$(5.3) \quad s_n f - \mathfrak{P}_+(s_n f) = s_n \mathfrak{R}_n f \quad \text{with} \quad (\mathfrak{R}_n f)(\zeta) = \sum_{k=-\infty}^{-n-1} \hat{f}(k) \zeta^k.$$

For the operator  $\mathfrak{R}_n$  it holds that  $\|\mathfrak{R}_n f\|_{\mathcal{B}} \rightarrow 0$  as  $n \rightarrow \infty$  for every  $f \in \mathcal{B}$ . This follows from Proposition 4.5 after (5.3) is multiplied by  $\overline{s_n}$ . Therefore, one gets from (5.3) that for every  $\epsilon > 0$  there exists an  $n_0 > 0$  such that

$$\|s_n f\|_{\mathcal{B}} \leq \|\mathfrak{P}_+(s_n f)\|_{\mathcal{B}} + \epsilon \quad \text{for all } n \geq n_0.$$

Together with (5.2) this shows that

$$(5.4) \quad \|f\|_{\mathcal{B}} - m_1 C_3 \epsilon \leq m_1 C_3 \|\mathfrak{P}_+(s_n f)\|_{\mathcal{B}} \quad \text{for all } n \geq n_0.$$

It is clear that  $\mathfrak{P}_+(s_n f) \in \mathcal{B}_+$ . Therefore, by the requirements of Lemma 5.1, inequality (4.3) holds such that

$$(5.5) \quad m_3 \|\mathfrak{P}_+(s_n f)\|_{\mathcal{B}}^2 \leq \|\mathfrak{P}_+(s_n f) \overline{\mathfrak{P}_+(s_n f)}\|_{\mathcal{B}} \\ = \|\overline{s_n} \mathfrak{P}_+(s_n f) \cdot s_n \overline{\mathfrak{P}_+(s_n f)}\|_{\mathcal{B}} = \|g_n \overline{g_n}\|_{\mathcal{B}}$$

wherein  $g_n = \mathfrak{A}_{-n} f = \overline{s_n} \mathfrak{P}_+(s_n f)$ . By Proposition 4.5, it holds therefore that  $\lim_{n \rightarrow \infty} \|f - g_n\|_{\mathcal{B}} = 0$ .

Finally, we consider the expression  $f\bar{f} - g_n\overline{g_n}$ . By the triangle inequality, one obtains

$$\begin{aligned}\|f\bar{f} - g_n\overline{g_n}\|_{\mathcal{B}} &\leq \|\bar{f}\|_{\mathcal{B}} \|f - g_n\|_{\mathcal{B}} + \|g_n\|_{\mathcal{B}} \|\overline{f - g_n}\|_{\mathcal{B}} \\ &\leq m_1(1 + m_5) \|f\|_{\mathcal{B}} \|f - g_n\|_{\mathcal{B}},\end{aligned}$$

where the second line follows from Lemma 2.4 and Proposition 4.5. Since the right-hand side of the last inequality converges to zero as  $n$  tends to infinity, so does the left-hand side. Therefore, for every  $\epsilon > 0$  there exists an  $n_1 \geq n_0 > 0$  such that

$$(5.6) \quad \|g_n\overline{g_n}\|_{\mathcal{B}} \leq \|f\bar{f}\|_{\mathcal{B}} + \epsilon \quad \text{for all } n \geq n_1.$$

Now, we can put together all the previous steps. This gives

$$\begin{aligned}(\|f\|_{\mathcal{B}} - m_1 C_3 \epsilon)^2 &\stackrel{(5.4)}{\leq} m_1^2 C_3^2 \|\mathfrak{P}_+(s_n f)\|_{\mathcal{B}}^2 \\ &\stackrel{(5.5)}{\leq} \frac{m_1^2 C_3^2}{m_3} \|g_n\overline{g_n}\|_{\mathcal{B}} \stackrel{(5.6)}{\leq} \frac{m_1^2 C_3^2}{m_3} (\|f\bar{f}\|_{\mathcal{B}} + \epsilon)\end{aligned}$$

for all  $n \geq n_1$ . Since  $\epsilon$  was chosen arbitrarily, one obtains

$$\frac{m_3}{m_1^2 C_3^2} \|f\|_{\mathcal{B}}^2 \leq \|f\bar{f}\|_{\mathcal{B}}$$

for all  $f \in \mathcal{B}$ . This is the statement of the theorem with  $m_6 = m_3/(m_1 C_3)^2$ .  $\square$

Lemmas 4.3 and 5.1 show that if the spectral factorization is bounded on a decomposing Banach algebra  $\mathcal{B}$ , then (5.1) holds for all elements in  $\mathcal{B}$ . However, as already mentioned in [15], this implies that  $\mathcal{B}$  is isomorphic to  $\mathcal{C}(\mathbb{T})$ , which is no decomposing Banach algebra. For the sake of completeness, we give a separate proof of this reasoning in the following.

LEMMA 5.2. *Let  $\mathcal{B}$  be a decomposing Banach algebra and assume that there exists a constant  $0 < m_6 < \infty$  such that (5.1) holds for all  $f \in \mathcal{B}$ . Then it holds that*

$$(5.7) \quad \|f\|_{\infty} \leq \|f\|_{\mathcal{B}} \leq \frac{2}{m_6} \|f\|_{\infty} \quad \text{for all } f \in \mathcal{B}.$$

*Proof.* The lower bound in (5.7) is a consequence of Proposition 2.3. To prove the upper bound, first let  $h \in \mathcal{B}$  be a real valued function. Then because of assumption (5.1), it holds that  $m_6 \|h\|_{\mathcal{B}}^2 \leq \|h\bar{h}\|_{\mathcal{B}} = \|h^2\|_{\mathcal{B}}$ . Moreover, since  $h^2$  belongs again to  $\mathcal{B}$ , (5.1) can be applied to  $h^2$ , which gives  $m_6 \|h^2\|_{\mathcal{B}}^2 \leq \|h^4\|_{\mathcal{B}}$ . Together with the previous inequality, one has  $m_6 m_6^2 \|h\|_{\mathcal{B}}^4 \leq m_6 \|h^2\|_{\mathcal{B}}^2 \leq \|h^4\|_{\mathcal{B}}$ . Applying this upper bound repeatedly, one obtains

$$\|h\|_{\mathcal{B}} \leq C_5 \|h\|_{\infty}^{1/2^n} \quad \text{with} \quad C_5 = \left( \prod_{k=0}^{n-1} (m_6)^{2^k} \right)^{-1/2^n} = (m_6)^{-\frac{2^n-1}{2^n}}.$$

By the spectral radius formula, it holds  $\|h\|_{\infty} = \lim_{n \rightarrow \infty} \|h^n\|_{\mathcal{B}}^{1/n}$ . For  $n \rightarrow \infty$  this gives in our case that

$$(5.8) \quad \|h\|_{\mathcal{B}} \leq \frac{1}{m_6} \|h\|_{\infty}$$

for every real valued function  $h \in \mathcal{B}$ . Now let  $f = f_1 + i f_2$  be a complex function in  $\mathcal{B}$  with real functions  $f_1, f_2 \in \mathcal{B}$ . Then it follows from (5.8) and Proposition 2.3 that  $\|f\|_{\mathcal{B}} \leq \frac{1}{m_6} (\|f_1\|_{\infty} + \|f_2\|_{\infty}) \leq \frac{2}{m_6} \|f\|_{\infty}$ , which is the upper bound in (5.7).  $\square$

With these preparations, we prove the following main result of this paper.

**THEOREM 5.3.** *There exists no decomposing Banach algebra  $\mathcal{B}$  on which the spectral factorization mapping is bounded.*

*Proof.* The theorem is proved by contradiction. Assume that the spectral factorization is bounded on the decomposing Banach algebra  $\mathcal{B}$ ; then (5.7) holds. Now, let  $f \in \mathcal{C}(\mathbb{T})$  be an arbitrary continuous function, and let  $p_n$ ,  $n = 1, 2, \dots$ , be a sequence of polynomials which converges to  $f$  in  $\mathcal{C}(\mathbb{T})$ :  $\lim_{n \rightarrow \infty} \|f - p_n\|_\infty = 0$ . This shows, together with (5.7), that  $p_n$  is a Cauchy sequence in  $\mathcal{B}$ , and since  $\mathcal{B}$  is complete, there exists a  $g \in \mathcal{B}$  such that  $\lim_{n \rightarrow \infty} \|g - p_n\|_{\mathcal{B}} = 0$ . Because of (5.7) this implies also that  $\lim_{n \rightarrow \infty} \|g - p_n\|_\infty = 0$ . By the triangle inequality, one has  $\|f - g\|_\infty \leq \|f - p_n\|_\infty + \|p_n - g\|_\infty$ . Both terms on the right-hand side converge to zero as  $n$  tends to infinity. This shows that  $f = g$  and therefore  $f \in \mathcal{B}$ .

Finally, let again  $f \in \mathcal{C}(\mathbb{T})$ , and let  $\mathfrak{A}_n$  be the approximation operator defined in (4.7). Then by (5.7) and Proposition 4.5, it holds that

$$(5.9) \quad \|\mathfrak{A}_n f\|_\infty \leq \|\mathfrak{A}_n f\|_{\mathcal{B}} \leq m_4 \|f\|_{\mathcal{B}} \leq \frac{2m_4}{m_6} \|f\|_\infty,$$

where the constants  $m_4, m_6$  are independent of  $n$ . However, this inequality does not hold for all continuous functions  $f \in \mathcal{C}(\mathbb{T})$ . As an example, consider for an arbitrary but fixed  $n \in \mathbb{N}$  the function  $f_n(e^{i\omega}) = \left(\frac{1}{\pi} \sum_{k=1}^n \frac{\sin(k\omega)}{k}\right) e^{in\omega}$ . Clearly,  $f_n \in \mathcal{C}(\mathbb{T})$  with  $\|f_n\|_\infty \leq 1$ , and it holds that

$$(\mathfrak{A}_n f_n)(e^{i\omega}) = \frac{1}{2\pi i} \sum_{k=0}^{n-1} \frac{e^{ik\omega}}{n-k}.$$

It follows that  $|(\mathfrak{A}_n f_n)(1)| = \frac{1}{2\pi} \sum_{k=1}^n \frac{1}{k}$ , which shows that  $\|\mathfrak{A}_n f_n\|_\infty \geq \frac{1}{2\pi} \log n$ . Since the right-hand side of (5.9) is a constant, (5.9) gives a contradiction for the function  $f_n$  and for a sufficiently large  $n$ . This shows that (5.7) cannot hold. Consequently, the spectral factorization mapping has to be unbounded in  $\mathcal{B}$ .  $\square$

**6. Discussions.** In a sense, the most vital axiom of a decomposing Banach algebra is the second part of the axiom (A1), namely, that  $f \in \mathcal{B}$  always implies that  $\mathfrak{P}_+ f \in \mathcal{B}$ , which is equivalent to the boundedness of the Riesz projection  $\mathfrak{P}_+$  on  $\mathcal{B}$ . Let us consider *Banach algebras of continuous functions*. These are Banach algebras  $\mathcal{A}$  that are closed subspaces of  $\mathcal{C}(\mathbb{T})$  and that satisfy the axioms (A2)–(A4) and the first part of (A1) of a decomposing Banach algebra. Then the boundedness of the Riesz projection  $\mathfrak{P}_+$  on  $\mathcal{A}$  will determine whether  $\mathcal{A}$  is a decomposing algebra or not.

In the following, let  $\mathcal{A}$  be a Banach algebra of continuous functions. Then Theorem 5.3 implies that the spectral factorization mapping  $\mathfrak{S}$  is unbounded on  $\mathcal{A}$  if the Riesz projection is bounded on  $\mathcal{A}$ . Next, we give a different condition for the unboundedness of the spectral factorization. To this end, we consider Banach algebras with the following property.

**DEFINITION 6.1** (log-property). *Let  $\mathcal{A}$  be a Banach algebra of continuous functions on  $\mathbb{T}$ . We say that  $\mathcal{A}$  possesses the log-property if every  $f \in \mathcal{A}_+$  has the property that  $|f(z)| > 0$  for all  $z \in \mathbb{D}$  implies  $\log f \in \mathcal{A}_+$ .*

**Remark 6.2.** The Wiener algebra (Example 2.5) and the algebra  $\lambda_\alpha$  of Hölder continuous functions (Example 2.6) are examples of algebras having the log-property.

With this property, one gets the following alternative condition for the unboundedness of the spectral factorization on Banach algebras of continuous functions.

**COROLLARY 6.3.** *If a Banach algebra of continuous functions  $\mathcal{A}$  possesses the log-property, then the spectral factorization is unbounded on  $\mathcal{A}$ .*

*Proof.* Since  $\mathcal{A} \subset \mathcal{C}(\mathbb{T}) \subset L^\infty(\mathbb{T})$ , every  $f \in \mathcal{A}_{\text{pos}}$  possesses a spectral factorization with a spectral factor  $f_+ \in H^\infty(\mathbb{D})$  (cf. Remark 3.3). Moreover, since  $f$  is continuous and  $\mathbb{T}$  is closed, there exists a  $\zeta_0 \in \mathbb{T}$  such that  $\inf_{\zeta \in \mathbb{T}} |f(\zeta)| = f(\zeta_0) =: c > 0$ . In contradiction to the statement of the corollary, we assume that the spectral factorization is bounded on  $\mathcal{A}$ . Then  $f_+ \in \mathcal{A}_+$ , and (3.1) shows that  $|f_+(\zeta)| \geq \sqrt{c} > 0$  for all  $\zeta \in \mathbb{D}$ . Since  $\mathcal{A}$  possesses the log-property,  $\log f_+ \in \mathcal{A}$ . Because of (3.3) it holds that  $\log f_+(z) = (\mathfrak{P}_+[\log f])(z) - \frac{1}{2} \alpha_0$ , in which the constant  $\alpha_0 = \frac{1}{2\pi} \int_{-\pi}^{\pi} \log f(e^{i\tau}) d\tau$  is just the zeroth Fourier coefficient of  $\log f$ . Since  $\log f_+ \in \mathcal{A}$ , this shows that the Riesz projection of  $\log f$  belongs to  $\mathcal{A}$  as well. Thus, under the assumption that  $\mathcal{A}$  has the log-property and that the spectral factorization is bounded on  $\mathcal{A}$ , we have that

$$(6.1) \quad \mathfrak{P}_+[\log f] \in \mathcal{A} \quad \text{for all } f \in \mathcal{A}_{\text{pos}}.$$

Let  $g \in \mathcal{A}$  be an arbitrary real valued function in  $\mathcal{A}$ . Then  $f := \exp g \in \mathcal{A}_{\text{pos}}$ , and it follows from (6.1) that  $\mathfrak{P}_+g \in \mathcal{A}$  whenever  $g \in \mathcal{A}$ . For complex functions  $g = g_1 + i g_2 \in \mathcal{A}$  with real functions  $g_1, g_2 \in \mathcal{A}$  one obtains  $\mathfrak{P}_+g = \mathfrak{P}_+g_1 + i \mathfrak{P}_+g_2 \in \mathcal{A}$ . This implies that  $\mathcal{A}$  is a decomposing Banach algebra, and by Theorem 5.3 it follows that the spectral factorization mapping  $\mathfrak{S}$  is unbounded on  $\mathcal{A}$ . This conflicts with the assumption that  $\mathfrak{S}$  is bounded and therefore proves the corollary.  $\square$

By (3.3), the spectral factorization mapping  $\mathfrak{S}$  is a concatenation of the logarithm of the Riesz projection and of the exponential function:  $\mathfrak{S} = \exp \circ \mathfrak{P}_+ \circ \log$ . If one considers Banach algebras of continuous functions  $\mathcal{A}$ , Theorem 5.3 shows that  $\mathfrak{S}$  will be unbounded if the Riesz projector  $\mathfrak{P}_+$  is bounded, and Corollary 6.3 shows that  $\mathfrak{S}$  will be unbounded if  $\mathcal{A}$  has the log-property. It is interesting to compare this behavior with the Banach algebra  $L^\infty(\mathbb{T})$ . On this algebra, the spectral factorization is bounded, but the Riesz projection is unbounded and  $L^\infty(\mathbb{T})$  does not possess the log-property.

It was shown that the spectral factorization is unbounded on every decomposing Banach algebra  $\mathcal{B}$ . However, it is possible to characterize subsets  $\mathcal{M}$  of  $\mathcal{B}$  such that the spectral factor is bounded for every  $f \in \mathcal{M}$ . These subsets  $\mathcal{M}$  are characterized by the minimum value of the spectral densities in  $\mathcal{M}$ : For a fixed constant  $c > 0$  and a certain decomposing Banach algebra  $\mathcal{B}$ , we consider the set  $\mathcal{M}(c, \mathcal{B}) := \{f \in \mathcal{B} : \|f\|_{\mathcal{B}} \leq 1, f(\zeta) \geq c \text{ for all } \zeta \in \mathbb{T}\}$  and the number

$$C(c, \mathcal{B}) = \sup_{f \in \mathcal{M}(c, \mathcal{B})} \|\log f\|_{\mathcal{B}}.$$

Assume that for a certain constant  $c > 0$  it holds that  $C(c, \mathcal{B}) < \infty$ ; then the spectral factorization is bounded on  $\mathcal{M}(c, \mathcal{B})$ .

**PROPOSITION 6.4.** *Let  $\mathcal{B}$  be a decomposing Banach algebra, and let  $c > 0$  such that the constant  $C(c, \mathcal{B}) < \infty$ ; then for all  $f \in \mathcal{M}(c, \mathcal{B})$  it holds that*

$$(6.2) \quad \|f_+\|_{\mathcal{B}} = \|\mathfrak{S}f\|_{\mathcal{B}} \leq \exp \left( \frac{1}{2} C(c, \mathcal{B}) \|\mathfrak{P}_+\|_{\mathcal{B} \rightarrow \mathcal{B}} \right).$$

*Proof.* For every  $f \in \mathcal{M}(c, \mathcal{B})$  holds

$$\left\| \frac{1}{2} \mathfrak{P}_+(\log f) \right\|_{\mathcal{B}} \leq \frac{1}{2} \|\mathfrak{P}_+\|_{\mathcal{B} \rightarrow \mathcal{B}} \|\log f\|_{\mathcal{B}} \leq \frac{1}{2} \|\mathfrak{P}_+\|_{\mathcal{B} \rightarrow \mathcal{B}} C(c, \mathcal{B}).$$

By the definition of the spectral factorization mapping (3.2), one obtains therewith

$$\|f_+\|_{\mathcal{B}} \leq \sum_{k=0}^{\infty} \frac{1}{k!} \left( \frac{1}{2} \right)^k \|\mathfrak{P}_+(\log f)\|_{\mathcal{B}}^k \leq \exp \left( \frac{1}{2} \|\mathfrak{P}_+\|_{\mathcal{B} \rightarrow \mathcal{B}} C(c, \mathcal{B}) \right)$$

which is the statement of the proposition.  $\square$

For which constants  $c$  the value  $C(c, \mathcal{B})$  remains bounded depends strongly on the algebra  $\mathcal{B}$ . This is illustrated by two examples.

*Example 6.5.* For the Wiener algebra  $\mathcal{W}$ , it follows from Wiener's classical result [22] that  $C(c, \mathcal{W}) \leq \log(1/[2c - 1])$  for every  $c > 1/2$ , and it can be shown [4] that  $C(c, \mathcal{W}) = +\infty$  for all  $c \leq 1/4$ . It is not quite clear whether  $C(c, \mathcal{W})$  is bounded for  $1/4 < c \leq 1/2$  or not.

*Example 6.6.* For the decomposing Banach algebra  $\lambda_\alpha$  of all Hölder continuous function on  $\mathbb{T}$ , it is easy to verify [3] that for every arbitrary constants  $c > 0$ , the value  $C(c, \lambda_\alpha)$  is upper bounded by  $|\log c| < \infty$ .

**7. Conclusions.** This paper presented a supplement to a result of Jacob and Partington [15] on the boundedness of the spectral factorization mapping on decomposing Banach algebras. It was shown that there exists no decomposing Banach algebra on which the spectral factorization is bounded. Together with the continuity result in [15], one has therefore that the spectral factorization is continuous but unbounded on every decomposing Banach algebra.

The boundedness of the spectral factorization mapping would allow us to bound the norm of the spectral factors in terms of the norm of the given spectrum. This possibility is of some importance in certain applications. As a practical example we mention the approximation of the spectral factors by polynomials. To this end, consider the Banach algebra  $\lambda_\alpha$  of Hölder continuous functions (see Example 2.6), and let  $\phi \in \lambda_\alpha$  be an arbitrary spectrum which should be approximated by a polynomial  $\phi_N$  of degree  $N$ . It is well known (see, e.g., [25, section III.13]) that the approximation error is upper bounded by

$$\|\phi - \phi_N\|_\infty \leq \frac{C}{N^\alpha} \|\phi\|_\alpha$$

with a fixed constant  $C$ . Thus, for all spectral densities with, say,  $\|\phi\|_\alpha \leq 1$ , a sufficient approximation degree  $N_0$  can be found such that the approximation error remain always below a desired threshold. However, if one wants to approximate the corresponding spectral factor  $\phi_+$ , no such minimal approximation degree  $N_0$  for all  $\phi$  with  $\|\phi\|_\alpha \leq 1$  can be found since  $\|\phi_+ - \phi_N\|_\infty \leq \frac{C}{N^\alpha} \|\phi_+\|_\alpha$ , and because of the unboundedness of the spectral factorization mapping, the right-hand side cannot be upper bounded by the norm of  $\phi$ . Thus, in order to determine a sufficient approximation degree for the approximation polynomial of  $\phi_+$ , one needs to determine the spectral factor and its norm, in general. If, on the other hand, the spectral factorization mapping would be bounded, it would be possible to find for every  $\epsilon > 0$  a degree  $N_0$  such that there always exists a polynomial  $\phi_{N_0}$  such that  $\|\phi_+ - \phi_{N_0}\|_\infty < \epsilon$  for all spectra with  $\|\phi\|_\alpha < 1$ , without the need to control the norm of the spectral factors.

# RELAXATION OF A CONTROL PROBLEM IN THE COEFFICIENTS WITH A FUNCTIONAL OF QUADRATIC GROWTH IN THE GRADIENT\*

JUAN CASADO-DÍAZ<sup>†</sup>, JULIO COUCE-CALVO<sup>†</sup>, AND JOSÉ D. MARTÍN-GÓMEZ<sup>†</sup>

**Abstract.** We study an optimal design problem consisting in mixing two anisotropic (electric or thermal) materials in order to minimize a functional depending on the gradient of the state. It is known that this type of problem has no solution in general, and then it is necessary to introduce a relaxed formulation. Here we prove that this relaxation is obtained by using composite materials, is constructed by homogenization, and takes a particular extension of the cost functional to these new materials. We obtain an integral representation of this relaxed cost functional. Besides, we show that our results contain some previous results obtained by other authors for isotropic materials.

**Key words.** control in the coefficients, elliptic PDE, optimal design

**AMS subject classification.** 49K20

**DOI.** 10.1137/070685890

**1. Introduction.** We consider a control problem for a linear elliptic partial differential equation where the control variable is the diffusion matrix (control problem in the coefficients). This type of problem appears in optimal design. Recall that the thermic or electric properties of a material are given by the corresponding diffusion matrix, and so choosing an optimal matrix diffusion is equivalent to choosing an optimal material. To simplify the exposition we consider a two-phase optimization problem; i.e., we assume that the materials are constructed by mixing two fixed materials (nonisotropic in general) represented by their diffusion matrices  $A$  and  $B$ , which we take to be symmetric and elliptic.

As a model problem we consider the following one: For a bounded open set  $\Omega \subset \mathbf{R}^N$ , we look for a measurable set  $\omega \subset \Omega$  such that for a given source term  $f \in L^2(\Omega)$  (or more generally in  $H^{-1}(\Omega)$ ) the solution  $u$  of

$$\begin{cases} -\operatorname{div}(A\chi_\omega + B\chi_{\Omega \setminus \omega})\nabla u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega \end{cases}$$

minimizes a given functional  $J$  on the Sobolev space  $H_0^1(\Omega)$ . We also assume that the measure of  $\omega$  is less than or equal to  $\kappa|\Omega|$ , with  $0 < \kappa < 1$ ; i.e., we dispose only of a limited quantity of material  $A$ .

It is well known (see, e.g., [20], [21]) that, in general, this problem has no solution (some existence results can be obtained in particular situations [12]), and so it is necessary to relax the problem. By denoting, for  $p \in [0, 1]$ ,  $\mathcal{K}(A, B, p)$  as the set of matrices constructed via homogenization, mixing  $A$  and  $B$  with respective proportions  $p$  and  $1-p$ , and assuming  $J$  sequentially continuous for the weak topology of  $H_0^1(\Omega)$ , it is well known (see, e.g., [1], [11], [16], [17], [22], [24], [26], [27], [29]) that the relaxation

<sup>†</sup>Dpto. de Ecuaciones Diferenciales y Análisis Numérico, Facultad de Matemáticas, C. Tarfia s/n, 41012 Sevilla, Spain (jcasadod@us.es, couce@us.es, jdmartin@us.es).

of the model control problem is obtained by replacing the set of controls

$$(1.1) \quad \{A\chi_\omega + B\chi_{\Omega \setminus \omega} : \omega \subset \Omega \text{ measurable}, |\omega| \leq \kappa|\Omega|\}$$

by the larger set

$$(1.2) \quad \left\{ (M, \theta) \text{ measurable} : \theta \in [0, 1], M \in \mathcal{K}(A, B, \theta) \text{ a.e. in } \Omega, \int_\Omega \theta dx \leq \kappa|\Omega| \right\}.$$

In the present paper we are interested in functionals depending on the gradient of the state function, and so they are not sequentially continuous in general on the weak topology of  $H_0^1(\Omega)$ . For simplicity, we restrict ourselves to the functional

$$(1.3) \quad J(u) = \int_\Omega F(\nabla u) dx + G(u), \quad u \in H_0^1(\Omega),$$

where  $F$  is a Hölder-continuous function in  $\mathbf{R}^N$  with a quadratic growth and  $G$  is sequentially continuous for the weak topology of  $H_0^1(\Omega)$ . Thus, the control problem considered in this paper is given by

$$(1.4) \quad \begin{cases} \inf \left\{ \int_\Omega F(\nabla u) dx + G(u) \right\}, \\ -\operatorname{div} (A\chi_\omega + B\chi_{\Omega \setminus \omega}) \nabla u = f \text{ in } \Omega, \\ u \in H_0^1(\Omega), \quad \omega \subset \Omega \text{ measurable}, |\omega| \leq \kappa|\Omega|. \end{cases}$$

Some control problems related to (1.4) have also been considered by other authors. In this way, for the case

$$(1.5) \quad A = \alpha I, \quad B = \beta I, \quad J(u) = \int_\Omega |\nabla(u - v)|^2 dx,$$

it is proved in [30] that there exists a dense subset of  $v \in H^1(\Omega)$  such that, by taking as control variable the functions of  $L^\infty(\Omega)$  valued in  $[0, 1]$ , instead of the characteristic functions of measurable subsets of  $\Omega$ , problem (1.4) has a unique solution (the fact that  $A = \alpha I$ ,  $B = \beta I$  is not relevant in the reasoning used in [30]).

Related to this result, we mention that, for  $N = 2$ ,  $A = \alpha I$ ,  $B = \beta I$ , and  $F(\xi) = G(|\xi|)$ , convex in  $\xi$ , and growth not necessarily quadratic, it is proved in [25] that a relaxation of (1.4) can be obtained by just replacing the characteristic functions by functions valued in  $[0, 1]$ .

On the other hand, a relaxation of problem (1.4) when  $A, B$ , and  $J$  are given by (1.5) is obtained in [3], [10], [18]. We also refer to [15], [31], where, from a partial relaxation, it is realized a numerical study of the problem.

Some relaxation and numerical results for (1.4) have also been obtained in [2] when  $A$  and  $B$  are not necessarily scalar matrices but  $B - A$  is small.

Other relaxation problems for anisotropic materials (in diffusion and elasticity) have been considered in [12], [13], [14], where the functional is sequentially continuous with respect to the weak topology of  $H_0^1(\Omega)$ , but constraints appear on the gradients of the state functions.

In the present paper, for general  $A, B$ , and  $F$ , we show that the relaxation of (1.4) is given by replacing (as when  $J$  was sequentially continuous in the weak topology of  $H_0^1(\Omega)$ ) the set of controls (1.1) by (1.2) and the functional  $J$  by

$$\int_\Omega H(\nabla u, M \nabla u, \theta) dx + G(u),$$

where  $H : \{(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1] : \eta \in \mathcal{K}(A, B, p)\xi\} \rightarrow \mathbf{R}$  is defined by (4.6).

We prove that the function  $H$  is continuous, satisfies the growth condition

$$|H(\xi, \eta, p)| \leq C(1 + |\xi|^2),$$

and has some convexity properties given in Proposition 4.6.

We also obtain a characterization of the set  $\mathcal{K}(A, B, p)\xi$  for every  $\xi \in \mathbf{R}^N$ , and we explicitly calculate  $H$  on

$$\{(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1] : \eta \in \partial\mathcal{K}(A, B, p)\xi\}$$

(here  $\partial$  denotes the boundary with respect to the affine hull). This can be useful to the study of optimality conditions for the relaxed problem. We refer to [1], [5], [6], [16], [24] for the study of optimality conditions for control problems in the coefficients.

Finally, we obtain an explicit expression of  $H$  in its whole domain for the case where

$$F(\xi) = sA\xi \cdot \xi,$$

where  $s \in \mathbf{R}$  and  $s(A - B)$  is nonnegative. This example contains in particular (see Corollary 6.2) the case where  $A$ ,  $B$ , and  $J$  are given by (1.5).

Although, to simplify the exposition, we have assumed that  $J$  is given by (1.3), our techniques apply for a more general functional given by

$$\int_{\omega} F_1(x, u, \nabla u) dx + \int_{\Omega \setminus \omega} F_2(x, u, \nabla u) dx + G(u),$$

with  $G$  as above and  $F_1, F_2$  satisfying similar conditions to  $F$ . It is also possible to consider more than two materials (but then, we do not have an explicit characterization of the domain of  $H$ ) and the more realistic case where the set of materials is invariable by rotations.

**2. Notation.** The space of linear applications from  $\mathbf{R}^N$  into  $\mathbf{R}^N$ , which we assume to be identified with the space of matrices of dimension  $N \times N$ , is denoted by  $\mathcal{M}_N$ . The subspace of  $\mathcal{M}_N$  corresponding to the symmetric matrices is denoted by  $\mathcal{M}_N^s$ .

The kernel and the range of  $M \in \mathcal{M}_N$  are, respectively, denoted by  $\text{Ker}(M)$  and  $\text{Ran}(M)$ .

For  $M \in \mathcal{M}_N^s$ , not necessarily invertible, we define  $M^\dagger : \text{Ran}(M) \rightarrow \text{Ran}(M)$  the pseudoinverse of  $M$ , i.e., the inverse of the restriction of  $M$  to its range.

The unitary cube in  $\mathbf{R}^N$ ,  $(0, 1)^N$  is denoted by  $Y$ .

For two sets  $Z$  and  $Z'$ , we denote by  $Z \triangle Z'$  its symmetric difference; i.e.,  $Z \triangle Z' = (Z \setminus Z') \cup (Z' \setminus Z)$ .

We use the subindex  $\sharp$  to mean  $Y$ -periodicity. For example, the space of functions in the Sobolev space  $H_{loc}^1(\mathbf{R}^N)$  which are  $Y$ -periodic is denoted by  $H_\sharp^1(Y)$ . Indeed, in the present paper all of the functions defined on  $Y$  are assumed to be extended to  $\mathbf{R}^N$  by  $Y$ -periodicity.

Throughout the paper we denote by  $A$  and  $B$  two fixed positive symmetric matrices.

We define  $\Xi : \text{Ran}(A - B) \rightarrow A^{-1}\text{Ran}(A - B) (= B^{-1}\text{Ran}(A - B))$  by

$$(2.1) \quad \Xi\zeta = \nu \Leftrightarrow \begin{cases} (B - A)\nu = \zeta \\ A\nu \in \text{Ran}(A - B) \end{cases} \Leftrightarrow \begin{cases} (B - A)\nu = \zeta \\ B\nu \in \text{Ran}(A - B) \end{cases}$$

for every  $\zeta \in \text{Ran}(A - B)$  or, equivalently,

$$(2.2) \quad \Xi = (rA + sB)^{-1}(B - A) \left( (B - A)(rA + sB)^{-1}(B - A) \right)^\dagger$$

for every  $r, s \geq 0$ ,  $r + s > 0$ . Note that if  $B - A$  is invertible, then  $\Xi = (B - A)^{-1}$ .

For  $p \in [0, 1]$ , we define  $\Lambda_p$  as the arithmetic mean of  $A$  and  $B$  with respective proportions  $p$  and  $1 - p$ ; i.e.,

$$\Lambda_p = pA + (1 - p)B.$$

We denote by  $\Omega \subset \mathbf{R}^N$  a fixed bounded open set, smooth enough for Meyer's theorem [19] to be satisfied and such that there exist  $\hat{\Omega}$  open bounded with  $\bar{\Omega} \subset \hat{\Omega}$  and a linear continuous prolongation operator from  $H^1(\Omega)$  into  $H_0^1(\hat{\Omega})$ .

For a sequence  $M_n \in L^\infty(\Omega; \mathcal{M}_N)$ , uniformly elliptic and bounded, and  $M \in L^\infty(\Omega; \mathcal{M}_N)$ , we write  $M_n \xrightarrow{H} M$  to mean that  $M_n$  converges to  $M$  in the sense of the  $H$ -convergence [22], [27]. Indeed, as we usually deal with symmetric matrices,  $H$ -convergence is equivalent to the  $G$ -convergence of Spagnolo [26].

For  $p \in [0, 1]$  we denote by  $\mathcal{K}(A, B, p)$  the set of materials constructed via homogenization mixing the materials corresponding to the diffusion matrices  $A$  and  $B$ , with respective proportions  $p$  and  $1 - p$ ; i.e.,

$$(2.3) \quad \mathcal{K}(A, B, p) = \left\{ M \in \mathcal{M}_N^s : \exists \omega_n \subset \mathbf{R}^N \text{ measurable, } \chi_{\omega_n} \xrightarrow{*} p \text{ in } L^\infty(\mathbf{R}^N), A\chi_{\omega_n} + B(1 - \chi_{\omega_n}) \xrightarrow{H} M \right\}.$$

Clearly,  $\mathcal{K}(A, B, 1) = \{A\}$ ,  $\mathcal{K}(A, B, 0) = \{B\}$ .

For  $\xi \in \mathbf{R}^N$ ,  $p \in [0, 1]$  we write

$$\mathcal{K}(A, B, p)\xi = \{ \eta \in \mathbf{R}^N : \exists M \in \mathcal{K}(A, B, p), \text{ with } \eta = M\xi \}.$$

**3. Preliminary results.** To our knowledge, an explicit characterization of the set  $\mathcal{K}(A, B, p)$  is known only for isotropic materials (see, e.g., [17], [29]). Fortunately, for the purpose of the present paper, we need only to know the set  $\mathcal{K}(A, B, p)\xi$  for every  $\xi \in \mathbf{R}^N$ . A characterization of this set is obtained in the present section.

We recall the following result due to Dal Maso and Kohn [9] (see also [1], [11]), which shows that the set  $\mathcal{K}(A, B, p)$  can be obtained via periodic homogenization.

**THEOREM 3.1.** *For  $p \in [0, 1]$ , the set of matrices  $M$  for which there exists  $Z \subset Y$ , with  $|Z| = p$ , such that for every  $\xi \in \mathbf{R}^N$ ,*

$$(3.1) \quad M\xi = \int_Y (A\chi_Z + B\chi_{Y \setminus Z})(\xi + \nabla w) dy,$$

with  $w$  the solution of

$$(3.2) \quad \begin{cases} w \in H_\#^1(Y), & \int_Y w dy = 0, \\ -\text{div}((A\chi_Z + B\chi_{Y \setminus Z})(\xi + \nabla w)) = 0 & \text{in } \mathbf{R}^N, \end{cases}$$

is dense in  $\mathcal{K}(A, B, p)$ .

The following result gives some properties of the solution  $w$  of (3.2).

LEMMA 3.2. For  $p \in (0, 1)$ , we consider  $\xi, \eta \in \mathbf{R}^N$  and  $Z \subset Y$  measurable, with  $|Z| = p$ , such that the solution  $w$  of (3.2) satisfies

$$(3.3) \quad \int_Y (A\chi_Z + B\chi_{Y \setminus Z})(\xi + \nabla w) dy = \eta.$$

Then the following equalities hold:

$$(3.4) \quad \int_Z A \nabla w \cdot \nabla w dy + \int_{Y \setminus Z} B \nabla w \cdot \nabla w dy = (\Lambda_p \xi - \eta) \cdot \xi,$$

$$(3.5) \quad (B - A) \int_Z \nabla w dy = -(B - A) \int_{Y \setminus Z} \nabla w dy = \Lambda_p \xi - \eta,$$

$$(3.6) \quad \begin{cases} \int_Z A \left( \nabla w - \frac{1}{p} \int_Z \nabla w dz \right) \cdot \left( \nabla w - \frac{1}{p} \int_Z \nabla w dz \right) dy \\ + \int_{Y \setminus Z} B \left( \nabla w - \frac{1}{1-p} \int_{Y \setminus Z} \nabla w dz \right) \cdot \left( \nabla w - \frac{1}{1-p} \int_{Y \setminus Z} \nabla w dz \right) dy \\ = (\Lambda_p \xi - \eta) \cdot \xi - \left( \frac{A}{p} + \frac{B}{1-p} \right) \left( \int_Z \nabla w dy \right) \cdot \left( \int_Z \nabla w dy \right). \end{cases}$$

*Proof.* By using  $w$  as a test function in (3.2), and taking into account (3.3), we easily get (3.4).

Since  $w$  is periodic, we have

$$\int_Z \nabla w dy + \int_{Y \setminus Z} \nabla w dy = 0.$$

On the other hand, by (3.3) we obtain

$$A \int_Z \nabla w dy + B \int_{Y \setminus Z} \nabla w dy = \eta - \Lambda_p \xi.$$

From these equalities we conclude (3.5).

To prove (3.6), it is enough to develop the left-hand side and then use (3.4).  $\square$

As a consequence of Lemma 3.2, we have the following.

PROPOSITION 3.3. If  $N = 1$ ,  $p \in [0, 1]$ , we have

$$(3.7) \quad \mathcal{K}(A, B, p) = \left\{ \left( \frac{p}{A} + \frac{1-p}{B} \right)^{-1} \right\}.$$

If  $N \geq 2$ ,  $p \in (0, 1)$ ,  $\xi \in \mathbf{R}^N$ , then, by denoting by  $E(\xi, p)$  the ellipsoid

$$E(\xi, p) = \left\{ \nu \in \mathbf{R}^N : \left( \frac{A}{p} + \frac{B}{1-p} \right) \nu \cdot \nu \leq (B - A) \nu \cdot \xi \right\},$$

we have

$$(3.8) \quad \mathcal{K}(A, B, p)\xi = \Lambda_p \xi + (A - B)E(\xi, p).$$

*Proof.* The case  $N = 1$  is well known. Indeed, it can be easily obtained by using the fact that for every  $Z \subset Y$ , with  $|Z| = p$ , the solution  $w$  of (3.2) satisfies

$$(3.9) \quad \xi + \frac{dw}{dx} = \begin{cases} \frac{\eta}{A} & \text{a.e. in } Z, \\ \frac{\eta}{B} & \text{a.e. in } Y \setminus Z, \end{cases}$$

with

$$(3.10) \quad \eta = \left( \frac{p}{A} + \frac{1-p}{B} \right)^{-1} \xi.$$

Assume now that  $N \geq 2$ ,  $p \in (0, 1)$ . For  $Z \subset Y$ , with  $|Z| = p$ , and the  $w \in H^1_{\sharp}(Y)$  solution of (3.2), the left-hand side of (3.6) is nonnegative, and so equality (3.5) proves that the vector

$$\nu = \int_Z \nabla w \, dy$$

is in  $E(\xi, p)$  and satisfies  $\eta = \Lambda_p \xi + (A - B)\nu$ . Since by Theorem 3.1 the set of  $\eta$  constructed in this way is dense in  $\mathcal{K}(A, B, p)\xi$ , we then deduce the inclusion

$$\mathcal{K}(A, B, p)\xi \subset \Lambda_p \xi + (A - B)E(\xi, p).$$

Reciprocally, let us now prove that every  $\nu \in E(\xi, p)$  satisfies that  $\Lambda_p \xi + (A - B)\nu$  belongs to  $\mathcal{K}(A, B, p)\xi$ .

If  $\nu$  belongs to  $\partial E(\xi, p) \setminus \{0\}$ , this can be easily shown by using a lamination of  $A$  and  $B$  with respective proportions  $p$  and  $1 - p$  in the direction of  $\nu$ . If  $\nu = 0$ , we consider a lamination as above but now in an orthogonal direction to  $(B - A)\xi$ .

If  $\nu$  belongs to the interior of  $E(\xi, p)$ , then, for  $\lambda > 1$  such that  $\lambda\nu$  belongs to  $\partial E(\xi, p)$ , we take two matrices  $M_1, M_2 \in \mathcal{K}(A, B, p)$  such that  $M_1\xi = \Lambda_p \xi$ ,  $M_2\xi = \Lambda_p \xi + \lambda(A - B)\nu$ . A lamination of  $M_1$  and  $M_2$  with respective proportions  $1 - 1/\lambda$  and  $1/\lambda$  in an orthogonal direction to  $(M_2 - M_1)\xi$  provides a matrix  $M \in \mathcal{K}(A, B, p)$  such that  $\Lambda_p \xi + (A - B)\nu = M\xi$ .  $\square$

**COROLLARY 3.4.** For  $N \geq 2$ ,  $p \in (0, 1)$ , and  $\xi \in \mathbf{R}^N$ , we have

$$(3.11) \quad \mathcal{K}(A, B, p)\xi = \left\{ \eta \in \mathbf{R}^N : \begin{aligned} &\Lambda_p \xi - \eta \in \text{Ran}(A - B), \\ &\left( (A - B) \left( \frac{A}{p} + \frac{B}{1-p} \right)^{-1} (A - B) \right)^{\dagger} (\Lambda_p \xi - \eta) \cdot (\Lambda_p \xi - \eta) \leq \xi \cdot (\Lambda_p \xi - \eta) \end{aligned} \right\}.$$

*Proof.* By Proposition 3.3, we have that  $\eta$  belongs to  $\mathcal{K}(A, B, p)\xi$  if and only if there exists  $\nu \in \mathbf{R}^N$ , such that  $\Lambda_p \xi - \eta = (B - A)\nu$  and

$$\left( \frac{A}{p} + \frac{B}{1-p} \right) \nu \cdot \nu \leq (\Lambda_p \xi - \eta) \cdot \xi$$

or, equivalently, if and only if  $\Lambda_p \xi - \eta \in \text{Ran}(A - B)$  and

$$(3.12) \quad \min \left\{ \left( \frac{A}{p} + \frac{B}{1-p} \right) \nu \cdot \nu : \Lambda_p \xi - \eta = (B - A)\nu \right\} \leq (\Lambda_p \xi - \eta) \cdot \xi.$$

The minimum of this problem is attained in  $\nu = \Xi(\Lambda_p \xi - \eta)$ , with  $\Xi$  defined by (2.1). By using the fact that by (2.2)

$$\Xi = \left( \frac{A}{p} + \frac{B}{1-p} \right)^{-1} (B - A) \left( (B - A) \left( \frac{A}{p} + \frac{B}{1-p} \right)^{-1} (B - A) \right)^{\dagger},$$

we obtain (3.11).  $\square$

As a consequence of this result, we have the following.

**COROLLARY 3.5.** *For  $N \geq 2$ ,  $p \in (0, 1)$ ,  $\xi \in \mathbf{R}^N$ , the set  $\mathcal{K}(A, B, p)\xi$  reduces to  $\{\Lambda_p \xi\}$  if and only if  $\xi \in \text{Ker}(A - B)$ .*

*Proof.* By Corollary 3.4, we have  $\mathcal{K}(A, B, p)\xi = \{\Lambda_p \xi\}$ , if and only if for every  $\zeta \in \text{Ran}(A - B)$ ,  $\zeta \neq 0$ , one has

$$\left( (A - B) \left( \frac{A}{p} + \frac{B}{1-p} \right)^{-1} (A - B) \right)^{\dagger} \zeta \cdot \zeta > \xi \cdot \zeta,$$

but this is equivalent to  $\xi \in \text{Ran}(A - B)^{\perp} = \text{Ker}(A - B)$ .  $\square$

**4. Formulation of the problem and main results.** Let us consider a function  $F : \mathbf{R}^N \rightarrow \mathbf{R}$  such that there exist  $L > 0$ ,  $\varrho \in (0, 1]$  which satisfy

$$(4.1) \quad |F(\xi) - F(\xi')| \leq L(1 + |\xi| + |\xi'|)^{2-\varrho} |\xi - \xi'|^{\varrho} \quad \forall \xi, \xi' \in \mathbf{R}^N.$$

Without loss of generality, we can also assume that

$$(4.2) \quad F(0) = 0.$$

These properties imply that  $F$  satisfies

$$(4.3) \quad |F(\xi)| \leq L(1 + |\xi|)^2 \quad \forall \xi \in \mathbf{R}^N.$$

For the open set  $\Omega$  and the matrices  $A, B$  given in section 2, our aim here is to obtain a relaxation of the problem

$$(4.4) \quad \begin{cases} \inf \left\{ \int_{\Omega} F(\nabla u) dx + G(u) \right\}, \\ -\text{div}(A\chi_{\omega} + B\chi_{\Omega \setminus \omega})\nabla u = f \text{ in } \Omega, \\ u \in H_0^1(\Omega), \quad \omega \subset \Omega \text{ measurable, } |\omega| \leq \kappa|\Omega|, \end{cases}$$

where  $G$  is a sequentially continuous functional in the weak topology of  $H_0^1(\Omega)$ ,  $f \in H^{-1}(\Omega)$ , and  $\kappa \in (0, 1)$ . For this purpose, given  $\delta > 0$ , we define  $H_{\delta} : \mathbf{R}^N \times \mathbf{R}^N \times [0, 1] \rightarrow \mathbf{R} \cup \{+\infty\}$  by

$$(4.5) \quad \begin{cases} H_{\delta}(\xi, \eta, p) = \inf \int_Y F(\xi + \nabla w) dy, \\ -\text{div}(A\chi_Z + B\chi_{Y \setminus Z})(\xi + \nabla w) = 0 \text{ in } \mathbf{R}^N, \quad w \in H_{\sharp}^1(Y), \\ \left| \int_Y (A\chi_Z + B\chi_{Y \setminus Z})(\xi + \nabla w) dy - \eta \right| < \delta, \\ Z \subset Y \text{ measurable, } |Z| = p, \end{cases}$$

for every  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$ . In the above expression, the infimum over the empty set is defined as  $+\infty$ .

By using the fact that  $H_\delta$  is decreasing with respect to  $\delta$ , we define  $H : \mathbf{R}^N \times \mathbf{R}^N \times [0, 1] \rightarrow \mathbf{R} \cup \{+\infty\}$  by

$$(4.6) \quad H(\xi, \eta, p) = \lim_{\delta \rightarrow 0} H_\delta(\xi, \eta, p) \quad \forall (\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1].$$

*Remark 4.1.* Definition (4.6) of  $H$  implies that for every  $(\xi, \eta, p) \in D(H)$  there exists a sequence of measurable sets  $Z_n \subset Y$ , with  $|Z_n| = p$ , such that by defining  $S_n \in L^\infty(\Omega; \mathcal{M}_n^s)$  by  $S_n = A\chi_{Z_n} + B\chi_{Y \setminus Z_n}$ , and taking the  $w_n \in H_\#^1(Y)$  solution of

$$-\operatorname{div} S_n(\xi + \nabla w_n) = 0 \quad \text{in } \mathbf{R}^N$$

and

$$\eta_n = \int_Y S_n(\xi + \nabla w_n) dy,$$

we have

$$(4.7) \quad \eta = \lim_{n \rightarrow \infty} \eta_n,$$

$$(4.8) \quad H(\xi, \eta, p) = \lim_{n \rightarrow \infty} \int_Y F(\xi + \nabla w_n) dy.$$

For  $N = 1$ , the following proposition gives an explicit expression of  $H$ .

**PROPOSITION 4.1.** *If  $N = 1$ , the function  $H$  is given by*

$$(4.9) \quad H(\xi, \eta, p) = \begin{cases} pF\left(\frac{\eta}{A}\right) + (1-p)F\left(\frac{\eta}{B}\right) & \text{if } \eta = \left(\frac{p}{A} + \frac{1-p}{B}\right)^{-1} \xi, \\ +\infty & \text{in another case.} \end{cases}$$

For  $N \geq 2$  we do not have an explicit expression for  $H$ , but we can show the following result.

**THEOREM 4.2.** *If  $N \geq 2$ , the function  $H$  satisfies the following properties.*

*The domain of  $H$  is given by*

$$(4.10) \quad \begin{aligned} \operatorname{Dom}(H) &\stackrel{\text{def}}{=} \{(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1] : H(\xi, \eta, p) < +\infty\} \\ &= \{(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1] : \eta \in \mathcal{K}(A, B, p)\xi\}. \end{aligned}$$

*The function  $H$  is lower semicontinuous in  $\operatorname{Dom}(H)$ , and, for*

$$\alpha = \min\{\text{eigenvalues of } A \text{ and } B\}, \quad \beta = \max\{\text{eigenvalues of } A \text{ and } B\},$$

*it satisfies*

$$(4.11) \quad |H(\xi, \eta, p)| \leq L \left(\frac{\beta}{\alpha} |\xi|\right)^q \left(1 + \frac{\beta}{\alpha} |\xi|\right)^{2-q} \quad \forall (\xi, \eta, p) \in \operatorname{Dom}(H).$$

*Moreover, we have*

$$(4.12) \quad H(\xi, A\xi, 1) = H(\xi, B\xi, 0) = F(\xi) \quad \forall \xi \in \mathbf{R}^N,$$

$$(4.13) \quad \begin{cases} H(\xi, \eta, p) = pF\left(\xi + \Xi\left(\frac{\Lambda_p \xi - \eta}{p}\right)\right) + (1-p)F\left(\xi - \Xi\left(\frac{\Lambda_p \xi - \eta}{1-p}\right)\right) \\ \forall (\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times (0, 1) \text{ with } \Lambda_p \xi - \eta \in \text{Ran}(A - B) \text{ and} \\ \left(\left((A - B)\left(\frac{A}{p} + \frac{B}{1-p}\right)^{-1}(A - B)\right)^\dagger (\Lambda_p \xi - \eta) \cdot (\Lambda_p \xi - \eta) = \xi \cdot (\Lambda_p \xi - \eta)\right). \end{cases}$$

If  $F$  is convex, then

$$(4.14) \quad \begin{aligned} F(\xi) &\leq \min \left\{ pF\left(\xi + \frac{\nu}{p}\right) + (1-p)F\left(\xi - \frac{\nu}{1-p}\right) : (B - A)\nu = \Lambda_p \xi - \eta, \nu \in E(\xi, p) \right\} \\ &\leq H(\xi, \eta, p) \quad \forall (\xi, \eta, p) \in \text{Dom}(H), p \in (0, 1). \end{aligned}$$

*Remark 4.2.* A consequence of Theorem 4.2 is that if  $N \geq 2$ , then  $H(\xi, \Lambda_p \xi, p) = F(\xi)$  for every  $\xi \in \mathbf{R}^N$  and every  $p \in [0, 1]$ .

*Remark 4.3.* If  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times (0, 1)$  is such that  $\Lambda_p \xi - \eta \in \text{Ran}(A - B)$  and

$$(4.15) \quad \left(\left((A - B)\left(\frac{A}{p} + \frac{B}{1-p}\right)^{-1}(A - B)\right)^\dagger (\Lambda_p \xi - \eta) \cdot (\Lambda_p \xi - \eta) = \xi \cdot (\Lambda_p \xi - \eta)\right),$$

then the set of  $\nu \in E(\xi, p)$  such that  $(B - A)\nu = \Lambda_p \xi - \eta$  reduces to  $\nu = \Xi(\Lambda_p \xi - \eta)$ . Therefore, (4.13) shows that the second inequality in (4.14) is an equality for such  $(\xi, \eta, p)$ .

By using the function  $H$ , we obtain the following theorem.

**THEOREM 4.3.** *For every  $G : H_0^1(\Omega) \rightarrow \mathbf{R}$  sequentially continuous in the weak topology of  $H_0^1(\Omega)$ , every  $\kappa \in (0, 1)$ , and every  $f \in H^{-1}(\Omega)$ , a relaxation of problem (4.4) is given by*

$$(4.16) \quad \begin{cases} \min \left\{ \int_{\Omega} H(\nabla u, M\nabla u, \theta) dx + G(u) \right\}, \\ -\text{div } M\nabla u = f \text{ in } \Omega, \\ u \in H_0^1(\Omega), \\ \theta \in L^\infty(\Omega), 0 \leq \theta \leq 1 \text{ a.e. in } \Omega, \int_{\Omega} \theta dx \leq \kappa|\Omega|, \\ M \text{ measurable, } M(x) \in \mathcal{K}(A, B, \theta(x)) \text{ for a.e. } x \in \Omega, \end{cases}$$

with  $H$  given by (4.6).

*Remark 4.4.* Problem (4.16) can also be written as

$$(4.17) \quad \begin{cases} \min \left\{ \int_{\Omega} H(\nabla u, \sigma, \theta) dx + G(u) \right\}, \\ -\text{div } \sigma = f \text{ in } \Omega, \\ u \in H_0^1(\Omega), \\ \theta \in L^\infty(\Omega), 0 \leq \theta \leq 1 \text{ a.e. in } \Omega, \int_{\Omega} \theta dx \leq \kappa|\Omega|, \\ \sigma \in \mathcal{K}(A, B, \theta)\nabla u \text{ a.e. in } \Omega \text{ measurable.} \end{cases}$$

Theorem 4.3 is a consequence of Theorem 4.5 below, which is interesting by itself. We need the following definition.

DEFINITION 4.4. *We say that  $(u_n, \sigma_n, \theta_n) \in H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega)$   $\mathcal{T}$ -converges to  $(u, \sigma, \theta) \in H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega)$  if and only if*

$$\begin{aligned} u_n &\rightharpoonup u \text{ in } H^1(\Omega), & |\nabla u_n|^2 &\text{ equi-integrable,} \\ \sigma_n &\rightharpoonup \sigma \text{ in } L^2(\Omega)^N, & \operatorname{div} \sigma_n &\rightarrow \operatorname{div} \sigma \text{ in } H^{-1}(\Omega)^N, \\ \theta_n &\overset{*}{\rightharpoonup} \theta \text{ in } L^\infty(\Omega). \end{aligned}$$

Remark 4.5. In the applications, we are interested in sequences  $(u_n, \sigma_n, \theta_n)$  such that there exists a sequence of uniformly elliptic and bounded matrix functions  $M_n$ , which satisfies  $M_n \nabla u_n = \sigma_n$ . Then we recall that, thanks to Meyer's regularity theorem [19], the weak convergence of  $u_n$  in  $H^1(\Omega)$  and the strong convergence of  $\sigma_n$  in  $L^2(\Omega)^N$  imply the equi-integrability of  $|\nabla u_n|^2$  at least for  $\Omega$  smooth and  $u_n$  satisfying "good" boundary conditions (if not, we always hold the equi-integrability on compact subsets of  $\Omega$ ).

THEOREM 4.5. *The lower semicontinuous envelope with respect to the  $\mathcal{T}$ -convergence of the functional  $\mathcal{F} : H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega) \rightarrow \mathbf{R} \cup \{+\infty\}$  defined by*

$$(4.18) \quad \mathcal{F}(u, \sigma, \theta) = \begin{cases} \int_{\Omega} F(\nabla u) dx & \text{if } \theta = \chi_{\omega}, \omega \subset \Omega \text{ measurable, } \sigma = \Lambda_{\theta} \nabla u, \\ +\infty & \text{in another case} \end{cases}$$

is given by

$$(4.19) \quad \overline{\mathcal{F}}(u, \sigma, \theta) = \begin{cases} \int_{\Omega} H(\nabla u, \sigma, \theta) dx & \text{if } 0 \leq \theta \leq 1, \sigma \in \mathcal{K}(A, B, \theta) \nabla u, \text{ a.e. in } \Omega, \\ +\infty & \text{in another case.} \end{cases}$$

Remark 4.6. Analogously to the proof of Theorem 4.3, we can use Theorem 4.5 to obtain the relaxation of some other related control problems. For example (assuming smoothness enough to have the equi-integrability of  $|\nabla u_n|^2$ , with  $u_n$  the state functions corresponding to a minimizing sequence), we can consider different boundary conditions for the state equation and some other restrictions. In this way, we can apply Theorem 4.5 to obtain a relaxation of the control problem defining  $H_{\delta}$  (see (4.5)). This permits us to prove that the function  $H$  given by (4.6) satisfies

$$(4.20) \quad \left\{ \begin{aligned} H(\xi, \eta, p) &= \inf \int_Y H(\xi + \nabla w, M(\xi + \nabla w), \theta) dy \\ &\quad \theta \in L^{\infty}_{\#}(Y), \quad 0 \leq \theta \leq 1 \text{ a.e. in } \mathbf{R}^N, \quad \int_Y \theta dy = p, \\ &\quad M \in \mathcal{K}(A, B, \theta) \text{ a.e. in } \mathbf{R}^N, \quad w \in H^1_{\#}(Y), \\ &\quad -\operatorname{div} M(\xi + \nabla w) = 0 \text{ in } \mathbf{R}^N, \\ &\quad \int_Y M(\xi + \nabla w) dy = \eta. \end{aligned} \right.$$

*Remark 4.7.* In Step 3 in the proof of Theorem 4.5, for  $(u, \sigma, \theta) \in \text{Dom}(\overline{\mathcal{F}})$  given, we show how to construct  $\omega_n \subset \Omega$  and  $u_n \in H^1(\Omega_n)$  such that the sequence  $(u_n, (A\chi_{\omega_n} + B\chi_{\omega_n})\nabla u_n, \chi_{\omega_n}) \in \text{Dom}(\mathcal{F})$  satisfies

$$\bar{\mathcal{F}}(u, \sigma, \theta) = \lim_{n \rightarrow \infty} \mathcal{F}(u_n, (A\chi_{\omega_n} + B\chi_{\omega_n})\nabla u_n, \chi_{\omega_n}).$$

By applying this procedure to a solution  $(u, \sigma, \theta)$  of problem (4.17), this gives a way to construct a minimizing sequence for problem (4.4). Unfortunately, to apply this procedure it is necessary, for  $(\xi, \eta, p) \in \text{Dom}(H)$ , to know how to construct  $Z_n \subset Y$  in the conditions of Remark 4.1. We do not know how to make this, in general. In particular, we do not know if this can be carried out by using laminations, as it happens in some particular cases where the function  $H$  can be explicitly calculated (see, e.g., [3], [10], and Remark 6.2 in the present paper). When  $\eta \in \partial\mathcal{K}(A, B, p)\xi$  (here  $\partial$  denotes the boundary with respect to the affine hull), the set  $Z_n$  is obtained by using a simple lamination in the direction of  $\nu = \Xi(\Lambda_p\xi - \eta)$ , if  $\eta \neq \Lambda_p\xi$ , or in an orthogonal direction to  $(B - A)\xi$ , if  $\eta = \Lambda_p\xi$ . In this sense, we remark that if  $H$  is derivable (which we do not know if it is true) and  $\theta, M, u$  is a solution of (4.16), then, by introducing the adjoint state  $q$  as the solution of

$$\begin{cases} -\text{div } M\nabla q = -\text{div}(\nabla_\xi H(\nabla u, M\nabla u, \theta) + M\nabla_\eta H(\nabla u, M\nabla u, \theta)) & \text{in } \Omega, \\ q \in H_0^1(\Omega), \end{cases}$$

the optimality conditions for problem (4.16) show (see, e.g., [1], [5], [16], [24] for related results) that a.e. on the set  $\{x \in \Omega : \nabla q(x) \neq \nabla_\eta H(\nabla u(x), M(x)\nabla u(x), \theta(x))\}$ , one has that  $M\nabla u \in \partial\mathcal{K}(A, B, \theta)\nabla u$ .

*Remark 4.8.* In order to solve numerically problem (4.16) the main difficulty is, as in the previous remark, that we have only an explicit expression of  $H$  on the points  $(\xi, \eta, p)$  such that  $\eta \in \partial\mathcal{K}(A, B, p)\xi$  (see (4.13)). But, as we observed above, if  $\theta, M, u$  is a solution of (4.16),  $H$  is sufficiently smooth, and  $\nabla q \neq \nabla_\eta H(\nabla u, M\nabla u, \theta)$  a.e. in  $\Omega$ , then  $M\nabla u \in \partial\mathcal{K}(A, B, \theta)\nabla u$  a.e. in  $\Omega$ . Moreover, in this case  $M$  is obtained by just one lamination. By taking into account these remarks, one can consider a numerical method consisting, for example, of taking a triangulation of  $\Omega$  and then searching the state function  $u$  piecewise affine, the proportion  $\theta$ , and the matrix  $M$  piecewise constants, with  $M$  corresponding to a lamination in each triangle (so the choice of  $M$  in each triangle is reduced to the choice of the corresponding lamination vector). This provides a numerical method similar to the one used in [15] and [31] for the case where  $F(\xi) = |\xi|^2$ ,  $A = \alpha I$ ,  $B = \beta I$ ,  $\alpha, \beta > 0$ .

By using the fact that by Theorem 4.5 the functional  $\bar{\mathcal{F}}$  is lower semicontinuous for the  $\mathcal{T}$ -convergence, we can deduce some convexity properties for  $H$ . The result is essentially a consequence of the compensated compactness theory of Murat [23] and Tartar [28].

**PROPOSITION 4.6.** *The function  $H$  defined by (4.6) satisfies the following convexity properties:*

(i) *If  $N = 1$ , then*

$$(4.21) \quad H(\lambda\xi_1 + (1 - \lambda)\xi_2, \eta, \lambda p_1 + (1 - \lambda)p_2) \leq \lambda H(\xi_1, \eta, p_1) + (1 - \lambda)H(\xi_2, \eta, p_2)$$

*for every  $\xi_1, \xi_2, \eta \in \mathbf{R}$  and every  $p_1, p_2, \lambda \in [0, 1]$ .*

(ii) *If  $N \geq 2$ , then*

$$(4.22) \quad \begin{aligned} & H(\lambda\xi_1 + (1 - \lambda)\xi_2, \lambda\eta_1 + (1 - \lambda)\eta_2, \lambda p_1 + (1 - \lambda)p_2) \\ & \leq \lambda H(\xi_1, \eta_1, p_1) + (1 - \lambda)H(\xi_2, \eta_2, p_2) \end{aligned}$$

for every  $\xi_1, \xi_2, \eta_1, \eta_2 \in \mathbf{R}^N$ , with  $(\xi_2 - \xi_1) \cdot (\eta_2 - \eta_1) = 0$ , and every  $p_1, p_2, \lambda \in [0, 1]$ .

As a consequence of this result we will prove the following proposition which improves Theorem 4.2.

**PROPOSITION 4.7.** *The function  $H$  is continuous on its domain.*

*Remark 4.9.* In Theorem 4.2, we gave a lower bound for  $H$  by assuming  $F$  convex. An analogous proof shows that for  $F$  concave we have

$$H(\xi, \eta, p) \leq \max \left\{ pF \left( \xi + \frac{\nu}{p} \right) + (1-p)F \left( \xi - \frac{\nu}{1-p} \right) : (B-A)\nu = \Lambda_p \xi - \eta, \nu \in E(\xi, p) \right\}$$

for every  $(\xi, \eta, p) \in \text{Dom}(H)$ . Indeed, since  $H$  is defined by a minimum, it is not difficult to obtain upper bounds for  $H$ . In this way, by using (4.13), (4.22), and  $H$  lower semicontinuous for the  $\mathcal{T}$ -convergence, we can use the reasoning at the end of the proof of Proposition 3.3 to show that for every  $F$  satisfying (4.1) and (4.2) (not necessarily concave), every  $(\xi, \eta, p) \in \text{Dom}(H)$ ,  $p \in (0, 1)$ , and every  $\nu \in E(\xi, p)$ , with  $(B-A)\nu = \Lambda_p \xi - \eta$ , we have

$$H(\xi, \eta, p) \leq \left( 1 - \frac{1}{\lambda} \right) F(\xi) + \frac{1}{\lambda} \left( pF \left( \xi + \frac{\lambda\nu}{p} \right) + (1-p)F \left( \xi - \frac{\lambda\nu}{1-p} \right) \right),$$

where

$$\lambda = \frac{(\Lambda_p \xi - \eta) \cdot \xi}{\left( \frac{A}{p} + \frac{B}{1-p} \right) \nu \cdot \nu} \in [0, 1].$$

In particular, for  $F$  concave, this proves that

$$H(\xi, \eta, p) \leq \min \left\{ pF \left( \xi + \frac{\nu}{p} \right) + (1-p)F \left( \xi - \frac{\nu}{1-p} \right) : (B-A)\nu = \Lambda_p \xi - \eta, \nu \in E(\xi, p) \right\}.$$

**5. Proofs of the results of section 4.** Throughout this section, for a measurable set  $Z \subset Y$  and  $\xi \in \mathbf{R}^N$ , we usually associate a matrix function  $S$ , defined by

$$(5.1) \quad S = A\chi_Z + B\chi_{Y \setminus Z},$$

and a function  $w$  solution of (3.2).

*Proof of Proposition 4.1.* The result is a simple consequence of Remark 4.1 and the fact that the solution  $w$  of (3.2) with  $|Z| = p \in [0, 1]$  satisfies (3.9), with  $\eta$  given by (3.10).  $\square$

In order to prove Theorem 4.2, we first obtain some bounds for  $\nabla w$ , with the  $w$  solution of (3.2). This will be done in Lemmas 5.1 and 5.2 below.

**LEMMA 5.1.** *For every  $Z \subset Y$  measurable and  $\xi \in \mathbf{R}^N$ , the function  $w$  satisfies*

$$(5.2) \quad \|\xi + \nabla w\|_{L^2(Y)^N} \leq \frac{\beta}{\alpha} |\xi|.$$

Moreover, there exist  $r > 2$  and  $C > 0$ , which depend only on  $\beta/\alpha$  and  $N$ , such that  $w \in W_{\sharp}^{1,r}(Y)$  and

$$(5.3) \quad \|\xi + \nabla w\|_{L^r(Y)^N} \leq C|\xi|.$$

*Proof.* The proof of (5.2) easily follows by using  $w$  as a test function in (3.2). Estimate (5.3) is a consequence of Meyer's regularity theorem [19] and (5.2).  $\square$

LEMMA 5.2. *There exist  $C > 0$  and  $\rho \in (0, 1)$  (which depend only on  $\beta/\alpha$  and  $N$ ) such that, for every  $\xi, \xi' \in \mathbf{R}^N$  and every  $Z, Z' \subset Y$  measurable, the corresponding functions  $S, S', w, w'$  satisfy*

$$(5.4) \quad \|\xi + \nabla w - \xi' - \nabla w'\|_{L^2(Y)^N} \leq C(|\xi - \xi'| + |\xi'| |Z \triangle Z'|^\rho),$$

$$(5.5) \quad \left| \int_Y S(\xi + \nabla w) dy - \int_Y S'(\xi' + \nabla w') dy \right| \leq C(|\xi - \xi'| + |\xi'| |Z \triangle Z'|^\rho).$$

*Proof.* By taking  $w - w'$  as a test function in the difference of the equations satisfied by  $w$  and  $w'$  and adding and subtracting convenient terms, we get

$$\begin{aligned} & \int_Y S(\xi + \nabla w - \xi' - \nabla w') \cdot (\xi + \nabla w - \xi' - \nabla w') dx \\ &= \int_Y (S' - S)(\xi' + \nabla w') \cdot (\xi + \nabla w - \xi' - \nabla w') dy \\ &+ \int_Y S(\xi + \nabla w - \xi' - \nabla w') \cdot (\xi - \xi') dy - \int_Y (S' - S)(\xi' + \nabla w') \cdot (\xi - \xi') dy. \end{aligned}$$

By using the ellipticity of  $S$ , Young's inequality, and  $S = S'$  in  $Y \setminus (Z \triangle Z')$ , we obtain

$$(5.6) \quad \int_Y |\xi + \nabla w - \xi' - \nabla w'|^2 dy \leq C \left( \int_{Z \triangle Z'} |\xi' + \nabla w'|^2 dy + |\xi - \xi'|^2 \right),$$

where  $C$  depends only on  $\beta/\alpha$ . The first term on the right-hand side of this inequality can be estimated by (5.3), which gives

$$(5.7) \quad \int_{Z \triangle Z'} |\xi' + \nabla w'|^2 dy \leq \left( \int_Y |\xi' + \nabla w'|^r dy \right)^{\frac{2}{r}} |Z \triangle Z'|^{1 - \frac{2}{r}} \leq C |\xi'|^2 |Z \triangle Z'|^{1 - \frac{2}{r}}.$$

By substituting (5.7) into (5.6) we get (5.4).

In order to prove (5.5) we now use

$$\begin{aligned} & \left| \int_Y S(\xi + \nabla w) dy - \int_Y S'(\xi' + \nabla w') dy \right| \\ & \leq \left| \int_Y S(\xi + \nabla w - \xi' - \nabla w') dy \right| + \left| \int_Y (S - S')(\xi' + \nabla w') dy \right| \\ & \leq C \left( \int_Y |\xi + \nabla w - \xi' - \nabla w'| dy + \int_{Z \triangle Z'} |\xi' + \nabla w'| dy \right). \end{aligned}$$

By using the Cauchy-Schwarz inequality, (5.4), and (5.7), we obtain (5.5).  $\square$

Let us now use Lemma 5.2 to study some semicontinuity properties for  $H_\delta$ .

LEMMA 5.3. *There exist  $C > 0$  (depending on  $L, \beta/\alpha, \varrho$ , and  $N$ ) and  $\rho \in (0, 1)$  (depending on  $\beta/\alpha$  and  $N$ ) such that, for every  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$  and every  $\delta, \varepsilon > 0$ , there exists  $\tau \in [0, \delta)$ , with*

$$(5.8) \quad \begin{aligned} & H_{\tau + \lambda' + |\eta - \eta'|}(\xi', \eta', p') \leq H_\delta(\xi, \eta, p) + (1 + |\xi| + |\xi'|)^{2-e} (\lambda')^e + \varepsilon \\ & \forall (\xi', \eta', p') \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1], \end{aligned}$$

where we have denoted

$$\lambda' = C(|\xi - \xi'| + |\xi'| |p - p'|^\rho).$$

*Proof.* To prove (5.8), we consider  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$  and  $\delta, \varepsilon > 0$ . If  $(\xi, \eta, p)$  does not belong to the domain of  $H_\delta$ , then (5.8) is trivial. In another case, by definition (4.5) of  $H_\delta$  there exists  $Z \subset Y$ , with  $|Z| = p$ , such that, by taking  $S$  and  $w$  as the corresponding functions associated to  $Z$  and  $\xi$  and defining  $\tau$  by

$$\tau = \left| \int_Y S(\xi + \nabla w) dy - \eta \right|,$$

we have  $\tau < \delta$  and

$$H_\delta(\xi, \eta, p) > \int_Y F(\xi + \nabla w) dy - \varepsilon.$$

Now we consider  $(\xi', \eta', p') \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$ . Then (by adding or subtracting a measurable set of  $Y$  to  $Z$ ) we construct a set  $Z'$ , with  $|Z'| = p'$  and  $|Z \triangle Z'| = |p - p'|$ . We take  $w'$  and  $S'$  as the corresponding functions associated to  $Z'$  and  $\xi'$ . From Lemma 5.2, there exist  $C > 0$  and  $\rho \in (0, 1)$ , which depend only on  $\beta/\alpha$  and  $N$ , such that (5.4) and (5.5) hold. By using then (4.1), (5.2), and (5.4), we have (for another constant  $C$ )

$$\begin{aligned} & \left| \int_Y (F(\xi + \nabla w) - F(\xi' + \nabla w')) dy \right| \\ & \leq L \int_Y (1 + |\xi + \nabla w| + |\xi' + \nabla w'|)^{2-e} |\xi + \nabla w - \xi' - \nabla w'|^e dy \\ & \leq L (1 + \|\xi + \nabla w\|_{L^2(Y)} + \|\xi' + \nabla w'\|_{L^2(Y)})^{2-e} \|\xi + \nabla w - \xi' - \nabla w'\|_{L^2(Y)}^e \\ & \leq C(1 + |\xi| + |\xi'|)^{2-e} (|\xi - \xi'| + |\xi'| |p - p'|^\rho)^e \leq (1 + |\xi| + |\xi'|)^{2-e} (\lambda')^e. \end{aligned}$$

On the other hand, by (5.5) and the definition of  $\tau$ , we have

$$\begin{aligned} & \left| \int_Y S'(\xi' + \nabla w') dy - \eta' \right| \leq \left| \int_Y S'(\xi' + \nabla w') dy - \int_Y S(\xi + \nabla w) dy \right| \\ & + \left| \int_Y S(\xi + \nabla w) dy - \eta \right| + |\eta - \eta'| \leq \lambda' + \tau + |\eta - \eta'|. \end{aligned}$$

Then, by definition (4.5) of  $H_\delta$ , we get

$$\begin{aligned} H_{\tau+\lambda'+|\eta-\eta'|}(\xi', \eta', p') & \leq \int_Y F(\xi' + \nabla w') dy \\ & \leq \int_Y F(\xi + \nabla w) dy + \left| \int_Y (F(\xi + \nabla w) - F(\xi' + \nabla w')) dy \right| \\ & \leq H_\delta(\xi, \eta, p) + \varepsilon + (1 + |\xi| + |\xi'|)^{2-e} (\lambda')^e. \quad \square \end{aligned}$$

*Remark 5.1.* Since  $H_\delta(\xi, \eta, p)$  is decreasing in  $\delta$  inequality (5.8) implies that

$$\begin{aligned} H_{\delta+\lambda'+|\eta-\eta'|}(\xi', \eta', p') & \leq H_\delta(\xi, \eta, p) + (1 + |\xi| + |\xi'|)^{2-e} (\lambda')^e + \varepsilon \\ \forall (\xi', \eta', p') & \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1] \end{aligned}$$

for every  $\varepsilon > 0$ . So by taking  $\varepsilon$  converging to zero we get

$$(5.9) \quad \begin{aligned} H_{\delta+\lambda'+|\eta-\eta'|}(\xi', \eta', p') &\leq H_\delta(\xi, \eta, p) + (1 + |\xi| + |\xi'|)^{2-e}(\lambda')^e \\ \forall (\xi', \eta', p') &\in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]. \end{aligned}$$

We are now in position to prove that  $H_\delta$  satisfies the following properties.

**PROPOSITION 5.4.** *For every  $\delta > 0$ ,  $H_\delta$  is upper semicontinuous in  $\mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$  and satisfies*

$$(5.10) \quad |H_\delta(\xi, \eta, p)| \leq L \left( \frac{\beta}{\alpha} |\xi| \right)^e \left( 1 + \frac{\beta}{\alpha} |\xi| \right)^{2-e} \quad \forall (\xi, \eta, p) \in \text{Dom}(H_\delta).$$

Moreover, the following lower semicontinuity result holds:

$$(5.11) \quad H_{\delta+s}(\xi, \eta, p) \leq \liminf_{n \rightarrow \infty} H_\delta(\xi_n, \eta_n, p_n) \quad \forall \delta, s > 0$$

for every  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$  and for every sequence  $(\xi_n, \eta_n, p_n) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$  which converges to  $(\xi, \eta, p)$ .

*Proof.* The proof of (5.10) immediately follows from definition (4.5) of  $H_\delta$ , by taking into account that (5.2), (4.2), and (4.1) imply that for every  $\xi \in \mathbf{R}^N$  and every  $Z \subset Y$  measurable the solution  $w$  of (3.2) satisfies

$$(5.12) \quad \left| \int_Y F(\xi + \nabla w) dy \right| \leq L \left( \frac{\beta}{\alpha} |\xi| \right)^e \left( 1 + \frac{\beta}{\alpha} |\xi| \right)^{2-e}.$$

To prove the upper semicontinuity of  $H$  we consider  $(\xi, \eta, p)$  and  $(\xi_n, \eta_n, p_n)$  as above. By (5.8), for every  $\delta, \varepsilon > 0$ , there exists  $\tau \in [0, \delta)$  (which does not depend on  $n$ ) such that

$$H_{\tau+\lambda_n+|\eta-\eta_n|}(\xi_n, \eta_n, p_n) \leq H_\delta(\xi, \eta, p) + (1 + |\xi| + |\xi_n|)^{2-e} \lambda_n^e + \varepsilon \quad \forall n \in \mathbf{N},$$

with  $\lambda_n = C(|\xi - \xi_n| + |\xi_n| |p - p_n|^\rho)$ . So, since for  $n$  large enough  $\tau + \lambda_n + |\eta - \eta_n| < \delta$  and  $H_\mu$  is decreasing in  $\mu$ , we have

$$H_\delta(\xi_n, \eta_n, p_n) \leq H_\delta(\xi, \eta, p) + (1 + |\xi| + |\xi_n|)^{2-e} \lambda_n^e + \varepsilon.$$

By taking the limsup in  $n$  and then letting  $\varepsilon$  decrease to zero, we deduce the upper semicontinuity of  $H_\delta$ .

In order to prove (5.11), we take  $(\xi, \eta, p)$ ,  $(\xi_n, \eta_n, p_n)$  as above. By (5.9) we have

$$H_{\delta+\lambda_n+|\eta-\eta_n|}(\xi, \eta, p) \leq H_\delta(\xi_n, \eta_n, p_n) + (1 + |\xi| + |\xi'_n|)^{2-e} \lambda_n^e,$$

with  $\lambda_n = C(|\xi - \xi_n| + |\xi| |p - p_n|^\rho)$ . So, by using as above the fact that  $H_\mu$  is decreasing in  $\mu$ , we have for every  $s > 0$  and  $n$  large enough

$$H_{\delta+s}(\xi, \eta, p) \leq H_\delta(\xi_n, \eta_n, p_n) + (1 + |\xi| + |\xi'_n|)^{2-e} \lambda_n^e.$$

By taking the liminf in  $n$  we deduce (5.11).  $\square$

Thanks to the previous results, we can now prove Theorem 4.2.

*Proof of Theorem 4.2.* By definition (4.6) of  $H$  and (5.12), we have that  $(\xi, \eta, p) \in \text{Dom}(H)$  if and only if for every  $\delta > 0$  there exists  $Z \subset Y$  measurable, with  $|Z| = p$ , such that the solution  $w$  of (3.2) satisfies

$$\left| \int_Y S(\nabla w + \xi) dy - \eta \right| < \delta.$$

By Theorem 3.1 this holds if and only if  $\eta$  belongs to  $\mathcal{K}(A, B, p)\xi$ . This proves (4.10).

In order to prove the lower semicontinuity of  $H$ , we consider  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$  and  $(\xi_n, \eta_n, p_n) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1]$ , which converges to  $(\xi, \eta, p)$ . By (5.11) with  $s = \delta$  and  $H_\delta(\xi_n, \eta_n, p_n) \leq H(\xi_n, \eta_n, p_n)$ , we have

$$H_{2\delta}(\xi, \eta, p) \leq \liminf_{n \rightarrow \infty} H(\xi_n, \eta_n, p_n) \quad \forall \delta > 0.$$

By taking the limit when  $\delta$  tends to zero we conclude that

$$H(\xi, \eta, p) \leq \liminf_{n \rightarrow \infty} H(\xi_n, \eta_n, p_n)$$

and then the lower semicontinuity of  $H$ .

Inequality (4.11) immediately follows from (5.10).

To show (4.12) it is enough to use Remark 4.1 and the fact that, if  $Z \subset Y$  has measure 0 or 1, the solution  $w$  of (3.2) is zero.

To prove (4.13), we consider  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times (0, 1)$  such that  $\Lambda_p \xi - \eta \in \text{Ran}(A - B)$  and

$$(5.13) \quad \left( (A - B) \left( \frac{A}{p} + \frac{B}{1-p} \right)^{-1} (A - B) \right)^\dagger (\Lambda_p \xi - \eta) \cdot (\Lambda_p \xi - \eta) = \xi \cdot (\Lambda_p \xi - \eta).$$

Then we consider  $Z_n, S_n, w_n, \eta_n$  as in Remark 4.1, and we define

$$\nu_n = \int_{Z_n} \nabla w_n dy = - \int_{Y \setminus Z_n} \nabla w_n dy.$$

By (3.5) and (3.6),  $\nu_n$  satisfies that  $(B - A)\nu_n = \Lambda_p \xi - \eta_n$  and

$$(5.14) \quad \begin{cases} \int_{Z_n} A \left( \nabla w_n - \frac{\nu_n}{p} \right) \cdot \left( \nabla w_n - \frac{\nu_n}{p} \right) dy \\ + \int_{Y \setminus Z_n} B \left( \nabla w_n + \frac{\nu_n}{1-p} \right) \cdot \left( \nabla w_n + \frac{\nu_n}{1-p} \right) dy \\ = (\Lambda_p \xi - \eta_n) \cdot \xi - \left( \frac{A}{p} + \frac{B}{1-p} \right) \nu_n \cdot \nu_n. \end{cases}$$

This implies in particular (use the fact that the left-hand side of (5.14) is nonnegative) that  $\nu_n$  is bounded, and so, up to a subsequence, we have that  $\nu_n$  converges to some  $\hat{\nu} \in \mathbf{R}^N$  such that  $(B - A)\hat{\nu} = \Lambda_p \xi - \eta$  and

$$(5.15) \quad \left( \frac{A}{p} + \frac{B}{1-p} \right) \hat{\nu} \cdot \hat{\nu} \leq (\Lambda_p \xi - \eta) \cdot \xi.$$

By using the fact that (5.13) can also be written as

$$(\Lambda_p \xi - \eta) \cdot \xi = \min \left\{ \left( \frac{A}{p} + \frac{B}{1-p} \right) \nu \cdot \nu : \Lambda_p \xi - \eta = (B - A)\nu \right\},$$

we then deduce that  $\hat{\nu}$  gives the minimum above, and so  $\hat{\nu} = \Xi(\Lambda_p \xi - \eta)$ . In particular, this implies that (5.15) is an equality, and then by passing to the limit in (5.14) we have

$$\lim_{n \rightarrow 0} \left( \int_{Z_n} \left| \nabla w_n - \frac{\nu_n}{p} \right|^2 dz + \int_{Y \setminus Z_n} \left| \nabla w_n + \frac{\nu_n}{1-p} \right|^2 dz \right) = 0,$$

which, joining to (4.1), allows us to calculate the limit which appears in the right-hand side of (4.8) and then to conclude (4.13).

To finish the proof of Theorem 4.2, let us now prove (4.14). For  $(\xi, \eta, p) \in \text{Dom}(H)$ ,  $p \in (0, 1)$ , we take  $Z_n$  and  $w_n$  as in Remark 4.1. By Lemma 3.2, we can assume that

$$\int_{Z_n} \nabla w_n dy \rightarrow \hat{\nu} \in E(\xi, p), \quad (B - A)\hat{\nu} = \Lambda_p \xi - \eta.$$

Jensen's inequality,  $w_n$ -periodic, and  $|Z_n| = p$  give

$$\begin{aligned} \int_Y F(\xi + \nabla w_n) dy &= \int_{Z_n} F(\xi + \nabla w_n) dy + \int_{Y \setminus Z_n} F(\xi + \nabla w_n) dy \\ &\geq pF\left(\xi + \frac{1}{p} \int_{Z_n} \nabla w_n dy\right) + (1-p)F\left(\xi - \frac{1}{1-p} \int_{Z_n} \nabla w_n dy\right). \end{aligned}$$

By taking the limit in this inequality we deduce that

$$H(\xi, \eta, p) = \lim_{n \rightarrow \infty} \int_Y F(\xi + \nabla w_n) dy \geq pF\left(\xi + \frac{\hat{\nu}}{p}\right) + (1-p)F\left(\xi - \frac{\hat{\nu}}{1-p}\right),$$

and then (4.14).  $\square$

To prove Theorem 4.5 we need the following corrector result. We use some ideas which appear in the proof of Theorem 3.1 given in [1] and [11].

LEMMA 5.5. *We consider a bounded open set  $\Omega \subset \mathbf{R}^N$ , a sequence of matrices  $M_n \in L^\infty(\Omega; \mathcal{M}_N)$ , uniformly bounded and elliptic, and a sequence  $u_n \in H^1(\Omega)$ . We assume that  $u_n$  converges weakly in  $H^1(\Omega)$  to a function  $u$  and that  $-\text{div } M_n \nabla u_n$  is compact in  $H^{-1}(\Omega)$ . For  $\varepsilon > 0$  small enough, we take*

$$(5.16) \quad \Omega_\varepsilon = \{x \in \Omega : \text{dis}(x, \partial\Omega) > \varepsilon\},$$

and, for  $h \in (0, \frac{\varepsilon}{\sqrt{N}})$ , we define  $w_n^h \in L^2(\Omega_\varepsilon; H_\#^1(Y))$  as the unique solution of

$$(5.17) \quad \begin{cases} w_n^h(x, \cdot) \in H_\#^1(Y), & \int_Y w_n^h(x, y) dy = 0, \\ -\text{div}_y M_n(x + hy)(\nabla u(x) + \nabla_y w_n^h(x, y)) = 0 & \text{in } \mathbf{R}^N, \text{ a.e. } x \in \Omega_\varepsilon. \end{cases}$$

Then we have

$$(5.18) \quad \lim_{h \rightarrow 0} \limsup_{n \rightarrow \infty} \|\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h\|_{L^2(\Omega_\varepsilon \times Y)^N} = 0.$$

*Proof.* By extracting a subsequence if necessary, we can assume that  $M_n$   $H$ -converges to a matrix-valued function  $M$ . Then, by (5.17), we get

$$(5.19) \quad \nabla u(x) \cdot y + w_n^h(x, y) \rightharpoonup \nabla u(x) \cdot y + w^h(x, y) \text{ in } H^1(Y), \text{ a.e. } x \in \Omega_\varepsilon,$$

when  $n$  tends to infinity, with  $w^h \in L^2(\Omega_\varepsilon; H_\#^1(Y))$  the unique solution of the problem

$$(5.20) \quad \begin{cases} w^h(x, \cdot) \in H_\#^1(Y), & \int_Y w^h(x, y) dy = 0, \\ -\operatorname{div}_y (M(x + hy)(\nabla u(x) + \nabla_y w^h(x, y))) = 0 & \text{in } \mathbf{R}^N, \text{ a.e. } x \in \Omega_\varepsilon. \end{cases}$$

By using in (5.20) the fact that  $M(x + hy)$  converges to  $M$  strongly in  $L^q(\Omega_\varepsilon \times Y; \mathcal{M}_N)$ ,  $1 \leq q < +\infty$ , and  $*$ -weakly in  $L^\infty(\Omega_\varepsilon \times Y; \mathcal{M}_N)$ , when  $h$  tends to zero, it is easy to prove that

$$(5.21) \quad w^h \rightarrow 0 \text{ in } L^2(\Omega_\varepsilon; H_\#^1(Y)).$$

On the other hand, the strong convergence in  $H^{-1}(\Omega)$  of  $-\operatorname{div} M_n \nabla u_n$  implies that

$$-\operatorname{div}_y [M_n(x + hy) \nabla u_n(x + hy)] \rightarrow -\operatorname{div}_y [M(x + hy) \nabla u(x + hy)] \text{ in } H^{-1}(Y)$$

for every  $x \in \Omega_\varepsilon$ , when  $n$  tends to infinity. Thanks to (5.17), we can then apply the div-curl lemma (see, e.g., [23], [28]) to deduce that

$$\begin{aligned} & M_n(x + hy) (\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h) \cdot (\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h) \\ & \rightharpoonup M(x + hy) (\nabla u(x + hy) - \nabla u - \nabla_y w^h) \cdot (\nabla u(x + hy) - \nabla u - \nabla_y w^h) \end{aligned}$$

in the sense of the distributions in  $Y$ , for a.e.  $x \in \Omega_\varepsilon$ , when  $n$  tends to infinity. By Meyer's theorem this convergence holds in  $L^1(Y)$  weakly, for a.e.  $x \in \Omega_\varepsilon$ , and thus we have

$$(5.22) \quad \begin{aligned} & \int_Y M_n(x + hy) (\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h) \cdot (\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h) dy \\ & \rightarrow \int_Y M(x + hy) (\nabla u(x + hy) - \nabla u - \nabla_y w^h) \cdot (\nabla u(x + hy) - \nabla u - \nabla_y w^h) dy \end{aligned}$$

for a.e.  $x \in \Omega_\varepsilon$ . Moreover, by (5.17) there exists  $C > 0$  such that  $\|\nabla u + \nabla_y w_n^h\|_{L^2(Y)^N} \leq C|\nabla u|$  a.e. in  $\Omega_\varepsilon$ , and so, for another constant  $C$ , we have

$$\begin{aligned} & \int_Y M_n(x + hy) (\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h) \cdot (\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h) dy \\ & \leq \frac{C}{h^N} \int_\Omega |\nabla u_n|^2 dx + C|\nabla u|^2, \text{ a.e. in } \Omega_\varepsilon, \end{aligned}$$

which together with (5.22) allows us to apply the Lebesgue dominated convergence theorem to deduce that

$$\begin{aligned} & \int_{\Omega_\varepsilon} \int_Y M_n(x + hy) (\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h) \cdot (\nabla u_n(x + hy) - \nabla u - \nabla_y w_n^h) dy dx \\ & \rightarrow \int_{\Omega_\varepsilon} \int_Y M(x + hy) (\nabla u(x + hy) - \nabla u - \nabla_y w^h) \cdot (\nabla u(x + hy) - \nabla u - \nabla_y w^h) dy dx, \end{aligned}$$

when  $n$  tends to infinity, for every  $h \in (0, \varepsilon/\sqrt{N})$ . By (5.21), the right-hand side of this equality tends to zero when  $h$  tends to zero, and then, thanks to the ellipticity of  $M$ , we get (5.18).  $\square$

*Proof of Theorem 4.5.* In the proof we will separate the cases  $N = 1$  and  $N \geq 2$ . We make this distinction because for  $N \geq 2$  we will use a convexity property of the set  $K(A, B, p)\xi$  which does not hold for  $N = 1$  (see Step 3 in the proof). On the other hand, we think it is interesting to show that the one-dimensional case follows by using elementary arguments.

The proof of the theorem will be divided in three steps.

In Step 1 we will consider the case  $N = 1$ , while steps 2 and 3 are devoted to  $N \geq 2$ .

In Step 2 we will prove the inequality

$$(5.23) \quad \begin{cases} \liminf_{n \rightarrow \infty} \mathcal{F}(u_n, \sigma_n, \theta_n) \geq \overline{\mathcal{F}}(u, \sigma, \theta) & \forall (u, \sigma, \theta) \in H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega) \\ \forall (u_n, \sigma_n, \theta_n) \in H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega), (u_n, \sigma_n, \theta_n) \xrightarrow{\mathcal{T}} (u, \sigma, \theta). \end{cases}$$

The proof of (5.23) will follow from Lemma 5.5, which provides an approximation of  $\nabla u_n$  in the strong topology of  $H^1(\omega)$  ( $\omega \subset \subset \Omega$ ) by using periodic homogenization.

In Step 3 we prove that for every  $(u, \sigma, \theta) \in H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega)$  there exists  $(u_n, \sigma_n, \theta_n) \in H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega)$  such that

$$(5.24) \quad (u_n, \sigma_n, \theta_n) \xrightarrow{\mathcal{T}} (u, \sigma, \theta), \quad \limsup_{n \rightarrow \infty} \mathcal{F}(u_n, \sigma_n, \theta_n) \leq \overline{\mathcal{F}}(u, \sigma, \theta)$$

which joined to (5.23) will give the proof of Theorem 4.5 in the case  $N \geq 2$ . The main idea to prove the existence of  $(u_n, \sigma_n, \theta_n)$  satisfying (5.24) will be to use an approximation by finite elements of  $(u, \sigma, \theta)$  which reduces the problem to the case where there exists a triangulation  $\tau$  such that  $\nabla u$ ,  $\sigma$ , and  $\theta$  are constant in each element of  $\tau$ .

*Step 1.* Let us first prove the result for  $N = 1$ .

Consider  $(u, \sigma, \theta) \in H^1(\Omega) \times L^2(\Omega) \times L^\infty(\Omega)$  and a sequence  $(u_n, \sigma_n, \theta_n) \in H^1(\Omega) \times L^2(\Omega) \times L^\infty(\Omega)$  which  $\mathcal{T}$ -converges to  $(u, \sigma, \theta)$ . Let us prove that

$$(5.25) \quad \overline{\mathcal{F}}(u, \sigma, \theta) \leq \liminf_{n \rightarrow \infty} \mathcal{F}(u_n, \sigma_n, \theta_n).$$

By definition (4.18) of  $\mathcal{F}$ , it is enough to consider the case where there exists a sequence of measurable sets  $\omega_n \subset \Omega$  such that

$$\theta_n = \chi_{\omega_n}, \quad \sigma_n = (A\chi_{\omega_n} + B\chi_{\Omega \setminus \omega_n}) \frac{du_n}{dx} \quad \text{a.e. in } \Omega,$$

and thus

$$(5.26) \quad \frac{du_n}{dx} = \frac{\sigma_n}{A} \chi_{\omega_n} + \frac{\sigma_n}{B} \chi_{\Omega \setminus \omega_n} \quad \text{a.e. in } \Omega.$$

Since  $\sigma_n$  converges weakly to  $\sigma$  in  $L^2(\Omega)$  and  $\frac{d\sigma_n}{dx}$  converges strongly to  $\frac{d\sigma}{dx}$  in  $H^{-1}(\Omega)$ , we have that  $\sigma_n$  converges strongly to  $\sigma$  in  $L^2(\Omega)$ . So by (5.26) we get

$$\frac{du}{dx} = \left( \frac{\theta}{A} + \frac{1-\theta}{B} \right) \sigma \quad \text{a.e. in } \Omega$$

and

$$\begin{aligned} \lim_{n \rightarrow \infty} \mathcal{F}(u_n, \sigma_n, \theta_n) &= \lim_{n \rightarrow \infty} \int_{\Omega} F\left(\frac{du_n}{dx}\right) dx \\ &= \lim_{n \rightarrow \infty} \int_{\Omega} \left( F\left(\frac{\sigma_n}{A}\right) \chi_{\omega_n} + F\left(\frac{\sigma_n}{B}\right) \chi_{\Omega \setminus \omega_n} \right) dx = \int_{\Omega} \left( F\left(\frac{\sigma}{A}\right) \theta + F\left(\frac{\sigma}{B}\right) (1 - \theta) \right) dx. \end{aligned}$$

By (4.9), we have then proved that  $(u, \sigma, \theta)$  belongs to  $\text{Dom}(H)$  a.e. in  $\Omega$  and

$$\overline{\mathcal{F}}(u, \sigma, \theta) = \int_{\Omega} H\left(\frac{du}{dx}, \sigma, \theta\right) dx = \lim_{n \rightarrow \infty} \mathcal{F}(u_n, \sigma_n, \theta_n).$$

To finish the proof of Step 1, we need to prove that for every  $(u, \sigma, \theta) \in H^1(\Omega) \times L^2(\Omega) \times L^\infty(\Omega)$  there exists  $(u_n, \sigma_n, \theta_n) \in H^1(\Omega) \times L^2(\Omega) \times L^\infty(\Omega)$ , which  $\mathcal{T}$ -converges to  $(u, \sigma, \theta)$  and satisfies

$$(5.27) \quad \limsup_{n \rightarrow \infty} \mathcal{F}(u_n, \sigma_n, \theta_n) \leq \overline{\mathcal{F}}(u, \sigma, \theta).$$

Clearly, it is enough to consider the case where  $(u, \sigma, \theta) \in \text{Dom}(H)$  a.e. in  $\Omega$ , but then  $\theta \in [0, 1]$  a.e. in  $\Omega$ , and so there exists  $\omega_n \subset \Omega$  such that  $\chi_{\omega_n}$  converges weakly-\* in  $L^\infty(\Omega)$  to  $\theta$ . By taking

$$\theta_n = \chi_{\omega_n}, \quad \sigma_n = \sigma, \quad \frac{du_n}{dx} = \frac{\sigma}{A} \chi_{\omega_n} + \frac{\sigma}{B} \chi_{\Omega \setminus \omega_n}$$

and reasoning as above, we deduce (5.27).

In the remainder of the proof we always assume that  $N \geq 2$ .

*Step 2.* Let us prove (5.23).

We can assume that

$$\liminf_{n \rightarrow \infty} \mathcal{F}(u_n, \sigma_n, \theta_n) < +\infty,$$

and thus, by extracting a subsequence if necessary, there exists a sequence of measurable sets  $\omega_n \subset \Omega$  such that  $\theta_n = \chi_{\omega_n}$  and  $\sigma_n = M_n \nabla u_n$ , with  $M_n = A \chi_{\omega_n} + B \chi_{\Omega \setminus \omega_n}$ . By using the compactness theorem for the  $H$ -convergence (see, e.g., [1], [11], [22], [26], [27]), we can also assume that there exists an elliptic matrix  $M \in L^\infty(\Omega; \mathcal{M}_N^s)$  such that  $M_n$   $H$ -converges to  $M$ . Since  $\text{div } \sigma_n$  converges strongly to  $\text{div } \sigma$  in  $H^{-1}(\Omega)$ , and  $M_n \nabla u_n = \sigma_n$ , we have

$$(5.28) \quad \sigma = M \nabla u \quad \text{a.e. in } \Omega.$$

In order to prove (5.23), we consider  $\varepsilon > 0$ . By defining  $\Omega_\varepsilon$  by (5.16) and taking  $h \in (0, \varepsilon/\sqrt{N})$  in such a way that  $\Omega_\varepsilon \subset \Omega - hy$  for every  $y \in Y$ , we have

$$\begin{aligned} \int_{\Omega} F(\nabla u_n) dx &= \int_{\Omega - hy} F(\nabla u_n(x + hy)) dx \\ (5.29) \quad &= \int_{\Omega_\varepsilon} F(\nabla u_n(x + hy)) dx + \int_{(\Omega - hy) \setminus \Omega_\varepsilon} F(\nabla u_n(x + hy)) dx \\ &= \int_{\Omega_\varepsilon} F(\nabla u_n(x + hy)) dx + \int_{\Omega \setminus (\Omega_\varepsilon + hy)} F(\nabla u_n) dx, \end{aligned}$$

and so, by integrating in  $y \in Y$ , we have

$$(5.30) \quad \int_{\Omega} F(\nabla u_n) dx = \int_Y \int_{\Omega_{\varepsilon}} F(\nabla u_n(x+hy)) dx dy + \int_Y \int_{\Omega \setminus (\Omega_{\varepsilon} + hy)} F(\nabla u_n) dx dy.$$

By using the fact that  $\Omega \setminus (\Omega_{\varepsilon} + hy) \subset \Omega \setminus \Omega_{2\varepsilon}$  for every  $y \in Y$ , (4.3), and the fact that  $|\nabla u_n|^2$  is equi-integrable (which follows from the definition of  $\mathcal{T}$ -convergence), we have

$$(5.31) \quad \begin{aligned} & \lim_{\varepsilon \rightarrow 0} \limsup_{n \rightarrow \infty} \left| \int_Y \int_{\Omega \setminus (\Omega_{\varepsilon} + hy)} F(\nabla u_n) dx dy \right| \\ & \leq L \lim_{\varepsilon \rightarrow 0} \limsup_{n \rightarrow \infty} \int_{\Omega \setminus \Omega_{2\varepsilon}} (1 + |\nabla u_n|)^2 dx = 0. \end{aligned}$$

To estimate the first term of (5.30), we use the decomposition

$$(5.32) \quad \begin{aligned} \int_Y \int_{\Omega_{\varepsilon}} F(\nabla u_n(x+hy)) dx dy &= \int_Y \int_{\Omega_{\varepsilon}} (F(\nabla u_n(x+hy)) - F(\nabla u + \nabla_y w_n^h)) dx dy \\ &\quad + \int_{\Omega_{\varepsilon}} \int_Y F(\nabla u + \nabla_y w_n^h) dy dx, \end{aligned}$$

with  $w_n^h$  given by (5.17). Thanks to (4.1) and (5.18), we have

$$(5.33) \quad \lim_{h \rightarrow 0} \limsup_{n \rightarrow \infty} \int_Y \int_{\Omega_{\varepsilon}} |F(\nabla u_n(x+hy)) - F(\nabla u + \nabla_y w_n^h)| dx dy = 0 \quad \forall \varepsilon > 0.$$

To estimate the second term on the right-hand side of (5.32), we denote for a.e.  $x \in \Omega_{\varepsilon}$  and a.e.  $y \in Y$

$$Z_n^h(x) = Y \cap \frac{\omega_n - x}{h}, \quad \theta_n^h(x) = |Z_n^h(x)| = \int_Y \theta_n(x+hy) dy,$$

$$M_n(x+hy) = A\chi_{\omega_n}(x+hy) + B\chi_{\Omega \setminus \omega_n}(x+hy) = A\chi_{Z_n^h(x)}(y) + B\chi_{Y \setminus Z_n^h(x)}(y),$$

$$\sigma_n^h(x) = \int_Y M_n(x+hy)(\nabla u + \nabla_y w_n^h) dy.$$

Then, by definition (5.17) of  $w_n^h$  and definition (4.6) of  $H$ , we obtain

$$(5.34) \quad \int_Y F(\nabla u + \nabla_y w_n^h) dy \geq H(\nabla u, \sigma_n^h, \theta_n^h), \quad \text{a.e. in } \Omega_{\varepsilon}.$$

By the  $H$ -convergence of  $M_n$  to  $M$  and the convergence in  $L^{\infty}(\Omega)$  weak-\* of  $\theta_n$  to  $\theta$ , we have that  $\sigma_n^h$  and  $\theta_n^h$ , respectively, converge a.e. in  $\Omega_{\varepsilon}$  to  $\sigma^h \in L^2(\Omega_{\varepsilon})^N$  and  $\theta^h \in L^{\infty}(\Omega_{\varepsilon})$ , defined by

$$\sigma^h(x) = \int_Y M(x+hy)(\nabla u + \nabla_y w^h) dy, \quad \theta^h(x) = \int_Y \theta(x+hy) dy, \quad \text{a.e. } x \in \Omega_{\varepsilon}.$$

From (4.11) and  $\|\nabla u + \nabla_y w_n^h\|_{L^2(Y)} \leq C|\nabla u|$  a.e. in  $\Omega$ , we also have

$$|H(\nabla u, \sigma_n^h, \theta_n^h)| \leq C(1 + |\nabla u|)^2 \quad \text{a.e. in } \Omega_{\varepsilon}.$$

Then, by (5.34), the lower semicontinuity of  $H$ , and Fatou's lemma we deduce that

$$\begin{aligned} \liminf_{n \rightarrow \infty} \int_{\Omega_\varepsilon} \int_Y F(\nabla u + \nabla_y w_n^h) dy dx &\geq \liminf_{n \rightarrow \infty} \int_{\Omega_\varepsilon} H(\nabla u, \sigma_n^h, \theta_n^h) dx \\ &\geq \int_{\Omega_\varepsilon} H(\nabla u, \sigma^h, \theta^h) dx \end{aligned}$$

for every  $h \in (0, \varepsilon/\sqrt{N})$ . By now using the fact that, for  $h$  tending to zero,  $\sigma^h$  converges strongly to  $\sigma$  in  $L^2(\Omega_\varepsilon)^N$  and  $\theta^h$  converges to  $\theta$  strongly in  $L^r(\Omega_\varepsilon)$ ,  $1 \leq r < +\infty$ , weak-\* in  $L^\infty(\Omega_\varepsilon)$ , we can use again the lower semicontinuity of  $H$  and Fatou's lemma to obtain

$$(5.35) \quad \liminf_{h \rightarrow 0} \liminf_{n \rightarrow \infty} \int_{\Omega_\varepsilon} \int_Y F(\nabla u + \nabla_y w_n^h) dy dx \geq \int_{\Omega_\varepsilon} H(\nabla u, \sigma, \theta) dx.$$

By (5.30), (5.31), (5.32), (5.33), and (5.35), by passing to the limit in (5.29), first in  $n$ , then in  $h$ , and then in  $\varepsilon$ , we have

$$\liminf_{n \rightarrow \infty} \int_{\Omega} F(\nabla u_n) dx \geq \int_{\Omega} H(\nabla u, \sigma, \theta) dx.$$

This proves (5.23).

*Step 3.* Let us prove that for every  $(u, \sigma, \theta) \in H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega)$  there exists  $(u_n, \sigma_n, \theta_n) \in H^1(\Omega) \times L^2(\Omega)^N \times L^\infty(\Omega)$ , which satisfies (5.24).

It is enough to consider the case where  $0 \leq \theta \leq 1$  and  $\sigma \in \mathcal{K}(A, B, \theta) \nabla u$  a.e. in  $\Omega$ .

We consider an open cube  $Q$ , with  $\bar{\Omega} \subset Q$ , and a prolongation of  $u$ , still denoted by  $u$ , in  $H_0^1(Q)$ . This prolongation exists thanks to  $\Omega$  being smooth. We also extend  $\theta$  and  $\sigma$  to the whole  $Q$  by  $\theta = 1$ ,  $\sigma = A \nabla u$  a.e. in  $Q \setminus \Omega$ . The multiapplication  $x \in \Omega \mapsto \{\tilde{M} \in \mathcal{K}(A, B, \theta(x)) : \tilde{M} \nabla u(x) = \sigma(x)\}$  is closed and measurable. The measurability follows by using the fact that for every closed set  $\mathcal{C} \subset \mathcal{M}_N^s$  we have

$$\{x \in \Omega : \exists \tilde{M} \in \mathcal{C} \cap \mathcal{K}(A, B, \theta(x)), \text{ with } \tilde{M} \nabla u(x) = \sigma(x)\} = \bigcap_{m \in \mathbf{N}} (\nabla u, \sigma, \theta)^{-1}(K_m),$$

where

$$K_m = \left\{ (\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times [0, 1] : \exists \tilde{M} \in \mathcal{K}(A, B, p) \cap \mathcal{C} \text{ with } |\tilde{M}\xi - \eta| \leq \frac{1}{m} \right\}$$

is closed for every  $m \in \mathbf{N}$ . Thus (see, e.g., [7]) there exists  $M \in L^\infty(\Omega; \mathcal{M}_N^s)$  such that  $M \in \mathcal{K}(A, B, \theta)$  and  $M \nabla u = \sigma$  a.e. in  $Q$ .

For a regular sequence of triangulations  $\tau_n = \{T_n^k\}_{1 \leq k \leq k_n}$  of  $Q$  by  $N$ -simplex, whose diameter tends to zero when  $n$  tends to infinity (see, e.g., [8]), we consider the space of finite elements

$$V_n = \{v_n \in C_0^0(\bar{Q}) : v_n \text{ is affine in } T_n^k \quad \forall k \in \{1, \dots, k_n\}\}.$$

Then we define  $\hat{u}_n$  as the solution of

$$\begin{cases} \hat{u}_n \in V_n, \\ \int_Q M \nabla \hat{u}_n \nabla v = \int_Q \sigma \nabla v dx \quad \forall v \in V_n, \end{cases}$$

and we take

$$\hat{\theta}_n = \sum_{k=1}^{k_n} \left( \frac{1}{|T_n^k|} \int_{T_n^k} \theta \, dx \right) \chi_{T_n^k}, \quad \hat{\sigma}_n = \sum_{k=1}^{k_n} \left( \frac{1}{|T_n^k|} \int_{T_n^k} M \nabla \hat{u}_n \, dx \right) \chi_{T_n^k}.$$

The sequence  $\hat{\theta}_n$  converges to  $\theta$  in  $L^r(Q)$ ,  $1 \leq r < +\infty$ , and in  $L^\infty(Q)$  weak-\*. Since  $\tau_n$  is regular, and  $\sigma = M \nabla u$  a.e. in  $Q$ , we also have that  $\hat{u}_n$  converges strongly in  $H_0^1(Q)$  to  $u$  (see, e.g., [8]). Thus,  $M \nabla \hat{u}_n$  and then  $\hat{\sigma}_n$  converge strongly to  $\sigma$  in  $L^2(Q)^N$ . By Egorov's theorem, there exist a subsequence of  $n$ , still denoted by  $n$ , and a sequence  $Q_n$  of closed subsets of  $Q$  such that

$$(5.36) \quad |Q - Q_n| < \frac{1}{n}, \quad C(|\nabla \hat{u}_n - \nabla u| + |\nabla u| |\hat{\theta}_n - \theta|^\rho) + |\hat{\sigma}_n - \sigma| < \frac{1}{n} \text{ in } Q_n,$$

with  $C > 0$  and  $\rho \in (0, 1)$  given by Lemma 5.3.

Since  $\nabla \hat{u}_n$  is constant in every  $N$ -simplex  $T_n^k$  of  $\tau_n$  and, for every  $\xi \in \mathbf{R}^N$ , the set  $\mathcal{K}(A, B, p)\xi$  is closed in  $\mathbf{R}^N$  and satisfies the following convexity property (this property does not hold for  $N = 1$ , and so it is the reason to prove the cases  $N = 1$ ,  $N \geq 2$  separately):

$$\lambda \mathcal{K}(A, B, p_1)\xi + (1 - \lambda) \mathcal{K}(A, B, p_2)\xi \subset \mathcal{K}(A, B, \lambda p_1 + (1 - \lambda)p_2)\xi \quad \forall \lambda, p_1, p_2 \in [0, 1],$$

we have

$$\hat{\sigma}_n = \left( \frac{1}{|T_n^k|} \int_{T_n^k} M \, dx \right) \nabla \hat{u}_n \in \mathcal{K} \left( A, B, \frac{1}{|T_n^k|} \int_{T_n^k} \theta \, dx \right) \nabla \hat{u}_n$$

in  $T_n^k$ , for every  $k \in \{1, \dots, k_n\}$ , i.e.,  $\hat{\sigma}_n \in \mathcal{K}(A, B, \hat{\theta}_n) \nabla \hat{u}_n$  a.e. in  $Q$ , or equivalently

$$(\nabla \hat{u}_n, \hat{\sigma}_n, \hat{\theta}_n) \in \text{Dom}(H) \text{ a.e. in } Q.$$

We consider an  $N$ -simplex  $T_n^k$ , with  $k \in \{1, \dots, k_n\}$ , and we denote by  $\xi_n^k = \nabla \hat{u}_n$ ,  $\eta_n^k = \hat{\sigma}_n$ , and  $p_n^k = \hat{\theta}_n$  the constant values of  $\nabla \hat{u}_n$ ,  $\hat{\sigma}_n$ , and  $\hat{\theta}_n$ , respectively, in  $T_n^k$ . From definition (4.5) of  $H_{\frac{2}{n}}(\xi_n^k, \eta_n^k, p_n^k)$ , there exists  $Z_n^k \subset Y$ , with  $|Z_n^k| = p_n^k$ , such that, by defining  $S_n^k \in L_{\#}^\infty(Y; \mathcal{M}_N^s)$  by  $S_n^k = A \chi_{Z_n^k} + B \chi_{Y \setminus Z_n^k}$  a.e. in  $Y$ , and taking  $w_n^k$  the solution of

$$\begin{cases} w_n^k \in H_{\#}^1(Y), & \int_Y w_n^k \, dy = 0, \\ -\text{div } S_n^k(\xi_n^k + \nabla w_n^k) = 0 & \text{in } \mathbf{R}^N, \end{cases}$$

we have

$$(5.37) \quad \left| \int_Y S_n^k(\xi_n^k + \nabla w_n^k) \, dy - \eta_n^k \right| < \frac{2}{n}$$

and

$$(5.38) \quad \int_Y F(\xi_n^k + \nabla w_n^k) \, dy < H_{\frac{2}{n}}(\xi_n^k, \eta_n^k, p_n^k) + \frac{1}{n}.$$

We take

$$(5.39) \quad \check{\sigma}_n = \sum_{k=1}^{k_n} \left( \int_Y S_n^k(\xi_n^k + \nabla w_n^k) \, dy \right) \chi_{T_n^k},$$

and by (5.37), we observe that

$$(5.40) \quad \int_Q |\check{\sigma}_n - \hat{\sigma}_n|^2 dx < \frac{4}{n^2} |Q|.$$

For  $n \in \mathbf{N}$ , and  $\varepsilon > 0$ , we define

$$\omega_{n,\varepsilon} = \bigcup_{k=1}^{k_n} \left[ T_n^k \cap \left( \bigcup_{l \in \mathbf{Z}^N} (\varepsilon l + \varepsilon Z_n^k) \right) \right],$$

$$M_{n,\varepsilon} = A\chi_{\omega_{n,\varepsilon}} + B(1 - \chi_{\omega_{n,\varepsilon}}),$$

and  $u_{n,\varepsilon} \in H_0^1(Q)$  as the solution of

$$(5.41) \quad -\operatorname{div} M_{n,\varepsilon} \nabla u_{n,\varepsilon} = -\operatorname{div} \check{\sigma}_n \quad \text{in } Q.$$

Since  $|Z_n^k| = p_n^k$ , the sequence  $\omega_{n,\varepsilon}$  satisfies

$$(5.42) \quad \chi_{\omega_{n,\varepsilon}} \xrightarrow{*} \hat{\theta}_n \quad \text{in } L^\infty(\Omega), \quad \text{when } \varepsilon \rightarrow 0.$$

By using the fact that  $\nabla \hat{u}_n = \xi_n^k$  in each  $T_n^k$  and the definition (5.39) of  $\check{\sigma}_n$ , we deduce by periodic homogenization (see, e.g., [1], [4], [11]) that

$$(5.43) \quad u_{n,\varepsilon} \rightharpoonup \hat{u}_n \quad \text{in } H_0^1(Q), \quad \text{when } \varepsilon \rightarrow 0,$$

$$(5.44) \quad M_{n,\varepsilon} \nabla u_{n,\varepsilon} \rightharpoonup \check{\sigma}_n \quad \text{in } L^2(Q)^N, \quad \text{when } \varepsilon \rightarrow 0,$$

$$(5.45) \quad \nabla u_{n,\varepsilon} - \sum_{k=1}^{k_n} \left( \xi_n^k + \nabla w_n^k \left( \frac{x}{\varepsilon} \right) \right) \chi_{T_n^k} \rightarrow 0 \quad \text{in } L^2(Q)^N, \quad \text{when } \varepsilon \rightarrow 0.$$

By (5.45), (4.1),  $\nabla w_n^k$ -periodic, and (5.38), we then have

$$(5.46) \quad \lim_{\varepsilon \rightarrow 0} \int_\Omega F(\nabla u_{n,\varepsilon}) dx = \sum_{k=1}^{k_n} \lim_{\varepsilon \rightarrow 0} \int_{T_n^k \cap \Omega} F \left( \xi_n^k + \nabla w_n^k \left( \frac{x}{\varepsilon} \right) \right) dx$$

$$= \sum_{k=1}^{k_n} \int_{T_n^k \cap \Omega} \int_Y F(\xi_n^k + \nabla w_n^k) dy dx < \int_\Omega H_{\frac{2}{n}}(\nabla \hat{u}_n, \hat{\sigma}_n, \hat{\theta}_n) dx + \frac{|\Omega|}{n}.$$

We consider a dense countable subset  $\{h_j\}$  of  $L^1(\Omega)$  and a dense countable subset  $\{g_j\}$  of  $L^2(\Omega)^N$ . By using (5.42), (5.43), (5.46), for every  $n \in \mathbf{N}$ , we choose  $\varepsilon_n > 0$  such that

$$(5.47) \quad \left| \int_\Omega (\chi_{\omega_{n,\varepsilon_n}} - \hat{\theta}_n) h_j dx \right| < \frac{1}{n} \quad \forall j \in \{1, \dots, n\},$$

$$(5.48) \quad \left| \int_\Omega (M_{n,\varepsilon_n} \nabla u_{n,\varepsilon_n} - \check{\sigma}_n) g_j dx \right| < \frac{1}{n} \quad \forall j \in \{1, \dots, n\},$$

$$(5.49) \quad \int_\Omega |u_{n,\varepsilon_n} - \hat{u}_n|^2 dx < \frac{1}{n},$$

$$(5.50) \quad \int_{\Omega} F(\nabla u_{n,\varepsilon_n}) dx < \int_{\Omega} H_{\frac{2}{n}}(\nabla \hat{u}_n, \hat{\sigma}_n, \hat{\theta}_n) dx + \frac{|\Omega|}{n}.$$

Then we define

$$u_n = u_{n,\varepsilon_n}, \quad \sigma_n = M_{n,\varepsilon_n} \nabla u_{n,\varepsilon_n}, \quad \theta_n = \chi_{\omega_{n,\varepsilon_n}}.$$

Thanks to (5.40) and  $\hat{\sigma}_n$  converging strongly to  $\sigma$  in  $L^2(\Omega)^N$ , we have that  $\check{\sigma}_n$  converges strongly to  $\sigma$  in  $L^2(\Omega)^N$ . So, by (5.41),  $u_n$  is bounded in  $H^1(\Omega)$ , which joined to (5.49) and  $\hat{u}_n$  converging strongly to  $u$  in  $H^1(\Omega)$  implies that  $u_n$  converges weakly to  $u$  in  $H^1(\Omega)$ . Equation (5.41) and the strong convergence of  $\check{\sigma}_n$  (see Remark 4.5) also give that  $|\nabla u_n|^2$  is equi-integrable and that  $-\operatorname{div} \sigma_n = -\operatorname{div} \check{\sigma}_n$  converges strongly to  $-\operatorname{div} \sigma$  in  $H^{-1}(\Omega)$ . By (5.48), we also have that  $\sigma_n$  converges weakly to  $\sigma$  in  $L^2(\Omega)^N$ . Finally (5.47) and the convergence of  $\hat{\theta}_n$  to  $\theta$  in  $L^\infty(Q)$  weak-\* proves that  $\theta_n$  converges to  $\theta$  in  $L^\infty(\Omega)$  weak-\*. Hence,  $(u_n, \sigma_n, \theta_n)$   $\mathcal{T}$ -converges to  $(u, \sigma, \theta)$ .

By (5.50) and the definition (4.18) of  $\mathcal{F}$ , we obtain

$$(5.51) \quad \mathcal{F}(u_n, \sigma_n, \theta_n) = \int_{\Omega} F(\nabla u_n) dx < \int_{\Omega} H_{\frac{2}{n}}(\nabla \hat{u}_n, \hat{\sigma}_n, \hat{\theta}_n) dx + \frac{|\Omega|}{n}.$$

On the other hand, by (5.36),  $H_\delta(\xi, \eta, p)$  decreasing in  $\delta$ , and (5.9), we have

$$\begin{aligned} H_{\frac{2}{n}}(\nabla \hat{u}_n, \hat{\sigma}_n, \hat{\theta}_n) &\leq H_{\frac{1}{n} + \lambda_n(x) + |\hat{\sigma}_n - \sigma|}(\nabla \hat{u}_n, \hat{\sigma}_n, \hat{\theta}_n) \\ &\leq H_{\frac{1}{n}}(\nabla u, \sigma, \theta) + (1 + |\nabla u| + |\nabla \hat{u}_n|)^{2-e} (\lambda_n)^e \\ &\leq H_{\frac{1}{n}}(\nabla u, \sigma, \theta) + (1 + |\nabla u| + |\nabla \hat{u}_n|)^{2-e} \frac{1}{n^e}, \end{aligned}$$

a.e. in  $Q_n$ , with

$$\lambda_n = C(|\nabla(\hat{u}_n - u)| + |\nabla u| |\hat{\theta}_n - \theta|^\rho).$$

By then using (5.10), we get

$$\begin{aligned} (5.52) \quad &\int_{\Omega} H_{\frac{2}{n}}(\nabla \hat{u}_n, \hat{\sigma}_n, \hat{\theta}_n) dx \\ &\leq \int_{Q_n \cap \Omega} H_{\frac{1}{n}}(\nabla u, \sigma, \theta) dx + \frac{1}{n^e} \int_{Q_n \cap \Omega} (1 + |\nabla u| + |\nabla \hat{u}_n|)^{2-e} dx \\ &\quad + L \int_{\Omega \setminus Q_n} \left( \frac{\beta}{\alpha} |\nabla \hat{u}_n| \right)^e \left( 1 + \frac{\beta}{\alpha} |\nabla \hat{u}_n| \right)^{2-e} dx. \end{aligned}$$

By the definition of  $H$  and (5.10) we can apply the Lebesgue dominated convergence theorem to deduce that

$$H_{\frac{1}{n}}(\nabla u, \sigma, \theta) \rightarrow H(\nabla u, \sigma, \theta) \quad \text{in } L^1(\Omega).$$

By using also the fact that  $\nabla \hat{u}_n$  converges strongly in  $L^2(\Omega)^N$  and that  $|\Omega \setminus Q_n|$  tends to zero, we then deduce by (5.51) and (5.52) that

$$\limsup_{n \rightarrow \infty} \mathcal{F}(u_n, \sigma_n, \theta_n) \leq \int_{\Omega} H(\nabla u, \sigma, \theta) dx = \overline{\mathcal{F}}(u, \sigma, \theta).$$

This proves (5.24).  $\square$

*Proof of Theorem 4.3.* We denote by  $I$  the infimum of problem (4.4) and by  $J$  the infimum of problem (4.16).

*Step 1.* Let us first prove that  $I$  is bigger than or equal to  $J$ . For this purpose it is enough to observe that thanks to (4.12)

$$\int_{\Omega} F(\nabla u) dx = \int_{\Omega} H(\nabla u, M\nabla u, \theta) dx,$$

when  $\theta = \chi_{\omega}$  with  $\omega \subset \Omega$  measurable and  $M = A\chi_{\omega} + B\chi_{\Omega \setminus \omega}$ . So in (4.4) we are minimizing the same functional as that in (4.16) but in a smaller set. This proves  $I \geq J$ .

*Step 2.* Let us now use the direct method of the calculus of variations to prove that problem (4.16) has a minimum. We consider  $\theta_n \in L^{\infty}(\Omega)$ , with  $0 \leq \theta_n \leq 1$  a.e. in  $\Omega$ ,

$$\int_{\Omega} \theta_n dx \leq \kappa |\Omega|,$$

and  $M_n \in \mathcal{K}(A, B, \theta)$  a.e. in  $\Omega$  such that the solution  $u_n$  of

$$\begin{cases} -\operatorname{div} M_n \nabla u_n = f & \text{in } \Omega, \\ u_n \in H_0^1(\Omega) \end{cases}$$

satisfies

$$\exists \lim_{n \rightarrow \infty} \left( \int_{\Omega} H(\nabla u_n, M_n \nabla u_n, \theta_n) dx + G(u_n) \right) = J.$$

Thanks to  $\theta_n$  being bounded in  $L^{\infty}(\Omega)$  and the compactness of the  $H$ -convergence, by extracting a subsequence if necessary, we can assume that there exist  $\theta \in L^{\infty}(\Omega)$  and  $M \in L^{\infty}(\Omega; \mathcal{M}_N^s)$  such that  $\theta_n$  converges weak-\* in  $L^{\infty}(\Omega)$  to  $\theta$  and  $M_n$   $H$ -converges to  $M$ . Therefore,  $(u_n, M_n \nabla u_n, \theta_n)$   $\mathcal{T}$ -converges to  $(u, M \nabla u, \theta)$  (the equi-integrability of  $|\nabla u_n|^2$  is an easy consequence of Meyer's theorem [19]), where

$$0 \leq \theta \leq 1 \quad \text{a.e. in } \Omega, \quad \int_{\Omega} \theta dx \leq \kappa |\Omega|, \quad M \in \mathcal{K}(A, B, \theta) \quad \text{a.e. in } \Omega,$$

$$\begin{cases} -\operatorname{div} M \nabla u = f & \text{in } \Omega, \\ u \in H_0^1(\Omega). \end{cases}$$

Since  $\overline{\mathcal{F}}$  is lower semicontinuous for the  $\mathcal{T}$ -convergence and  $G$  is sequentially continuous for the weak convergence in  $H_0^1(\Omega)$ , we have

$$J = \lim_{n \rightarrow \infty} \left( \int_{\Omega} H(\nabla u_n, M_n \nabla u_n, \theta_n) dx + G(u_n) \right) \geq \int_{\Omega} H(\nabla u, M \nabla u, \theta) dx + G(u).$$

Thus  $u, M, \theta$  is a solution of (4.16), and hence  $J$  is a minimum.

*Step 3.* To finish the proof of Theorem 4.3, let us now prove that, for every solution  $u, M, \theta$  of (4.16), there exists a sequence  $\omega_n$  of measurable subsets of  $\Omega$ , with  $|\omega_n| \leq \kappa |\Omega|$  such that the solution  $u_n$  of

$$(5.53) \quad \begin{cases} -\operatorname{div} (A\chi_{\omega_n} + B\chi_{\Omega \setminus \omega_n}) \nabla u_n = f & \text{in } \Omega, \\ u_n \in H_0^1(\Omega) \end{cases}$$

satisfies

$$(5.54) \quad \lim_{n \rightarrow \infty} \left( \int_{\Omega} F(\nabla u_n) dx + G(u_n) \right) = J,$$

and it is such that  $(u_n, (A\chi_{\omega_n} + B\chi_{\Omega \setminus \omega_n})\nabla u_n, \chi_{\omega_n})$   $\mathcal{T}$ -converges to  $(u, M\nabla u, \theta)$ .

By Theorem 4.5, we know that there exist  $\tilde{\omega}_n \subset \Omega$  measurable and  $\tilde{u}_n \in H_0^1(\Omega)$  such that, for  $\tilde{M}_n = (A\chi_{\tilde{\omega}_n} + B\chi_{\Omega \setminus \tilde{\omega}_n})$ , the sequence  $(\tilde{u}_n, \tilde{M}_n \nabla \tilde{u}_n, \chi_{\tilde{\omega}_n})$   $\mathcal{T}$ -converges to  $(u, M\nabla u, \theta)$  and

$$(5.55) \quad \lim_{n \rightarrow \infty} \int_{\Omega} F(\nabla \tilde{u}_n) dx = \int_{\Omega} H(\nabla u, M\nabla u, \theta) dx.$$

From the compactness of the  $H$ -convergence, we can also assume that there exists  $\hat{M}$  such that  $\tilde{M}_n$   $H$ -converges to  $\hat{M}$ . Then  $\hat{M} \in \mathcal{K}(A, B, \theta)$  a.e. in  $\Omega$  and, thanks to the definition of  $\mathcal{T}$ -convergence,  $\hat{M}\nabla u = M\nabla u$  a.e. in  $\Omega$ . The weak- $*$  convergence of  $\chi_{\tilde{\omega}_n}$  to  $\theta$  also implies that

$$\lim_{n \rightarrow \infty} |\tilde{\omega}_n| = \int_{\Omega} \theta dx \leq \kappa |\Omega|.$$

Now, for every  $n \in \mathbb{N}$ , we consider  $\omega_n \subset \tilde{\omega}_n$  measurable such that

$$|\tilde{\omega}_n \setminus \omega_n| = \max \{ |\tilde{\omega}_n| - \kappa |\Omega|, 0 \} \rightarrow 0,$$

and we define  $u_n$  as the solution of (5.53).

By taking into account

$$-\operatorname{div} \tilde{M}_n \nabla u_n = f - \operatorname{div} (\tilde{M}_n - M_n) \nabla u_n \quad \text{in } \Omega,$$

with  $M_n = A\chi_{\omega_n} + B\chi_{\Omega \setminus \omega_n}$ , the equi-integrability of  $|\nabla u_n|^2$ , and the fact that

$$(5.56) \quad \lim_{n \rightarrow \infty} \left| \{x \in \Omega : \tilde{M}_n(x) - M_n(x) \neq 0\} \right| = \lim_{n \rightarrow \infty} |\tilde{\omega}_n \setminus \omega_n| = 0,$$

we have that  $(\tilde{M}_n - M_n)\nabla u_n$  tends to zero in  $L^2(\Omega)^N$  strongly. Therefore  $-\operatorname{div} \tilde{M}_n \nabla u_n$  tends to  $f$  strongly in  $H^{-1}(\Omega)$ . By the definition of  $\mathcal{T}$ -convergence and  $-\operatorname{div} M\nabla u = f$  in  $\Omega$ , we also have that  $-\operatorname{div} \tilde{M}_n \nabla \tilde{u}_n$  converges strongly to  $f$  in  $H^{-1}(\Omega)$ . The div-curl lemma then gives that  $\tilde{M}_n \nabla(u_n - \tilde{u}_n) \cdot \nabla(u_n - \tilde{u}_n)$  converges to zero in the sense of the distributions. The equi-integrability of  $|\nabla u_n|^2$  and  $|\nabla \tilde{u}_n|^2$  implies that this convergence holds in fact in  $L^1(\Omega)$  weakly, and so

$$\lim_{n \rightarrow \infty} \int_{\Omega} \tilde{M}_n \nabla(u_n - \tilde{u}_n) \cdot \nabla(u_n - \tilde{u}_n) dx = 0,$$

which by the ellipticity of  $\tilde{M}_n$  implies that  $\nabla(u_n - \tilde{u}_n)$  converges strongly to zero in  $L^2(\Omega)^N$ . Thus,  $(u_n, M_n \nabla u_n, \chi_{\omega_n})$   $\mathcal{T}$ -converges to  $(u, M\nabla u, \theta)$ , and, by (4.1), the sequential continuity of  $G$  with respect to the weak topology in  $H_0^1(\Omega)$ , and (5.55), we have

$$\begin{aligned} \lim_{n \rightarrow \infty} \left( \int_{\Omega} F(\nabla u_n) dx + G(u_n) \right) &= \lim_{n \rightarrow \infty} \left( \int_{\Omega} F(\nabla \tilde{u}_n) dx + G(u_n) \right) \\ &= \int_{\Omega} H(\nabla u, M\nabla u, \theta) dx + G(u) = J. \quad \square \end{aligned}$$

*Proof of Proposition 4.6.* We consider  $\lambda, p_1, p_2 \in [0, 1]$ ,  $\xi_1, \xi_2, \eta_1, \eta_2 \in \mathbf{R}^N$  such that  $\eta_1 = \eta_2$  for  $N = 1$ , and  $(\xi_1 - \xi_2) \cdot (\eta_1 - \eta_2) = 0$  for  $N > 1$ .

We take  $\chi = \sum_{k \in \mathbf{Z}} \chi_{(k, k+\lambda)} \in L^\infty_\#(0, 1)$ .

If  $\xi_1 \neq \xi_2$ , we define  $u_n \in W^{1,\infty}_{loc}(\mathbf{R}^N)$ ,  $\sigma_n \in L^\infty(\mathbf{R}^N)^N$ , and  $\theta_n \in L^\infty(\mathbf{R}^N)$  by

$$u_n(x) = \xi_2 \cdot x + \frac{1}{n} \int_0^{n(\xi_1 - \xi_2) \cdot x} \chi(s) ds, \quad \sigma_n(x) = \eta_2 + (\eta_1 - \eta_2) \chi(n(\xi_1 - \xi_2) \cdot x),$$

$$\theta_n(x) = p_2 + (p_1 - p_2) \chi(n(\xi_1 - \xi_2) \cdot x), \quad \text{a.e. } x \in \mathbf{R}^N,$$

respectively, and we observe that, by defining

$$u(x) = (\lambda \xi_1 + (1 - \lambda) \xi_2) \cdot x, \quad \sigma(x) = \lambda \eta_1 + (1 - \lambda) \eta_2,$$

$$\theta(x) = \lambda p_1 + (1 - \lambda) p_2, \quad \text{a.e. } x \in \mathbf{R}^N,$$

we have that, for every smooth bounded open set  $\omega \subset \mathbf{R}^N$ ,  $u_n$  converges to  $u$  in  $W^{1,\infty}(\omega)$  weak-\*,  $\sigma_n$  converges to  $\sigma$  in  $L^\infty(\omega)^N$  weak-\*, and  $\theta_n$  converges to  $\theta$  in  $L^\infty(\omega)$  weak-\* and  $\operatorname{div} \sigma_n = 0$  in  $\omega$ . In particular,  $(u_n, \sigma_n, \theta_n)$   $\mathcal{T}$ -converges to  $(u, \sigma, \theta)$ . Since the functional  $\overline{\mathcal{F}}$  defined by (4.19) is lower semicontinuous in  $\omega$  for the  $\mathcal{T}$ -convergence (use Theorem 4.5, with  $\Omega$  replaced by  $\omega$ ), we get

$$\begin{aligned} & \int_\omega H(\lambda \xi_1 + (1 - \lambda) \xi_2, \lambda \eta_1 + (1 - \lambda) \eta_2, \lambda p_1 + (1 - \lambda) p_2) dx \\ &= \overline{\mathcal{F}}(u, \sigma, \theta) \leq \lim_{n \rightarrow \infty} \overline{\mathcal{F}}(u_n, \sigma_n, \theta_n) \\ &= \lim_{n \rightarrow \infty} \int_\omega \left( H(\xi_1, \eta_1, p_1) \chi(n(\xi_1 - \xi_2) \cdot x) + H(\xi_2, \eta_2, p_2) (1 - \chi(n(\xi_1 - \xi_2) \cdot x)) \right) dx \\ &= \int_\omega \left( \lambda H(\xi_1, \eta_1, p_1) + (1 - \lambda) H(\xi_2, \eta_2, p_2) \right) dx, \end{aligned}$$

which by the arbitrariness of  $\omega$  implies (4.22) (or (4.21) if  $N = 1$ ).

If  $\xi_1 = \xi_2$  (and then  $N > 1$ ), we reason analogously, by taking  $\zeta \neq 0$  orthogonal to  $\eta_1 - \eta_2$  and defining

$$u_n(x) = \xi_1 \cdot x, \quad \sigma_n(x) = \eta_2 + (\eta_1 - \eta_2) \chi(n\zeta \cdot x),$$

$$\theta_n(x) = p_2 + (p_1 - p_2) \chi(n\zeta \cdot x), \quad \text{a.e. } x \in \mathbf{R}^N. \quad \square$$

*Proof of Proposition 4.7.* We recall that convex and bounded functions are locally Lipschitz in the interior of their domain. This can be easily generalized to functions of several variables, convex in each one of these variables. Then Proposition 4.6 and (4.11) prove that  $H$  is continuous in the interior of its domain. On the other hand, we consider  $(\xi, \eta, p) \in \operatorname{Dom}(H)$ ,  $p \in (0, 1)$ . By reasoning similarly as in the proof of Theorem 4.2, it is not difficult to show that if  $p$  is close to 0 or 1, then  $H(\xi, \eta, p)$  is close to  $F(\xi)$  and that if

$$\xi \cdot (\Lambda_p \xi - \eta) - \left( (A - B) \left( \frac{A}{p} + \frac{B}{1-p} \right)^{-1} (A - B) \right)^\dagger (\Lambda_p \xi - \eta) \cdot (\Lambda_p \xi - \eta)$$

is small, then

$$\left| H(\xi, \eta, p) - pF \left( \xi + \Xi \left( \frac{\Lambda_p \xi - \eta}{p} \right) \right) - (1-p)F \left( \xi - \Xi \left( \frac{\Lambda_p \xi - \eta}{1-p} \right) \right) \right|$$

is small. This proves the continuity of  $H$  in the boundary of its domain.  $\square$

**6. Example.** In this section we give an example in dimension  $N \geq 2$  of a quadratic function  $F$  for which we obtain an explicit expression of the function  $H$  defined by (4.6) in its whole domain. This is given by the following theorem.

**THEOREM 6.1.** *We consider  $N \geq 2$ ,  $A, B \in \mathcal{M}_N^s$  definite positive,  $s \in \mathbf{R}$  such that  $s(A - B)$  is definite nonnegative, and*

$$F(\xi) = sA\xi \cdot \xi \quad \forall \xi \in \mathbf{R}^N.$$

*Then, for every  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times (0, 1)$  such that  $\eta \in \mathcal{K}(A, B, p)\xi$ , we have that the function  $H$  defined by (4.6) is given by*

$$(6.1) \quad H(\xi, \eta, p) = sA\xi \cdot \xi + s(\Lambda_p \xi - \eta) \cdot \xi + \frac{s}{1-p}(A - B)\nu \cdot \nu,$$

*where  $\nu$  is any vector in  $\mathbf{R}^N$  which satisfies  $(B - A)\nu = \Lambda_p \xi - \eta$ .*

*In the cases  $p = 0$ ,  $p = 1$ , we have*

$$H(\xi, A\xi, 1) = H(\xi, B\xi, 0) = sA\xi \cdot \xi \quad \forall \xi \in \mathbf{R}^N.$$

*Remark 6.1.* Since  $\text{Ran}(A - B) = \text{Ker}(A - B)^\perp$ , it is clear that the second member of (6.1) does not depend on the choice of  $\nu$ . By taking  $\nu = (A - B)^\dagger(\Lambda_p \xi - \eta)$ , we have

$$H(\xi, \eta, p) = sA\xi \cdot \xi + s(\Lambda_p \xi - \eta) \cdot \xi + \frac{s}{1-p}(A - B)^\dagger(\Lambda_p \xi - \eta) \cdot (\Lambda_p \xi - \eta)$$

for every  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times (0, 1)$  such that  $\eta \in \mathcal{K}(A, B, p)\xi$ .

*Proof of Theorem 6.1.* By (4.12) it is enough to prove (6.1).

For  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times (0, 1)$  such that  $\eta \in \mathcal{K}(A, B, p)\xi$ , we consider  $Z_n$ ,  $S_n$ ,  $w_n$ ,  $\eta_n$  as in Remark 4.1, and we define

$$\nu_n = \int_{Z_n} \nabla w_n dy = - \int_{Y \setminus Z_n} \nabla w_n dy.$$

By using that  $\nabla w_n$  has mean value zero and (3.4), we have

$$(6.2) \quad \begin{aligned} \int_Y sA(\xi + \nabla w_n) \cdot (\xi + \nabla w_n) dy &= sA\xi \cdot \xi + \int_Y sA \nabla w_n \cdot \nabla w_n dy \\ &= sA\xi \cdot \xi + s(\Lambda_p \xi - \eta_n) \cdot \xi + \int_{Y \setminus Z_n} s(A - B) \nabla w_n \cdot \nabla w_n dy. \end{aligned}$$

Thanks to  $s(A - B)$  nonnegative, the Cauchy-Schwarz inequality proves that

$$\begin{aligned} s(A - B)\nu_n \cdot \nu_n &= - \int_{Y \setminus Z_n} s(A - B) \nabla w_n \cdot \nu_n dy \\ &\leq \int_{Y \setminus Z_n} (s(A - B) \nabla w_n \cdot \nabla w_n)^{\frac{1}{2}} (s(A - B)\nu_n \cdot \nu_n)^{\frac{1}{2}} dy \\ &\leq \left( \int_{Y \setminus Z_n} s(A - B) \nabla w_n \cdot \nabla w_n dy \right)^{\frac{1}{2}} \left( (1 - p)s(A - B)\nu_n \cdot \nu_n \right)^{\frac{1}{2}} \end{aligned}$$

and so

$$\frac{s}{1-p}(A - B)\nu_n \cdot \nu_n \leq \int_{Y \setminus Z_n} s(A - B) \nabla w_n \cdot \nabla w_n dy,$$

which substituted in (6.2) and then passed to the limit in  $n$  proves that

$$(6.3) \quad H(\xi, \eta, p) \geq sA\xi \cdot \xi + s(\Lambda_p \xi - \eta) \cdot \xi + \frac{s}{1-p}(A-B)\nu \cdot \nu,$$

where  $\nu$  equals the limit of  $\nu_n$  (it exists for a subsequence) and satisfies  $(A-B)\nu = \eta - \Lambda_p \xi$ .

In order to prove the contrary inequality, we remark that if  $\eta \in \Lambda_p \xi + \text{Ran}(A-B)$  is such that

$$(6.4) \quad \left( (A-B) \left( \frac{A}{p} + \frac{B}{1-p} \right)^{-1} (A-B) \right)^\dagger (\Lambda_p \xi - \eta) \cdot (\Lambda_p \xi - \eta) = \xi \cdot (\Lambda_p \xi - \eta),$$

then (6.1) follows from Theorem 4.2 by taking  $\nu = \Xi(\Lambda_p \xi - \eta)$  and using

$$\left( \frac{A}{p} + \frac{B}{1-p} \right) \nu \cdot \nu = (\Lambda_p \xi - \eta) \cdot \xi.$$

Thus, it is enough to consider the case where  $\eta \in \Lambda_p \xi + \text{Ran}(A-B)$  satisfies

$$(6.5) \quad \left( (A-B) \left( \frac{A}{p} + \frac{B}{1-p} \right)^{-1} (A-B) \right)^\dagger (\Lambda_p \xi - \eta) \cdot (\Lambda_p \xi - \eta) < \xi \cdot (\Lambda_p \xi - \eta).$$

By taking as above  $\nu = \Xi(\Lambda_p \xi - \eta)$ , we have

$$\eta = \Lambda_p \xi + (A-B)\nu, \quad \left( \frac{A}{p} + \frac{B}{1-p} \right) \nu \cdot \nu < (B-A)\nu \cdot \xi.$$

The last inequality implies that there exists  $r \in (0, p)$  such that

$$\left( \frac{1}{p-r} - \frac{1}{p} \right) A\nu \cdot \nu = (B-A)\nu \cdot \xi - \left( \frac{A}{p} + \frac{B}{1-p} \right) \nu \cdot \nu.$$

For  $\hat{\nu} = \nu/(1-r)$  we then have that  $\hat{\eta} = \Lambda_{\hat{p}} \xi + (A-B)\hat{\nu}$ ,  $\hat{p} = (p-r)/(1-r)$  are such that  $\hat{\eta} \in \Lambda_{\hat{p}} \xi + \text{Ran}(A-B)$  and that (6.4) holds with  $\eta$  and  $p$ , respectively, replaced by  $\hat{\eta}$  and  $\hat{p}$ . By taking into account

$$p = r + (1-r)\hat{p}, \quad \eta = rA\xi + (1-r)\hat{\eta}$$

and using the convexity property (4.22) of  $H$ , we then obtain

$$(6.6) \quad \begin{aligned} H(\xi, \eta, p) &\leq rH(\xi, A\xi, 1) + (1-r)H(\xi, \hat{\eta}, \hat{p}) \\ &= sA\xi \cdot \xi + s(A-B)\nu \cdot \xi + \frac{s}{1-p}(A-B)\nu \cdot \nu. \end{aligned}$$

This finishes the proof of Theorem 6.1.  $\square$

*Remark 6.2.* By the proof of Theorem 6.1, we see that the sequence  $Z_n$  given by Remark 4.1 must be chosen in such a way that the value of  $\nabla w_n$  in  $Y \setminus Z_n$  is close to a constant. For  $N \geq 2$ ,  $(\xi, \eta, p) \in \mathbf{R}^N \times \mathbf{R}^N \times (0, 1)$ ,  $\eta \in \mathcal{K}(A, B, p)\xi$ ,  $\eta \neq \Lambda_p \xi$ , this can be carried on by using two laminations as follows: We take  $\nu = \Xi(\Lambda_p \xi - \eta)$  and  $r$  and  $\hat{p}$  as in the proof of Theorem 6.1, and then we construct a matrix  $M$  by a lamination of  $A$  and  $B$  in the direction of  $\nu$  with respective proportions  $\hat{p}$  and  $1-\hat{p}$  and

then a lamination of  $A$  and  $M$  in an orthogonal direction to  $(M - A)\xi$  with respective proportions  $r$  and  $1 - r$ . This is the idea that we used in the proof of inequality (6.6).

As a particular case of Theorem 6.1, we have the following result.

**COROLLARY 6.2.** *Assume that  $N \geq 2$ ,  $A = \alpha I$ ,  $B = \beta I$ , with  $0 < \alpha < \beta$ , and for  $s \in \mathbf{R}$  take  $F(\xi) = s|\xi|^2$  for every  $\xi \in \mathbf{R}^N$ . Then the function  $H$  defined by (4.6) satisfies*

$$\begin{aligned} H(\xi, \eta, p) &= s|\xi|^2 + \frac{s}{\beta}(\Lambda_p \xi - \eta) \cdot \xi + \frac{s}{\beta(\beta - \alpha)p} |\Lambda_p \xi - \eta|^2 & \text{if } s \geq 0, \\ H(\xi, \eta, p) &= s|\xi|^2 + \frac{s}{\alpha}(\Lambda_p \xi - \eta) \cdot \xi - \frac{s}{\alpha(\beta - \alpha)(1 - p)} |\Lambda_p \xi - \eta|^2 & \text{if } s \leq 0 \end{aligned}$$

for every  $\xi \in \mathbf{R}^N$ ,  $p \in (0, 1)$ ,  $\eta \in \mathcal{K}(A, B, p)\xi$ .

*Proof.* It is enough to apply Theorem 6.1 where the matrices  $A$  and  $B$  and the constant  $s$  must be replaced, respectively, by  $\beta I$ ,  $\alpha I$ , and  $s/\beta$  in the case  $s \geq 0$  and by  $\alpha I$ ,  $\beta I$ , and  $s/\alpha$  in the case  $s \leq 0$ .  $\square$

**Remark 6.3.** Corollary 6.2 and Theorem 4.3 give the relaxation of the problem

$$\begin{cases} \inf \left\{ s \int_{\Omega} |\nabla u|^2 dx \right\}, \\ -\operatorname{div}(\alpha \chi_{\omega} + \beta \chi_{\Omega \setminus \omega}) \nabla u = f \quad \text{in } \Omega, \\ u \in H_0^1(\Omega), \\ \omega \subset \Omega \text{ measurable, } |\omega| \leq \kappa |\Omega|. \end{cases}$$

In the case where  $s > 0$ , this relaxation was obtained by Bellido and Pedregal in [3] (see also [15]) for  $N = 2$  and independently by Grabovsky in [10] for arbitrary  $N$ . The method used in the present paper is different from the ones used by these authors.

# DISSIPATIVE BOUNDARY CONDITIONS FOR ONE-DIMENSIONAL NONLINEAR HYPERBOLIC SYSTEMS\*

JEAN-MICHEL CORON<sup>†</sup>, GEORGES BASTIN<sup>‡</sup>, AND BRIGITTE D'ANDRÉA-NOVEL<sup>§</sup>

**Abstract.** We give a new sufficient condition on the boundary conditions for the exponential stability of one-dimensional nonlinear hyperbolic systems on a bounded interval. Our proof relies on the construction of an explicit strict Lyapunov function. We compare our sufficient condition with other known sufficient conditions for nonlinear and linear one-dimensional hyperbolic systems.

**Key words.** nonlinear hyperbolic systems, boundary conditions, stability, Lyapunov function

**AMS subject classifications.** 35F30, 35F25, 93D20, 93D30

**DOI.** 10.1137/070706847

**1. Introduction.** We are concerned with the following one-dimensional  $n \times n$  nonlinear hyperbolic system:

$$(1.1) \quad u_t + F(u)u_x = 0, \quad x \in [0, 1], \quad t \in [0, +\infty),$$

where  $u : [0, \infty) \times [0, 1] \rightarrow \mathbb{R}^n$  and  $F : \mathbb{R}^n \rightarrow \mathcal{M}_{n,n}(\mathbb{R})$ ,  $\mathcal{M}_{n,n}(\mathbb{R})$  denoting, as usual, the set of  $n \times n$  real matrices. We consider the case where, possibly after an appropriate state transformation,  $F(0)$  is a diagonal matrix with distinct and nonzero eigenvalues:

$$(1.2) \quad \begin{aligned} F(0) &:= \text{diag} (\Lambda_1, \Lambda_2, \dots, \Lambda_n), \\ \Lambda_i &> 0 \quad \forall i \in \{1, \dots, m\}, \\ \Lambda_i &< 0 \quad \forall i \in \{m+1, \dots, n\}, \end{aligned}$$

$$(1.3) \quad \Lambda_i \neq \Lambda_j \quad \forall (i, j) \in \{1, \dots, n\}^2 \text{ such that } i \neq j.$$

In (1) and in what follows,  $\text{diag} (\Lambda_1, \Lambda_2, \dots, \Lambda_n)$  denotes the diagonal matrix whose  $i$ th element on the diagonal is  $\Lambda_i$ .

Our concern is to analyze the asymptotic behavior of the classical solutions of the system under the following boundary condition:

$$(1.4) \quad \begin{pmatrix} u_+(t, 0) \\ u_-(t, 1) \end{pmatrix} = G \begin{pmatrix} u_+(t, 1) \\ u_-(t, 0) \end{pmatrix}, \quad t \in [0, +\infty),$$

where the map  $G : \mathbb{R}^n \rightarrow \mathbb{R}^n$  vanishes at 0, while  $u_+ \in \mathbb{R}^m$ ,  $u_- \in \mathbb{R}^{n-m}$  are defined by requiring that  $u := (u_+^{\text{tr}}, u_-^{\text{tr}})^{\text{tr}}$ . The problem is to find the map  $G$  such that

the boundary condition (1.4) is dissipative, i.e., implies that the equilibrium solution  $u \equiv 0$  of system (1.1) with the boundary condition (1.4) is exponentially stable.

This problem has been considered in the literature for more than 20 years. To our knowledge, the first results were published by Slemrod in [21] and Greenberg and Li in [9] for the special case of  $2 \times 2$  (i.e.,  $u \in \mathbb{R}^2$ ) systems. A generalization to  $n \times n$  systems was given by the Li school. Let us mention in particular [17] by Qin, [25] by Zhao, and [14, Theorem 1.3, page 173] by Li. All these results rely on a systematic use of direct estimates of the solutions and their derivatives along the characteristic curves. They give rise to sufficient dissipative boundary conditions which are kinds of “small gain conditions.” The weakest sufficient condition [14, Theorem 1.3, page 173] is formulated as follows:  $\rho(|G'(0)|) < 1$ , where  $\rho(A)$  denotes the spectral radius of  $A \in \mathcal{M}_{n,n}(\mathbb{R})$  and  $|A|$  denotes the matrix whose elements are the absolute values of the elements of  $A \in \mathcal{M}_{n,n}(\mathbb{R})$ .

In this paper we follow a different approach, which is based on a Lyapunov stability analysis. The special case of  $2 \times 2$  systems and  $F(u)$  diagonal has recently been treated in our previous paper [6]. In the present paper, by using a more general strict Lyapunov function (see section 4), we get a new weaker dissipative boundary condition, stated as follows:

$$\inf \{ \|\Delta G'(0)\Delta^{-1}\|; \Delta \in \mathcal{D}_{n,+} \} < 1,$$

where  $\|\cdot\|$  denotes the usual 2-norm of matrices in  $\mathcal{M}_{n,n}(\mathbb{R})$  and  $\mathcal{D}_{n,+}$  denotes the set of diagonal matrices whose elements on the diagonal are strictly positive.

Moreover, our proof is rather elementary, and the existence of a strict Lyapunov function may be useful for studying robustness issues.

Our paper is organized as follows. In section 2, after some mathematical preliminaries, a precise technical definition of our new dissipative boundary condition is followed by the statement of our exponential stability theorem. Section 3 is then devoted to a discussion of the optimality properties of our dissipative boundary condition and to a comparison of this condition with other stability criteria from the literature, namely the criterion [14, Theorem 1.3, p. 173] mentioned above and a stability criterion for *linear* hyperbolic systems due to Silkowski. The proof of our exponential stability theorem, including the Lyapunov stability analysis, is thoroughly given in section 4. The paper ends with two appendices, where some technical properties of our dissipative boundary condition are given.

## 2. A sufficient condition for exponential stability. For

$$x := (x_1, \dots, x_n)^{\text{tr}} \in \mathbb{C}^n,$$

$|x|$  denotes the usual Hermitian norm of  $x$ :

$$|x| := \sqrt{\sum_{i=1}^n |x_i|^2}.$$

For  $n \in \mathbb{N} \setminus \{0\}$  and  $m \in \mathbb{N} \setminus \{0\}$ , we denote by  $\mathcal{M}_{n,m}(\mathbb{R})$  the set of  $n \times m$  real matrices. We define, for  $K \in \mathcal{M}_{n,m}(\mathbb{R})$ ,

$$\|K\| := \max\{|Kx|; x \in \mathbb{R}^n, |x| = 1\} = \max\{|Kx|; x \in \mathbb{C}^n, |x| = 1\},$$

and, if  $n = m$ ,

$$(2.1) \quad \rho_1(K) := \inf \{ \|\Delta K \Delta^{-1}\|; \Delta \in \mathcal{D}_{n,+} \},$$

where  $\mathcal{D}_{n,+}$  denotes the set of  $n \times n$  real diagonal matrices with strictly positive diagonal elements.

For  $\varepsilon$ , let  $B_\varepsilon$  be the open ball of  $\mathbb{R}^n$  of radius  $\varepsilon$ . We assume that, for some  $\varepsilon_0 > 0$ ,  $F : B_{\varepsilon_0} \rightarrow \mathcal{M}_{n,n}(\mathbb{R})$  is of class  $C^2$  and that there exists  $m \in \{0, \dots, n\}$  and  $n$  real numbers  $\Lambda_1, \dots, \Lambda_n$  such that

$$(2.2) \quad \Lambda_i > 0 \quad \forall i \in \{1, \dots, m\} \text{ and } \Lambda_i < 0 \quad \forall i \in \{m+1, \dots, n\},$$

$$(2.3) \quad F(0) = \text{diag}(\Lambda_1, \dots, \Lambda_n),$$

$$(2.4) \quad \Lambda_i \neq \Lambda_j \quad \forall (i, j) \in \{1, \dots, n\}^2 \text{ such that } i \neq j.$$

For  $u \in \mathbb{R}^n$ ,  $u_+ \in \mathbb{R}^m$  and  $u_- \in \mathbb{R}^{n-m}$  are defined by requiring

$$u = \begin{pmatrix} u_+ \\ u_- \end{pmatrix}.$$

As mentioned in the introduction, we are mainly interested in analyzing the asymptotic convergence of the classical solutions of the following Cauchy problem:

$$(2.5) \quad u_t + F(u)u_x = 0, \quad x \in [0, 1], \quad t \in [0, +\infty),$$

$$(2.6) \quad \begin{pmatrix} u_+(t, 0) \\ u_-(t, 1) \end{pmatrix} = G \begin{pmatrix} u_+(t, 1) \\ u_-(t, 0) \end{pmatrix}, \quad t \in [0, +\infty),$$

$$(2.7) \quad u(0, x) = u^0(x), \quad x \in [0, 1].$$

Concerning  $G$ , we assume that  $G : B_{\varepsilon_0} \rightarrow \mathbb{R}^n$  is of class  $C^2$  and satisfies  $G(0) = 0$ . We define  $F_+(u) \in \mathcal{M}_{m,n}(\mathbb{R})$ ,  $F_-(u) \in \mathcal{M}_{(n-m),n}(\mathbb{R})$ ,  $G_+(u) \in \mathbb{R}^m$ , and  $G_-(u) \in \mathbb{R}^{n-m}$  by requiring

$$F(u) = \begin{pmatrix} F_+(u) \\ F_-(u) \end{pmatrix}, \quad G(u) = \begin{pmatrix} G_+(u) \\ G_-(u) \end{pmatrix}.$$

Regarding the existence of the solutions to the Cauchy problem (2.5)–(2.7), we have the following proposition.

**PROPOSITION 2.1.** *There exists  $\delta_0 > 0$  such that, for every  $u^0 \in H^2((0, 1), \mathbb{R}^n)$  satisfying*

$$|u^0|_{H^2((0,1),\mathbb{R}^n)} \leq \delta_0$$

*and the compatibility conditions*

$$(2.8) \quad \begin{pmatrix} u_+^0(0) \\ u_-^0(1) \end{pmatrix} = G \begin{pmatrix} u_+^0(1) \\ u_-^0(0) \end{pmatrix},$$

$$(2.9) \quad F_+(u^0(0))u_x^0(0) = \left[ G'_{+u_+} \begin{pmatrix} u_+^0(1) \\ u_-^0(0) \end{pmatrix} \right] F_+(u^0(1))u_x^0(1) \\ + \left[ G'_{+u_-} \begin{pmatrix} u_+^0(1) \\ u_-^0(0) \end{pmatrix} \right] F_-(u^0(0))u_x^0(0),$$

$$(2.10) \quad F_-(u^0(1))u_x^0(1) = \left[ G'_{-u_+} \begin{pmatrix} u_+^0(1) \\ u_-^0(0) \end{pmatrix} \right] F_+(u^0(1))u_x^0(1) \\ + \left[ G'_{-u_-} \begin{pmatrix} u_+^0(1) \\ u_-^0(0) \end{pmatrix} \right] F_-(u^0(0))u_x^0(0),$$

the Cauchy problem (2.5)–(2.7) has a unique maximal classical solution

$$u \in C^0([0, T], H^2((0, 1), \mathbb{R}^n))$$

with  $T \in [0, +\infty]$ . Moreover, if

$$|u(t, \cdot)|_{H^2((0, 1), \mathbb{R}^n)} \leq \delta_0 \quad \forall t \in [0, T],$$

then  $T = +\infty$ .

For a proof of this proposition, see, for instance, [12] by Kato, [13, pp. 2–3] by Lax, [16, pp. 35–43] by Majda, or [20, pp. 106–114] by Serre. Actually [12, 13, 16, 20] deal with  $\mathbb{R}$  instead of  $[0, 1]$ , but the proofs given there can be adapted to treat this new case. See also [15, pp. 96–107] by Li and Yu for the well-posedness of the Cauchy problem (2.5)–(2.7) in the framework of functions  $u$  of class  $C^1$ . Let us briefly explain how to adapt these proofs in order to get, for example, the existence of a solution  $u \in C^0([0, T], H^2((0, 1), \mathbb{R}^n))$  to the Cauchy problem (2.5)–(2.7) if  $m = n$  (just to simplify the notation), for  $T \in (0, +\infty)$  given, and for every  $u^0 \in H^2((0, 1), \mathbb{R}^n)$  satisfying the compatibility conditions (2.8)–(2.9) (when  $m = n$ , condition (2.10) disappears) and such that  $|u^0|_{H^2((0, 1), \mathbb{R}^n)}$  is small enough (the smallness depending on  $T$  in general). We first deal with the case where

$$T \in (0, \min\{\Lambda_1^{-1}, \dots, \Lambda_n^{-1}\}).$$

The basic ingredient is the following fixed point method, which is related to the one given in [15, page 97] (see also the pioneering works [12] and [13, pp. 2–3], where the authors deal with  $\mathbb{R}$  instead of  $[0, 1]$ ). For  $R > 0$  and for  $u^0 \in H^2((0, 1), \mathbb{R}^n)$  satisfying the compatibility conditions (2.8)–(2.9), let  $C_R(u^0)$  be the set of

$$u \in L^\infty((0, T), H^2((0, 1), \mathbb{R}^n)) \cap W^{1, \infty}((0, T), H^1((0, 1), \mathbb{R}^n)) \\ \cap W^{2, \infty}((0, T), L^2((0, 1), \mathbb{R}^n))$$

such that

$$|u|_{L^\infty((0, T), H^2((0, 1), \mathbb{R}^n))} \leq R, \\ |u|_{W^{1, \infty}((0, T), H^1((0, 1), \mathbb{R}^n))} \leq R, \\ |u|_{W^{2, \infty}((0, T), L^2((0, 1), \mathbb{R}^n))} \leq R, \\ u(\cdot, 1) \in H^2((0, T), \mathbb{R}^n) \text{ and } |u(\cdot, 1)|_{H^2((0, T), \mathbb{R}^n)} \leq R^2, \\ u(0, \cdot) = u^0, \\ u_t(0, \cdot) = -F(u^0)u_x^0.$$

The set  $C_R(u^0)$  is a closed subset of  $L^\infty((0, T), L^2((0, 1), \mathbb{R}^n))$  (at least if  $|u^0|_{H^2((0, 1), \mathbb{R}^n)}$  is small enough so that  $|u^0|_{C^0([0, 1], \mathbb{R}^n)} < \varepsilon_0$ ). Given  $R > 0$ , the set  $C_R(u^0)$  is not empty if  $|u^0|_{H^2((0, 1), \mathbb{R}^n)}$  is small enough. Let  $\mathcal{F} : C_R(u^0) \rightarrow L^\infty((0, T), H^2((0, 1), \mathbb{R}^n)) \cap W^{1, \infty}((0, T), H^1((0, 1), \mathbb{R}^n)) \cap W^{2, \infty}((0, T), L^2((0, 1), \mathbb{R}^n))$  be defined by  $\mathcal{F}(\tilde{u}) = u$ , where  $u$  is the solution of the linear hyperbolic Cauchy problem

$$(2.11) \quad u_t + F(\tilde{u})u_x = 0, \quad u(t, 0) = G(\tilde{u}(t, 1)), \quad t \in [0, T],$$

$$u(0, x) = u^0(x), \quad x \in [0, 1].$$

The set  $C_R(u^0)$  is a closed subset of  $L^\infty((0, T), L^2((0, 1), \mathbb{R}^n))$  (at least if  $|u^0|_{H^2((0, 1), \mathbb{R}^n)}$  is small enough so that  $|u^0|_{L^\infty((0, 1), \mathbb{R}^n)} \leq \varepsilon_0/2$ ). Moreover, given  $R > 0$ ,  $C_R(u^0)$  is not empty if  $|u^0|_{H^2((0, 1), \mathbb{R}^n)}$  is small enough. Using standard energy estimates and the finite speed of propagation inherent in (2.11), one gets the existence of  $M > 0$  and  $R_0 > 0$  such that, for every  $R \in (0, R_0]$ , there exists  $\delta > 0$  such that, for every  $u^0 \in H^2((0, 1), \mathbb{R}^n)$  such that  $|u^0|_{H^2((0, 1), \mathbb{R}^n)} \leq \delta$  and satisfying the compatibility conditions (2.8)–(2.9),

$$(2.12) \quad \mathcal{F}(C_R(u^0)) \subset C_R(u^0)$$

and

$$\begin{aligned} & |\mathcal{F}(\tilde{u}_2) - \mathcal{F}(\tilde{u}_1)|_{L^\infty((0, T), L^2((0, 1), \mathbb{R}^n))} + M|\mathcal{F}(\tilde{u}_2)(\cdot, 1) - \mathcal{F}(\tilde{u}_1)(\cdot, 1)|_{L^2((0, 1), \mathbb{R}^n)} \\ & \leq \frac{1}{2}|\tilde{u}_2 - \tilde{u}_1|_{L^\infty((0, T), L^2((0, 1), \mathbb{R}^n))} + \frac{M}{2}|\tilde{u}_2(\cdot, 1) - \tilde{u}_1(\cdot, 1)|_{L^2((0, 1), \mathbb{R}^n)} \quad \forall (\tilde{u}_1, \tilde{u}_2) \in C_R(u^0). \end{aligned}$$

This allows us to prove that  $\mathcal{F}$  has a fixed point  $u \in C_R(u^0)$ ; i.e., there exists a solution  $u \in C_R(u^0)$  to the Cauchy problem (2.5)–(2.7). In order to get the extra regularity property  $u \in C^0([0, T], H^2((0, 1), \mathbb{R}^n))$ , one can adapt [16, pp. 44–46] by noticing that, when one uses usual energy estimates to get (2.12), one also gets, for  $u := \mathcal{F}(\tilde{u})$  with  $\tilde{u} \in C_R(u^0)$ , the “hidden regularity”  $u_{xx}(\cdot, 1) \in L^2((0, T), \mathbb{R}^n)$  together with estimates on  $|u_{xx}(\cdot, 1)|_{L^2((0, T), \mathbb{R}^n)}$  which are sufficient to take care of the boundary terms which now appear when one does integrations by parts. The case of general  $T \in (0 + \infty)$  follows by applying the above result to  $[0, T_1], [T_1, 2T_1], [2T_1, 3T_1], \dots$ , with  $T_1$  given in  $(0, \min\{\Lambda_1^{-1}, \dots, \Lambda_n^{-1}\})$ . This concludes our sketch of the proof of Proposition 2.1.

We adopt the following definition of the exponential stability of the equilibrium solution  $u \equiv 0$ .

**DEFINITION 2.2.** *The equilibrium solution  $u \equiv 0$  of the nonlinear hyperbolic system (2.5)–(2.6) is exponentially stable (for the  $H^2$ -norm) if there exist  $\varepsilon > 0$ ,  $\nu > 0$ , and  $C > 0$  such that, for every  $u^0 \in H^2((0, 1), \mathbb{R}^n)$  satisfying  $|u^0|_{H^2((0, 1), \mathbb{R}^n)} \leq \varepsilon$  and the compatibility conditions (2.8)–(2.10), the classical solution  $u$  to the Cauchy problem (2.5)–(2.7) is defined on  $[0, +\infty)$  and satisfies*

$$(2.13) \quad |u(t, \cdot)|_{H^2((0, 1), \mathbb{R}^n)} \leq Ce^{-\nu t}|u_0|_{H^2((0, 1), \mathbb{R}^n)} \quad \forall t \in [0, +\infty).$$

Our main result is the following theorem.

**THEOREM 2.3.** *If  $\rho_1(G'(0)) < 1$ , then the equilibrium  $u \equiv 0$  of the quasi-linear hyperbolic system (2.5)–(2.6) is exponentially stable.*

The proof of this theorem is given in section 4.

As mentioned in the introduction, the next section is devoted to a comparison of our dissipative boundary condition (i.e.,  $\rho_1(G'(0)) < 1$ ) with other stability criteria from the literature, namely the criterion given in [14, Theorem 1.3, page 173] and a stability criterion for linear hyperbolic systems.

**3. Comparison with other stability conditions.** In this section, we first compare our condition  $\rho_1(G'(0)) < 1$  for exponential stability (Theorem 2.3) with a prior condition found by Li [14, Theorem 1.3, page 173]. In the second part of this section we shall compare our condition to conditions for the stability of *linear* hyperbolic systems.

**3.1. Comparison with the Li condition.** Let us first introduce some notation and definitions. For  $K \in \mathcal{M}_{n,m}(\mathbb{R})$ , we denote by  $K_{ij}$  the term on the  $i$ th line and  $j$ th column of the matrix  $K$  and denote by  $|K|$  the matrix in  $\mathcal{M}_{n,m}(\mathbb{R})$  defined by

$$|K|_{ij} := |K_{ij}| \quad \forall i \in \{1, \dots, n\}, \forall j \in \{1, \dots, m\}.$$

We define, for  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ ,

$$R_2(K) := \text{Max} \left\{ \sum_{j=1}^n |K_{ij}|; i \in \{1, \dots, n\} \right\},$$

$$\rho_2(K) := \text{Inf} \{R_2(\Delta K \Delta^{-1}); \Delta \in \mathcal{D}_{n,+}\}.$$

Note that, by [14, Lemma 2.4, page 146],

$$(3.1) \quad \rho_2(K) = \rho(|K|),$$

where, for  $A \in \mathcal{M}_{n,n}(\mathbb{R})$ ,  $\rho(A)$  is the spectral radius of  $A$ . In the following theorem, we recall the sufficient condition for exponential stability introduced by Li.

**THEOREM 3.1** (see [14, Theorem 1.3, page 173]). *Assume that  $\rho_2(G'(0)) < 1$ ; then  $0 \in C^1([0, 1], \mathbb{R}^n)$  is locally exponentially stable in the  $C^1([0, 1])$ -norm for the hyperbolic system (2.5)–(2.6); i.e., there exist  $\varepsilon > 0$ ,  $\nu > 0$ , and  $C > 0$  such that, for every  $u^0 \in C^1([0, 1], \mathbb{R}^n)$  satisfying  $|u^0|_{C^1([0, 1], \mathbb{R}^n)} \leq \varepsilon$  and the compatibility conditions (2.8)–(2.10), the Cauchy problem (2.5)–(2.7) has a unique solution  $u$  in  $C^1([0, +\infty) \times [0, 1], \mathbb{R}^n)$ , and this solution satisfies*

$$|u(t, \cdot)|_{C^1([0, 1], \mathbb{R}^n)} \leq C e^{-\nu t} |u^0|_{C^1([0, 1], \mathbb{R}^n)} \quad \forall t \in [0, +\infty).$$

The following proposition and (3.3) show that our new sufficient condition, namely  $\rho_1(G'(0)) < 1$ , is weaker than the previous one.

**PROPOSITION 3.2.** *For every  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ ,*

$$(3.2) \quad \rho_1(K) \leq \rho_2(K).$$

Let us point out that there are matrices  $K$  such that inequality (3.2) is strict. For example, for  $a > 0$ , let

$$K_a := \begin{pmatrix} a & a \\ -a & a \end{pmatrix} \in \mathcal{M}_{2,2}(\mathbb{R}).$$

Then

$$(3.3) \quad \rho_1(K_a) = \sqrt{2}a < 2a = \rho_2(K_a).$$

**Remark 3.3.** In fact, in [14, Theorem 1.3, page 173], it is assumed that  $G_+$  depends only on  $u_-$  and that  $G_-$  depends only on  $u_+$ . However, if one takes

$$K := \begin{pmatrix} 0 & K_a \\ K_a & 0 \end{pmatrix} \in \mathcal{M}_{4,4}(\mathbb{R}),$$

$n = 4$ ,  $m = 2$ , and  $G(u) := Ku$ , which are allowed by the type of boundary conditions considered in [14, Theorem 1.3, page 173], one again gets  $\rho_1(K) = \sqrt{2}a < 2a = \rho_2(K)$ .

*Proof of Proposition 3.2.* Let us first prove the following lemma.

LEMMA 3.4. *For every  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ , for every  $D \in \mathcal{D}_{n,+}$ , for every  $\Delta \in \mathcal{D}_{n,+}$ , for every  $X \in \mathbb{R}^n$ , and for every  $Y \in \mathbb{R}^n$ ,*

$$(3.4) \quad Y^{\text{tr}} \Delta K \Delta^{-1} X \leq \frac{1}{2} R_2(D \Delta^{-1} K^{\text{tr}} \Delta D^{-1}) |X|^2 + \frac{1}{2} R_2(D \Delta K \Delta^{-1} D^{-1}) |Y|^2.$$

*Proof of Lemma 3.4.* Replacing, if necessary,  $K$  by  $\Delta K \Delta^{-1}$ , we may assume without loss of generality that  $\Delta$  is the identity map of  $\mathbb{R}^n$ . We write  $X := (X_1, \dots, X_n)^{\text{tr}} \in \mathbb{R}^n$ ,  $Y := (Y_1, \dots, Y_n)^{\text{tr}} \in \mathbb{R}^n$ ,  $D := \text{diag}(D_1, \dots, D_n)$ . One has

$$(3.5) \quad \begin{aligned} Y^{\text{tr}} K X &= \sum_{i=1}^n Y_i \left( \sum_{j=1}^n K_{ij} X_j \right) = \sum_{i=1}^n \sum_{j=1}^n \frac{K_{ij}}{D_i D_j} D_i Y_i D_j X_j \\ &\leq \frac{1}{2} Q_1 + \frac{1}{2} Q_2, \end{aligned}$$

with

$$Q_1 := \sum_{i=1}^n \sum_{j=1}^n \frac{|K_{ij}|}{D_i D_j} D_j^2 X_j^2 \text{ and } Q_2 := \sum_{i=1}^n \sum_{j=1}^n \frac{|K_{ij}|}{D_i D_j} D_i^2 Y_i^2.$$

Note that

$$(3.6) \quad \begin{aligned} Q_1 &= \sum_{j=1}^n \left( \sum_{i=1}^n |K_{ij}| D_i^{-1} D_j \right) X_j^2 = \sum_{j=1}^n \left( \sum_{i=1}^n |(D^{-1} K D)^{\text{tr}}|_{ji} \right) X_j^2 \\ &\leq \sum_{j=1}^n R_2((D^{-1} K D)^{\text{tr}}) X_j^2 = R_2(D K^{\text{tr}} D^{-1}) |X|^2. \end{aligned}$$

Similarly,

$$(3.7) \quad \begin{aligned} Q_2 &= \sum_{i=1}^n \left( \sum_{j=1}^n D_i |K_{ij}| D_j^{-1} \right) Y_i^2 = \sum_{i=1}^n \left( \sum_{j=1}^n |(D K D^{-1})_{ij}| \right) Y_i^2 \\ &\leq \sum_{i=1}^n R_2(D K D^{-1}) Y_i^2 = R_2(D K D^{-1}) |Y|^2. \end{aligned}$$

Inequality (3.4) follows from (3.5), (3.6), and (3.7). This concludes the proof of Lemma 3.4.  $\square$

Let us go back to the proof of Proposition 3.2. One easily sees that

$$(3.8) \quad \{(D \Delta^{-1}, D \Delta); D \in \mathcal{D}_{n,+}, \Delta \in \mathcal{D}_{n,+}\} = \mathcal{D}_{n,+} \times \mathcal{D}_{n,+}.$$

Equality (3.8) implies that

$$(3.9) \quad \begin{aligned} &\rho_2(K^{\text{tr}}) + \rho_2(K) \\ &= \inf \{ R_2(D \Delta^{-1} K^{\text{tr}} \Delta D^{-1}) + R_2(D \Delta K \Delta^{-1} D^{-1}); D \in \mathcal{D}_{n,+}, \Delta \in \mathcal{D}_{n,+} \}. \end{aligned}$$

Using (3.1), we have

$$(3.10) \quad \rho_2(K^{\text{tr}}) = \rho(|K^{\text{tr}}|) = \rho(|K|^{\text{tr}}) = \rho(|K|) = \rho_2(K),$$

which, together with (3.9), gives

$$(3.11) \quad \inf \{R_2(D\Delta^{-1}|K|^{\text{tr}}\Delta D^{-1}) + R_2(D\Delta|K|\Delta^{-1}D^{-1}); D \in \mathcal{D}_{n,+}, \Delta \in \mathcal{D}_{n,+}\} \\ = 2\rho_2(K).$$

Finally, let us note that, for every  $\Delta$  in  $\mathcal{D}_{n,+}$ ,

$$(3.12) \quad \sup \{Y^{\text{tr}}\Delta K\Delta^{-1}X; X \in \mathbb{R}^n, Y \in \mathbb{R}^n, |X| = |Y| = 1\} = \|\Delta K\Delta^{-1}\| \geq \rho_1(K).$$

Proposition 3.2 follows from (3.4), (3.11), and (3.12).  $\square$

**3.2. Comparison with stability conditions for linear hyperbolic systems.** Replacing, if necessary,  $y(t, x)$  by

$$\begin{pmatrix} y_+(t, x) \\ y_-(t, 1-x) \end{pmatrix},$$

it may be assumed, without loss of generality, that the speeds of propagation  $\Lambda_i$  are all positive. More precisely we consider the special case of linear hyperbolic systems

$$(3.13) \quad y_t + \Lambda y_x = 0, \quad y(t, 0) = Ky(t, 1),$$

where

$$(3.14) \quad \Lambda := \text{diag}(\Lambda_1, \dots, \Lambda_n), \quad \text{with } \Lambda_i > 0 \quad \forall i \in \{1, \dots, n\}.$$

In order to avoid compatibility conditions, one can deal with the case where  $y(t, \cdot) \in L^2((0, 1), \mathbb{R}^n)$  (instead of  $y(t, \cdot) \in H^2((0, 1), \mathbb{R}^n)$ , as we consider above for the nonlinear hyperbolic system (2.5)–(2.6)). It is well known that the Cauchy problem associated with (3.13) is well posed in  $L^2((0, 1), \mathbb{R}^n)$ ; that is, for every  $y^0 \in L^2((0, 1), \mathbb{R}^n)$ , there exists a unique

$$y \in C^0([0, +\infty), L^2((0, 1), \mathbb{R}^n))$$

solution of (3.13) satisfying the initial condition

$$(3.15) \quad y(0, \cdot) = y^0.$$

Of course, (3.13) has to be understood in the classical weak sense; i.e., for every  $\varphi \in C^1([0, +\infty) \times [0, 1]; \mathbb{R}^n)$  with compact support and satisfying

$$\varphi^{\text{tr}}(t, 1)\Lambda - \varphi_+^{\text{tr}}(t, 0)\Lambda K = 0 \quad \forall t \in [0, +\infty),$$

we have

$$\int_0^{+\infty} \int_0^1 (\varphi_t^{\text{tr}} + \varphi_x^{\text{tr}}\Lambda) y dx dt + \int_0^1 \varphi^{\text{tr}}(0, x) y^0(x) dx = 0.$$

See, for example, [5, section 2.1].

As usual, we say that  $0 \in L^2((0, 1), \mathbb{R}^n)$  is exponentially stable for (3.13) (for the norm of  $L^2((0, 1), \mathbb{R}^n)$ ) if there exist  $\nu > 0$  and  $C > 0$  such that, for every  $y^0 \in L^2((0, 1), \mathbb{R}^n)$ , the solution of the Cauchy problem (3.13), (3.15) satisfies

$$|y(t, \cdot)|_{L^2((0, 1), \mathbb{R}^n)} \leq C e^{-\nu t} |y^0|_{L^2((0, 1), \mathbb{R}^n)} \quad \forall t \in [0, +\infty).$$

One easily checks that (3.13) is equivalent to

$$(3.16) \quad \phi_i(t) = \sum_{j=1}^n K_{ij} \phi_j(t - r_j) \quad \forall i \in \{1, \dots, n\},$$

with

$$\phi_j(t) := y_j(t, 0), \quad r_j := \frac{1}{\Lambda_j}, \quad j \in \{1, \dots, n\}.$$

Hence (3.13) can be considered as a linear time-delay system. By a classical result on linear time-delay systems (see, e.g., [10, Theorem 3.5 page 275] by Hale and Verduyn Lunel),  $0 \in L^2((0, 1), \mathbb{R}^n)$  is exponentially stable for the system (3.13) if and only if there exists  $\delta > 0$  such that

$$(3.17) \quad \left( \det (\text{Id}_n - (\text{diag} (e^{-r_1 z}, \dots, e^{-r_n z})) K) = 0, z \in \mathbb{C} \right) \Rightarrow (\Re(z) \leq -\delta),$$

where  $\text{Id}_n$  is the identity map of  $\mathbb{R}^n$  and  $\Re(z)$  denotes the real part of the complex number  $z$ . Note that  $\rho_1(K) < 1$  implies the existence of  $\delta > 0$  such that (3.17) holds. Indeed, let us assume that  $\rho_1(K) < 1$ . Then, by (2.1), there exist  $\mu \in (0, 1)$  and  $D \in \mathcal{D}_{n,+}$  such that

$$(3.18) \quad \|DKD^{-1}\| \leq \mu.$$

Let us assume that  $z \in \mathbb{C}$  is such that

$$\det (\text{Id}_n - (\text{diag} (e^{-r_1 z}, \dots, e^{-r_n z})) K) = 0.$$

Then

$$\begin{aligned} & \det (\text{Id}_n - (\text{diag} (e^{-r_1 z}, \dots, e^{-r_n z})) DKD^{-1}) \\ &= \det (D(\text{Id}_n - (\text{diag} (e^{-r_1 z}, \dots, e^{-r_n z})) K)D^{-1}) \\ &= \det (\text{Id}_n - (\text{diag} (e^{-r_1 z}, \dots, e^{-r_n z})) K) = 0, \end{aligned}$$

which implies that

$$(3.19) \quad \|(\text{diag} (e^{-r_1 z}, \dots, e^{-r_n z})) DKD^{-1}\| \geq 1.$$

Since

$$\begin{aligned} \|(\text{diag} (e^{-r_1 z}, \dots, e^{-r_n z})) DKD^{-1}\| &\leq \|\text{diag} (e^{-r_1 z}, \dots, e^{-r_n z})\| \|DKD^{-1}\| \\ &\leq e^{-\min\{r_1 \Re(z), \dots, r_n \Re(z)\}} \|DKD^{-1}\|, \end{aligned}$$

one has, also using (3.18) and (3.19),

$$(3.20) \quad e^{-\min\{r_1 \Re(z), \dots, r_n \Re(z)\}} \mu \geq 1.$$

Inequality (3.20) implies that (3.17) holds with  $\delta := \ln(\mu)/(\max\{r_1, \dots, r_n\}) < 0$ .

The converse is false: the existence of  $\delta > 0$  such that (3.17) holds does not imply that  $\rho_1(K) < 1$ . For example, let us choose  $r_1 := 1$ ,  $r_2 := 2$ , and

$$K := \begin{pmatrix} a & a \\ a & a \end{pmatrix}, \quad a \in \mathbb{R}.$$

(This example is borrowed from [10, page 285].) It is easily seen that  $\rho_1(K) = 2|a|$ . Hence  $\rho_1(K) < 1$  is equivalent to  $a \in (-1/2, 1/2)$ . However, the existence of  $\delta > 0$  such that (3.17) holds is equivalent to  $a \in (-1, 1/2)$ .

If we want to try to apply results on the stability of the linear hyperbolic system (3.13) in order to get the stability of our nonlinear hyperbolic system (2.5)–(2.6), since  $F(u)$  depends on  $u$ , it is natural to ask for the robustness of the stability of the linear hyperbolic system (3.13) with respect to small changes on the  $\Lambda_i$ 's, i.e., on the speeds of propagation. (One can easily see that the stability is robust with respect to small changes on  $K$ .) Let us adopt the following definition.

**DEFINITION 3.5.** *The linear system (3.13) is robustly exponentially stable with respect to the speeds of propagation if there exists  $\varepsilon > 0$  such that, for every  $\tilde{\Lambda} := \text{diag}(\tilde{\Lambda}_1, \dots, \tilde{\Lambda}_n) \in \mathcal{D}_{n,+}$  such that*

$$|\tilde{\Lambda}_i - \Lambda_i| \leq \varepsilon \quad \forall i \in \{1, \dots, n\},$$

*$0 \in L^2((0, 1), \mathbb{R}^n)$  is exponentially stable for the perturbed linear hyperbolic system*

$$y_t + \tilde{\Lambda} y_x = 0, \quad y(t, 0) = K y(t, 1).$$

One has, then, the following theorem, which is due to Silkowski (see [10, Theorem 6.1, page 286]; see also [26, 11]).

**THEOREM 3.6.** *Let*

$$(3.21) \quad \rho_0(K) := \max\{\rho(\text{diag}(e^{\iota\theta_1}, \dots, e^{\iota\theta_n})K); (\theta_1, \dots, \theta_n)^{\text{tr}} \in \mathbb{R}^n\},$$

*with  $\iota := \sqrt{-1}$ . If the  $(r_1, \dots, r_n)$  are rationally independent, the linear system (3.13) is exponentially stable if and only if  $\rho_0(K) < 1$ . In particular (note that  $\rho_0(K)$  depends continuously on  $K$ ), whatever  $(r_1, \dots, r_n) \in (0, +\infty)^n$  is, the linear system (3.13) is robustly exponentially stable with respect to the speeds of propagation if and only if  $\rho_0(K) < 1$ .*

From this theorem the interest of comparing  $\rho_0(K)$  and  $\rho_1(K)$  is clear. This is done in the following proposition.

**PROPOSITION 3.7.** *For every  $n \in \mathbb{N}$  and for every  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ ,*

$$(3.22) \quad \rho_0(K) \leq \rho_1(K).$$

*For every  $n \in \{1, 2, 3, 4, 5\}$  and for every  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ ,*

$$(3.23) \quad \rho_0(K) = \rho_1(K).$$

*For every  $n \in \mathbb{N} \setminus \{1, 2, 3, 4, 5\}$ , there exists  $K \in \mathcal{M}_{n,n}(\mathbb{R})$  such that*

$$(3.24) \quad \rho_0(K) < \rho_1(K).$$

The proof of Proposition 3.7 is given in Appendix B.

**4. Proof of Theorem 2.3.** For the clarity of the analysis, we first deal in detail with the case where  $m = n$  and then give only the main modifications to deal with the case  $m < n$ . When  $m = n$  the boundary condition (2.6) reads

$$(4.1) \quad u(t, 0) = G(u(t, 1)), \quad t \in [0, +\infty),$$

and the compatibility conditions (2.8)–(2.10) become

$$(4.2) \quad u^0(0) = G(u^0(1)),$$

$$(4.3) \quad F(u^0(0))u_x^0(0) = G'(u^0(1))F(u^0(1))u_x^0(1).$$

Let us introduce some simplifying notation,

$$(4.4) \quad \Lambda := F(0) \in \mathcal{D}_{n,+}, \quad K := G'(0), \quad v := u_x, \quad w := v_x = u_{xx},$$

and let us denote by  $\mathcal{S}_n$  the set of  $n \times n$  real symmetric matrices and by  $\mathcal{S}_{n,+}$  the set of  $n \times n$  real symmetric positive definite matrices.

We shall repeatedly use the following lemma.

**LEMMA 4.1.** *Let  $\Lambda := \text{diag}(\Lambda_1, \dots, \Lambda_n) \in \mathcal{D}_n$  be such that (2.4) holds. Let  $\Delta \in \mathcal{D}_n$ . Then there exist a positive real number  $\eta$  and a map  $N : \{M \in \mathcal{M}_{n,n}(\mathbb{R}); \|M - \Lambda\| < \eta\} \rightarrow \mathcal{S}_n$  of class  $C^\infty$  such that*

$$N(\Lambda) = \Delta,$$

$$N(M)M - M^{\text{tr}}N(M) = 0 \quad \forall M \in \mathcal{M}_{n,n}(\mathbb{R}) \text{ such that } \|M - \Lambda\| < \eta.$$

*Proof of Lemma 4.1.* Let  $\mathcal{A}_n$  be the set of matrices  $A \in \mathcal{M}_{n,n}(\mathbb{R})$  such that  $A^{\text{tr}} = -A$ . For  $M \in \mathcal{M}_{n,n}(\mathbb{R})$ , let us consider the following linear map:

$$\begin{aligned} \mathcal{L}_M : \mathcal{S}_n &\rightarrow \mathcal{A}_n \times \mathcal{D}_n, \\ S &\mapsto (SM - M^{\text{tr}}S, \text{Diag}(S)), \end{aligned}$$

where  $\text{Diag}(S) := \text{diag}(S_{11}, \dots, S_{nn})$ . Noticing that

$$S\Lambda - \Lambda^{\text{tr}}S = (\Lambda_j - \Lambda_i)S_{ij} \quad \forall i \in \{1, \dots, n\}, \forall j \in \{1, \dots, n\}, \forall S \in \mathcal{S}_n$$

and using (2.4), it is easily checked that  $\mathcal{L}_\Lambda : \mathcal{S}_n \rightarrow \mathcal{A}_n \times \mathcal{D}_n$  is an isomorphism. Hence there exists  $\eta > 0$  such that, for every  $M \in \mathcal{M}_{n,n}(\mathbb{R})$  such that  $\|M - \Lambda\| < \eta$ ,  $\mathcal{L}_M$  is an isomorphism. It then suffices to define  $N$  by

$$N(M) = \mathcal{L}_M^{-1}(0, \Delta).$$

This concludes the proof of Lemma 4.1.  $\square$

For the stability analysis, we now introduce the Lyapunov function candidate

$$(4.5) \quad V(u, v, w) = V_1(u) + V_2(u, v) + V_3(u, v, w),$$

with

$$(4.6) \quad V_1(u) = \int_0^1 u^{\text{tr}} Q(u) u e^{-\mu x} dx,$$

$$(4.7) \quad V_2(u, v) = \int_0^1 v^{\text{tr}} R(u) v e^{-\mu x} dx,$$

$$(4.8) \quad V_3(u, v, w) = \int_0^1 w^{\text{tr}} S(u) w e^{-\mu x} dx,$$

where  $\mu > 0$ ,  $Q(u)$ ,  $R(u)$ , and  $S(u)$  are symmetric positive definite matrices which will be defined later.

*Remark 4.2.* The weight  $e^{-\mu x}$  is essential to get a strict Lyapunov function. It is similar to the one introduced in [4] to stabilize the Euler equation of incompressible fluids (see the definition of  $V$  given on page 1886 of [4]). It has also been used by Xu and Sallet in [24] for quite general linear hyperbolic systems (see also [22] by Tchoussou, Besson, and Xu).

Let us compute the time derivative  $\dot{V}_1$  of  $V_1$  along the classical  $C^1$ -solutions of system (2.5) with boundary conditions (4.1). One has

$$\begin{aligned}\dot{V}_1 &= \int_0^1 \left\{ 2u^{\text{tr}} Q(u) u_t + u^{\text{tr}} (Q(u))_t u \right\} e^{-\mu x} dx \\ &= \int_0^1 \left\{ -2u^{\text{tr}} Q(u) F(u) u_x + u^{\text{tr}} [Q'(u) u_t] u \right\} e^{-\mu x} dx,\end{aligned}$$

where  $Q'(u)$  is the linear map from  $\mathbb{R}^n$  to  $\mathcal{S}_n$  which stands for the derivative of  $Q$  at the point  $u$ . Hence

$$(4.9) \quad \dot{V}_1 = \int_0^1 \left\{ -\left(u^{\text{tr}} Q(u) F(u) u\right)_x + u^{\text{tr}} (Q(u) F(u))_x u - u^{\text{tr}} [Q'(u) F(u) v] u \right\} e^{-\mu x} dx.$$

For  $f \in C^0([0, 1], \mathbb{R}^n)$ , we denote by  $|f|_0$  its  $C^0$ -norm:  $|f|_0 := \max\{|f(x)|; x \in [0, 1]\}$ . From now on,  $V_1$  and  $\dot{V}_1$  are considered as functionals defined, respectively, by (4.6) and (4.9) on the set  $\mathcal{V}_1$  of  $u \in C^1([0, 1], \mathbb{R}^n)$  satisfying  $|u|_0 < \varepsilon_0$  and the compatibility condition

$$(4.10) \quad u_0 = G(u_1),$$

with  $u_0 := u(0)$  and  $u_1 := u(1)$ .

Since  $\rho_1(K) < 1$  by assumption, there exists  $D \in \mathcal{D}_{n,+}$  such that  $\|DKD^{-1}\| < 1$ . The matrix  $Q(u)$  is selected as the matrix  $N(F(u))$  of Lemma 4.1 with  $\Delta := D^2 \Lambda^{-1}$ .

Our estimates on  $V_1$  and  $\dot{V}_1$  are in the following lemma.

**LEMMA 4.3.** *There exists  $\mu_1 > 0$  such that, for every  $\mu \in (0, \mu_1)$ , there exist positive real constants  $\alpha_1, \beta_1, \delta_1$  such that, for every  $u \in \mathcal{V}_1$  such that  $|u|_0 \leq \delta_1$ ,*

$$(4.11) \quad \frac{1}{\beta_1} \int_0^1 |u|^2 dx \leq V_1(u) \leq \beta_1 \int_0^1 |u|^2 dx,$$

$$(4.12) \quad \dot{V}_1(u) \leq -\alpha_1 V_1(u) + \beta_1 \int_0^1 |u|^2 |u_x| dx.$$

*Proof of Lemma 4.3.* Throughout this proof,  $u$  is assumed to be in  $\mathcal{V}_1$ . From the construction of  $Q$ ,

$$(4.13) \quad Q(0)F(0) = Q(0)\Lambda = D^2 \in \mathcal{D}_{n,+},$$

and there exists  $\delta_{11} \in (0, \varepsilon_0/2)$  such that

$$(4.14) \quad Q(a) \in \mathcal{S}_{n,+} \text{ and } Q(a)F(a) \in \mathcal{S}_{n,+} \quad \forall a \in \mathbb{R}^n \text{ such that } |a| \leq \delta_{11}.$$

Clearly, from (4.14), we obtain that, for every  $\mu > 0$ , there exists  $\beta_1 > 0$  such that (4.11) holds if  $|u|_0 \leq \delta_{11}$ .

Let us now deal with the estimate (4.12) on  $\dot{V}_1 (= \dot{V}_1(u))$ . Let us decompose  $\dot{V}_1$  in the following way:

$$(4.15) \quad \dot{V}_1 = \mathcal{T}_{11} + \mathcal{T}_{12} + \mathcal{T}_{13},$$

with

$$(4.16) \quad \mathcal{T}_{11} := -\mu \int_0^1 \left( u^{\text{tr}} Q(u) F(u) u \right) e^{-\mu x} dx,$$

$$(4.17) \quad \mathcal{T}_{12} := - \int_0^1 \left( u^{\text{tr}} Q(u) F(u) u e^{-\mu x} \right)_x dx,$$

$$(4.18) \quad \mathcal{T}_{13} := \int_0^1 \left\{ u^{\text{tr}} \left( [Q'(u)v] F(u) + Q(u) [F'(u)v] - [Q'(u)F(u)v] \right) u \right\} e^{-\mu x} dx.$$

*Analysis of the first term  $\mathcal{T}_{11}$ .* By (4.11) and (4.14), for every  $\mu > 0$ , there exists a positive real constant  $\alpha_1 > 0$  such that, if  $|u|_0 \leq \delta_{11}$ ,

$$(4.19) \quad \mathcal{T}_{11} \leq -\alpha_1 V_1.$$

*Analysis of the second term  $\mathcal{T}_{12}$ .* One has

$$\begin{aligned} \mathcal{T}_{12} &= - \left[ u^{\text{tr}} Q(u) F(u) u e^{-\mu x} \right]_0^1 \\ &= - \left( u_1^{\text{tr}} Q(u_1) F(u_1) u_1 e^{-\mu} - u_0^{\text{tr}} Q(u_0) F(u_0) u_0 \right). \end{aligned}$$

Let us introduce a notation in order to deal with estimates on “higher order terms.” We denote by  $\mathcal{O}(X, Y)$ , with  $X \geq 0$  and  $Y \geq 0$ , quantities such that there exist  $C > 0$  and  $\varepsilon > 0$ , independent of  $u, v$  and  $w$ , satisfying

$$(Y \leq \varepsilon) \Rightarrow (|\mathcal{O}(X, Y)| \leq CX).$$

Using the compatibility condition (4.10), we have

$$\begin{aligned} \mathcal{T}_{12} &= - \left( u_1^{\text{tr}} Q(u_1) F(u_1) u_1 e^{-\mu} - (G(u_1))^{\text{tr}} Q(G(u_1)) F(G(u_1)) G(u_1) \right) \\ (4.20) \quad &= -u_1^{\text{tr}} \left( Q(0) \Lambda e^{-\mu} - K^{\text{tr}} Q(0) \Lambda K \right) u_1 + \mathcal{O}(|u_1|^3; |u_1|). \end{aligned}$$

For  $u_1 \in \mathbb{R}^n$ , we define  $\zeta := Du_1$ . Then, using (4.13), we have, for every  $u_1 \in \mathbb{R}^n$ ,

$$u_1^{\text{tr}} K^{\text{tr}} Q(0) \Lambda K u_1 = u_1^{\text{tr}} K^{\text{tr}} D D K u_1 = (\zeta^{\text{tr}} D^{-1} K^{\text{tr}} D) (D K D^{-1} \zeta) = |D K D^{-1} \zeta|^2.$$

Hence, using (4.13) once again, we have, for every  $u_1 \in \mathbb{R}^n$ ,

$$(4.21) \quad u_1^{\text{tr}} K^{\text{tr}} Q(0) \Lambda K u_1 \leq \|D K D^{-1}\|^2 \zeta^{\text{tr}} \zeta = \|D K D^{-1}\|^2 u_1^{\text{tr}} Q(0) \Lambda u_1.$$

From this inequality and the fact that  $\|D K D^{-1}\| < 1$ , it follows that, taking  $\mu > 0$  small enough (which is always implicitly assumed),  $Q(0) \Lambda e^{-\mu} - K^{\text{tr}} Q(0) \Lambda K$  is a

positive definite matrix. Then, using (4.20), there exists  $\delta_{12} > 0$  such that, if  $|u_1| \leq \delta_{12}$ ,

$$(4.22) \quad \mathcal{T}_{12} \leq 0.$$

*Analysis of the third term  $\mathcal{T}_{13}$ .* The integrand of  $\mathcal{T}_{13}$  is linear with respect to  $v$  and, at least, quadratic with respect to  $u$ . It follows that, increasing the value of  $\beta_1$  if necessary, there exists a real positive constant  $\delta_{13}$  such that, for  $|u|_0 \leq \delta_{13}$ ,

$$(4.23) \quad \mathcal{T}_{13} \leq \beta_1 \int_0^1 |u|^2 |v| dx.$$

Then, collecting inequalities (4.19), (4.22), and (4.23) together, if

$$|u|_0 \leq \delta_1 := \min\{\delta_{11}, \delta_{12}, \delta_{13}\},$$

we conclude that

$$(4.24) \quad \dot{V}_1 = \mathcal{T}_{11} + \mathcal{T}_{12} + \mathcal{T}_{13} \leq -\alpha_1 V_1 + \beta_1 \int_0^1 |u|^2 |v| dx.$$

This completes the proof of Lemma 4.3.  $\square$

From Lemma 4.3 it appears that it is clearly necessary to examine the dynamics of  $v = u_x$  in order to carry out the Lyapunov stability analysis. This is the reason why the Lyapunov function (4.5) is extended with terms involving  $v$ . By time differentiation of the system equations (2.5) and (4.1), it may be shown that  $v$  satisfies the dynamics

$$(4.25) \quad v_t + F(u)v_x + [F'(u)v]v = 0, \quad x \in [0, 1], \quad t \in [0, +\infty),$$

$$(4.26) \quad F(u(t, 0))v(t, 0) = G'(u(t, 1))F(u(t, 1))v(t, 1), \quad t \in [0, +\infty).$$

Let us compute the time derivative of  $V_2$  along the classical  $C^1$ -solutions of system (4.25) with boundary conditions (4.26). One has

$$(4.27) \quad \begin{aligned} \dot{V}_2 &= \int_0^1 \left\{ 2v^{\text{tr}} R(u)v_t + v^{\text{tr}} (R(u))_t v \right\} e^{-\mu x} dx \\ &= \int_0^1 \left\{ -2v^{\text{tr}} R(u)F(u)v_x - 2v^{\text{tr}} R(u)[F'(u)v]v - v^{\text{tr}} [R'(u)F(u)v]v \right\} e^{-\mu x} dx. \end{aligned}$$

From now on,  $V_2$  and  $\dot{V}_2$  are considered as functionals defined, respectively, by (4.7) and (4.27) on the set  $\mathcal{V}_2$  of  $(u, v) \in C^2([0, 1], \mathbb{R}^n) \times C^1([0, 1], \mathbb{R}^n)$  such that

$$(4.28) \quad |u|_0 < \varepsilon_0,$$

$$(4.29) \quad u_x = v,$$

$$(4.30) \quad u_0 = G(u_1),$$

$$(4.31) \quad F(u_0)v_0 = G'(u_1)F(u_1)v_1,$$

where  $u_0 := u(0)$ ,  $u_1 := u(1)$  as above, and  $v_0 := v(0)$ ,  $v_1 := v(1)$ .

The matrix  $R(u)$  is selected as the matrix  $N(F(u))$  of Lemma 4.1 now with  $\Delta := \Lambda D^2$ . Our estimates on  $V_2$  and  $\dot{V}_2$  are in the following lemma.

LEMMA 4.4. *There exists  $\mu_2 > 0$  such that, for every  $\mu \in (0, \mu_2)$ , there exist positive real constants  $\alpha_2, \beta_2, \delta_2$  such that, for every  $(u, v) \in \mathcal{V}_2$  such that  $|u|_0 \leq \delta_2$ ,*

$$(4.32) \quad \frac{1}{\beta_2} \int_0^1 |v|^2 dx \leq V_2(u, v) \leq \beta_2 \int_0^1 |v|^2 dx,$$

$$(4.33) \quad \dot{V}_2(u, v) \leq -\alpha_2(V_2(u, v) + |v_1|^2) + \beta_2 \int_0^1 |v|^3 dx.$$

*Proof of Lemma 4.4.* Throughout this proof,  $(u, v)$  is assumed to be in  $\mathcal{V}_2$ . By the construction of  $R$ , we have

$$(4.34) \quad F(0)^{-1}R(0) = \Lambda^{-1}R(0) = D^2 \in \mathcal{D}_{n,+}$$

and the existence of  $\delta_{21} \in (0, \varepsilon_0/2)$  such that

$$(4.35) \quad R(a) \in \mathcal{S}_{n,+} \text{ and } R(a)F(a) \in \mathcal{S}_{n,+} \quad \forall a \in \mathbb{R}^n \text{ such that } |a| \leq \delta_{21}.$$

Clearly, from (4.35), for every  $\mu > 0$ , there exists  $\beta_2 > 0$  such that (4.32) holds if  $|u|_0 \leq \delta_{21}$ .

Let us now deal with the estimate (4.33) on  $\dot{V}_2 (= \dot{V}_2(u, v))$ . Let us decompose  $\dot{V}_2$  in the following way:

$$(4.36) \quad \dot{V}_2 = \mathcal{T}_{21} + \mathcal{T}_{22} + \mathcal{T}_{23},$$

with

$$\mathcal{T}_{21} := -\mu \int_0^1 (v^{\text{tr}} R(u) F(u) v) e^{-\mu x} dx,$$

$$\mathcal{T}_{22} := - \int_0^1 (v^{\text{tr}} R(u) F(u) v e^{-\mu x})_x dx,$$

$$\mathcal{T}_{23} := \int_0^1 \left\{ v^{\text{tr}} \left( [(R(u)F(u))_x v] - 2R(u)[F'(u)v] - [R'(u)F(u)v] \right) v \right\} e^{-\mu x} dx.$$

*Analysis of the first term  $\mathcal{T}_{21}$ .* By (4.32) and (4.35), for every  $\mu > 0$ , there exists a positive real constant  $\alpha_{21} > 0$  such that, if  $|u|_0 \leq \delta_{21}$ ,

$$(4.37) \quad \mathcal{T}_{21} \leq -\alpha_{21} V_2.$$

*Analysis of the second term  $\mathcal{T}_{22}$ .* One has

$$\begin{aligned} \mathcal{T}_{22} &= - \left[ v^{\text{tr}} R(u) F(u) v e^{-\mu x} \right]_0^1 \\ &= - \left( v_1^{\text{tr}} R(u_1) F(u_1) v_1 e^{-\mu} - v_0^{\text{tr}} R(u_0) F(u_0) v_0 \right). \end{aligned}$$

Under the boundary condition (4.31), we have

$$\begin{aligned} \mathcal{T}_{22} &= -v_1^{\text{tr}} \left( R(u_1) F(u_1) e^{-\mu} - F(u_1)^{\text{tr}} (G'(u_1))^{\text{tr}} \right. \\ &\quad \left. (F(G(u_1))^{-1})^{\text{tr}} R(G(u_1)) G'(u_1) F(u_1) \right) v_1, \end{aligned}$$

which implies that

$$(4.38) \quad \mathcal{T}_{22} = -v_1^{\text{tr}} \left( R(0)\Lambda e^{-\mu} - \Lambda K^{\text{tr}} \Lambda^{-1} R(0) K \Lambda \right) v_1 + \mathcal{O}(|v_1|^2 |u_1|; |u_1|).$$

We define  $\zeta := Dv_1$ . Then, using (4.34), we have, for every  $v_1 \in \mathbb{R}^n$ ,

$$(4.39) \quad v_1^{\text{tr}} K^{\text{tr}} \Lambda^{-1} R(0) K v_1 = v_1^{\text{tr}} K^{\text{tr}} D D K v_1 = (\zeta^{\text{tr}} D^{-1} K^{\text{tr}} D) (D K D^{-1} \zeta) = |D K D^{-1} \zeta|^2.$$

Therefore, using (4.34) once again, we get that, for every  $v_1 \in \mathbb{R}^n$ ,

$$(4.40) \quad v_1^{\text{tr}} K^{\text{tr}} \Lambda^{-1} R(0) K v_1 \leq \|D K D^{-1}\|^2 \zeta^{\text{tr}} \zeta = \|D K D^{-1}\|^2 v_1^{\text{tr}} \Lambda^{-1} R(0) v_1.$$

From (4.40) and the fact that  $\|D K D^{-1}\| < 1$ , it follows that, choosing  $\mu > 0$  small enough,  $\Lambda^{-1} R(0) e^{-\mu} - K^{\text{tr}} \Lambda^{-1} R(0) K$  is a positive definite matrix, which, in turn, implies that the matrix  $R(0)\Lambda e^{-\mu} - \Lambda K^{\text{tr}} \Lambda^{-1} R(0) K \Lambda$  is also positive definite. Hence there exist  $\alpha_{22} > 0$  and  $\delta_{22} > 0$  such that, if  $|u_1| \leq \delta_{22}$ , we have

$$(4.41) \quad \mathcal{T}_{22} \leq -\alpha_{22} |v_1|^2.$$

*Analysis of the third term  $\mathcal{T}_{23}$ .* The integrand of  $\mathcal{T}_{23}$  is, at least, cubic with respect to  $v$ . It follows that, increasing the value of  $\beta_2$  if necessary, there exists  $\delta_{23} \in (0, \varepsilon_0/2)$  such that, for  $|u|_0 \leq \delta_{23}$ ,

$$(4.42) \quad \mathcal{T}_{23} \leq \beta_2 \int_0^1 |v|^3 dx.$$

Then, collecting inequalities (4.37), (4.41), and (4.42) together, we conclude that if  $|u|_0 \leq \delta_2 := \min\{\delta_{21}, \delta_{22}, \delta_{23}\}$  and if  $\alpha_2 := \min\{\alpha_{21}, \alpha_{22}\}$ , then

$$(4.43) \quad \dot{V}_2 = \mathcal{T}_{21} + \mathcal{T}_{22} + \mathcal{T}_{23} \leq -\alpha_2 (V_2 + |v_1|^2) + \beta_2 \int_0^1 |v|^3 dx.$$

This completes the proof of Lemma 4.4.  $\square$

Note that  $V_2$  is not sufficient to get an upper bound on  $\int_0^1 |v|^3 dx$ . For that reason, we also need to consider the dynamics of  $w$  to complete the Lyapunov stability analysis. By a further time differentiation of the system equations (4.25)–(4.26), we obtain

$$(4.44) \quad \begin{aligned} w_t + F(u)w_x + [F'(u)w]v + 2[F'(u)v]w + [F''(u)(v, v)]v &= 0, \\ x \in [0, 1], \quad t \in [0, +\infty), \end{aligned}$$

under the boundary condition

$$(4.45) \quad F(u_0)w_0 + [F'(u_0)v_0]v_0 = [H'(u_1)F(u_1)v_1]v_1 + H(u_1)F(u_1)w_1 + H(u_1)[F'(u_1)v_1]v_1,$$

with the notation  $w_0 := w(0)$ ,  $w_1 := w(1)$ , and  $H(u) := F(G(u))^{-1}G'(u)F(u)$ . Using the previous boundary conditions (4.30) and (4.31), this boundary condition (4.45) may be written in compact form as

$$(4.46) \quad w_0 = F(G(u_1))^{-1}H(u_1)F(u_1)w_1 + \mathcal{Z}(u_1, v_1),$$

where  $\mathcal{Z}$  is continuous on a neighborhood of  $0 \in \mathbb{R}^n \times \mathbb{R}^n$  and such that

$$(4.47) \quad \mathcal{Z}(u_1, v_1) = \mathcal{O}(|v_1|^2; |u_1|).$$

Let us compute the time derivative of  $V_3$  along the classical  $C^1$ -solutions of system (4.44) with boundary conditions (4.46). One has

$$(4.48) \quad \begin{aligned} \dot{V}_3 &= \int_0^1 \left\{ 2w^{\text{tr}} S(u) w_t + w^{\text{tr}} (S(u))_t w \right\} e^{-\mu x} dx \\ &= \int_0^1 \left\{ -2w^{\text{tr}} S(u) F(u) w_x - 2w^{\text{tr}} S(u) \left( [F'(u)w]v + 2[F'(u)v]w + [F''(u)(v, v)]v \right) \right. \\ &\quad \left. - w^{\text{tr}} [S'(u)F(u)v]w \right\} e^{-\mu x} dx. \end{aligned}$$

From now on,  $V_3$  and  $\dot{V}_3$  are considered as functionals defined, respectively, by (4.8) and (4.48) on the set  $\mathcal{V}_3$  of  $(u, v, w) \in C^3([0, 1], \mathbb{R}^n) \times C^2([0, 1], \mathbb{R}^n) \times C^1([0, 1], \mathbb{R}^n)$  such that

$$(4.49) \quad |u|_0 < \varepsilon_0,$$

$$(4.50) \quad u_x = v, \quad v_x = w,$$

$$(4.51) \quad u_0 = G(u_1),$$

$$(4.52) \quad F(u_0)v_0 = G'(u_1)F(u_1)v_1,$$

$$(4.53) \quad w_0 = F(G(u_1))^{-1}H(u_1)F(u_1)w_1 + \mathcal{Z}(u_1, v_1),$$

with  $u_0 := u(0)$ ,  $u_1 := u(1)$ ,  $v_0 := v(0)$ , and  $v_1 := v(1)$  as above, and  $w_0 := w(0)$  and  $w_1 := w(1)$ .

The matrix  $S(u)$  is selected as the matrix  $N(F(u))$  of Lemma 4.1 now with  $\Delta := \Lambda^2 D^2 \Lambda$ . Our estimates on  $V_3$  and  $\dot{V}_3$  are in the following lemma.

LEMMA 4.5. *There exists  $\mu_3 > 0$  such that, for every  $\mu \in (0, \mu_3)$ , there exist positive real constants  $\alpha_3, \beta_3, \delta_3$  such that, for every  $(u, v, w) \in \mathcal{V}_3$  such that  $|u|_0 + |v|_0 \leq \delta_3$ , one has*

$$(4.54) \quad \frac{1}{\beta_3} \int_0^1 |w|^2 dx \leq V_3(u, v, w) \leq \beta_3 \int_0^1 |w|^2 dx,$$

$$(4.55) \quad \dot{V}_3(u, v, w) \leq -\alpha_3 V_3(u, v, w) + \beta_3 |v_1|^4 + \beta_3 \int_0^1 (|v|^2 |w| + |w|^2 |v|) dx.$$

*Proof of Lemma 4.5.* Throughout this proof, we assume that  $(u, v, w) \in \mathcal{V}_3$ . By the construction of  $S$ , we have

$$(4.56) \quad \Lambda^{-2} S(0) \Lambda^{-1} = D^2 \in \mathcal{D}_{n,+}$$

and the existence of  $\delta_{31} \in (0, \varepsilon_0/2)$  such that

$$(4.57) \quad S(a) \in \mathcal{S}_{n,+} \text{ and } S(a)F(a) \in \mathcal{S}_{n,+} \quad \forall a \in \mathbb{R}^n \text{ such that } |u| \leq \delta_{31}.$$

Clearly, from (4.57), we obtain that, for every  $\mu > 0$ , there exists  $\beta_3 > 0$  such that (4.54) holds if  $|u|_0 \leq \delta_{31}$ .

Let us now deal with the estimate (4.55) on  $\dot{V}_3 (= \dot{V}_3(u, v, w))$ . Let us decompose  $\dot{V}_3$  in the following way:

$$(4.58) \quad \dot{V}_3 = \mathcal{T}_{31} + \mathcal{T}_{32} + \mathcal{T}_{33},$$

with

$$\begin{aligned} \mathcal{T}_{31} &:= -\mu \int_0^1 \left( w^{\text{tr}} S(u) F(u) w \right) e^{-\mu x} dx, \\ \mathcal{T}_{32} &:= - \int_0^1 \left( w^{\text{tr}} S(u) F(u) w e^{-\mu x} \right)_x dx, \\ \mathcal{T}_{33} &:= - \int_0^1 \left\{ -w^{\text{tr}} \left( [(S(u)F(u))_x v] + [S'(u)F(u)v] \right) w + 2w^{\text{tr}} S(u) [F'(u)w] v \right. \\ &\quad \left. + 4w^{\text{tr}} S(u) [F'(u)v] w + 2w^{\text{tr}} [F''(u)(v, v)] v \right\} e^{-\mu x} dx. \end{aligned}$$

*Analysis of the first term  $\mathcal{T}_{31}$ .* By (4.54) and (4.57), for every  $\mu > 0$ , there exists a positive real constant  $\alpha_3 > 0$  such that, if  $|u|_0 \leq \delta_{31}$ ,

$$(4.59) \quad \mathcal{T}_{31} \leq -\alpha_3 V_3.$$

*Analysis of the second term  $\mathcal{T}_{32}$ .*

$$\begin{aligned} \mathcal{T}_{32} &= - \left[ w^{\text{tr}} S(u) F(u) w e^{-\mu x} \right]_0^1 \\ &= - \left( w_1^{\text{tr}} S(u_1) F(u_1) w_1 e^{-\mu} - w_0^{\text{tr}} S(u_0) F(u_0) w_0 \right). \end{aligned}$$

Under the boundary conditions (4.51) and (4.53), we have, also using (4.47),

$$\begin{aligned} \mathcal{T}_{32} &= -w_1^{\text{tr}} \left( S(u_1) F(u_1) e^{-\mu} \right. \\ &\quad \left. - F(u_1)^{\text{tr}} H(u_1)^{\text{tr}} (F(G(u_1))^{-1})^{\text{tr}} S(G(u_1)) H(u_1) F(u_1) \right) w_1 \\ &\quad + \mathcal{O}(|v_1|^4 + |v_1|^2 |w_1|; |u_1|) \\ &= -w_1^{\text{tr}} \left( S(0) \Lambda e^{-\mu} - \Lambda^2 K^{\text{tr}} \Lambda^{-2} S(0) \Lambda^{-1} K \Lambda^2 \right) w_1 \\ &\quad + \mathcal{O}(|v_1|^4 + |v_1|^2 |w_1| + |w_1|^2 |u_1|; |u_1|). \end{aligned} \quad (4.60)$$

For  $w_1 \in \mathbb{R}^n$ , we define  $\zeta := Dw_1$ . Then, using (4.56), we have, for every  $w_1 \in \mathbb{R}^n$ ,

$$\begin{aligned} w_1^{\text{tr}} K^{\text{tr}} \Lambda^{-2} S(0) \Lambda^{-1} K w_1 &= w_1^{\text{tr}} K^{\text{tr}} D D K w_1 \\ &= (\zeta^{\text{tr}} D^{-1} K^{\text{tr}} D) (D K D^{-1} \zeta) = |D K D^{-1} \zeta|^2. \end{aligned}$$

Therefore, for every  $w_1 \in \mathbb{R}^n$ , we have, using (4.56) once again,

$$w_1^{\text{tr}} K^{\text{tr}} \Lambda^{-2} S(0) \Lambda^{-1} K w_1 \leq \|D K D^{-1}\|^2 \zeta^{\text{tr}} \zeta = \|D K D^{-1}\|^2 w_1^{\text{tr}} \Lambda^{-2} S(0) \Lambda^{-1} w_1.$$

From this inequality and the fact that  $\|DKD^{-1}\|^2 < 1$ , it follows that, choosing  $\mu > 0$  small enough,  $\Lambda^{-2}S(0)\Lambda^{-1}e^{-\mu} - K^{\text{tr}}\Lambda^{-2}S(0)\Lambda^{-1}K$  is a positive definite symmetric matrix, which, in turn, implies that the matrix

$$(4.61) \quad S(0)\Lambda e^{-\mu} - \Lambda^2 K^{\text{tr}} \Lambda^{-2} S(0) \Lambda^{-1} K \Lambda^2$$

is also positive definite. Moreover, for every  $\eta > 0$  and for every  $(v_1, w_1) \in \mathbb{R}^n \times \mathbb{R}^n$ ,

$$|v_1|^2 |w_1| \leq \frac{1}{4\eta} |v_1|^4 + \eta |w_1|^2.$$

Hence, taking  $\eta > 0$  small enough and also using (4.60), one gets the existence of  $\delta_{32} > 0$  and  $\beta_{32} > 0$  such that, if  $|u|_0 + |v|_0 \leq \delta_{32}$ ,

$$(4.62) \quad \mathcal{T}_{32} \leq \beta_{32} |v_1|^4.$$

*Analysis of the third term  $\mathcal{T}_{33}$ .* Note that

$$(F(u)G(u))_x = [F'(u)v]G(u) + F(u)G'(u)v.$$

It follows that there exist  $\delta_{33} > 0$  and  $\beta_{33} > 0$  such that, if  $|u|_0 + |v|_0 \leq \delta_{33}$ , then

$$(4.63) \quad \mathcal{T}_{33} \leq \beta_{33} \int_0^1 (|v|^2 |w| + |w|^2 |v|) dx.$$

Then, collecting inequalities (4.59), (4.62), and (4.63) together, we conclude that if  $|u|_0 + |v|_0 \leq \delta_3 := \min\{\delta_{31}, \delta_{32}, \delta_{33}\}$  and  $\beta_3 := \max\{\beta_{32}, \beta_{33}\}$ , then

$$(4.64) \quad \dot{V}_3 = \mathcal{T}_{31} + \mathcal{T}_{32} + \mathcal{T}_{33} \leq -\alpha_3 V_3 + \beta_3 |v_1|^4 + \beta_3 \int_0^1 (|v|^2 |w| + |w|^2 |v|) dx.$$

This completes the proof of Lemma 4.5.  $\square$

Finally, we deal with  $V$  (see (4.5)) and  $\dot{V}$ , which are now considered as functionals on the set  $\mathcal{V}$  of  $u \in C^3([0, 1], \mathbb{R}^n)$  satisfying (4.49), (4.51), (4.52), and (4.53) with  $v := u_x$  and  $w := u_{xx}$ ,  $u_0 := u(0)$ ,  $u_1 := u(1)$ ,  $v_0 := u_x(0)$ ,  $v_1 := u_x(1)$ ,  $w_0 := u_{xx}(0)$ , and  $w_1 := u_{xx}(1)$ . Of course, we “define”  $\dot{V}$  by  $\dot{V}(u) := \dot{V}_1(u) + \dot{V}_2(u, u_x) + \dot{V}_3(u, u_x, u_{xx})$ . The following lemma holds.

LEMMA 4.6. *Let  $\mu \in (0, \min\{\mu_1, \mu_2, \mu_3\})$ . There exist positive real constants  $\alpha$ ,  $\beta$ , and  $\delta$  such that, for every  $u \in \mathcal{V}$  such that  $|u|_0 + |u_x|_0 \leq \delta$ , we have*

$$(4.65) \quad \frac{1}{\beta} \int_0^1 (|u|^2 + |u_x|^2 + |u_{xx}|^2) dx \leq V(u) \leq \beta \int_0^1 (|u|^2 + |u_x|^2 + |u_{xx}|^2) dx,$$

$$(4.66) \quad \dot{V} \leq -\alpha V.$$

*Proof of Lemma 4.6.* Throughout this proof,  $u$  is assumed to be in  $\mathcal{V}$ . Let  $\bar{\delta} := \min\{\delta_1, \delta_2, \delta_3\}$ ,  $\bar{\alpha} := \min\{\alpha_1, \alpha_2, \alpha_3\}$ , and  $\bar{\beta} := \max\{\beta_1, \beta_2, \beta_3\}$ . It readily follows from (4.11), (4.32), and (4.54) that if  $|u|_0 + |u_x|_0 \leq \bar{\delta}$ , then

$$(4.67) \quad \frac{1}{\bar{\beta}} \int_0^1 (|u|^2 + |u_x|^2 + |u_{xx}|^2) dx \leq V(u) \leq \bar{\beta} \int_0^1 (|u|^2 + |u_x|^2 + |u_{xx}|^2) dx.$$

In order to check (4.66) (for  $\delta > 0$  small enough and  $\beta > 0$  large enough), let us first point out that, for every  $\eta > 0$ ,

$$\begin{aligned} \int_0^1 |u_x|^2 |u_{xx}| dx &\leq \int_0^1 \left( \frac{1}{4\eta} |u_x|^4 + \eta |u_{xx}|^2 \right) dx \\ (4.68) \qquad \qquad \qquad &\leq \frac{1}{4\eta} |u_x|_0^2 \int_0^1 |u_x|^2 dx + \eta \int_0^1 |u_{xx}|^2 dx. \end{aligned}$$

In order to get (4.66), it suffices to use (4.12), (4.33), (4.54), (4.55), (4.67), (4.68) with  $\eta := \alpha_3/(2\beta_3)^2$  and to point out that

$$\begin{aligned} \int_0^1 |u|^2 |u_x| dx &\leq |u_x|_0 \int_0^1 |u|^2 dx, \\ \int_0^1 |u_x|^3 dx &\leq |u_x|_0 \int_0^1 |u_x|^2 dx, \\ \int_0^1 |u_{xx}|^2 |u_x| dx &\leq |u_x|_0 \int_0^1 |u_{xx}|^2 dx. \end{aligned}$$

This concludes the proof of Lemma 4.6.  $\square$

Finally, let us explain how to deduce Theorem 2.3 from Proposition 2.1 and Lemma 4.6. By the Sobolev inequality (see, for instance, [3, Théorème VII, page 129]), there exists  $C > 0$  such that, for every  $u$  in the Sobolev space  $H^2((0, 1), \mathbb{R}^n)$ ,

$$(4.69) \qquad |u|_0 + |u_x|_0 \leq C_0 |u|_{H^2((0,1), \mathbb{R}^n)},$$

with

$$|u|_{H^2((0,1), \mathbb{R}^n)} := \left( \int_0^1 (|u|^2 + |u_x|^2 + |u_{xx}|^2) dx \right)^{1/2}.$$

We choose  $\mu \in (0, \min\{\mu_1, \mu_2, \mu_3\})$ . Let us point out that a simple density argument shows that (4.65) and (4.66) hold for every  $u \in H^2((0, 1), \mathbb{R}^n)$  satisfying (4.51), (4.52), and  $|u|_0 + |u_x|_0 \leq \delta$ . Let

$$(4.70) \qquad \varepsilon := \min \left\{ \frac{\delta}{2C_0\beta}, \frac{\delta_0}{\beta} \right\}.$$

Note that  $\beta \geq 1$ . Using Lemma 4.6, (4.69), and (4.70), the following implications hold for every  $u \in H^2((0, 1), \mathbb{R}^n)$  satisfying (4.51) and (4.52):

$$(4.71) \qquad (|u|_{H^2((0,1), \mathbb{R}^n)} \leq \varepsilon) \Rightarrow \left( |u|_0 + |u_x|_0 \leq \frac{\delta}{2} \text{ and } V(u) \leq \beta \varepsilon^2 \right),$$

$$(4.72) \qquad (|u|_0 + |u_x|_0 \leq \delta \text{ and } V(u) \leq \beta \varepsilon^2) \Rightarrow \left( |u|_0 + |u_x|_0 \leq \frac{\delta}{2} \text{ and } |u|_{H^2((0,1), \mathbb{R}^n)} \leq \delta_0 \right),$$

$$(4.73) \qquad (|u|_0 + |u_x|_0 \leq \delta) \Rightarrow (\dot{V}(u) \leq 0).$$

Now let  $u^0 \in H^2((0, 1), \mathbb{R}^n)$  satisfying (4.2), (4.3), and

$$|u^0|_{H^2((0,1),\mathbb{R}^n)} \leq \varepsilon.$$

Let  $u \in C^0([0, T], H^2((0, 1), \mathbb{R}^n))$  be the maximal classical solution the Cauchy problem (2.5)–(2.7). Using implications (4.71) to (4.73), one gets that

$$(4.74) \quad |u(t, \cdot)|_{H^2((0,1),\mathbb{R}^n)} \leq \delta_0 \quad \forall t \in [0, T],$$

$$(4.75) \quad |u(t, \cdot)|_0 + |u_x(t, \cdot)|_0 \leq \delta \quad \forall t \in [0, T].$$

Using Proposition 2.1 and (4.74), one gets that  $T = +\infty$ . Using Lemma 4.6 and (4.75), one gets that

$$|u(t, \cdot)|_{H^2((0,1),\mathbb{R}^n)}^2 \leq \beta V(u(t, \cdot)) \leq \beta V(u^0) e^{-\alpha t} \leq \beta^2 |u^0|_{H^2((0,1),\mathbb{R}^n)}^2 e^{-\alpha t}.$$

This concludes the proof of Theorem 2.3 when  $m = n$ .  $\square$

Let us now explain the modifications we use in order to deal with the case  $0 < m < n$  (of course, the case  $m = 0$  can be reduced to the case  $m = n$  by considering  $\tilde{u}(t, x) := u(t, 1 - x)$ ).

One first needs the following parametric version of Lemma 4.1.

**LEMMA 4.7.** *Let  $\Lambda := \text{diag}(\Lambda_1, \dots, \Lambda_n) \in \mathcal{D}_n$  be such that (2.4) holds. There exist a positive real number  $\eta$  and a map  $\mathcal{N} : \{M \times \Delta \in \mathcal{M}_{n,n}(\mathbb{R}) \times \mathcal{D}_n; \|M - \Lambda\| < \eta\} \rightarrow \mathcal{S}_n$  of class  $C^\infty$  such that*

$$\mathcal{N}(\Lambda, \Delta) = \Delta \quad \forall \Delta \in \mathcal{D}_n^\rho,$$

$$\mathcal{N}(M, \Delta)M - M^{\text{tr}}\mathcal{N}(M, \Delta) = 0 \quad \forall (M, \Delta) \in \mathcal{M}_{n,n}(\mathbb{R}) \times \mathcal{D}_n \text{ such that } \|M - \Lambda\| < \eta.$$

*Proof of Lemma 4.7.* With the notation of the proof of Lemma 4.1, it suffices to define  $\mathcal{N}(M, D)$  by  $\mathcal{N}(M, D) := \mathcal{L}_M^{-1}(0, \Delta)$ .  $\square$

The Lyapunov function  $V$  now has the following structure:

$$(4.76) \quad V(u, v, w) = V_1(u) + V_2(u, v) + V_3(u, v, w),$$

with

$$(4.77) \quad V_1(u) = \int_0^1 u^{\text{tr}} Q(x, u) u dx,$$

$$(4.78) \quad V_2(u, v) = \int_0^1 v^{\text{tr}} R(x, u) v dx,$$

$$(4.79) \quad V_3(u, v, w) = \int_0^1 w^{\text{tr}} S(x, u) w dx,$$

where  $Q(x, u)$ ,  $R(x, u)$ , and  $S(x, u)$  are symmetric positive definite matrices depending on  $x \in [0, 1]$  defined in the following way. We fix  $D \in \mathcal{D}_{n,+}$  such that  $\|DKD^{-1}\| < 1$ . Let  $\mu \in (0, +\infty)$ , which will be chosen small enough later. Let us recall that  $|\Lambda| = \text{diag}(|\Lambda_1|, \dots, |\Lambda_n|) = \text{diag}(\Lambda_1, \dots, \Lambda_m, |\Lambda_{m+1}|, \dots, |\Lambda_n|)$ .

(i) We define  $Q(x, u)$  by

$$Q(x, u) := \mathcal{N}(F(u), D^2 |\Lambda|^{-1} \text{diag}(e^{-\mu x}, \dots, e^{-\mu x}, e^{\mu x}, \dots, e^{\mu x})).$$

(ii) We define  $R(x, u)$  by

$$R(x, u) := \mathcal{N}(F(u), D^2|\Lambda|\text{diag}(e^{-\mu x}, \dots, e^{-\mu x}, e^{\mu x}, \dots, e^{\mu x})).$$

(iii) Finally, we define  $R(x, u)$  by

$$S(x, u) := \mathcal{N}(F(u), D^2|\Lambda|^3\text{diag}(e^{-\mu x}, \dots, e^{-\mu x}, e^{\mu x}, \dots, e^{\mu x})).$$

(In the above equalities and in the following, in  $\text{diag}(e^{-\mu x}, \dots, e^{-\mu x}, e^{\mu x}, \dots, e^{\mu x})$ ,  $e^{-\mu x}$  is repeated  $m$  times and  $e^{\mu x}$  is repeated  $(n - m)$  times.) In order to deal with the boundary conditions on  $u$  and  $v$ , let us define

$$(4.80) \quad a_0 := \begin{pmatrix} u_+(0) \\ u_-(1) \end{pmatrix}, \quad a_1 := \begin{pmatrix} u_+(1) \\ u_-(0) \end{pmatrix}, \quad b_0 := \begin{pmatrix} v_+(0) \\ v_-(1) \end{pmatrix}, \quad b_1 := \begin{pmatrix} v_+(1) \\ v_-(0) \end{pmatrix}.$$

The boundary condition (4.10) is now (see (2.6))

$$(4.81) \quad a_0 = G(a_1).$$

Now  $\mathcal{V}_1$  is defined as the set of  $u \in C^1([0, 1], \mathbb{R}^n)$  such that (4.81) holds and  $|u|_0 < \varepsilon_0$ .

Clearly, the estimate on  $V_1$  given in Lemma 4.3 still holds. Let us check that the estimate of this lemma on  $\dot{V}_1$  also holds.

The decomposition (4.15)–(4.18) becomes

$$\dot{V}_1 = \mathcal{T}_{11} + \mathcal{T}_{12} + \mathcal{T}_{13},$$

with

$$\mathcal{T}_{11} := \int_0^1 u^{\text{tr}} Q_x(x, u) F(u) u dx,$$

$$\mathcal{T}_{12} := - \int_0^1 (u^{\text{tr}} Q(x, u) F(u) u)_x dx,$$

$$\mathcal{T}_{13} := \int_0^1 u^{\text{tr}} \left( [Q'_u(x, u)v] F(u) + Q(x, u)[F'(u)v] - [Q'_u(x, u)F(u)v] \right) u dx.$$

Noticing that

$$Q_x(x, 0) = -\mu D^2 \Lambda^{-1} \text{diag}(e^{-\mu x}, \dots, e^{-\mu x}, e^{\mu x}, \dots, e^{\mu x}),$$

the term  $\mathcal{T}_{11}$  can be treated as above. Similarly the term  $\mathcal{T}_{13}$  can also be treated as above. Concerning  $\mathcal{T}_{12}$ , one has

$$(4.82) \quad \begin{aligned} \mathcal{T}_{12} &= -u_1 Q(1, u_1) F(u_1) u_1 + u_0 Q(0, u_0) F(u_0) u_0 \\ &= -u_1^{\text{tr}} D^2 |\Lambda|^{-1} \Lambda u_1 + u_0^{\text{tr}} D^2 |\Lambda|^{-1} \Lambda u_0 + \mathcal{O}(|u_1|^3; |u_1|) + \mathcal{O}(\mu |u_1|^2; \mu). \end{aligned}$$

Let

$$\begin{aligned} K_{++} &\in \mathcal{M}_{m,m}(\mathbb{R}), & K_{+-} &\in \mathcal{M}_{m,(n-m)}(\mathbb{R}), \\ K_{-+} &\in \mathcal{M}_{(n-m),n}(\mathbb{R}), & K_{--} &\in \mathcal{M}_{(n-m),(n-m)}(\mathbb{R}) \end{aligned}$$

be such that

$$K = \begin{pmatrix} K_{++} & K_{+-} \\ K_{-+} & K_{--} \end{pmatrix}.$$

Using (4.80) and (4.81), one has

$$(4.83) \quad u_0 = \begin{pmatrix} K_{++} & K_{+-} \\ 0 & \text{Id}_{n-m} \end{pmatrix} a_1 + \mathcal{O}(|a_1|^2; |a_1|), \quad u_1 = \begin{pmatrix} \text{Id}_m & 0 \\ K_{-+} & K_{--} \end{pmatrix} a_1 + \mathcal{O}(|a_1|^2; |a_1|).$$

Using (4.82) and (4.83), straightforward computations lead to

$$(4.84) \quad \mathcal{T}_{12} = -a_1^{\text{tr}}(D^2 - K^{\text{tr}}D^2K)a_1 + \mathcal{O}(|a_1|^3; |a_1|) + \mathcal{O}(\mu|a_1|^2; \mu).$$

However,  $\|DKD^{-1}\| < 1$  implies (and is in fact equivalent to) the property “the symmetric matrix  ${}^{\text{tr}}(D^2 - K^{\text{tr}}D^2K)$  is positive definite,” which, together with (4.84), implies again the existence of  $\delta_{12} > 0$  such that (4.22) holds if  $|a_1| \leq \delta_{12}$ . Hence Lemma 4.3 still holds.

Similarly it can be checked that Lemmas 4.4 and 4.5 also hold, except that in (4.33) and (4.55),  $|v_1|$  has to be replaced by  $|b_1|$  (and the definitions of  $\mathcal{V}_2$  and  $\mathcal{V}_3$  have to be modified in order to deal with the new compatibility conditions). The proof of Theorem 2.3 is then completed as in the case  $m = n$ .

*Remark 4.8.* One can give a lower bound on the exponential decay in Theorem 2.3. Indeed, it follows from our proof of this theorem that, if  $\rho_1(G'(0)) < 1$ , for every  $\nu \in (0, -\min\{|\lambda_1|, \dots, |\lambda_n|\} \ln(\rho_1(G'(0))))$ , there exist  $\varepsilon > 0$  and  $C > 0$  such that, for every  $u^0 \in H^2((0, 1), \mathbb{R}^n)$  satisfying  $|u^0|_{H^2((0, 1), \mathbb{R}^n)} \leq \varepsilon$  and the compatibility conditions (2.8)–(2.10), the classical solution  $u$  to the Cauchy problem (2.5)–(2.7) is defined on  $[0, +\infty)$  and satisfies (2.13).

**5. Conclusion and final remarks.** We have presented a new sufficient condition on the boundary conditions for the exponential stability of one-dimensional nonlinear hyperbolic systems on a bounded interval. Our analysis relies on the construction of an explicit strict Lyapunov function. Moreover, we have compared our sufficient condition with other known sufficient conditions for nonlinear and linear systems. We conclude the paper with two additional comments.

1. The Lyapunov stability analysis presented in this paper can be extended to nonlinear hyperbolic systems of the form

$$(5.1) \quad u_t + F(u)u_x = h(u),$$

i.e., systems having a nonzero right-hand side  $h(u)$  with the map  $h : \mathbb{R}^n \rightarrow \mathbb{R}^n$  of class  $C^2$  vanishing at zero ( $h(0) = 0$ ). Our main theorem (Theorem 2.3) can be extended, in a straightforward way, to system (5.1) with boundary conditions (1.4), provided  $\|h'(0)\|$  is sufficiently small.

2. For the sake of simplicity, we have assumed throughout the paper that the diagonal matrix  $F(0)$  has *distinct* nonzero diagonal entries. It turns out that this assumption may be slightly relaxed when the matrix  $F(u)$  is block-diagonal. Indeed, in such a case, it is sufficient to assume that the  $\Lambda_i$  values are different in each block, but different blocks may share identical  $\Lambda_i$  values. This situation typically occurs when the system  $u_t + F(u)u_x = 0$  is a model

for a network of interconnected  $2 \times 2$  hyperbolic systems. Typical examples are hydraulic networks modeled by Saint Venant equations [7], road networks modeled by Aw–Rascle equations [1, 8], or pipeline networks modeled by isentropic Euler equations [2].

**Appendix A. Some properties of the function  $\rho_1$ .** In this appendix we give some properties which are useful for estimating and computing  $\rho_1$ . Some of these properties are used to prove Proposition 3.7.

PROPOSITION A.1. *Let  $l \in \{1, \dots, n-1\}$ . Let  $K_1 \in \mathcal{M}_{l,l}(\mathbb{R})$ ,  $K_2 \in \mathcal{M}_{l,n-l}(\mathbb{R})$ ,  $K_3 \in \mathcal{M}_{n-l,l}(\mathbb{R})$ ,  $K_4 \in \mathcal{M}_{n-l,n-l}(\mathbb{R})$  and let  $K \in \mathcal{M}_{n,n}(\mathbb{R})$  be defined by*

$$K := \begin{pmatrix} K_1 & K_2 \\ K_3 & K_4 \end{pmatrix}.$$

Then

$$(A.1) \quad \rho_1(K) \geq \max\{\rho_1(K_1), \rho_1(K_4)\}.$$

Moreover, if  $K_2 = 0$  or  $K_3 = 0$ , then

$$(A.2) \quad \rho_1(K) = \max\{\rho_1(K_1), \rho_1(K_4)\}.$$

*Proof of Proposition A.1.* Let  $D \in \mathcal{D}_{n,+}$ . Let  $D_1 \in \mathcal{D}_{l,+}$  and  $D_2 \in \mathcal{D}_{n-l,+}$  be such that

$$D = \begin{pmatrix} D_1 & 0 \\ 0 & D_2 \end{pmatrix}.$$

Let

$$M := DKD^{-1}.$$

We have

$$M^{\text{tr}}M = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix},$$

with

$$M_{11} := D_1^{-1}K_1^{\text{tr}}D_1^2K_1D_1^{-1} + D_1^{-1}K_3^{\text{tr}}D_2^2K_3D_1^{-1},$$

$$M_{12} := D_1^{-1}K_1^{\text{tr}}D_1^2K_2D_2^{-1} + D_1^{-1}K_3^{\text{tr}}D_2^2K_4D_2^{-1},$$

$$M_{21} := D_2^{-1}K_2^{\text{tr}}D_1^2K_1D_1^{-1} + D_2^{-1}K_4^{\text{tr}}D_2^2K_3D_1^{-1},$$

$$M_{22} := D_2^{-1}K_2^{\text{tr}}D_1^2K_2D_2^{-1} + D_2^{-1}K_4^{\text{tr}}D_2^2K_4D_2^{-1}.$$

For  $X \in \mathbb{R}^l$ , let  $\tilde{X} \in \mathbb{R}^n$  be defined by

$$\tilde{X} := \begin{pmatrix} X \\ 0 \end{pmatrix}.$$

Note that  $|\tilde{X}| = |X|$  and that

$$\begin{aligned}\tilde{X}^{\text{tr}} M^{\text{tr}} M \tilde{X} &= X^{\text{tr}} D_1^{-1} K_1^{\text{tr}} D_1^2 K_1 D_1^{-1} X + X^{\text{tr}} D_1^{-1} K_3^{\text{tr}} D_2^2 K_3 D_1^{-1} X \\ &\geq X^{\text{tr}} D_1^{-1} K_1^{\text{tr}} D_1^2 K_1 D_1^{-1} X.\end{aligned}$$

Hence

$$\begin{aligned}\max\{Z^{\text{tr}} M^{\text{tr}} Z; Z \in \mathbb{R}^n, |Z| = 1\} &\geq \max\{X^{\text{tr}} D_1^{-1} K_1^{\text{tr}} D_1^2 K_1 D_1^{-1} X; X \in \mathbb{R}^l, |X| = 1\} \\ &\geq \rho_1(K_1)^2,\end{aligned}$$

which implies that  $\rho_1(K_1) \leq \rho_1(K)$ . Similarly  $\rho_1(K_4) \leq \rho_1(K)$ . This proves (A.1).

Let us now prove (A.2). We deal only with the case  $K_3 = 0$  (the case  $K_2 = 0$  being similar). Let  $\eta > 0$ . Let  $D_1 \in \mathcal{D}_{l,+}$  and  $D_2 \in \mathcal{D}_{n-l,+}$  be such that

$$(A.3) \quad \|D_1 K_1 D_1^{-1}\| \leq \rho_1(K_1) + \eta, \quad \|D_2 K_4 D_2^{-1}\| \leq \rho_1(K_4) + \eta.$$

Let  $\varepsilon > 0$  and

$$D := \begin{pmatrix} \varepsilon D_1 & 0 \\ 0 & D_2 \end{pmatrix} \in \mathcal{D}_{n,+}, \quad M := D K D^{-1} \in \mathcal{M}_{n,n}(\mathbb{R}).$$

Let  $Z \in \mathbb{R}^n$  and let  $X \in \mathbb{R}^l$  and  $Y \in \mathbb{R}^{n-l}$  be such that

$$Z = \begin{pmatrix} X \\ Y \end{pmatrix}.$$

We have

$$\begin{aligned}Z^{\text{tr}} M^{\text{tr}} M Z &= X^{\text{tr}} D_1^{-1} K_1^{\text{tr}} D_1^2 K_1 D_1^{-1} X + 2\varepsilon X^{\text{tr}} D_1^{-1} K_1^{\text{tr}} D_1^2 K_2 D_2^{-1} Y \\ &\quad + \varepsilon^2 Y^{\text{tr}} D_2^{-1} K_2^{\text{tr}} D_1^2 K_2 D_2^{-1} Y + Y^{\text{tr}} D_2^{-1} K_4^{\text{tr}} D_2^2 K_4 D_2^{-1} Y.\end{aligned}$$

Hence there exists a constant  $C > 0$  independent of  $Z$  and  $\varepsilon > 0$  such that

$$(A.4) \quad Z^{\text{tr}} M^{\text{tr}} M Z \leq (\|D_1 K_1 D_1^{-1}\| |X|)^2 + (\|D_2 K_4 D_2^{-1}\| |Y|)^2 + C\varepsilon |Z|^2.$$

From (2.1), (A.3), and (A.4), we obtain that

$$(A.5) \quad \rho_1(K)^2 \leq \max\{(\rho_1(K_1) + \eta)^2, (\rho_1(K_4) + \eta)^2\} + C\varepsilon.$$

Letting  $\varepsilon \rightarrow 0$  and  $\eta \rightarrow 0$  in (A.5), one gets that  $\rho_1(K)^2 \leq \max\{\rho_1(K_1)^2, \rho_1(K_4)^2\}$ . This concludes the proof of Proposition A.1.  $\square$

**PROPOSITION A.2.** *The map  $\rho_1 : \mathcal{M}_{n,n}(\mathbb{R}) \rightarrow [0, +\infty)$  is continuous.*

*Proof of Proposition A.2.* We proceed by induction on  $n$ . For  $n = 1$  the function  $\rho_1$  satisfies  $\rho(k) = |k|$  for every  $k \in \mathbb{R} = \mathcal{M}_{1,1}(\mathbb{R})$  and is therefore continuous. We now assume that  $\rho_1$  is continuous on  $\mathcal{M}_{p,p}(\mathbb{R})$  for every  $p \in \{1, \dots, n-1\}$  and prove that  $\rho_1$  is continuous on  $\mathcal{M}_{n,n}(\mathbb{R})$ . Since, for every  $D \in \mathcal{D}_{n,+}$ , the function  $K \in \mathcal{M}_{n,n}(\mathbb{R}) \mapsto \|K\| \in \mathbb{R}$  is continuous, it readily follows from (2.1) that  $\rho_1$  is upper semicontinuous on  $\mathcal{M}_{n,n}(\mathbb{R})$ . It remains only to check that  $\rho_1$  is lower semicontinuous.

We argue by contradiction: let  $K \in \mathcal{D}_{n,n}(\mathbb{R})$  and let  $(K_k)_{k \in \mathbb{N}}$  be a sequence of elements of  $\mathcal{M}_{n,n}(\mathbb{R})$  such that

$$(A.6) \quad K_k \rightarrow K \text{ as } k \rightarrow +\infty,$$

$$(A.7) \quad \lim_{k \rightarrow +\infty} \rho_1(K_k) < \rho_1(K).$$

Let  $(D_k)_{k \in \mathbb{N}}$  be a sequence of elements of  $\mathcal{D}_{n,+}$  such that

$$(A.8) \quad \|D_k K_k D_k^{-1}\| \leq \rho_1(K_k) + k^{-1} \quad \forall k \in \mathbb{N} \setminus \{0\}.$$

Note that, denoting by  $(e_1, \dots, e_n)$  the canonical basis of  $\mathbb{R}^n$ ,

$$|A_{ij}| = |e_i^{\text{tr}} A e_j| \leq \|A\| \quad \forall A \in \mathcal{M}_{n,n}(\mathbb{R}), \forall i \in \{1, \dots, n\}, \forall j \in \{1, \dots, n\}.$$

Hence, if we denote by  $K_{ijk}$  the term on the  $i$ th line and  $j$ th column of the matrix  $K_k$ ,

$$(A.9) \quad |K_{ijk}| \frac{d_{ik}}{d_{jk}} \leq \|D_k K_k D_k^{-1}\| \quad \forall (i, j) \in \{1, \dots, n\}^2, \forall k \in \mathbb{N},$$

where  $(d_{ik})_{i \in \{1, \dots, n\}}$  is defined by  $D_k = \text{diag}(d_{1k}, \dots, d_{nk})$ . After suitable reorderings (note that  $\rho_1(\Sigma A \Sigma^{-1}) = \rho_1(A)$  for every  $A \in \mathcal{M}_{n,n}(\mathbb{R})$  and for every permutation matrix  $\Sigma$ ) and extracting subsequences if necessary, we may assume without loss of generality that

$$(A.10) \quad d_{1k} \leq d_{2k} \leq \dots \leq d_{(n-1)k} \leq d_{nk} \quad \forall k \in \mathbb{N}.$$

A simple scaling argument also shows that we may assume without loss of generality that

$$(A.11) \quad d_{1k} = 1 \quad \forall k \in \mathbb{N}.$$

Extracting subsequences if necessary, there exist  $l \in \{1, \dots, n\}$ ,  $(d_1, \dots, d_l) \in [1, +\infty)^l$  such that

$$(A.12) \quad d_{ik} \rightarrow d_i \text{ as } k \rightarrow +\infty \quad \forall i \in \{1, \dots, l\},$$

$$(A.13) \quad d_{ik} \rightarrow +\infty \text{ as } k \rightarrow +\infty \quad \forall i \in \{l+1, \dots, n\}.$$

We first treat the case where  $l = n$ . Let  $D := \text{diag}(d_1, \dots, d_n) \in \mathcal{D}_{n,+}$ . From (A.12), we have

$$(A.14) \quad D_k \rightarrow D \text{ as } k \rightarrow +\infty.$$

From (2.1), we have

$$(A.15) \quad \rho_1(K) \leq \|DKD^{-1}\|,$$

which, together with (A.8) and (A.14), implies that

$$\liminf_{k \rightarrow +\infty} \rho_1(K_k) \geq \rho_1(K),$$

in contradiction with (A.7).

It remains to deal with the case where  $l < n$ . Let us denote  $K_{ij}$  the term on the  $i$ th line and  $j$ th column of the matrix  $K$ . From (A.6), (A.7), (A.8), (A.9), (A.12), and (A.13), one gets that

$$(A.16) \quad K_{ij} = 0 \quad \forall (i, j) \in \{l+1, \dots, n\} \times \{1, \dots, l\}.$$

Let  $K^1 \in \mathcal{M}_{l,l}(\mathbb{R})$ ,  $K^2 \in \mathcal{M}_{l,n-l}(\mathbb{R})$ ,  $K^4 \in \mathcal{M}_{n-l,n-l}(\mathbb{R})$  be such that

$$K = \begin{pmatrix} K^1 & K^2 \\ 0 & K^4 \end{pmatrix}.$$

Similarly, for  $k \in \mathbb{N}$ , let  $K_k^1 \in \mathcal{M}_{l,l}(\mathbb{R})$ ,  $K_k^2 \in \mathcal{M}_{l,n-l}(\mathbb{R})$ ,  $K_k^3 \in \mathcal{M}_{n-l,l}(\mathbb{R})$ ,  $K_k^4 \in \mathcal{M}_{n-l,n-l}(\mathbb{R})$  be defined by

$$K := \begin{pmatrix} K_k^1 & K_k^2 \\ K_k^3 & K_k^4 \end{pmatrix}.$$

From (A.2), we have

$$(A.17) \quad \rho_1(K) = \max\{\rho_1(K^1), \rho_1(K^4)\}.$$

From (A.1), we have

$$(A.18) \quad \rho_1(K_k) \geq \max\{\rho_1(K_k^1), \rho_1(K_k^4)\} \quad \forall k \in \mathbb{N}.$$

From our induction hypothesis (the continuity of  $\rho_1$  on  $\mathcal{M}_{p,p}(\mathbb{R})$  for every  $p \in \{1, \dots, n-1\}$ ) and (A.6), we get that

$$\lim_{k \rightarrow +\infty} \rho_1(K_k^1) = \rho_1(K^1), \quad \lim_{k \rightarrow +\infty} \rho_1(K_k^4) = \rho_1(K^4),$$

which, together with (A.17) and (A.18), again leads to a contradiction with (A.7). This concludes the proof of Proposition A.2.  $\square$

Our next proposition shows a case where the value of  $\rho_1(K)$  may be given directly. (For a converse of this proposition, see Proposition B.1.)

**PROPOSITION A.3.** *Let  $l \in \{1, \dots, n\}$ . Let  $(A_j)_{j \in \{1, \dots, l\}}$  and  $(B_j)_{j \in \{1, \dots, l\}}$  be two sequences of vectors in  $\mathbb{R}^n$  such that*

$$(A.19) \quad A_j^{\text{tr}} A_k = B_j^{\text{tr}} B_k \quad \forall (j, k) \in \{1, \dots, l\}^2,$$

$$(A.20) \quad \sum_{j=1}^l A_{ij}^2 = \sum_{j=1}^l B_{ij}^2 \quad \forall i \in \{1, \dots, n\},$$

where  $A_{ij}$  (resp.,  $B_{ij}$ ) is the element on the  $i$ th line of the vector  $A_j$  (resp.,  $B_j$ ). We assume that the  $l$  vectors  $A_1, \dots, A_l$  are linearly independent. Let  $R \geq 0$  and let  $K \in \mathcal{M}_{n,n}(\mathbb{R})$  be such that

$$(A.21) \quad KA_j = RB_j \quad \forall j \in \{1, \dots, l\},$$

$$(A.22) \quad |KX| \leq R|X| \quad \forall X \in \mathbb{R}^n \text{ such that } X^{\text{tr}} A_j = 0 \quad \forall j \in \{1, l\}.$$

Then  $\rho_1(K) = R$ .

*Proof of Proposition A.3.* It readily follows from the assumptions of this proposition that  $\|K\| = R$ . Hence it remains only to check that

$$(A.23) \quad \|DKD^{-1}\| \geq R \quad \forall D \in \mathcal{D}_{n,+}.$$

Let  $D := \text{diag}(D_1, \dots, D_n) \in \mathcal{D}_{n,+}$ . For  $j \in \{1, \dots, l\}$ , let us define

$$E_j := (E_{1j}, \dots, E_{nj})^{\text{tr}} \in \mathbb{R}^n \setminus \{0\}, \quad F_j := (F_{1j}, \dots, F_{nj})^{\text{tr}} \in \mathbb{R}^n \setminus \{0\}$$

by

$$E_j := DA_j, \quad F_j := DB_j.$$

We have, for every  $j \in \{1, \dots, l\}$ ,

$$(A.24) \quad DKD^{-1}E_j = RF_j,$$

$$(A.25) \quad E_{ij} = D_i A_{ij}, \quad F_{ij} = D_i B_{ij} \quad \forall i \in \{1, \dots, n\}.$$

Using (A.20), (A.24), and (A.25), we get

$$\begin{aligned} \sum_{j=1}^l |DKD^{-1}E_j|^2 &= R^2 \sum_{j=1}^l \left( \sum_{i=1}^n F_{ij}^2 \right) \\ &= R^2 \sum_{i=1}^n D_i^2 \left( \sum_{j=1}^l B_{ij}^2 \right) \\ &= R^2 \sum_{i=1}^n D_i^2 \left( \sum_{j=1}^l A_{ij}^2 \right) \\ &= R^2 \sum_{j=1}^l |E_j|^2. \end{aligned}$$

In particular, there exists  $p \in \{1, \dots, l\}$ , such that

$$|DKD^{-1}E_p|^2 \geq R^2 |E_p|^2,$$

which, together with the fact that  $E_p \neq 0$ , implies that  $\|DKD^{-1}\| \geq R$ . This concludes the proof of Proposition A.3.  $\square$

**Appendix B. Proof of Proposition 3.7.** Inequality (3.22) is obvious: indeed, for every  $(\theta_1, \dots, \theta_n)^{\text{tr}} \in \mathbb{R}^n$  and for every  $D \in \mathcal{D}_{n,+}$ ,

$$\begin{aligned} \rho(\text{diag}(e^{\iota\theta_1}, \dots, e^{\iota\theta_n})K) &= \rho(D \text{diag}(e^{\iota\theta_1}, \dots, e^{\iota\theta_n})KD^{-1}) \\ &= \rho(\text{diag}(e^{\iota\theta_1}, \dots, e^{\iota\theta_n})DKD^{-1}) \\ &\leq \|\text{diag}(e^{\iota\theta_1}, \dots, e^{\iota\theta_n})DKD^{-1}\| \\ &\leq \|\text{diag}(e^{\iota\theta_1}, \dots, e^{\iota\theta_n})\| \|DKD^{-1}\| = \|DKD^{-1}\|. \end{aligned}$$

The proof of (3.23) for every  $n \in \{1, 2, 3, 4, 5\}$  is more complicated and relies on various independent propositions. The first proposition provides the converse (up to the  $D$ ) to Proposition A.3 for generic  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ .

PROPOSITION B.1. *Let  $K \in \mathcal{M}_{n,n}(\mathbb{R})$  be such that, for every  $M > 0$ , there exists  $\delta > 0$  such that*

$$(B.1) \quad \left( D := (D_1, \dots, D_n) \in \mathcal{D}_{n,+}, \sum_{i=1}^n D_i = 1, \min\{D_1, \dots, D_n\} < \delta \right) \\ \Rightarrow (\|DKD^{-1}\| > M).$$

(It is easily checked that this property holds, for example, if  $K_{ij} \neq 0$ , for every  $(i, j) \in \{1, \dots, n\}^2$  such that  $i \neq j$ , which is a generic property.) Then there exist  $D \in \mathcal{D}_{n,+}$ , an integer  $l \in \{1, \dots, n\}$ ,  $l$  vectors  $A_j \in \mathbb{R}^n$ ,  $j \in \{1, \dots, l\}$ , and  $l$  vectors  $B_j \in \mathbb{R}^n$ ,  $j \in \{1, \dots, l\}$ , such that (A.19) and (A.20) hold and

$$(B.2) \quad \text{the vectors } A_j \in \mathbb{R}^n, j \in \{1, \dots, l\}, \text{ are linearly independent,}$$

$$(B.3) \quad DKD^{-1}A_j = \rho_1(K)B_j \quad \forall j \in \{1, \dots, l\},$$

$$(B.4) \quad |DKD^{-1}X| \leq \rho_1(K)|X| \quad \forall X \in \mathbb{R}^n.$$

Remark B.2. Proposition B.1 is false if assumption (B.1) is removed. Indeed, let us take  $n = 2$  and

$$K = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Then  $\rho_1(K) = 0$ , and it is easily seen that the conclusion of Proposition B.1 does not hold.

*Proof of Proposition B.1.* From (B.1), one gets the existence of  $\tilde{D} \in \mathcal{D}_{n,+}$  such that

$$(B.5) \quad \|\tilde{D}K\tilde{D}^{-1}\| = \rho_1(K).$$

Replacing  $K$  by  $\tilde{D}K\tilde{D}^{-1}$ , we may assume without loss of generality that  $\tilde{D}$  is the identity map  $\text{Id}_n$  of  $\mathbb{R}^n$ . Then

$$(B.6) \quad \|K\| = \rho_1(K).$$

Clearly, (B.1) implies that  $K \neq 0$ , and therefore, by (B.6),

$$(B.7) \quad \rho_1(K) \neq 0.$$

(In fact, if  $K = 0$ , the conclusion of Proposition B.1 obviously holds.) Note that (B.6) implies (B.4) with  $D := \text{Id}_n$ . Let  $p \in \{1, \dots, n\}$  be the dimension of the kernel of  $K^{\text{tr}}K - \rho_1(K)^2 \text{Id}_n$  and let  $(X_1, \dots, X_p)$  be an orthonormal basis of this kernel. For  $j \in \{1, \dots, p\}$ , let  $Y_j := KX_j$ . One has

$$(B.8) \quad |Y_j|^2 = X_j^{\text{tr}}K^{\text{tr}}KX_j = \rho_1(K)^2|X_j|^2 \quad \forall j \in \{1, \dots, p\},$$

$$(B.9) \quad Y_k^{\text{tr}}Y_j = X_k^{\text{tr}}K^{\text{tr}}KX_j = \rho_1(K)^2X_k^{\text{tr}}X_j = 0 \quad \forall (k, j) \in \{1, \dots, p\}^2 \text{ such that } k \neq j.$$

For  $i \in \{1, \dots, n\}$  and  $j \in \{1, \dots, p\}$ , let us denote by  $X_{ij}$  (resp.,  $Y_{ij}$ ) the  $i$ th component of  $X_j$  (resp.,  $Y_j$ ). For  $j \in \{1, \dots, p\}$ , let us denote by  $E_j$  the element of  $\mathbb{R}^n$  whose  $i$ th component is

$$(B.10) \quad E_{ij} := Y_{ij}^2 - X_{ij}^2.$$

Let us assume, for the moment, that

$$(B.11) \quad \forall \tau \in \mathbb{R}^n, \text{ there exists } j \in \{1, \dots, p\} \text{ such that } \tau^{\text{tr}} E_j \geq 0.$$

Applying the separation principle for convex sets to  $\{0\}$  and the convex hull of the vectors  $E_j$ ,  $j \in \{1, \dots, p\}$  (see, e.g., [19, Theorem 3.4(b), page 58]), it follows from (B.11) that  $0 \in \mathbb{R}^n$  is in the convex hull of the vectors  $E_1, \dots, E_p$ : there exist  $p$  nonnegative real numbers  $t_1, \dots, t_p$  such that

$$\sum_{j=1}^p t_j = 1, \quad \sum_{j=1}^p t_j E_j = 0.$$

Let  $l \in \{1, \dots, p\}$  be the number of the  $t_i$ 's which are not equal to 0. Reordering the  $X_i$ 's if necessary, we may assume that

$$t_j > 0 \quad \forall j \in \{1, \dots, l\}, \quad t_j = 0 \quad \forall j \in \{l+1, \dots, p\}.$$

For  $j \in \{1, \dots, l\}$ , we define  $A_j \in \mathbb{R}^n$  and  $B_j \in \mathbb{R}^n$  by

$$(B.12) \quad A_j := \sqrt{t_j} X_j, \quad B_j := \sqrt{t_j} Y_j.$$

Then it is easily checked that the vectors  $A_1, \dots, A_l$  are linearly independent, that (A.19) and (A.20) hold (one even has  $A_k^{\text{tr}} A_j = B_k^{\text{tr}} B_j = 0$  for every  $(k, j) \in \{1, \dots, l\}^2$  such that  $k \neq j$ ), and that (B.3) holds with  $D := \text{Id}_n$ .

It remains only to prove (B.11). Let  $\tau := (\tau_1, \dots, \tau_n)^{\text{tr}} \in \mathbb{R}^n$ . For  $s \in \mathbb{R}$ , let

$$D(s) := \text{diag}(1 + s\tau_1, \dots, 1 + s\tau_n) \in \mathcal{D}_n.$$

For  $s$  small enough,  $D(s) \in \mathcal{D}_{n,+}$ , and therefore, by (B.6),

$$(B.13) \quad \|D(s)KD(s)^{-1}\|^2 \geq \|K\|^2 = \|D(0)KD(0)^{-1}\|^2.$$

Let us estimate the left-hand side of (B.13). By a classical theorem due to Rellich (see, e.g., [18, Theorem XII.3, page 4]) on perturbations of the spectrum of self-adjoint operators, there exist  $\varepsilon > 0$ ,  $p$  real functions  $\lambda_1, \dots, \lambda_p$  of class  $C^1$  from  $(-\varepsilon, \varepsilon)$  into  $\mathbb{R}$ , and  $p$  maps  $x_1, \dots, x_p$  of class  $C^1$  from  $(-\varepsilon, \varepsilon)$  into  $\mathbb{R}^n$  such that

$$(B.14) \quad \lambda_j(0) = \rho_1(K)^2, \quad x_j(0) = X_j \quad \forall j \in \{1, \dots, p\},$$

$$(B.15) \quad D(s)^{-1}K^{\text{tr}}D(s)^2KD(s)^{-1}x_j(s) = \lambda_j(s)x_j(s) \quad \forall s \in (-\varepsilon, \varepsilon), \forall j \in \{1, \dots, p\},$$

$$(B.16) \quad x_j(s)^{\text{tr}}x_j(s) = 1 \quad \forall s \in (-\varepsilon, \varepsilon), \forall j \in \{1, \dots, p\},$$

$$(B.17) \quad x_j(s)^{\text{tr}}x_k(s) = 0 \quad \forall s \in (-\varepsilon, \varepsilon), \forall (j, k) \in \{1, \dots, p\}^p \text{ such that } k \neq j,$$

$$(B.18) \quad \|D(s)KD(s)^{-1}\|^2 = \max\{\lambda_1(s), \dots, \lambda_p(s)\} \quad \forall s \in (-\varepsilon, \varepsilon).$$

Differentiating (B.15) with respect to  $s$  and using (B.10), (B.14), (B.16), and (B.17), one gets

$$(B.19) \quad \lambda'_j(0) = 2\rho_1(K)^2 \tau^{\text{tr}} E_j \quad \forall j \in \{1, \dots, p\}.$$

Property (B.11) follows from (B.7), (B.13), (B.18), and (B.19). This concludes the proof of Proposition B.1.  $\square$

The number  $l$  appearing in Proposition B.1 turns out to be important to compare  $\rho_0$  and  $\rho_1$ : we have the following proposition.

**PROPOSITION B.3.** *Let  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ ,  $D \in \mathcal{D}_{n,+}$ ,  $l \in \{1, \dots, n\}$ ,  $l$  vectors  $A_j \in \mathbb{R}^n$ ,  $j \in \{1, \dots, l\}$ , and  $l$  vectors  $B_j \in \mathbb{R}^n$ ,  $j \in \{1, \dots, l\}$ , be such that (A.20), (B.2), (B.3), and (B.4) hold. If  $l = 1$ , there exist  $X \in \mathbb{R}^n$  and  $\Upsilon := \text{diag}(\Upsilon_1, \dots, \Upsilon_n) \in \mathcal{D}_n$  such that*

$$(B.20) \quad |X| \neq 0,$$

$$(B.21) \quad \Upsilon_i \in \{1, -1\} \quad \forall i \in \{1, \dots, n\},$$

$$(B.22) \quad KX = \rho_1(K)\Upsilon X.$$

If  $l = 2$ , there exist  $X \in \mathbb{C}^n$  and  $(\Upsilon_1, \dots, \Upsilon_n) \in \mathbb{C}^n$  such that

$$(B.23) \quad |X| \neq 0,$$

$$(B.24) \quad |\Upsilon_i| = 1 \quad \forall i \in \{1, \dots, n\},$$

$$(B.25) \quad KX = \rho_1(K)\text{diag}(\Upsilon_1, \dots, \Upsilon_n)X.$$

In both cases ( $l = 1$  or  $l = 2$ ), one has (3.23).

*Proof of Proposition B.3.* Let us first consider the case  $l = 1$ . Let  $i \in \{1, \dots, n\}$ . From (A.20), one has  $|A_{i1}| = B_{i1}$ , and therefore there exists  $\Upsilon_i \in \{-1, 1\}$  such that  $B_{i1} = \varepsilon_i A_{i1}$ . From (B.3), one gets (B.22) if one defines  $X$  by  $X := D^{-1}A_1$ . Let us check that (3.23) holds. Let  $(\theta_1, \dots, \theta_n)^{\text{tr}} \in \mathbb{R}^n$  be defined by

$$\theta_i = 0 \text{ if } \Upsilon_i = 1, \quad \theta_i = -\pi \text{ if } \Upsilon_i = -1.$$

Then (B.22) implies that

$$(B.26) \quad \text{diag}(e^{\iota\theta_1}, \dots, e^{\iota\theta_n})KX = \rho_1(K)X.$$

From (3.21), (B.20), and (B.26), we get that

$$(B.27) \quad \rho_0(K) \geq \rho_1(K),$$

which, together with (3.22), gives (3.23).

Let us now turn to the case  $l = 2$ . Let  $i \in \{1, \dots, n\}$ . From (A.20), one has

$$|A_{i1} + \iota A_{i2}| = |B_{i1} + \iota B_{i2}|,$$

and therefore there exists  $\Upsilon_i \in \mathbb{C}$  such that  $|\Upsilon_i| = 1$  and  $B_{i1} + \iota B_{i2} = \Upsilon_i(A_{i1} + \iota A_{i2})$ . From (B.3), one gets (B.22) if one defines  $X$  by  $X := D^{-1}(A_1 + \iota A_2)$ . Finally, the proof of (3.23) is the same as in the case  $l = 1$ . This concludes the proof of Proposition B.3.  $\square$

The next proposition deals with the case  $n = l$ .

PROPOSITION B.4. Let  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ ,  $D \in \mathcal{D}_{n,+}$ ,  $l \in \{1, \dots, n\}$ ,  $l$  vectors  $A_j \in \mathbb{R}^n$ ,  $j \in \{1, \dots, l\}$ , and  $l$  vectors  $B_j \in \mathbb{R}^n$ ,  $j \in \{1, \dots, l\}$ , be such that (A.20), (B.2), (B.3), and (B.4) hold. If  $l = n$ , there exist  $X \in \mathbb{C}^n$  satisfying (B.23) and  $\theta \in \mathbb{R}$  such that

$$(B.28) \quad KX = e^{-i\theta} \rho_1(K)X$$

and (3.23) again holds.

*Proof of Proposition B.4.* If  $\rho_1(K) = 0$ , then  $K = 0$  and the conclusion of Proposition B.4 holds. If  $\rho_1(K) > 0$ , it follows from (A.19), (B.2), and (B.3) and the assumption  $l = n$  that  $\rho_1(K)^{-1}KDKD^{-1}$  is an isometry. Hence there exist  $Y \in \mathbb{C}^n \setminus \{0\}$  and  $\theta \in \mathbb{R}$  such that  $\rho_1(K)^{-1}KDKD^{-1}Y = e^{-i\theta}Y$ , which implies (B.28) if  $X := D^{-1}Y$ . Finally, (3.23) again follows from (B.23) and (B.28). This concludes the proof of Proposition B.4.  $\square$

Note that  $\rho_0$  is continuous. Hence, from Proposition A.2, Proposition B.1, Proposition B.3, and Proposition B.4, in order to get (3.23) (for every  $n \in \{1, \dots, 5\}$ ) of Proposition 3.7, it remains to address, with the notation of the conclusion of Proposition B.1, the cases  $(l, n) = (3, 4)$ ,  $(l, n) = (3, 5)$ , and  $(l, n) = (4, 5)$ . This is done in the following proposition.

PROPOSITION B.5. Let  $K \in \mathcal{M}_{n,n}(\mathbb{R})$ ,  $D \in \mathcal{D}_{n,+}$ ,  $l \in \{1, \dots, n\}$ ,  $l$  vectors  $A_j \in \mathbb{R}^n$ ,  $j \in \{1, \dots, l\}$ , and  $l$  vectors  $B_j \in \mathbb{R}^n$ ,  $j \in \{1, \dots, l\}$ , be such that (A.20), (B.2), (B.3), and (B.4) hold. If  $(l, n) \in \{(3, 4), (3, 5), (4, 5)\}$ , there exist  $X \in \mathbb{C}^n$  and  $(Y_1, \dots, Y_n) \in \mathbb{C}^n$  such that (B.23), (B.24), and (B.25) hold. In particular, one has (3.23).

*Proof of Proposition B.5.* The fact that (3.23) is implied by the assumptions of Proposition B.5, (B.23), (B.24), and (B.25) has already been pointed out in the proof of Proposition B.3. The case  $(l, n) = (3, 4)$  follows from the case  $(l, n) = (3, 5)$  by replacing  $K \in \mathcal{M}_{4,4}(\mathbb{R})$  by the matrix

$$\tilde{K} := \begin{pmatrix} K & 0 \\ 0 & 0 \end{pmatrix}.$$

Hence we may assume that  $n = 5$ . Taking  $X := D^{-1}(Y_1A_1 + Y_2A_2 + \dots + Y_lA_l)$  it suffices to prove the existence of  $Y := (Y_1, Y_2, \dots, Y_l)^{\text{tr}} \in \mathbb{C}^l \setminus \{0\}$  such that

$$(B.29) \quad |Y_1B_{i1} + Y_2B_{i2} + \dots + Y_lB_{il}|^2 - |Y_1A_{i1} + Y_2A_{i2} + \dots + Y_lA_{il}|^2 = 0 \quad \forall i \in \{1, 2, 3, 4, 5\}.$$

Let us recall that, for  $p \in \mathbb{N} \setminus \{0\}$ ,  $\mathcal{S}_p$  denotes the set of elements  $Q \in \mathcal{M}_{p,p}$  such that  $Q^{\text{tr}} = Q$ . For  $i \in \{1, 2, 3, 4, 5\}$ , there exists a unique  $Q_i \in \mathcal{S}_l$  such that, for every  $Y := (Y_1, Y_2, \dots, Y_l)^{\text{tr}} \in \mathbb{C}^l$ ,

$$Y^{\text{tr}}Q_i\bar{Y}^{\text{tr}} = |Y_1B_{i1} + Y_2B_{i2} + \dots + Y_lB_{il}|^2 - |Y_1A_{i1} + Y_2A_{i2} + \dots + Y_lA_{il}|^2,$$

with  $\bar{Y} := (\bar{Y}_1, \bar{Y}_2, \dots, \bar{Y}_l)$  ( $\bar{z}$  denoting the complex conjugate of  $z \in \mathbb{C}$ ). Then (B.29) is equivalent to

$$(B.30) \quad Y^{\text{tr}}Q_i\bar{Y}^{\text{tr}} = 0 \quad \forall i \in \{1, 2, 3, 4, 5\}.$$

For a matrix  $M \in \mathcal{M}_{p,p}(\mathbb{C})$ , let us denote by  $\text{tr}(M)$  its trace. Using (A.20) we have that

$$\text{tr}(Q_i) = 0 \quad \forall i \in \{1, 2, 3, 4, 5\}.$$

Using (A.19), one gets that

$$Y^{\text{tr}} Q_1 \bar{Y}^{\text{tr}} + Y^{\text{tr}} Q_2 \bar{Y} + Y^{\text{tr}} Q_3 \bar{Y} + Y^{\text{tr}} Q_4 \bar{Y} + Y^{\text{tr}} Q_5 \bar{Y} = 0 \quad \forall Y \in \mathbb{C}^l.$$

Hence (B.30) is equivalent to

$$Y^{\text{tr}} Q_i \bar{Y}^{\text{tr}} = 0 \quad \forall i \in \{1, 2, 3, 4\}.$$

Therefore Proposition B.5 is a consequence of the following proposition due to Voisin [23].

PROPOSITION B.6. *Let  $l \in \{3, 4\}$ . Let  $Q_1, Q_2, Q_3$ , and  $Q_4$  be four elements of  $\mathcal{S}_l$  such that*

$$(B.31) \quad \text{tr}(Q_i) = 0 \quad \forall i \in \{1, 2, 3, 4\}.$$

*Then there exists  $Y \in \mathbb{C}^l \setminus \{0\}$  such that*

$$(B.32) \quad Y^{\text{tr}} Q_i \bar{Y} = 0 \quad \forall i \in \{1, 2, 3, 4\}.$$

*Proof of Proposition B.6.* We reproduce the proof of [23]. For  $l \in \mathbb{N}$ , let  $\overline{\mathcal{S}_{l,+}}$  be the set of semidefinite positive  $S \in \mathcal{S}_l$ . The first step is the following lemma.

LEMMA B.7. *Let  $l, p$ , and  $n$  be three positive integers. Let  $Q_i, i \in \{1, \dots, n\}$ , be  $n$  elements of  $\mathcal{S}_l$ . Assume that*

$$(B.33) \quad \text{tr}(Q_i) = 0 \quad \forall i \in \{1, \dots, n\},$$

$$(B.34) \quad n < \frac{(p+1)(p+2)}{2} - 1.$$

*Then there exists  $S \in \overline{\mathcal{S}_{l,+}} \setminus \{0\}$  such that*

$$(B.35) \quad \text{the rank of } S \text{ is less than or equal to } p,$$

$$(B.36) \quad \text{tr}(SQ_i) = 0 \quad \forall i \in \{1, \dots, n\}.$$

*Proof of Proposition B.7.* Let

$$C := \{S \in \overline{\mathcal{S}_{l,+}}; \text{tr}(S) = l, \text{tr}(SQ_i) = 0 \quad \forall i \in \{1, \dots, n\}\}.$$

The set  $C$  is a closed convex bounded subset of  $\mathcal{M}_{l,l}(\mathbb{R})$ . By (B.33),  $\text{Id}_l \in C$ , and therefore  $C$  is not empty. Hence, by the Krein–Milman theorem (see, e.g., [19, Theorem 3.21, page 70]), the convex set  $C$  has at least an extreme point. Let  $S$  be an extreme point of  $C$ . Then  $S \in \overline{\mathcal{S}_{l,+}} \setminus \{0\}$  and satisfies (B.36). It remains only to check that (B.35) holds. Let  $k$  be the rank of  $S$ . There exist an orthonormal matrix  $O \in \mathcal{M}_{l,l}(\mathbb{R})$  and a definite positive matrix  $S_0 \in \mathcal{S}_k$  such that

$$(B.37) \quad S = O^{\text{tr}} \begin{pmatrix} S_0 & 0 \\ 0 & 0 \end{pmatrix} O.$$

Let

$$(B.38) \quad \Pi := \left\{ O^{\text{tr}} \begin{pmatrix} S' & 0 \\ 0 & 0 \end{pmatrix} O; S' \in \mathcal{S}_k, \text{tr}(S') = 0 \right\} \subset \mathcal{S}_l.$$

Let us assume that

$$(B.39) \quad n < \frac{k(k+1)}{2} - 1.$$

Since  $\Pi$  is a vector subspace of  $\mathcal{S}_l$  of dimension  $(k(k+1)/2) - 1$ , (B.39) implies that there exists  $S_0 \in \Pi \setminus \{0\}$  such that

$$(B.40) \quad \text{tr} (S_0 Q_i) = 0 \quad \forall i \in \{1, \dots, n\}.$$

Then, for  $\tau \in \mathbb{R}$  with  $|\tau|$  small enough,  $S + \tau S_0$  is in  $C$ , which contradicts the fact that  $S$  is an extreme point of  $C$ . Hence (B.39) does not hold, which, together with (B.34), implies that  $k \leq p$ . This concludes the proof of Lemma B.7.  $\square$

Let us go back to the proof of Proposition B.6. We apply Lemma B.7 with  $n = 4$  and  $p = 2$  (then (B.34) holds). We get the existence of  $S \in \overline{\mathcal{S}_{l,+}} \setminus \{0\}$  satisfying

$$(B.41) \quad \text{the rank of } S \text{ is less than or equal to } 2,$$

$$(B.42) \quad \text{tr} (S Q_i) = 0 \quad \forall i \in \{1, \dots, 4\}.$$

Let  $\lambda_1 > 0$ ,  $\lambda_2 \geq 0$ , and 0 be the eigenvalues of  $S$ . Let

$$S_0 = \begin{pmatrix} \lambda_1 & 0 & 0 \\ 0 & \lambda_2 & 0 \\ 0 & 0 & 0 \end{pmatrix} \in \overline{\mathcal{S}_{l,+}}.$$

There exists an orthonormal matrix  $O$  such that

$$(B.43) \quad S = O^{\text{tr}} S_0 O.$$

Let  $Z := (\sqrt{\lambda_1}, \iota\sqrt{\lambda_2}, 0) \in \mathbb{C}^l \setminus \{0\}$  and  $Y := O^{\text{tr}} Z \in \mathbb{C}^l \setminus \{0\}$ . Then, using (B.42) and (B.43), one gets that, for every  $i \in \{1, \dots, 4\}$ ,

$$\begin{aligned} 2Y^{\text{tr}} Q_i \bar{Y} &= \text{tr} ((Y \bar{Y}^{\text{tr}} + \bar{Y} Y)^{\text{tr}} Q_i) = \text{tr} (O^{\text{tr}} (Z \bar{Z}^{\text{tr}} + \bar{Z} Z^{\text{tr}}) O Q_i) \\ &= 2\text{tr} (O^{\text{tr}} S_0^{\text{tr}} O Q_i) = \text{tr} (S Q_i) = 0, \end{aligned}$$

which concludes the proof of Proposition B.6 and therefore the proof of Proposition B.5.  $\square$

Finally, in order to end the proof of Proposition 3.7, it remains only to check that, for  $n = 6$  and therefore for every  $n \geq 6$ , there exists  $K \in \mathcal{M}_{n,n}(\mathbb{R})$  such that  $l = 3$  and (3.24) hold. This is done in the following example.

*Example B.8.* Let  $(u_1, v_1, w_1)^{\text{tr}} \in \mathbb{R}^3$ ,  $(u_2, v_2, w_2)^{\text{tr}} \in \mathbb{R}^3$ ,  $(x_1, y_1, z_1)^{\text{tr}} \in \mathbb{R}^3$ , and  $(x_2, y_2, z_2)^{\text{tr}} \in \mathbb{R}^3$ . We define  $A_1 \in \mathbb{R}^6$ ,  $A_2 \in \mathbb{R}^6$ ,  $A_3 \in \mathbb{R}^6$ ,  $B_1 \in \mathbb{R}^6$ ,  $B_2 \in \mathbb{R}^6$ , and

$B_3 \in \mathbb{R}^6$  by

$$A_1 := \begin{pmatrix} 1 \\ 0 \\ 0 \\ 1 \\ u_1 \\ u_2 \end{pmatrix}, \quad A_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ v_1 \\ v_2 \end{pmatrix}, \quad A_3 := \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \\ w_1 \\ w_2 \end{pmatrix},$$

$$B_1 := \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1/\sqrt{2} \\ x_1 \\ x_2 \end{pmatrix}, \quad B_2 := \begin{pmatrix} 1 \\ 0 \\ 1/\sqrt{2} \\ -1/\sqrt{2} \\ y_1 \\ y_2 \end{pmatrix}, \quad B_3 := \begin{pmatrix} 0 \\ 1 \\ 1/\sqrt{2} \\ 0 \\ z_1 \\ z_2 \end{pmatrix}.$$

One easily checks that (A.20) holds if (and only if)

$$(B.44) \quad u_1^2 + v_1^2 + w_1^2 = x_1^2 + y_1^2 + z_1^2,$$

$$(B.45) \quad u_2^2 + v_2^2 + w_2^2 = x_2^2 + y_2^2 + z_2^2.$$

Similarly (A.19) holds if (and only if)

$$(B.46) \quad \frac{3}{2} + u_1^2 + u_2^2 - x_1^2 - x_2^2 = 0,$$

$$(B.47) \quad -1 + v_1^2 + v_2^2 - y_1^2 - y_2^2 = 0,$$

$$(B.48) \quad -\frac{1}{2} + w_1^2 + w_2^2 - z_1^2 - z_2^2 = 0,$$

$$(B.49) \quad \frac{1}{2} + u_1 v_1 + u_2 v_2 - x_1 y_1 - x_2 y_2 = 0,$$

$$(B.50) \quad u_1 w_1 + u_2 w_2 - x_1 z_1 - x_2 z_2 = 0,$$

$$(B.51) \quad -\frac{1}{2} + v_1 w_1 + v_2 w_2 - y_1 z_1 - y_2 z_2 = 0.$$

Note that (B.44), (B.46), (B.47), and (B.48) imply (B.45).

We take  $l := 3$  and  $R := 1$ . We define  $K \in \mathcal{M}_{6,6}(\mathbb{R})$  by requiring (A.21) and

$$KX = 0 \quad \forall X \in \mathbb{R}^6 \text{ such that } X^{\text{tr}} A_1 = X^{\text{tr}} A_2 = X^{\text{tr}} A_3 = 0.$$

From Proposition A.3 we get that if (B.44) and (B.46) to (B.51) hold, then

$$\rho_1(K) = 1.$$

Let us assume, for the moment, that (B.46) to (B.51) hold. If (3.24) does not hold, we have  $\rho_0(K) = \rho_1(K) = 1$ , and therefore there exist  $X \in \mathbb{C}^6$  and  $(\Upsilon_1, \dots, \Upsilon_6)^{\text{tr}} \in \mathbb{C}^n$  such that (B.23), (B.24), and (B.25) hold. Clearly,

$$(B.52) \quad |KX| = |X|.$$

Since

$$|K(Y + Z)| = |Y| \quad \forall Y \in \mathbb{C}A_1 + \mathbb{C}A_2 + \mathbb{C}A_3,$$

$$\forall Z \in \mathbb{C}^n \text{ such that } Z^{\text{tr}}A_1 = Z^{\text{tr}}A_2 = Z^{\text{tr}}A_3 = 0,$$

it follows from (B.52) that  $X \in \mathbb{C}A_1 + \mathbb{C}A_2 + \mathbb{C}A_3$ . Hence, there exist  $\xi_1 \in \mathbb{C}$ ,  $\xi_2 \in \mathbb{C}$ , and  $\xi_3 \in \mathbb{C}$  such that

$$(B.53) \quad X = \xi_1 A_1 + \xi_2 A_2 + \xi_3 A_3.$$

Using (B.25), one gets  $(KX)_1 = \Upsilon_1 X_1$  and  $(KX)_2 = \Upsilon_1 X_2$ , which, together with (A.21) and (B.24), imply that

$$(B.54) \quad |\xi_1| = |\xi_2| = |\xi_3|.$$

Using (B.23) and (B.54) one sees that, without loss of generality, we may assume that

$$\xi_1 = 1, \quad |\xi_2| = |\xi_3| = 1.$$

Hence there exist  $\theta_2 \in \mathbb{R}$  and  $\theta_3 \in \mathbb{R}$  such that

$$(B.55) \quad \xi_2 = e^{i\theta_2}, \quad \xi_3 = e^{i\theta_3}.$$

Now using  $|(KX)_3| = |X_3|$ , one gets

$$|\xi_2 + \xi_3| = \sqrt{2},$$

which, together with (B.55), is equivalent to

$$\cos(\theta_3 - \theta_2) = 0;$$

i.e., there exists  $\varepsilon_3 \in \{1, -1\}$  such that

$$(B.56) \quad \xi_3 = \varepsilon_3 \iota \xi_2.$$

Proceeding similarly with the fourth of  $KX$ , one gets the existence of  $\varepsilon_2 \in \{1, -1\}$  such that

$$(B.57) \quad \xi_2 = \varepsilon_2 \iota.$$

Then  $|(KX)_5| = |X_5|$  and  $|(KX)_6| = |X_6|$  are equivalent to

$$(B.58) \quad (u_1 + \varepsilon_1 w_1)^2 + v_1^2 = (x_1 + \varepsilon_1 z_1)^2 + y_1^2,$$

$$(B.59) \quad (u_2 + \varepsilon_1 w_2)^2 + v_2^2 = (x_2 + \varepsilon_1 z_2)^2 + y_2^2$$

with

$$\varepsilon_1 := -\varepsilon_2 \varepsilon_3 \in \{1, -1\}.$$

Let

$$(B.60) \quad \begin{aligned} F : \quad & \mathbb{R}^{12} & \rightarrow & \mathbb{R}^7, \\ P := (u_1, v_1, w_1, x_1, y_1, z_1, u_2, v_2, w_2, x_2, y_2, z_2)^{\text{tr}} & \mapsto & F(P) \end{aligned}$$

be defined by

$$F(P) := \begin{pmatrix} \frac{3}{2} + u_1^2 + u_2^2 - x_1^2 - x_2^2 \\ -1 + v_1^2 + v_2^2 - y_1^2 - y_2^2 \\ -\frac{1}{2} + w_1^2 + w_2^2 - z_1^2 - z_2^2 \\ \frac{1}{2} + u_1 v_1 + u_2 v_2 - x_1 y_1 - x_2 y_2 \\ u_1 w_1 + u_2 w_2 - x_1 z_1 - x_2 z_2 \\ -\frac{1}{2} + v_1 w_1 + v_2 w_2 - y_1 z_1 - y_2 z_2 \\ u_1^2 + v_1^2 + w_1^2 - x_1^2 - y_1^2 - z_1^2 \end{pmatrix}.$$

Let  $\Sigma$  be the subset of  $\mathbb{R}^{12}$  defined by

$$\Sigma := \{P \in \mathbb{R}^{12}; F(P) = 0 \text{ and the rank of } F'(P) \text{ is } 7\}.$$

Let

$$\tilde{P} := \left(0, 1, 0, 1, 0, 0, -\frac{1}{4}, \frac{1}{2}, \frac{3}{4}, \frac{3}{4}, \frac{1}{2}, -\frac{1}{4}\right)^{\text{tr}} \in \mathbb{R}^{12}.$$

One easily checks that  $F(\tilde{P}) = 0$ . Straightforward computations give

$$(B.61) \quad F'(\tilde{P}) = \begin{pmatrix} 0 & 0 & 0 & -2 & 0 & 0 & -\frac{1}{2} & 0 & 0 & -\frac{3}{2} & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{3}{2} & 0 & 0 & \frac{1}{2} \\ 1 & 0 & 0 & 0 & -1 & 0 & \frac{1}{2} & -\frac{1}{4} & 0 & -\frac{1}{2} & -\frac{3}{4} & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & \frac{3}{4} & 0 & -\frac{1}{4} & \frac{1}{4} & 0 & -\frac{3}{4} \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & \frac{3}{4} & \frac{1}{2} & 0 & \frac{1}{4} & -\frac{1}{2} \\ 0 & 2 & 0 & -2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

In particular, the rank of  $F'(\tilde{P})$  is 7. Hence  $\tilde{P}$  is in  $\Sigma$ , and the set  $\Sigma$  is not empty and is a submanifold of  $\mathbb{R}^{12}$  of dimension  $12 - 7 = 5$ . The tangent space to this manifold at  $\tilde{P}$  is  $\text{Ker } F'(\tilde{P})$ . Let  $G_+$  be the map

$$\begin{aligned} G_+ : \quad & \mathbb{R}^{12} \quad \rightarrow \quad \mathbb{R}^2, \\ P := (u_1, v_1, w_1, x_1, y_1, z_1, u_2, v_2, w_2, x_2, y_2, z_2)^{\text{tr}} \quad & \mapsto \quad G_+(P) \end{aligned}$$

defined by

$$G_+(P) := \begin{pmatrix} (u_1 + w_1)^2 + v_1^2 - (x_1 + z_1)^2 - y_1^2 \\ (u_2 + w_2)^2 + v_2^2 - (x_2 + z_2)^2 - y_2^2 \end{pmatrix}.$$

Similarly, let  $G_-$  be the map

$$\begin{aligned} G_- : \quad \mathbb{R}^{12} &\rightarrow \mathbb{R}^2, \\ P := (u_1, v_1, w_1, x_1, y_1, z_1, u_2, v_2, w_2, x_2, y_2, z_2)^{\text{tr}} &\mapsto G_-(P) \end{aligned}$$

defined by

$$G_-(P) := \begin{pmatrix} (u_1 - w_1)^2 + v_1^2 - (x_1 - z_1)^2 - y_1^2 \\ (u_2 - w_2)^2 + v_2^2 - (x_2 - z_2)^2 - y_2^2 \end{pmatrix}.$$

Let  $S_+ \subset \mathbb{R}^{12}$  and  $S_- \subset \mathbb{R}^{12}$  be defined by

$$S_+ := \{P \in \mathbb{R}^{12}; G_+(P) = 0\},$$

$$S_- := \{P \in \mathbb{R}^{12}; G_-(P) = 0\}.$$

It suffices to check that

$$(B.62) \quad \Sigma \text{ is not a subset of } S_- \cup S_+.$$

Note that  $\tilde{P} \in S_- \cap S_+$  and

$$(B.63) \quad G'_-(\tilde{P}) = \begin{pmatrix} 0 & 2 & 0 & -2 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -2 & 1 & 2 & -2 & -1 & 2 \end{pmatrix},$$

$$(B.64) \quad G'_+(\tilde{P}) = \begin{pmatrix} 0 & 2 & 0 & -2 & 0 & -2 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & -1 & -1 & -1 \end{pmatrix}.$$

In particular the rank of  $G'_-(\tilde{P})$  and the rank of  $G'_+(\tilde{P})$  are both equal to 2. Hence, if  $r > 0$  is small enough, the set  $\{P \in S_-; |P - \tilde{P}| < r\}$  and the set  $\{P \in S_+; |P - \tilde{P}| < r\}$  are submanifolds of  $\mathbb{R}^{12}$  of dimension  $12 - 2 = 10$  whose tangent spaces at  $\tilde{P}$  are  $\text{Ker } G'_-(\tilde{P})$  and  $\text{Ker } G'_+(\tilde{P})$ , respectively. Therefore (B.62) holds if

$$(B.65) \quad \text{Ker } F'(\tilde{P}) \text{ is not a subset of } \text{Ker } G'_-(\tilde{P}) \cup \text{Ker } G'_+(\tilde{P}).$$

Property (B.65) follows from (B.61), (B.63), and (B.64). This concludes the proof of Proposition 3.7.  $\square$

## A HYBRID EXTRAGRADIENT-VISCOSITY METHOD FOR MONOTONE OPERATORS AND FIXED POINT PROBLEMS\*

PAUL-EMILE MAINGÉ†

**Abstract.** This paper deals with an iterative method, in a real Hilbert space, for approximating a common element of the set of fixed points of a demicontractive operator (possibly quasi-nonexpansive or strictly pseudocontractive) and the set of solutions of a variational inequality problem for a monotone, Lipschitz continuous mapping. The considered algorithm can be regarded as a combination of a variation of the hybrid steepest descent method and the so-called extragradient method. Under classical conditions, we prove the strong convergence of the sequences of iterates given by the considered scheme.

**Key words.** fixed point problem, variational inequality, monotone mapping, hybrid steepest descent, extragradient method

**AMS subject classifications.** 90C25, 49M45, 65C25

**DOI.** 10.1137/060675319

**1. Introduction.** Variational inequalities as well as fixed point problems are well known to be very useful and efficient tools in mathematics. They provide a unified framework for studying many problems arising in engineering sciences, structural analysis, and other fields (see, e.g., [14, 15, 46, 47, 51, 53]). A closely related subject of current interest is the problem of finding common elements of the set of fixed points of operators and the set of solutions of variational inequalities [35, 48, 54]. The motivation for this subject is mainly due to its possible applications to mathematical modeling of concrete complex problems. Indeed, a classical strategy to construct such mathematical models consists in introducing constraints which can be expressed as subproblems of a more general problem. In some cases, these constraints can be given by variational inequalities [37], by fixed point problems [46, 47], or by problems of different types [1]. The purpose of our work is to propose a strongly convergent iterative method for computing a common element of the set of fixed points of a wide class of operators and the set of solutions of a variational inequality problem for a non-strictly monotone mapping. It is worthwhile recalling that strongly convergent algorithms are of fundamental importance for solving problems in infinite dimensional spaces (see, for instance, [3]).

Throughout this paper,  $\mathcal{H}$  is a real Hilbert space with an inner product  $\langle \cdot, \cdot \rangle$  and its induced norm  $\| \cdot \|$ . Let us denote by  $\Omega$  the set of solutions of the following variational inequality problem, which we abbreviate as  $VIP(A, C)$  (see [14, 15, 24, 43]):

$$(1.1) \quad \text{find } u \in C \quad \text{such that} \quad \langle v - u, Au \rangle \geq 0 \quad \forall v \in C,$$

where  $C$  is a nonempty closed convex set in  $\mathcal{H}$  and  $A : \mathcal{H} \rightarrow \mathcal{H}$  is a monotone mapping on  $C$ , i.e.,

$$\langle Ax - Ay, x - y \rangle \geq 0 \quad \forall x, y \in C.$$

---

Also consider an operator  $T : \mathcal{H} \rightarrow \mathcal{H}$  such that  $\text{Fix}(T) \cap \Omega \neq \emptyset$ , where  $\text{Fix}(T)$  is the fixed point set of  $T$ , namely the set of solutions of the following problem:

$$(1.2) \quad \text{find } u \in \mathcal{H} \quad \text{such that} \quad u = Tu.$$

In the present work, we are interested in approximating a common solution of (1.1) and (1.2), which can be obviously written as

$$(1.3) \quad \text{find } u \in \Omega \cap \text{Fix}(T).$$

There is an extensive literature on numerical approaches to solving either variational inequalities (e.g., projection methods [5, 15, 22, 23, 31, 41, 42], merit functions [45], outer approximation methods [9]), or fixed point problems for different classes of mappings (e.g., outer approximation methods [3], viscosity approximation methods [2, 7, 8, 17, 20, 25, 28, 34, 38, 39, 49], relaxed or Mann-type algorithms [10, 26, 30], inertial-type algorithms [29]). A natural way we can attempt to construct a method for solving (1.3) is to combine solution techniques for fixed point problems and those for variational inequalities. Such combinations would probably give rise to different kinds of methods of more or less practical interest regarding convergence properties and requirements on the operators. In the present work, we will restrict ourselves to the study of an iterative process which involves projection methods, relaxation, and viscosity approximations.

An outline of this paper is as follows. In section 2, an overview of some related methods is presented. In section 3, we propose a new extragradient-viscosity algorithm for solving (1.3). Section 4 is devoted to our main convergence result and its proof. In section 5, we apply the main convergence theorem to some specific examples.

**2. Some existing algorithms.** Before we proceed with other related methods, we give some reminders regarding projection-type methods, relaxed (or Mann-type) iterations, and viscosity-type approximations.

On the one hand, projection-type methods related to (1.1) were suggested by its equivalent fixed point formulation:

$$(2.1) \quad \text{find } u \in C \quad \text{such that} \quad u = P_C(u - \lambda Au),$$

where  $\lambda \in (0, +\infty)$  and  $P_C : \mathcal{H} \rightarrow C$  is the metric projection from  $\mathcal{H}$  onto  $C$ , characterized for all  $x \in \mathcal{H}$  by  $P_C(x) \in C$  and  $|P_C(x) - x| = \min_{y \in C} |x - y|$  (also see Remark 4.1). In particular, the simplest of these projection methods was given for  $\mathcal{H} = \mathbb{R}^n$  (finite dimensional case) by the following algorithm ([5, 41]):

$$(2.2) \quad \begin{cases} x_0 \in \mathbb{R}^n, \\ x_{n+1} = P_C(x_n - \lambda Ax_n) \quad \forall n \geq 0, \end{cases}$$

where  $\lambda$  is a judiciously chosen positive stepsize. However, for convergence, this last algorithm requires the restrictive assumption that  $A$  be either strongly monotone and Lipschitz continuous on  $C$ , or co-coercive on  $C$ . Let us recall that  $A$  is called *strongly monotone* on  $C$  if there exists  $\theta > 0$  such that  $\langle Ax - Ay, x - y \rangle \geq \theta |x - y|^2$  for all  $x, y \in C$ ; *Lipschitz continuous* on  $C$  if there exists  $k > 0$  such that  $|Ax - Ay| \leq k|x - y|$  for all  $x, y \in C$ ; *co-coercive* (also called *inverse strongly monotone*) on  $C$  if there exists  $\theta > 0$  such that  $\langle Ax - Ay, x - y \rangle \geq \theta |Ax - Ay|^2$  for all  $x, y \in C$ .

To overcome the drawbacks of (2.2), Korpelevich [23] introduced the following so-called extragradient method (also see [22, 31, 42] for extensions):

$$(2.3) \quad \begin{cases} x_0 \in \mathbb{R}^n, \\ \bar{x}_n = P_C(x_n - \lambda A x_n), \\ x_{n+1} = P_C(x_n - \lambda A \bar{x}_n) \quad \forall n \geq 0, \end{cases}$$

where  $A : \mathbb{R}^n \rightarrow \mathbb{R}^n$  is monotone,  $k$ -Lipschitz continuous on  $C$  (i.e.,  $|Ax - Ay| \leq k|x - y|$  for all  $x, y \in C$ ) and  $\lambda \in (0, 1/k)$ . He proved that the two sequences  $(x_n)$  and  $(\bar{x}_n)$  converge to the same point in the solution set  $\Omega$ .

On the other hand, a classical method for computing fixed points of an operator  $T : \mathcal{H} \rightarrow \mathcal{H}$  was given by Mann's iteration [30]:

$$(2.4) \quad x_{n+1} = \alpha_n x_n + (1 - \alpha_n) T x_n,$$

where  $(\alpha_n) \subset (0, 1)$ . It has been applied successfully to various concrete problems in the finite dimensional setting [10]. However, in infinite dimensional spaces, the iterative method (2.4) does not converge strongly in general, even when  $T$  belongs to a relatively small class of nonexpansive mappings (i.e.,  $|Tx - Ty| \leq |x - y|$  for all  $x, y \in \mathcal{H}$ ), except for very restrictive conditions on the operator  $T$  and the space  $\mathcal{H}$ .

As an alternative to Mann's iteration, viscosity approximations were proposed to select a particular fixed point of a nonexpansive operator  $T : \mathcal{H} \rightarrow \mathcal{H}$ , by the following process [2, 7, 8, 17, 25, 49]:

$$(2.5) \quad \begin{cases} x_0 \in \mathcal{H}, \\ x_{n+1} = \alpha_n w + (1 - \alpha_n) T x_n \quad \forall n \geq 0, \end{cases}$$

where  $w$  is any element in  $\mathcal{H}$  and where  $(\alpha_n) \subset (0, 1)$  is a slow decreasing sequence, in the sense that  $\alpha_n \rightarrow 0$  and  $\sum_{n \geq 0} \alpha_n = \infty$ . The iteration (2.5) was introduced first by Halpern [17] in the case when  $w = 0$ . It is well known that, under some additional conditions on  $(\alpha_n)$ , the sequence given by (2.5) converges strongly to  $P_{\text{Fix}(T)}(w)$ , where  $P_{\text{Fix}(T)}$  is the metric projection from  $\mathcal{H}$  onto  $\text{Fix}(T)$ . Later on, similar convergence results were established by Moudafi [34] in the case when the constant element  $w$  is replaced by a more general contraction (also see [20, 28]).

Now, let us recall some existing methods for solving (1.3), such as the following.

(1) A typical algorithm when  $T$  is nonexpansive (i.e.,  $|Tx - Ty| \leq |x - y|$  for all  $x, y \in \mathcal{H}$ ) and  $A$  is  $(1/k)$ -co-coercive (i.e.,  $\langle Ax - Ay, x - y \rangle \geq (1/k)|Ax - Ay|^2$  for all  $x, y \in \mathcal{H}$ ) was discussed by Takahashi and Toyoda [48]:

$$(2.6) \quad \begin{cases} x_0 \in C, \\ x_{n+1} = \alpha_n x_n + (1 - \alpha_n) T P_C(x_n - \lambda_n A x_n) \quad \forall n \geq 0, \end{cases}$$

where  $(\alpha_n) \subset (0, 1)$  and  $(\lambda_n) \subset (0, 2/k)$ . It combines Mann's iteration [30] and the basic projection method. They proved that the sequence  $(x_n)$  generated by (2.6) converges weakly to some element in  $\text{Fix}(T) \cap \Omega$ .

(2) Another iterative process based on Korpelevich's extragradient method [23] and Mann's iteration [30] was proposed later by Nadezhkina and Takahashi [35] when  $T$  is nonexpansive and  $A$  is monotone and  $k$ -Lipschitz continuous (i.e.,  $|Ax - Ay| \leq k|x - y|$  for all  $x, y \in \mathcal{H}$ ):

$$(2.7) \quad \begin{cases} x_0 \in \mathcal{H}, \\ y_n = P_C(x_n - \lambda_n A x_n), \\ x_{n+1} = \alpha_n x_n + (1 - \alpha_n) T P_C(x_n - \lambda_n A y_n) \quad \forall n \geq 0, \end{cases}$$

where  $(\lambda_n) \subset [a, b]$  for some  $a, b \in (0, 1/k)$  and  $(\alpha_n) \subset [c, d]$  for some  $c, d \in (0, 1)$ . They showed that the two sequences  $(x_n)$  and  $(y_n)$  given by (2.7) converge weakly to the same point in  $\text{Fix}(T) \cap \Omega$ . Observe that the assumptions required for convergence are weaker for (2.7) than for (2.6), since co-coercivity implies Lipschitz continuity.

(3) Recently, a variation of Nadezhkina and Takahashi's process [35] was suggested by Zeng and Yao [54]. This last algorithm combines Korpelevich's extragradient method [23] and the Halpern-type iteration [2, 25, 49]. The main result obtained can be summarized as follows.

**THEOREM 2.1** (see [54, Theorem 3.1]). *Let  $C$  be a nonempty closed convex subset of a real Hilbert space  $\mathcal{H}$ . Let  $A : C \rightarrow \mathcal{H}$  be a monotone,  $k$ -Lipschitz continuous mapping and  $T : C \rightarrow C$  be a nonexpansive mapping such that  $\text{Fix}(T) \cap \Omega \neq \emptyset$ . Let  $(x_n)$  and  $(y_n)$  be the sequences generated by*

$$(2.8) \quad \begin{cases} x_0 \in \mathcal{H}, \\ y_n = P_C(x_n - \lambda_n A x_n), \\ x_{n+1} = \alpha_n x_0 + (1 - \alpha_n) T P_C(x_n - \lambda_n A y_n) \quad \forall n \geq 0, \end{cases}$$

where  $(\lambda_n)$  and  $(\alpha_n)$  satisfy the conditions

- (a)  $(k\lambda_n) \subset [a, b]$  for some  $a, b \in (0, 1)$ ;
- (b)  $(\alpha_n) \subset (0, 1)$ ,  $\sum_{n \geq 0} \alpha_n = \infty$ ,  $\alpha_n \rightarrow 0$ .

Then the sequences  $(x_n)$  and  $(y_n)$  converge strongly to the same point  $P_{\text{Fix}(T) \cap \Omega} x_0$  provided  $|x_{n+1} - x_n| \rightarrow 0$ .

*Remark 2.1.* The original condition (a) of Theorem 3.1 in [54] is “ $(k\lambda_n) \subset (0, 1 - \delta)$  for some  $\delta \in (0, 1)$ ,” which allows  $\lambda_n \rightarrow 0$ , but it seems there is something wrong; nevertheless, a correct condition is given in Theorem 2.1.

**3. A new extragradient-viscosity algorithm.** It is noteworthy that the convergence results given by Takahashi and Toyoda [48] for (2.6) do not include important classes of mappings, even in the finite dimensional setting. Consider, for instance, the case of a linear complementary problem, with an associated matrix which is positively semidefinite but not positively definite. It is then easily checked that the corresponding mapping  $A$  is monotone and Lipschitz continuous but not co-coercive. The method (2.7) of Nadezhkina and Takahashi [35] is then applicable to a wider class of problems; however, its efficiency is valid only in finite dimensional spaces, because only weak convergence is obtained. Furthermore, in all the previously mentioned examples, the mapping  $T$  is assumed to be nonexpansive, while certain operators arising for instance in subgradient-projection techniques are not nonexpansive but quasi-nonexpansive (see Definition 3.2 and also, e.g., [3, 29, 52]).

In this paper, we propose an alternative method (algorithm (3.6)) for solving (1.3) in the more general case when  $A$  is monotone and Lipschitz continuous while  $T$  is demicontractive and demiclosed. Regarding this framework,  $\Omega$  is a closed convex set (see [6]), as is  $\text{Fix}(T)$  (see Remark 4.2); hence so is  $\Omega \cap \text{Fix}(T)$ . A strong convergence theorem is also established (Theorem 4.1). For convergence, our method does not require such a restrictive condition as  $|x_{n+1} - x_n| \rightarrow 0$ , which is needed by Zeng and Yao [54]; additionally it covers a much more general class of problems.

Let us recall some definitions of common use in optimization theory.

**DEFINITION 3.1** (see [16]). *A mapping  $T : \mathcal{H} \rightarrow \mathcal{H}$  is called demiclosed if, for any sequence  $(z_k) \subset \mathcal{H}$  and  $z \in \mathcal{H}$ , the following holds:*

$$z_k \rightarrow z \quad \text{weakly}, \quad (I - T)(z_k) \rightarrow 0 \quad \text{strongly} \quad \Rightarrow \quad z \in \text{Fix}(T).$$

DEFINITION 3.2 (see [32, 33, 36]). A mapping  $T : \mathcal{H} \rightarrow \mathcal{H}$  is called (i) quasi-nonexpansive if  $|Tx - q| \leq |x - q|$  for all  $(x, q) \in \mathcal{H} \times \text{Fix}(T)$ ; (ii)  $\rho$ -strictly pseudocontractive if  $|Tx - Ty|^2 \leq |x - y|^2 + \rho|x - y - (Tx - Ty)|^2$  for all  $(x, y) \in \mathcal{H} \times \mathcal{H}$  (for some  $\rho \in [0, 1)$ ); (iii) demicontractive if there exists  $\beta \in [0, 1)$  such that

$$(3.1) \quad |Tx - q|^2 \leq |x - q|^2 + \beta|x - Tx|^2 \quad \forall (x, q) \in \mathcal{H} \times \text{Fix}(T).$$

Remark 3.1. It is easily checked (thanks to (4.3)) that (3.1) can be equivalently rewritten as

$$(3.2) \quad \langle x - Tx, x - q \rangle \geq (1/2)(1 - \beta)|x - Tx|^2 \quad \forall (x, q) \in \mathcal{H} \times \text{Fix}(T).$$

A mapping satisfying (3.1) or (3.2) will be referred to as  $\beta$ -demicontractive. Let us observe that the set of demicontractive operators contains fundamental classes of mappings (nonexpansive, quasi-nonexpansive, and strictly pseudocontractive maps with fixed points), commonly found in various areas of applied mathematics [19, 32, 33]. More precisely, the class of 0-demicontractive mappings contains all the quasi-nonexpansive operators, while this latter set of mappings contains that of nonexpansive operators with fixed points. In addition, it is easily checked that all the nonexpansive operators are  $\rho$ -strictly pseudocontractive, while this latter type of operators (with fixed points) is  $\rho$ -demicontractive. Moreover, the strictly pseudocontractive maps as well as many quasi-nonexpansive operators (including subgradient-projection operators [3, 29]) are well known to be demiclosed.

To select a particular solution of (1.3), we will focus our attention on solving the variational inequality problem  $VIP(\mathcal{F}, \Omega \cap \text{Fix}(T))$ :

$$(3.3) \quad \text{find } x_* \in \text{Fix}(T) \cap \Omega \quad \text{s.t.} \quad \langle v - x_*, \mathcal{F}(x_*) \rangle \geq 0 \quad \forall v \in \text{Fix}(T) \cap \Omega,$$

where  $T$  is assumed to be demicontractive and  $\mathcal{F} : C \rightarrow \mathcal{H}$  satisfies the following two conditions:

- (LC)  $\mathcal{F}$  is  $L$ -Lipschitz continuous (for some  $L \geq 0$ ),  
i.e.,  $|\mathcal{F}(x) - \mathcal{F}(y)| \leq L|x - y| \quad \forall x, y \in C$ ;
- (SM)  $\mathcal{F}$  is  $\eta$ -strongly monotone (for some  $\eta > 0$ ),  
i.e.,  $\langle \mathcal{F}(x) - \mathcal{F}(y), x - y \rangle \geq \eta|x - y|^2 \quad \forall x, y \in C$ .

It is routine to see that the existence and the uniqueness of a solution of (3.3) are ensured by the conditions (LC) and (SM) and by the fact that  $\Omega \cap \text{Fix}(T)$  is a nonempty closed and convex set (thanks to the considered hypothesis).

The algorithm, which we propose in the sequel, is based on the extragradient method and some variant of the following so-called *hybrid steepest descent method* initiated in [51, 52] (also see [50]):

$$(3.4) \quad \begin{cases} x_0 \in \mathcal{H}, \\ x_{n+1} = Tx_n - \alpha_{n+1}\mathcal{F}(Tx_n) \quad \forall n \geq 0, \end{cases}$$

where  $(\alpha_n) \subset (0, 1)$  is a slow decreasing sequence. This latter process was suggested by Yamada [51] as an extension of viscosity approximation methods for solving the variational inequality  $VIP(\mathcal{F}, \text{Fix}(T))$  in the case when  $\mathcal{F}$  is strongly monotone and Lipschitz continuous. Strong convergence theorems were obtained for (3.4) when  $T$  belongs to a subclass of the quasi-nonexpansive maps (so-called *quasi-shrinking operators*). Note that, by letting  $z_n = Tx_n$  ( $(x_n)$  being the sequence given by (3.4)), we immediately obtain

$$(3.5) \quad z_{n+1} = T(z_n - \alpha_{n+1}\mathcal{F}(z_n)).$$

Furthermore, when  $T$  is a projection operator and  $\mathcal{F}$  is the gradient of a real-valued function, (3.5) reduces to the gradient projection method. This latter algorithm is nothing but an extension of the steepest descent method from unconstrained to constrained minimization (see, e.g., [4] for a brief review on this topic).

For solving (3.3), we investigate the asymptotic behavior of the sequence  $(x_n)$  generated, from an arbitrary  $x_0$  in  $\mathcal{H}$ , by the following algorithm:

$$(3.6) \quad \begin{cases} x_0 \in \mathcal{H}, \\ y_n = P_C(x_n - \lambda_n A x_n), \\ t_n = P_C(x_n - \lambda_n A y_n), \\ x_{n+1} := [(1-w)I + wT]v_n, \quad v_n := t_n - \alpha_n \mathcal{F}(t_n), \end{cases}$$

where  $I : \mathcal{H} \rightarrow \mathcal{H}$  is the identity mapping and the parameters are such that  $(\alpha_n) \subset [0, 1)$ ,  $(\lambda_n) \subset (0, \infty)$ , and  $w \in (0, 1)$ . In the special case when  $A = 0$  and  $C = \mathcal{H}$  (hence  $\Omega = \mathcal{H}$ ), (3.6) reduces to a relaxed version of (3.5). In the same frame, (3.3) reduces to  $VIP(\mathcal{F}, \text{Fix}(T))$ , which is exactly the problem considered by Yamada and Ogura [51, 52] in the less general case of certain quasi-nonexpansive mappings. In the case when  $T = I$  and  $\alpha_n = 0$ , (3.6) becomes Korpelevich's extragradient method [23]. Clearly, (3.6) can be regarded as a combination of the extragradient method and a relaxed variant of the hybrid steepest descent method. Note that the relaxation process induced by the mapping  $(1-w)I + wT$  in (3.6) was mainly suggested by the work of Suzuki [44] (see also [19, 30, 51]). It is also interesting to see that the limit attained by the iterates of the method (2.8) is nothing but the solution of (3.3) in the particular case when  $\mathcal{F} := I - x_0$ .

Under classical assumptions on the operators and the parameters, we prove that the sequences  $(x_n)$ ,  $(y_n)$ , and  $(t_n)$  generated by the scheme (3.6) converge strongly to the unique solution of (3.3). Then by the algorithm (3.6), we provide an efficient selecting-type method for solving the initial mixed problem (1.3) for a new broad class of maps. Moreover, the techniques used are simple and different from the usual ones.

**4. Main convergence result.** In this section, we establish our main convergence result given by the following theorem.

**THEOREM 4.1.** *Let  $\beta \in [0, 1)$ . Suppose  $A : \mathcal{H} \rightarrow \mathcal{H}$  is monotone on  $C$  and  $k$ -Lipschitz continuous on  $\mathcal{H}$ . Suppose  $T : \mathcal{H} \rightarrow \mathcal{H}$  is  $\beta$ -demicomtractive, demiclosed with  $\text{Fix}(T) \cap \Omega \neq \emptyset$ . Let  $\mathcal{F} : \mathcal{H} \rightarrow \mathcal{H}$  satisfy (LC) and (SM) and assume that the following conditions hold:*

- (H1)  $w \in (0, \frac{1-\beta}{2}]$ ;
- (H2)  $(\alpha_n) \subset [0, 1)$ ,  $\alpha_n \rightarrow 0$ ;
- (H3)  $(k\lambda_n) \subset [\delta_1, \delta_2]$  (where  $0 < \delta_1 \leq \delta_2 < 1$ );
- (SP)  $\sum_{n \geq 0} \alpha_n = \infty$ .

*Then the sequences  $(x_n)$ ,  $(y_n)$ , and  $(t_n)$  generated by (3.6) converge strongly to  $x_*$ , the unique solution of (3.3).*

Before proving Theorem 4.1, we need a sequence of preliminaries. In particular, we state some crucial inequalities resulting from (3.6). We also prove the boundedness of the sequences generated by (3.6), and we give sufficient conditions so that the weak cluster points of these sequences lies in the solution set  $\Omega \cap \text{Fix}(T)$ .

**4.1. Estimates on the numerical method.** In what follows, we first establish useful inequalities related to the extragradient part and the fixed point part of the method (3.6). To begin with, we recall some classical results related to  $P_C$ , the metric projection from  $\mathcal{H}$  onto  $C$  (a nonempty convex and closed subset of  $\mathcal{H}$ ).

*Remark 4.1.*  $P_C : \mathcal{H} \rightarrow C$  is a nonexpansive operator defined for all  $x \in \mathcal{H}$  by  $P_C x := \operatorname{argmin}_{z \in C} |z - x|$ . Furthermore,  $P_C$  is alternatively characterized by the following inequality (see, for instance, [47])

$$(4.1) \quad \langle x - P_C x, P_C x - y \rangle \geq 0 \quad \forall (x, y) \in \mathcal{H} \times C,$$

or equivalently

$$(4.2) \quad |x - y|^2 \geq |x - P_C x|^2 + |y - P_C x|^2 \quad \forall (x, y) \in \mathcal{H} \times C.$$

The equivalence of (4.1) and (4.2) can be deduced from the obvious equality:

$$(4.3) \quad \langle a, b \rangle = -(1/2)|a - b|^2 + (1/2)|a|^2 + (1/2)|b|^2.$$

The next lemma is concerned with estimates regarding the extragradient part of the method. It is obtained with the same techniques as in [54], and its proof is given for the sake of completeness.

**LEMMA 4.2.** *Suppose  $A : \mathcal{H} \rightarrow \mathcal{H}$  is  $k$ -Lipschitz continuous on  $\mathcal{H}$  and let  $(t_n)$ ,  $(y_n)$ , and  $(x_n)$  be sequences in  $\mathcal{H}$  such that*

$$(4.4) \quad y_n = P_C(x_n - \lambda_n A x_n) \quad \text{and} \quad t_n = P_C(x_n - \lambda_n A y_n).$$

*Then the following inequality holds:*

$$(4.5) \quad |y_n - t_n| \leq k\lambda_n |x_n - y_n|.$$

*If, in addition,  $\Omega \neq \emptyset$  and  $A$  is monotone on  $C$ , then the following holds:*

$$(4.6) \quad |t_n - u|^2 \leq |x_n - u|^2 - (1 - k^2 \lambda_n^2) |x_n - y_n|^2,$$

*where  $u$  is any element in  $\Omega$ .*

*Proof.* From (4.4), we have  $|y_n - t_n| = |P_C(x_n - \lambda_n A x_n) - P_C(x_n - \lambda_n A y_n)|$ ; since  $P_C$  is nonexpansive and  $A$  is assumed to be  $k$ -Lipschitz continuous, we get  $|y_n - t_n| \leq \lambda_n |A x_n - A y_n| \leq k\lambda_n |x_n - y_n|$ , that is, (4.5). Let us prove (4.6). Given  $u \in \Omega$  (hence  $u \in C$ ) and using (4.4), we have  $|t_n - u| = |u - P_C(x_n - \lambda_n A y_n)|$ , which by (4.2) yields  $|t_n - u|^2 \leq |x_n - u - \lambda_n A y_n|^2 - |x_n - t_n - \lambda_n A y_n|^2$ , namely

$$(4.7) \quad |t_n - u|^2 \leq |x_n - u|^2 - |x_n - t_n|^2 + 2\lambda_n \langle A y_n, u - t_n \rangle.$$

The last term in the right-hand side of (4.7) can be rewritten as

$$(4.8) \quad \langle A y_n, u - t_n \rangle = \langle A y_n - A u, u - y_n \rangle + \langle A u, u - y_n \rangle + \langle A y_n, y_n - t_n \rangle.$$

It is easily seen that the first and second terms in the right-hand side of (4.8) are negative, because of the monotonicity of  $A$  on  $C$ , the fact that  $u$  is a solution of  $VIP(A, C)$ , and since  $y_n \in C$ . Clearly, we then deduce  $\langle A y_n, u - t_n \rangle \leq \langle A y_n, y_n - t_n \rangle$ , which by (4.7) amounts to  $|t_n - u|^2 \leq |x_n - u|^2 - |x_n - t_n|^2 + 2\lambda_n \langle A y_n, y_n - t_n \rangle$ , namely

$$(4.9) \quad |t_n - u|^2 \leq |x_n - u|^2 - |x_n - y_n|^2 - |y_n - t_n|^2 + 2\langle x_n - \lambda_n A y_n - y_n, t_n - y_n \rangle.$$

Furthermore, setting  $u_n := x_n - \lambda_n A x_n$  (hence  $y_n := P_C(u_n)$ ), we immediately have

$$\langle x_n - \lambda_n A y_n - y_n, t_n - y_n \rangle = \langle u_n - P_C(u_n), t_n - P_C(u_n) \rangle + \lambda_n \langle A x_n - A y_n, t_n - y_n \rangle.$$

In light of (4.1), we observe that the first term in the right-hand side of this last equality is negative, which entails  $\langle x_n - \lambda_n A y_n - y_n, t_n - y_n \rangle \leq \lambda_n \langle A x_n - A y_n, t_n - y_n \rangle$ . Hence, using the Lipschitz continuity of  $A$ , we obtain

$$\langle x_n - \lambda_n A y_n - y_n, t_n - y_n \rangle \leq (k\lambda_n |x_n - y_n|) \times |t_n - y_n|,$$

which by Young's inequality leads to

$$\langle x_n - \lambda_n A y_n - y_n, t_n - y_n \rangle \leq (1/2)(k\lambda_n)^2 |x_n - y_n|^2 + (1/2)|t_n - y_n|^2.$$

By joining this last inequality to (4.9), we get the desired result.  $\square$

In the following remark, we put out some fundamental properties induced by the relaxation process occurring in the fixed point part of the method.

*Remark 4.2.* Let  $T$  be a  $\beta$ -demicontractive self-mapping on  $\mathcal{H}$  with  $\text{Fix}(T) \neq \emptyset$  and set  $T_w := (1 - w)I + wT$  for  $w \in (0, 1]$ . Then  $T_w$  is quasi-nonexpansive if  $w \in [0, 1 - \beta]$ . Indeed, for any arbitrary element  $(x, q) \in \mathcal{H} \times \text{Fix}(T)$ , we have

$$|T_w x - q|^2 = |x - q|^2 - 2w \langle x - q, x - Tx \rangle + w^2 |Tx - x|^2,$$

which by (3.2) yields

$$(4.10) \quad |T_w x - q|^2 \leq |x - q|^2 - w(1 - \beta - w)|Tx - x|^2.$$

Furthermore, it is routine to see that  $\text{Fix}(T) = \text{Fix}(T_w)$  if  $w \neq 0$ . As a consequence,  $T_w$  is quasi-nonexpansive for  $w \in [0, 1 - \beta]$  and  $\text{Fix}(T)$  is then a closed convex subset of  $\mathcal{H}$  (see [52, Proposition 1], [21, Corollary 1]).

Now, we state our main inequality resulting from the combination of the extra-gradient part and the fixed point part of the method.

**LEMMA 4.3.** *Let  $\beta \in [0, 1)$ . Suppose  $T : \mathcal{H} \rightarrow \mathcal{H}$  is  $\beta$ -demicontractive with  $\text{Fix}(T) \cap \Omega \neq \emptyset$ , and let a mapping  $\mathcal{F} : \mathcal{H} \rightarrow \mathcal{H}$  satisfy (LC) and (SM). Suppose  $A : \mathcal{H} \rightarrow \mathcal{H}$  is monotone on  $C$ ,  $k$ -Lipschitz continuous on  $\mathcal{H}$ . Assume in addition that the following condition holds:*

$$(H1) \quad w \in (0, \frac{1-\beta}{2}].$$

*Then the sequence  $(x_n)$ ,  $(t_n)$ , and  $(y_n)$  given by (3.6) satisfies, for all  $n \geq 0$ ,*

$$(4.11) \quad \begin{aligned} & |x_{n+1} - q|^2 - |x_n - q|^2 \\ & + |x_{n+1} - t_n|^2 + (1 - \lambda_n^2 k^2) |x_n - y_n|^2 \leq -2\alpha_n \langle x_{n+1} - q, \mathcal{F}(t_n) \rangle, \end{aligned}$$

where  $q$  is any element in  $\text{Fix}(T) \cap \Omega$ .

*Proof.* Let  $q \in \text{Fix}(T) \cap \Omega$ . From (3.6) and (4.10), we get

$$(4.12) \quad |x_{n+1} - q|^2 \leq |v_n - q|^2 - w(1 - \beta - w)|v_n - Tv_n|^2,$$

while by (3.6) we have  $Tv_n - v_n = (1/w)(x_{n+1} - v_n)$ . Consequently, setting  $\rho := (1/w)(1 - \beta - w)$ , we obtain

$$(4.13) \quad |x_{n+1} - q|^2 \leq |v_n - q|^2 - \rho |x_{n+1} - v_n|^2.$$

Hence, for  $w \in (0, \frac{1-\beta}{2}]$  (so that  $\rho \geq 1$ ) and recalling that  $v_n = t_n - \alpha_n \mathcal{F}(t_n)$ , we deduce

$$(4.14) \quad \begin{aligned} & |x_{n+1} - q|^2 \leq |v_n - q|^2 - |x_{n+1} - v_n|^2 \\ & = |(t_n - q) - \alpha_n \mathcal{F}(t_n)|^2 - |(t_n - x_{n+1}) - \alpha_n \mathcal{F}(t_n)|^2 \\ & = |t_n - q|^2 - 2\alpha_n \langle x_{n+1} - q, \mathcal{F}(t_n) \rangle - |x_{n+1} - t_n|^2, \end{aligned}$$

which by Lemma 4.2 entails the desired result.  $\square$

The underlying idea for proving the strong convergence of the method (3.6) relies on the estimate (4.11), but we also need to check that the iterates of (3.6) satisfy some other classical properties.

**4.2. Boundedness of the iterates.** In the next lemma, we establish the boundedness of the sequences generated by the method (3.6). This property will be needed, for instance, to ensure the existence of weak cluster points for these sequences.

**LEMMA 4.4.** *Let  $\beta \in [0, 1]$ . Suppose  $T : \mathcal{H} \rightarrow \mathcal{H}$  is  $\beta$ -demicontractive with  $\Omega \cap \text{Fix}(T) \neq \emptyset$ , and let  $\mathcal{F} : \mathcal{H} \rightarrow \mathcal{H}$  satisfy (LC) and (SM). Suppose  $A : \mathcal{H} \rightarrow \mathcal{H}$  is monotone on  $C$  and  $k$ -Lipschitz continuous on  $\mathcal{H}$ . Assume, in addition,  $w \in (0, 1 - \beta]$ ,  $(k\lambda_n) \subset [0, 1]$ , and  $(\alpha_n) \subset [0, \delta)$  (for some small enough  $\delta > 0$ ). Then the sequences  $(x_n)$ ,  $(t_n)$ , and  $(y_n)$  generated by (3.6) are bounded.*

*Proof.* Without loss of generality, we assume  $0 < \eta < L$  (where  $\eta$  and  $L$  are constants given by conditions (SM) and (LC)). Fix  $\mu > 0$  and let  $x, y \in \mathcal{H}$ . From (SM) and (LC), we obtain

$$\begin{aligned} |(\mu\mathcal{F} - I)(x) - (\mu\mathcal{F} - I)(y)|^2 &= \mu^2 |\mathcal{F}(x) - \mathcal{F}(y)|^2 - 2\mu \langle x - y, \mathcal{F}(x) - \mathcal{F}(y) \rangle + |x - y|^2 \\ &\leq \mu^2 L^2 |x - y|^2 - 2\mu\eta |x - y|^2 + |x - y|^2, \end{aligned}$$

so that

$$(4.15) \quad |(\mu\mathcal{F} - I)(x) - (\mu\mathcal{F} - I)(y)| \leq (\sqrt{1 - 2\mu\eta + \mu^2 L^2}) |x - y|.$$

Furthermore, taking  $q \in \text{Fix}(T) \cap \Omega$  and recalling that  $v_{n+1} = t_{n+1} - \alpha_{n+1}\mathcal{F}(t_{n+1})$ , we have

$$\begin{aligned} |v_{n+1} - (q - \alpha_{n+1}\mathcal{F}(q))| &= |(t_{n+1} - \alpha_{n+1}\mathcal{F}(t_{n+1})) - (q - \alpha_{n+1}\mathcal{F}(q))| \\ &= \left| \left(1 - \frac{\alpha_{n+1}}{\mu}\right) (t_{n+1} - q) - \frac{\alpha_{n+1}}{\mu} [(\mu\mathcal{F} - I)(t_{n+1}) - (\mu\mathcal{F} - I)(q)] \right| \\ &\leq \left(1 - \frac{\alpha_{n+1}}{\mu}\right) |t_{n+1} - q| + \frac{\alpha_{n+1}}{\mu} |(\mu\mathcal{F} - I)(t_{n+1}) - (\mu\mathcal{F} - I)(q)|, \end{aligned}$$

provided that  $(\alpha_n) \subset [0, \mu)$ , which by (4.15) yields

$$(4.16) \quad |v_{n+1} - (q - \alpha_{n+1}\mathcal{F}(q))| \leq \left(1 - \frac{\alpha_{n+1}}{\mu}\nu\right) |t_{n+1} - q|,$$

where  $\nu := 1 - \sqrt{1 - 2\mu\eta + \mu^2 L^2}$ . Clearly, we have  $\nu \in (0, 1)$  provided that  $\mu \in (0, \mu_0)$ , where  $\mu_0$  is some small enough positive value. Using (4.6) and observing that  $T_w := (1 - w)I + wT$  is quasi-nonexpansive for  $w \in (0, 1 - \beta]$  (see Remark 4.2), we additionally have

$$(4.17) \quad |t_{n+1} - q| \leq |x_{n+1} - q| = |T_w v_n - q| \leq |v_n - q|,$$

provided that  $(k\lambda_n) \subset [0, 1]$ . Combining (4.16) and (4.17), we then get

$$|v_{n+1} - (q - \alpha_{n+1}\mathcal{F}(q))| \leq \left(1 - \frac{\alpha_{n+1}}{\mu}\nu\right) |v_n - q|.$$

As a consequence, we deduce

$$\begin{aligned} |v_{n+1} - q| &\leq |v_{n+1} - (q - \alpha_{n+1}\mathcal{F}(q))| + |(q - \alpha_{n+1}\mathcal{F}(q)) - q| \\ &\leq \left(1 - \frac{\alpha_{n+1}\nu}{\mu}\right) |v_n - q| + \alpha_{n+1}|\mathcal{F}(q)| \\ &= \left(1 - \frac{\alpha_{n+1}\nu}{\mu}\right) |v_n - q| + \left(\frac{\alpha_{n+1}\nu}{\mu}\right) \left(\frac{\mu|\mathcal{F}(q)|}{\nu}\right), \end{aligned}$$

hence, for all  $n \geq 0$ , we get  $\max\{|v_{n+1} - q|, \frac{\mu|\mathcal{F}(q)|}{\nu}\} \leq \max\{|v_n - q|, \frac{\mu|\mathcal{F}(q)|}{\nu}\}$ , so that  $|v_n - q| \leq \max\{|v_0 - q|, \frac{\mu|\mathcal{F}(q)|}{\nu}\}$ . Thus  $(v_n)$  is bounded, which by (4.17) leads to the boundedness of  $(x_n)$  and  $(t_n)$ . That of  $(y_n)$  is then deduced from the formula  $y_n = P_C(x_n - \lambda_n A x_n)$  (because  $A$  and  $P_C$  are Lipschitz continuous and  $(\lambda_n)$  is assumed to be bounded).  $\square$

**4.3. Preliminary convergence analysis.** In what follows, we are interested in locating the set of weak cluster points of the sequence  $(t_n)$  generated by (3.6). To this end, we recall some results of fundamental importance.

*Remark 4.3.* Let  $N_C : C \rightarrow 2^{\mathcal{H}}$  be the normal cone to  $C$ , defined for all  $x \in C$  by  $N_C x := \{w \in \mathcal{H}; \langle x - z, w \rangle \geq 0 \ \forall z \in C\}$  and let  $B : \mathcal{H} \rightarrow 2^{\mathcal{H}}$  be the mapping defined for any  $x \in \mathcal{H}$  by

$$(4.18) \quad Bx := \begin{cases} Ax + N_C x & \text{if } x \in C, \\ \emptyset & \text{otherwise,} \end{cases}$$

where  $A : C \rightarrow \mathcal{H}$  is assumed to be monotone and Lipschitz continuous. Then  $B$  is maximal monotone (see, for instance, [6, 40, 54]); namely its graph defined by  $G(B) = \{(x, y) \in \mathcal{H} \times \mathcal{H}; y \in Bx\}$  is not properly contained in the graph of any other monotone mapping. In other words, for all  $(x, y) \in \mathcal{H} \times \mathcal{H}$ , there holds

$$\langle x - v, y - w \rangle \geq 0 \quad \forall (v, w) \in G(B) \quad \Rightarrow \quad y \in Bx.$$

Furthermore, as a classical result we have

$$0 \in Bu \quad \Leftrightarrow \quad u \in \Omega.$$

Consequently, we immediately deduce the following key property:

$$(4.19) \quad \langle u - v, -w \rangle \geq 0 \quad \forall (v, w) \in G(B) \quad \Rightarrow \quad u \in \Omega.$$

Throughout the next lemma, we give sufficient conditions ensuring that the weak cluster points of  $(t_n)$  belong to the set  $\Omega$ . This lemma was given implicitly in [54], but its proof needs to be detailed for the sake of completeness.

**LEMMA 4.5.** *Suppose  $A : \mathcal{H} \rightarrow \mathcal{H}$  is monotone and Lipschitz continuous on  $C$ . Let  $(\lambda_n) \subset [\delta, \infty)$  (for some  $\delta > 0$ ) and let  $(t_n)$ ,  $(y_n)$ , and  $(x_n)$  be sequences in  $\mathcal{H}$  such that  $(y_n) \subset C$  and  $t_n = P_C(x_n - \lambda_n A y_n)$ . Assume in addition that there exists a subsequence  $(t_{n_k})$  of  $(t_n)$  such that*

- (i)  $(t_{n_k})$  converges weakly to some  $u$  in  $C$ ;
- (ii)  $|x_{n_k} - y_{n_k}| \rightarrow 0$  and  $|t_{n_k} - y_{n_k}| \rightarrow 0$ .

*Then  $u$  belongs to the set  $\Omega$ .*

*Proof.* Let  $B$  be the mapping defined in (4.18). According to Remark 4.3,  $B$  is maximal monotone, because  $A$  is assumed to be monotone and Lipschitz continuous

on  $C$ , so that the key property (4.19) holds. To reach the conclusion of the lemma, we then prove that the limit  $u$  in condition (i) satisfies this latter property. Given  $(v, w)$  in  $G(B)$  (the graph of  $B$ ), we easily have  $w - Av \in N_C v$ , so that  $\langle v - z, w - Av \rangle \geq 0$  for all  $z \in C$ . In particular, since  $(t_n) \subset C$ , we get

$$(4.20) \quad \langle v - t_{n_k}, w \rangle \geq \langle v - t_{n_k}, Av \rangle.$$

From (4.1), we additionally have  $\langle x_{n_k} - \lambda_{n_k} Ay_{n_k} - t_{n_k}, t_{n_k} - v \rangle \geq 0$ , because  $t_n := P_C(x_n - \lambda_n Ay_n)$  and  $v \in C$ , which by (4.20) yields

$$\begin{aligned} \langle v - t_{n_k}, w \rangle &\geq \langle v - t_{n_k}, Av \rangle - \frac{1}{\lambda_{n_k}} \langle t_{n_k} - v, x_{n_k} - \lambda_{n_k} Ay_{n_k} - t_{n_k} \rangle \\ &= \langle v - t_{n_k}, Av - At_{n_k} \rangle + \langle v - t_{n_k}, At_{n_k} - Ay_{n_k} \rangle - \left\langle v - t_{n_k}, \frac{t_{n_k} - x_{n_k}}{\lambda_{n_k}} \right\rangle; \end{aligned}$$

hence, by the monotonicity of  $A$ , we obtain

$$(4.21) \quad \langle v - t_{n_k}, w \rangle \geq \langle v - t_{n_k}, At_{n_k} - Ay_{n_k} \rangle - \left\langle v - t_{n_k}, \frac{t_{n_k} - x_{n_k}}{\lambda_{n_k}} \right\rangle.$$

Clearly,  $(t_{n_k})$  is a bounded sequence, because it is assumed to be weakly convergent (by condition (i)). Then, in light of condition (ii) (hence  $|At_{n_k} - Ay_{n_k}| \rightarrow 0$  by the Lipschitz continuity of  $A$ ), recalling that  $t_{n_k}$  converges weakly to  $u$ , and passing to the limit in (4.21), we obtain  $\langle v - u, w \rangle \geq 0$  (since  $\lambda_n \geq \delta > 0$ ). Therefore, by the key property (4.19) we conclude that  $u \in \Omega$ .  $\square$

At once, we give sufficient conditions so that any weak cluster-point of the sequence  $(t_n)$  given by (3.6) lies in the solution set  $\text{Fix}(T) \cap \Omega$ .

LEMMA 4.6. *Suppose  $A : \mathcal{H} \rightarrow \mathcal{H}$  is monotone on  $C$  and  $k$ -Lipschitz continuous on  $\mathcal{H}$ ,  $T : \mathcal{H} \rightarrow \mathcal{H}$  is demiclosed with  $\text{Fix}(T) \cap \Omega \neq \emptyset$  and let  $\mathcal{F} : \mathcal{H} \rightarrow \mathcal{H}$  satisfy (LC). Suppose also the following conditions hold:*

(C1)  $(\lambda_n) \subset [\delta, \infty)$  (for some  $\delta > 0$ );

(H2)  $(\alpha_n) \subset [0, 1)$ ,  $\alpha_n \rightarrow 0$ .

*Let  $(t_n)$ ,  $(y_n)$ ,  $(x_n)$  be the sequences generated by (3.6) and assume further that there exists a subsequence  $(t_{n_k})$  of  $(t_n)$  such that*

(i)  $|t_{n_k} - x_{n_k+1}| \rightarrow 0$ ; (ii)  $|x_{n_k} - y_{n_k}| \rightarrow 0$ ; (iii)  $|t_{n_k} - y_{n_k}| \rightarrow 0$ .

*Then any weak cluster-point of  $(t_{n_k})$  belongs to  $\text{Fix}(T) \cap \Omega$ .*

*Proof.* Let  $u \in \mathcal{H}$  be a weak cluster-point of  $(t_{n_k})$ ; that is, there exists a bounded subsequence of  $(t_{n_k})$  (labeled  $(t_{m_k})$ ) which converges weakly to  $u$ . By (i), (ii), and (iii), we also have  $|x_{m_k+1} - t_{m_k}| \rightarrow 0$  and  $|x_{m_k} - y_{m_k}| \rightarrow 0$  and  $|t_{m_k} - y_{m_k}| \rightarrow 0$ . If in addition  $\alpha_n \rightarrow 0$ , we easily deduce that  $v_{m_k} := t_{m_k} - \alpha_{m_k} \mathcal{F}(t_{m_k})$  converges weakly to  $u$  (because  $\mathcal{F}(t_{m_k})$  is bounded thanks to (LC); hence  $\alpha_{m_k} |\mathcal{F}(t_{m_k})| \rightarrow 0$ ), which by (3.6) entails

$$|Tv_{m_k} - v_{m_k}| = (1/w)|x_{m_k+1} - v_{m_k}| = (1/w)|(x_{m_k+1} - t_{m_k}) + \alpha_{m_k} \mathcal{F}(t_{m_k})| \rightarrow 0.$$

As  $T$  is assumed to be demiclosed, we then obtain  $u \in \text{Fix}(T)$ . Furthermore, recalling that  $|x_{m_k} - y_{m_k}| \rightarrow 0$ ,  $|t_{m_k} - y_{m_k}| \rightarrow 0$ ,  $\lambda_n \geq \delta > 0$  and applying Lemma 4.5, we get  $u \in \Omega$ . Consequently, the set of weak cluster-points of  $(t_{n_k})$  is included in  $\Omega \cap \text{Fix}(T)$ , which ends the proof.  $\square$

Now we are in position to prove our main convergence result.

**4.4. Proof of Theorem 4.1.** To prove the strong convergence of the method, we set  $\Gamma_n := |x_n - x_*|^2$  and we focus our analysis on the fact that the real sequence  $(\Gamma_n)$  is either monotonous at infinity (Case 1) or not (Case 2):

• *Case 1.* There exists  $n_0$  such that the sequence  $(\Gamma_n)_{n \geq n_0}$  is either nonincreasing or nondecreasing.

• *Case 2.* For any  $n_0$ , there exist integers  $p \geq n_0$  and  $q \geq n_0$  such that  $\Gamma_p \leq \Gamma_{p+1}$  and  $\Gamma_{q+1} \leq \Gamma_q$ .

More precisely, regarding the situation when  $(\Gamma_n)$  is monotonous at infinity (Case 1) and bounded (hence convergent), we prove that its only possible limit is zero. Concerning the alternative situation (Case 2), we exhibit some subsequence  $(\Gamma_{\phi(n)})$  of  $(\Gamma_n)$  such that  $\Gamma_n \leq \Gamma_{\phi(n)}$  for all  $n \geq m_0$  (where  $m_0$  is some large enough integer) and  $\Gamma_{\phi(n)} \rightarrow 0$  (as  $n \rightarrow \infty$ ).

*Remark 4.4.* In Case 2 above, we know that, for any integer  $n_0$ , there exists another integer  $q$  such that  $q \geq n_0$  and  $\Gamma_q \leq \Gamma_{q+1}$ . Let  $n_0$  be such that  $\Gamma_{n_0} \leq \Gamma_{n_0+1}$  and introduce the set of integers defined for all  $n \geq n_0$  by

$$(4.22) \quad J_n = \{k \in \mathbb{N}; \quad n_0 \leq k \leq n, \quad \Gamma_k \leq \Gamma_{k+1}\}.$$

It is obviously seen that  $J_n \neq \emptyset$ ,  $J_n \subset J_{n+1}$ ,  $1 \leq \text{Card}(J_n) \leq n - n_0 + 1$  and  $\text{Card}(J_n) \rightarrow +\infty$  as  $n \rightarrow \infty$ , where  $\text{Card}(J_n)$  denotes the cardinal of  $J_n$ . Also consider the sequence  $(\tau(n)) \subset \mathbb{N}$  defined for all  $n \geq n_0$  by

$$(4.23) \quad \tau(n) := \max(J_n).$$

Clearly,  $(\tau(n))_{n \geq n_0}$  is a nondecreasing sequence (since  $J_n \subset J_{n+1}$ ) such that  $\tau(n) \rightarrow +\infty$  as  $n \rightarrow +\infty$  and  $\Gamma_{\tau(n)} \leq \Gamma_{\tau(n)+1}$  (for  $n \geq n_0$ ). Furthermore, for all  $n \geq n_0$ , we have either  $\tau(n) = n$  or  $\tau(n) < n$ . The former case yields  $\Gamma_n = \Gamma_{\tau(n)} \leq \Gamma_{\tau(n)+1}$ , while the latter case amounts to  $\Gamma_{\tau(n)+1} > \Gamma_{\tau(n)+2} > \dots > \Gamma_{n-1} > \Gamma_n$  (i.e.,  $\Gamma_j > \Gamma_{j+1}$  for  $\tau(n) + 1 \leq j \leq n - 1$ ), so that  $\Gamma_n \leq \Gamma_{\tau(n)+1}$ . As a consequence, we obtain

$$(4.24) \quad 0 \leq \Gamma_n \leq \Gamma_{\tau(n)+1} \quad \forall n \geq n_0.$$

Then, to prove the strong convergence of the method, it is sufficient to prove that  $\Gamma_{\tau(n)+1} \rightarrow 0$  as  $n \rightarrow \infty$ .

To begin with, the boundedness of  $(x_n)$ ,  $(y_n)$ , and  $(t_n)$  is a straightforward consequence of Lemma 4.4. It is then immediate that there exists a constant  $C \geq 0$  verifying  $|\langle x_{n+1} - x_*, \mathcal{F}(t_n) \rangle| \leq C$  for all  $n \geq 0$ , which by Lemma 4.3 and condition (H3) entails

$$(4.25) \quad \Gamma_{n+1}^2 - \Gamma_n^2 + |x_{n+1} - t_n|^2 + (1 - \delta_2^2)|x_n - y_n|^2 \leq 2C\alpha_n,$$

where  $\delta_2$  is some constant in  $(0, 1)$ . The rest of the proof can be divided into the following two cases.

*Case 1.* Assume  $(\Gamma_n)$  is monotonous at infinity. In other words, for  $n_0$  large enough,  $(\Gamma_n)_{n \geq n_0}$  is either nondecreasing or nonincreasing; hence  $(\Gamma_n)$  is convergent (being also bounded). Set  $\lambda = \lim_{n \rightarrow \infty} |x_n - x_*|$ ; we assume  $\lambda > 0$  and we show that this latter hypothesis is impossible. Clearly, we have  $\Gamma_{n+1}^2 - \Gamma_n^2 \rightarrow 0$  (since the sequence  $(\Gamma_n)$  is convergent), which by (4.25) yields

$$(4.26) \quad |x_{n+1} - t_n| \rightarrow 0 \quad \text{and} \quad |x_n - y_n| \rightarrow 0$$

(since  $\alpha_n \rightarrow 0$  by (H2)); hence by (4.5) we get  $|t_n - y_n| \rightarrow 0$ . Using condition (SM), we additionally have  $\langle t_n - x_*, \mathcal{F}(t_n) - \mathcal{F}(x_*) \rangle \geq \eta |t_n - x_*|^2$ , namely

$$(4.27) \quad \langle x_{n+1} - x_*, \mathcal{F}(t_n) \rangle \geq \eta |t_n - x_*|^2 + \langle t_n - x_*, \mathcal{F}(x_*) \rangle + \langle x_{n+1} - t_n, \mathcal{F}(t_n) \rangle.$$

Let us estimate separately each term in the right-hand side of the above inequality. Since  $(t_n)$  is a bounded sequence, so is the quantity  $\langle t_n - u_*, \mathcal{F}(u_*) \rangle$ . It is then immediate that there exists a subsequence  $(t_{m_k})$  of  $(t_n)$  such that

$$(4.28) \quad \liminf_{n \rightarrow \infty} \langle t_n - u_*, \mathcal{F}(u_*) \rangle = \lim_{k \rightarrow \infty} \langle t_{m_k} - u_*, \mathcal{F}(u_*) \rangle.$$

Observe also that there exists another subsequence of  $(t_{m_k})$  (again denoted  $(t_{m_k})$ ) which converges weakly to some element  $v$  in  $\mathcal{H}$ . Applying Lemma 4.6, we then have  $v \in \text{Fix}(T) \cap \Omega$ . Consequently, by the weak convergence of  $(t_{m_k})$  and recalling that  $u_*$  is solution of (3.3), we get  $\liminf_{k \rightarrow \infty} \langle t_{m_k} - u_*, \mathcal{F}(u_*) \rangle = \langle v - u_*, \mathcal{F}(u_*) \rangle \geq 0$ , which by (4.28) amounts to

$$(4.29) \quad \liminf_{n \rightarrow \infty} \langle t_n - x_*, \mathcal{F}(x_*) \rangle \geq 0.$$

Moreover, observing that  $|x_n - t_n| \rightarrow 0$  (since  $|x_n - y_n| \rightarrow 0$  and  $|t_n - y_n| \rightarrow 0$ ) and recalling that  $\lim_{n \rightarrow \infty} |x_n - x_*| = \lambda$ , we immediately have

$$(4.30) \quad \lim_{n \rightarrow \infty} |t_n - x_*| = \lambda.$$

In addition, as  $(t_n)$  is a bounded sequence,  $|x_{n+1} - t_n| \rightarrow 0$ , and using the Lipschitz continuity of  $\mathcal{F}$  (given by (LC)), we get

$$(4.31) \quad \lim_{n \rightarrow \infty} \langle x_{n+1} - t_n, \mathcal{F}(t_n) \rangle = 0.$$

Therefore, by (4.26)–(4.31), we obtain  $\liminf_{n \rightarrow \infty} \langle x_{n+1} - x_*, \mathcal{F}(t_n) \rangle \geq \eta \lambda^2$ . Thus, for  $\epsilon = (1/2)\eta \lambda^2$  (hence  $\epsilon > 0$ ), there exists some integer  $n_1$  such that, for  $n \geq n_1$ , there holds  $\langle x_{n+1} - x_*, \mathcal{F}(t_n) \rangle \geq \eta \lambda^2 - \epsilon = \frac{1}{2}\eta \lambda^2$ . Then, for  $n \geq n_1$  and taking into account Lemma 4.3, we deduce  $|x_{n+1} - x_*|^2 - |x_n - x_*|^2 \leq -\alpha_n(\eta \lambda^2)$ , which leads to  $|x_{n+1} - x_*|^2 - |x_{n_1} - x_*|^2 \leq -\lambda^2 \eta \sum_{k=n_1}^n \alpha_k$ . As  $\sum_k \alpha_k = \infty$  (by condition (SP)), we observe that this last inequality amounts to  $\lim_{n \rightarrow \infty} |x_{n+1} - x_*|^2 = -\infty$  if  $\lambda > 0$ , which is absurd. As a straightforward consequence, we deduce  $\lambda = 0$ ; namely,  $(x_n)$  converges strongly to  $x_*$  and so do  $(y_n)$  and  $(t_n)$  (since  $|x_n - y_n| \rightarrow 0$  and  $|t_n - y_n| \rightarrow 0$ ).

*Case 2.* Assume  $(\Gamma_n)$  is not monotonous at infinity and let  $(\tau(n))_{n \geq n_0}$  be the sequence introduced in (4.23). As  $\Gamma_{\tau(n)} \leq \Gamma_{\tau(n)+1}$  (for  $n \geq n_0$ ) and referring to (4.25), we get  $|x_{\tau(n)+1} - t_{\tau(n)}|^2 + (1 - \delta_2^2)|x_{\tau(n)} - y_{\tau(n)}|^2 \leq 2C\alpha_{\tau(n)} \rightarrow 0$ , so that

$$(4.32) \quad |x_{\tau(n)+1} - t_{\tau(n)}| \rightarrow 0 \quad \text{and} \quad |x_{\tau(n)} - y_{\tau(n)}| \rightarrow 0;$$

hence by (4.5) we obtain

$$(4.33) \quad |t_{\tau(n)} - y_{\tau(n)}| \rightarrow 0.$$

Now we can prove that the sequence  $(t_{\tau(n)})$  converges strongly to  $x_*$  as  $n \rightarrow \infty$ . Let  $(t_{\tau(n_k)})$  be any subsequence of  $(t_{\tau(n)})$  which converges weakly to some  $q$  in  $\mathcal{H}$  (as  $k \rightarrow \infty$ ). Clearly, the existence of such a subsequence is ensured by the boundedness

of  $(t_{\tau(n)})$ . It is also observed that  $|x_{\tau(n_k)+1} - t_{\tau(n_k)}| \rightarrow 0$ ,  $|x_{\tau(n_k)} - y_{\tau(n_k)}| \rightarrow 0$ , and  $|t_{\tau(n_k)} - y_{\tau(n_k)}| \rightarrow 0$  as  $k \rightarrow \infty$  (thanks to (4.32) and (4.33)), which by Lemma 4.6 amounts to  $q \in \text{Fix}(T) \cap \Omega$ . Furthermore, using Lemma 4.3 and given any  $j \geq 0$ , we have  $\langle x_{j+1} - x_*, \mathcal{F}(t_j) \rangle > 0 \Rightarrow \Gamma_{j+1} < \Gamma_j$ . As a consequence, since  $\Gamma_{\tau(n)} \leq \Gamma_{\tau(n)+1}$ , we get

$$(4.34) \quad \langle x_{\tau(n)+1} - x_*, \mathcal{F}(t_{\tau(n)}) \rangle \leq 0 \quad \forall n \geq n_0.$$

For  $n \geq n_0$  and using (SM), we additionally have

$$\begin{aligned} \eta |t_{\tau(n)} - x_*|^2 &\leq \langle t_{\tau(n)} - x_*, \mathcal{F}(t_{\tau(n)}) - \mathcal{F}(x_*) \rangle \\ &= \langle x_{\tau(n)+1} - x_*, \mathcal{F}(t_{\tau(n)}) \rangle + \langle t_{\tau(n)} - x_{\tau(n)+1}, \mathcal{F}(t_{\tau(n)}) \rangle - \langle t_{\tau(n)} - x_*, \mathcal{F}(x_*) \rangle, \end{aligned}$$

which by (4.34) entails

$$(4.35) \quad |t_{\tau(n)} - x_*|^2 \leq (1/\eta) [\langle t_{\tau(n)} - x_{\tau(n)+1}, \mathcal{F}(t_{\tau(n)}) \rangle - \langle t_{\tau(n)} - x_*, \mathcal{F}(x_*) \rangle].$$

It is also immediate that  $\lim_{k \rightarrow \infty} \langle t_{\tau(n_k)} - x_*, \mathcal{F}(x_*) \rangle = \langle q - x_*, \mathcal{F}(x_*) \rangle$  and that  $\lim_{k \rightarrow \infty} \langle t_{\tau(n_k)} - x_{\tau(n_k)+1}, \mathcal{F}(t_{\tau(n_k)}) \rangle = 0$ , which by (4.35) and (3.3) amounts to

$$\limsup_{k \rightarrow +\infty} |t_{\tau(n_k)} - x_*|^2 \leq -(1/\eta) \langle q - x_*, \mathcal{F}(x_*) \rangle \leq 0;$$

hence  $\lim_{k \rightarrow +\infty} |t_{\tau(n_k)} - x_*| = 0$ . It is then routine to see that the whole sequence  $(t_{\tau(n)})$  converges strongly to  $x_*$ . Therefore, by (4.32), (4.33), and the uniqueness of  $x_*$ , we deduce that  $|x_{\tau(n)} - x_*| \rightarrow 0$  and  $|x_{\tau(n)+1} - x_{\tau(n)}| \rightarrow 0$ . It is then immediate that  $\lim_{n \rightarrow \infty} \Gamma_{\tau(n)+1} = 0$ , which by (4.24) leads to  $\lim_{n \rightarrow \infty} \Gamma_n = 0$ ; that is,  $(x_n)$  converges strongly to  $x_*$ . In light of (4.25) and recalling that  $\Gamma_n \rightarrow 0$ , we also obtain  $|x_n - y_n| \rightarrow 0$  (hence  $|y_n - x_*| \rightarrow 0$ ), which by (4.5) entails  $|t_n - y_n| \rightarrow 0$  (hence  $|t_n - x_*| \rightarrow 0$ ).  $\square$

**5. Applications.** In the same manner as in [35, 54], we derive two applications of Theorem 4.1.

**THEOREM 5.1.** *Suppose  $A : \mathcal{H} \rightarrow \mathcal{H}$  is monotone and  $k$ -Lipschitz continuous on  $\mathcal{H}$  and  $T : \mathcal{H} \rightarrow \mathcal{H}$  is nonexpansive with  $\text{Fix}(T) \cap A^{-1}(0) \neq \emptyset$ . Let  $(x_n)$ ,  $(y_n)$ , and  $(t_n)$  be the sequences generated by*

$$(5.1) \quad \begin{cases} x_0 \in \mathcal{H}, \\ y_n = x_n - \lambda_n A x_n, \\ t_n = x_n - \lambda_n A y_n, \\ x_{n+1} := [(1-w)I + wT]v_n, \quad v_n := \alpha_n u + (1 - \alpha_n)t_n, \end{cases}$$

where  $u$  is any element in  $\mathcal{H}$  and where  $(\alpha_n)$ ,  $(\lambda_n)$ , and  $w$  satisfy the following conditions:

- (H1)'  $w \in (0, \frac{1}{2}]$ ;
- (H2)  $(\alpha_n) \subset [0, 1)$ ,  $\alpha_n \rightarrow 0$ ;
- (H3)  $(k\lambda_n) \subset [\delta_1, \delta_2]$  (where  $0 < \delta_1 \leq \delta_2 < 1$ );
- (SP)  $\sum_{n \geq 0} \alpha_n = \infty$ .

Then the sequences  $(x_n)$ ,  $(y_n)$ , and  $(t_n)$  converge strongly to  $P_{\text{Fix}(T) \cap A^{-1}(0)}(u)$  (i.e., the nearest element of  $u$  in  $\text{Fix}(T) \cap A^{-1}(0)$ ).

*Proof.* This result is a straightforward consequence of Theorem 4.1 with  $C := \mathcal{H}$  (hence  $\Omega = A^{-1}(0)$  and  $P_C = I$ ),  $\mathcal{F} := I - u$  (hence  $\mathcal{F}$  is Lipschitz continuous and strongly monotone) and recalling that a nonexpansive mapping is 0-demicontractive and demiclosed.  $\square$

The second application is related to the approximation of common zeroes of monotone operators (see also [27]).

**THEOREM 5.2.** *Let  $A : \mathcal{H} \rightarrow \mathcal{H}$  be monotone and  $k$ -Lipschitz continuous mapping on  $\mathcal{H}$  and let  $J_r^D := (I + \lambda D)^{-1}$  (for  $r > 0$ ) be the resolvent of  $D : \mathcal{H} \rightarrow 2^{\mathcal{H}}$ , a maximal monotone mapping such that  $A^{-1}(0) \cap D^{-1}(0) \neq \emptyset$ . Let  $(x_n)$ ,  $(y_n)$ , and  $(t_n)$  be the sequences generated by*

$$(5.2) \quad \begin{cases} x_0 \in \mathcal{H}, \\ y_n = x_n - \lambda_n A x_n, \\ t_n = x_n - \lambda_n A y_n, \\ x_{n+1} := [(1-w)I + wJ_r^D]v_n, \quad v_n := \alpha_n u + (1 - \alpha_n)t_n, \end{cases}$$

where  $u \in \mathcal{H}$  and  $(\alpha_n)$ ,  $(\lambda_n)$ , and  $w$  satisfy the conditions (H1)', (H2), (H3), and (SP) in Theorem 5.1.

Then the sequences  $(x_n)$ ,  $(y_n)$ , and  $(t_n)$  converge strongly to  $P_{D^{-1}(0) \cap A^{-1}(0)}(u)$  (i.e., the nearest element of  $u$  in  $D^{-1}(0) \cap A^{-1}(0)$ ).

*Proof.* This result is immediately deduced from Theorem 4.1 with  $C := \mathcal{H}$  (hence  $\Omega = A^{-1}(0)$  and  $P_C = I$ ),  $\mathcal{F} := I - u$  (hence  $\mathcal{F}$  is Lipschitz continuous and strongly monotone) and recalling that  $J_r^D$  is a nonexpansive mapping (hence 0-demicontractive and demiclosed) such that  $\text{Fix}(J_r^D) = D^{-1}(0)$ .  $\square$

**6. Conclusion.** The purpose of this article is to establish the convergence in norm of some new splitting iterative methods for finding solutions of infinite dimensional problems involving both monotone variational inequalities and fixed point problems. These algorithms are based on known processes (extragradient, relaxation, viscosity), and the main theorem (Theorem 4.1) improves, in either form or requirements of operators, most of the existing known results on this subject, including some recent ones: Nadezhkina and Takahashi [35], Zeng and Yao [54]. To the best of our knowledge, there is no existing result that is an equivalent of Theorem 4.1 in terms of a continuous dynamical system. Note also that the (demicontractive) operators occurring in the considered fixed point problems are not necessarily continuous (contrary to nonexpansive mappings which are Lipschitz continuous), so that our analysis is completely different from usual analyses regarding viscosity approximations. Moreover, it is very probable that the techniques of analysis proposed in this paper may pave the way for forthcoming developments regarding more general equilibrium [12] and fixed point problems, especially in designing new algorithms including inexact or perturbed technology [11, 13, 18] as well as inertial-type extrapolation [29].

## MIXED $H_2/H_\infty$ CONTROL VIA NONSMOOTH OPTIMIZATION\*

P. APKARIAN<sup>†</sup>, D. NOLL<sup>‡</sup>, AND A. RONDEPIERRE<sup>§</sup>

**Abstract.** We present a new approach to mixed  $H_2/H_\infty$  output feedback control synthesis. Our method uses nonsmooth mathematical programming techniques to compute locally optimal  $H_2/H_\infty$ -controllers, which may have a predefined structure. We prove global convergence of our method and present tests to validate it numerically.

**Key words.** mixed  $H_2/H_\infty$  output feedback control, multiobjective control, robustness and performance, nonsmooth optimization, trust region technique

**1. Introduction.** Mixed  $H_2/H_\infty$  output feedback control is a prominent example of a multiobjective design problem, where the feedback controller has to respond favorably to several performance specifications. Typically in  $H_2/H_\infty$  synthesis, the  $H_\infty$  channel is used to enhance the robustness of the design, whereas the  $H_2$  channel guarantees good performance of the system. Due to its importance in practice, mixed  $H_2/H_\infty$  control has been addressed in various ways over the years, and we briefly review the main trends.

The interest in  $H_2/H_\infty$  synthesis was originally piqued by three publications [22, 23, 27] in the late 1980s and early 1990s. The numerical methods proposed by these authors are based on coupled Riccati equations in tandem with homotopy methods, but the numerical success of these strategies remains to be established. With the rise of linear matrix inequalities (LMIs) in the later 1990s, different strategies which convexify the problem became increasingly popular. The price to pay for convexifying is either a considerable conservatism, or controllers with a large state dimension [29, 25].

In [45, 47, 48] Scherer developed LMI formations for  $H_2/H_\infty$  synthesis for full-order controllers [48] and reduced the problem to solving LMIs in tandem with nonlinear algebraic equalities [48, 45]. In this form,  $H_2/H_\infty$  problems could in principle be solved via nonlinear semidefinite programming techniques like specSDP [24, 40, 50] or Pennon [31, 32, 36], if only these techniques were suited for medium or large size problems. Alas, one of the disappointing lessons learned in recent years from investigating BMI (bilinear matrix inequality) and LMI problems is that this is just not the case. Due to the presence of Lyapunov variables, whose number grows quadratically with the system size [14, p. 20ff], BMI and LMI programs quickly lead to problem sizes where existing numerical methods fail.

Following [3, 4, 5, 7, 6], we address  $H_2/H_\infty$  synthesis by employing a new strategy which avoids the use of Lyapunov variables. This leads to a nonsmooth and semi-infinite optimization program, which we solve with a spectral bundle method, inspired by the nonconvex spectral bundle method of [37, 38] and [3, 5]. Important forerunners [19, 41, 28] are based on convexity and optimize functions of the form  $\lambda_1 \circ A$  with affine  $A$ . We have developed our method further to deal with typical control applications like multidisk [6] and multifrequency band synthesis [7], design under integral quadratic constraints (IQCs) [4, 9, 8], and loop-shaping techniques [2, 1].

The structure of the paper is as follows. The problem setting is given in section 2. Computing the  $H_2$  and  $H_\infty$  norms is briefly recalled in sections 3 and 4. The algorithm and its rationale are presented in section 5. Global convergence is established in section 6. The implementation is discussed in section 7, and numerical test examples are discussed in section 8. Our terminology follows [17, 30, 52].

**2. Problem setting.** We consider a plant in state space form:

$$(2.1) \quad P : \begin{bmatrix} \dot{x} \\ z_\infty \\ z_2 \\ y \end{bmatrix} = \begin{bmatrix} A & B_\infty & B_2 & B \\ C_\infty & D_\infty & 0 & D_{\infty u} \\ C_2 & 0 & 0 & D_{2u} \\ C & D_{y\infty} & D_{y2} & 0 \end{bmatrix} \begin{bmatrix} x \\ w_\infty \\ w_2 \\ u \end{bmatrix},$$

where  $x \in \mathbb{R}^{n_x}$  is the state,  $u \in \mathbb{R}^{n_u}$  is the control,  $y \in \mathbb{R}^{n_y}$  is the output,  $w_\infty \rightarrow z_\infty$  is the  $H_\infty$  performance channel, and  $w_2 \rightarrow z_2$  is the  $H_2$  performance channel. We seek an output feedback controller:

$$(2.2) \quad K : \begin{bmatrix} \dot{x}_K \\ u \end{bmatrix} = \begin{bmatrix} A_K & B_K \\ C_K & D_K \end{bmatrix} \begin{bmatrix} x_K \\ y \end{bmatrix},$$

where  $x_K \in \mathbb{R}^{n_K}$  is the state of the controller, such that the closed-loop system, obtained by substituting (2.2) into (2.1), satisfies the following properties:

1. *Internal stability.*  $K$  stabilizes  $P$  exponentially in closed-loop.
2. *Fixed  $H_\infty$  performance.* The  $H_\infty$  performance channel has a prespecified performance level  $\|T_{w_\infty \rightarrow z_\infty}(K)\|_\infty \leq \gamma_\infty$ .
3. *Optimal  $H_2$  performance.* The  $H_2$  performance  $\|T_{w_2 \rightarrow z_2}(K)\|_2$  is minimized among all  $K$  satisfying properties 1 and 2.

We will solve the  $H_2/H_\infty$  synthesis problem by way of the following mathematical program:

$$(2.3) \quad \begin{aligned} & \text{minimize} && f(K) := \|T_{w_2 \rightarrow z_2}(K)\|_2^2 \\ & \text{subject to} && g(K) := \|T_{w_\infty \rightarrow z_\infty}(K)\|_\infty^2 \leq \gamma_\infty^2, \end{aligned}$$

where  $T_{w_2 \rightarrow z_2}(K, s)$  denotes the transfer function of the  $H_2$  closed-loop performance channel, while  $T_{w_\infty \rightarrow z_\infty}(K, s)$  stands for the  $H_\infty$  robustness channel. Notice that  $f(K)$  is a smooth function, whereas  $g(K)$  is not, being an infinite maximum of maximum eigenvalue functions. The unknown  $K$  is in the space  $\mathbb{R}^{(n_K+n_u) \times (n_K+n_y)}$ , so the dimension  $n = (n_K + n_y)(n_K + n_u)$  of (2.3) is usually small, which is particularly attractive when small or medium size controllers for large systems are sought. Notice that as a BMI or LMI problem,  $H_2/H_\infty$  synthesis (2.3) would feature  $n_x^2$  additional Lyapunov variables, which would arise through the use of the bounded real lemma. See, e.g., [46, 14].

*Remark.* Naturally, the approach chosen in (2.3) to fix the  $H_\infty$  performance and optimize  $H_2$  performance is just one among many other strategies in multiobjective optimization. One could just as well optimize the  $H_\infty$  norm subject to an  $H_2$  norm constraint, or minimize a weighted sum or even the maximum of both criteria. Other ideas have been considered, and even game theoretic approaches exist [35].

**3. The  $H_2$  norm.** In program (2.3) we minimize composite functions  $f = \|\cdot\|_2^2 \circ T_{w_2 \rightarrow z_2}$ , where  $\|\cdot\|_2$  denotes the  $H_2$  norm. Let us for brevity write  $T_2 := T_{w_2 \rightarrow z_2}$  for the  $H_2$  transfer channel in (2.1). The corresponding plant  $P^2$  is obtained by deleting the  $w_\infty$  column and the  $z_\infty$  line in  $P$ . The objective function can be written as

$$f(K) = \|T_2(K, \cdot)\|_2^2 = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \text{Tr}(T_2(K, j\omega)^H T_2(K, j\omega)) d\omega.$$

Algorithmically it is convenient to compute function values using a state space realization of  $P^2$ :

$$P^2(s) = \begin{bmatrix} 0 & D_{2u} \\ D_{y2} & 0 \end{bmatrix} + \begin{bmatrix} C_2 \\ C \end{bmatrix} (sI - A)^{-1} \begin{bmatrix} B_2 & B \end{bmatrix}.$$

Introducing the closed-loop state space data,

$$\begin{aligned} \mathcal{A}(K) &= \begin{bmatrix} A + BD_K C & BC_K \\ B_K C & A_K \end{bmatrix}, & \mathcal{B}_2(K) &= \begin{bmatrix} B_2 + BD_K D_{y2} \\ B_K D_{y2} \end{bmatrix}, \\ \mathcal{C}_2(K) &= [C_2 + D_{2u} D_K C \quad D_{2u} C_K], & \mathcal{D}_2(K) &= D_{2u} D_K D_{y2} = 0, \end{aligned}$$

we assume either  $D_{2u} = 0$  or  $D_{y2} = 0$ , or that the controller  $K$  is strictly proper, to ensure finiteness of the  $H_2$  norm. Then a realization of the closed-loop transfer function  $T_2$  is given as

$$T_2(K, s) = \mathcal{C}_2(K)(sI - \mathcal{A}(K))^{-1} \mathcal{B}_2(K)$$

and (see, e.g., [21]) the objective function  $f$  may be rewritten as

$$f(K) = \text{Tr}(\mathcal{B}_2(K)^T X(K) \mathcal{B}_2(K)) = \text{Tr}(\mathcal{C}_2(K) Y(K) \mathcal{C}_2(K)^T),$$

where  $X(K)$  and  $Y(K)$  are the solutions of two Lyapunov equations:

$$\begin{aligned} (3.1) \quad & \mathcal{A}(K)^T X(K) + X(K) \mathcal{A}(K) + \mathcal{C}_2(K)^T \mathcal{C}_2(K) = 0, \\ & \mathcal{A}(K) Y(K) + Y(K) \mathcal{A}(K)^T + \mathcal{B}_2(K) \mathcal{B}_2(K)^T = 0. \end{aligned}$$

As observed in [43, section 3], one proves differentiability of the objective  $f$  over the set  $D$  of closed-loop stabilizing controllers  $K$ . In order to write the derivative  $f'(K)dK$  in a gradient form, we introduce the gradient  $\nabla f(K)$  of  $f$  at  $K$  defined by

$$f'(K)dK = \text{Tr}[\nabla f(K)^T dK],$$

meaning that  $\nabla f(K)$  is now an element of the same matrix space as  $K$ . These results lead to the following lemma, which is an extension of [43, Theorem 3.2].

**LEMMA 3.1.** *The objective function  $f$  is differentiable on the open set  $D$  of closed-loop stabilizing gains. For  $K \in D$ , the gradient of  $f$  at  $K$  is*

$$\nabla f(K) = 2 [B^T X(K) + D_{2u}^T \mathcal{C}_2(K)] Y(K) C^T + 2 B^T X(K) \mathcal{B}_2(K) D_{y2}^T,$$

where  $X(K)$  and  $Y(K)$  solve (3.1).

**4. The  $H_\infty$  norm.** The next element required in (2.3) is the constraint function  $g = \|\cdot\|_\infty^2 \circ T_{w_\infty \rightarrow z_\infty}$ , a composite function of the  $H_\infty$  norm. To compute it we will use a frequency domain representation of the  $H_\infty$  norm. Let us for brevity write  $T_\infty := T_{w_\infty \rightarrow z_\infty}$ . The corresponding plant is  $P^\infty$ , obtained by deleting the  $w_2$  column and the  $z_2$  line in  $P$ . The constraint function  $g$  may be written as

$$g(K) = \max_{\omega \in [0, \infty]} \bar{\sigma}(T_\infty(K, j\omega))^2 = \max_{\omega \in [0, \infty]} \lambda_1(T_\infty(K, j\omega)^H T_\infty(K, j\omega)),$$

where  $\bar{\sigma}$  is the maximum singular value of a matrix, and  $\lambda_1$  is the maximum eigenvalue of a Hermitian matrix. We rewrite this as

$$g(K) = \max_{\omega \in [0, \infty]} g(K, \omega), \quad g(K, \omega) = \lambda_1(T_\infty(K, j\omega)^H T_\infty(K, j\omega)).$$

Then it is clear that  $g(K)$  is nonsmooth with two possible sources of nonsmoothness, the infinite maximum and the maximum eigenvalue function, which is convex but nonsmooth. We present two basic results, which allow us to exploit the structure of  $g$  algorithmically. The following can be found in several places; see, e.g., [12, 11].

LEMMA 4.1. *Let  $K$  be closed-loop stabilizing. Then  $g(K) = \|T_\infty(K)\|_\infty^2 < \infty$ , and the set of active frequencies at  $K$ , defined as  $\Omega(K) = \{\omega \in [0, \infty] : g(K) = g(K, \omega)\}$ , is either finite or  $\Omega(K) = [0, \infty]$ .*

The case  $\Omega(K) = [0, \infty]$  is when the closed-loop system is all-pass. It may very well arise in practice; for instance, full order ( $n_x = n_K$ ) optimal  $H_\infty$  controllers are all-pass; see [26]. A similar result holds for full-order  $H_2/H_\infty$  control; see [20]. But we never observed it in cases where the order of the controller  $n_K < n_x$  is way smaller than the order of the system.

The following result was already used in [5, 6]. It allows us to compute Clarke subgradients of the  $H_\infty$  norm and its composite function  $g$ . To represent it, we find it convenient to introduce the notation

$$\begin{bmatrix} T_\infty(K, s) & G_{12}^\infty(K, s) \\ G_{21}^\infty(K, s) & \star \end{bmatrix} = \begin{bmatrix} \mathcal{C}_\infty(K) \\ C \end{bmatrix} (sI - \mathcal{A}(K))^{-1} \begin{bmatrix} \mathcal{B}_\infty(K) & B \end{bmatrix} + \begin{bmatrix} \mathcal{D}_\infty(K) & D_{\infty u} \\ D_{y\infty} & \star \end{bmatrix},$$

where the closed-loop state space data  $(\mathcal{A}(K), \mathcal{B}_\infty(K), \mathcal{C}_\infty(K), \mathcal{D}_\infty(K))$  are given by

$$\begin{aligned} \mathcal{A}(K) &= \begin{bmatrix} A + BD_K C & BC_K \\ B_K C & A_K \end{bmatrix}, & \mathcal{B}_\infty(K) &= \begin{bmatrix} B_\infty + BD_K D_{y\infty} \\ B_K D_{y\infty} \end{bmatrix}, \\ \mathcal{C}_\infty(K) &= [C_\infty + D_{\infty u} D_K C \quad D_{\infty u} C_K], & \mathcal{D}_\infty(K) &= D_\infty + D_{\infty u} D_K D_{y\infty}. \end{aligned}$$

LEMMA 4.2 (see [5, section IV], [13, p. 304]). *Suppose  $K$  is closed-loop stabilizing and  $\Omega(K)$  is finite. Then the Clarke subdifferential of  $g$  at  $K$  is the set*

$$\partial g(K) = \left\{ \Phi_Y : Y = (Y_\omega)_{\omega \in \Omega(K)}, Y_\omega \succeq 0, \sum_{\omega \in \Omega(K)} \text{Tr}(Y_\omega) = 1, Y_\omega \in \mathbb{S}^{r_\omega} \right\},$$

where  $r_\omega$  is the multiplicity of  $\lambda_1(T_\infty(K, j\omega)^H T_\infty(K, j\omega))$ , and where

$$\Phi_Y = \sum_{\omega \in \Omega(K)} 2\text{Re}(G_{21}^\infty(K, j\omega) T_\infty(K, j\omega)^H Q_\omega Y_\omega Q_\omega^H G_{12}^\infty(K, j\omega))^T.$$

Here the columns of the  $m \times r_\omega$  matrix  $Q_\omega$  form an orthonormal basis of the eigenspace of  $T_\infty(K, j\omega)^H T_\infty(K, j\omega) \in \mathbb{S}^m$  associated with its maximum eigenvalue.

*Remark.* Notice that the result extends to the all-pass case by replacing convex combinations over a finite set  $\Omega(K)$  by Radon probability measures on  $[0, \infty]$ . This may still be exploited algorithmically, should the case of an all-pass system ever arise in practice. Since this never occurred in our tests, this line is not investigated here.

**5. Nonsmooth algorithm.** In this central section we present our main result, a nonsmooth and nonconvex optimization method for program (2.3). In subsection 5.1 we will have a look at the necessary optimality conditions for program (2.3). The algorithm is elaborated and presented in subsections 5.2–5.4. The convergence proof will follow in section 6.

As the reader will notice, our method can be applied to a larger class of programs with a structure similar to (2.3). In consequence, during what follows we aim at a certain level of generality. In particular, to comply with the more standard notation in optimization, we denote the decision variable as  $x \in \mathbb{R}^n$ , where  $n = (n_K + n_u)(n_K + n_y)$  in our previous terminology. This means vectorization of the matrix variable previously denoted  $K$ .

**5.1. Optimality conditions.** Following an idea in [42], we address program (2.3) by introducing a progress function:

$$(5.1) \quad F(y; x) = \max \left\{ f(y) - f(x) - \mu[g(x) - \gamma_\infty^2]_+; [g(y) - \gamma_\infty^2] - [g(x) - \gamma_\infty^2]_+ \right\},$$

where  $\mu > 0$  is a fixed parameter. All we need to know about  $f$  is that it is of class  $C^2$ , while  $g$  is assumed to be of the form

$$g(x) = \max_{\omega \in [0, \infty]} g(x, \omega) = \max_{\omega \in [0, \infty]} \lambda_1(G(x, \omega)),$$

with  $G : \mathbb{R}^n \times [0, \infty] \rightarrow \mathbb{S}^m$  of class  $C^2$  in the variable  $x \in \mathbb{R}^n$ , and jointly continuous in  $(x, \omega)$ . This is in accordance with our previous terminology, where  $G(x, \omega) = T_\infty(K, j\omega)^H T_\infty(K, j\omega)$  with  $x = \text{vec}(K)$ , and where  $m = n_{z_\infty}$  or  $m = n_{w_\infty}$ , and where  $n = (n_K + n_y)(n_K + n_u)$ . We have the following preparatory lemma.

**LEMMA 5.1.** (1) *If  $\bar{x} \in \mathbb{R}^n$  is a local minimum of (2.3), then  $\bar{x}$  is also a local minimum of  $F(\cdot; \bar{x})$ . In particular, this implies  $0 \in \partial_1 F(\bar{x}; \bar{x})$ .*

(2) *If  $\bar{x}$  satisfies the F. John necessary optimality conditions for program (2.3), then  $0 \in \partial_1 F(\bar{x}; \bar{x})$ .*

(3) *Conversely, suppose  $0 \in \partial_1 F(\bar{x}; \bar{x})$  for some  $\bar{x} \in \mathbb{R}^n$ . Then we have the following possibilities: Either*

- (i)  *$g(\bar{x}) > \gamma_\infty^2$ , in which case  $\bar{x}$  is a critical point of  $g$ , called a critical point of constraint violation, or*
- (ii)  *$g(\bar{x}) \leq \gamma_\infty^2$ , in which case  $\bar{x}$  satisfies the F. John necessary optimality conditions for program (2.3). In addition, there are two subcases: Either*
  - (a)  *$\bar{x}$  is a Karush–Kuhn–Tucker (KKT) point of (2.3), or*
  - (b)  *$\bar{x}$  fails to be a KKT point of (2.3). This could only happen when  $g(\bar{x}) = \gamma_\infty^2$  and at the same time  $0 \in \partial g(\bar{x})$ .*

*Proof.* (a) Let us prove statement (1). Notice that  $F(\bar{x}; \bar{x}) = 0$ . We therefore have to show  $F(x; \bar{x}) \geq 0$  for  $x$  in a neighborhood of  $\bar{x}$ . If  $x$  is feasible in (2.3), i.e.,  $g(x) \leq \gamma_\infty^2$ , then  $F(x; \bar{x}) = \max\{f(x) - f(\bar{x}); g(x) - \gamma_\infty^2\} \geq f(x) - f(\bar{x}) \geq 0$  for  $x$  in a neighborhood of  $\bar{x}$ . Here we use the fact that  $\bar{x}$ , being optimal, is feasible, so  $[g(\bar{x}) - \gamma_\infty^2]_+ = 0$ . On the other hand, when  $x$  is infeasible, we find  $F(x; \bar{x}) \geq g(x) - \gamma_\infty^2 > 0$ . This settles statement (1).

(b) To prepare the remaining statements, let us first notice that  $0 \in \partial_1 F(\bar{x}; \bar{x})$  is equivalent to the following condition: There exists  $0 \leq \bar{t} \leq 1$  such that  $0 = \bar{t}f'(\bar{x}) + (1 - \bar{t})\phi$  for some  $\phi \in \partial g(\bar{x})$ , where both branches of  $F(\bar{x}; \bar{x})$  have to be active as soon as  $0 < \bar{t} < 1$ . The latter allows one to distinguish the cases  $g(\bar{x}) > \gamma_\infty^2$  and  $g(\bar{x}) \leq \gamma_\infty^2$ .

(c) First consider the case  $g(\bar{x}) > \gamma_\infty^2$ . Here the left-hand branch of  $F(\bar{x}; \bar{x})$ , being strictly negative, cannot be active, which means  $\bar{t} = 0$ . In consequence,  $0 \in \partial g(\bar{x})$ . This is the case of a critical point of constraint violation, so it proves (i) in (3).

(d) Next consider the case  $g(\bar{x}) \leq \gamma_\infty^2$ . In order to show that  $\bar{x}$  satisfies the F. John necessary optimality conditions, it remains to check complementarity. If  $g(\bar{x}) = \gamma_\infty^2$ , there is nothing to prove, so assume  $g(\bar{x}) < \gamma_\infty^2$ . Then the right-hand branch of  $F(\bar{x}; \bar{x})$  is negative, so it cannot be active, meaning that  $(1 - \bar{t}) = 0$ . Since this is the Lagrange multiplier for the constraint, this proves the first part of statement (3)(ii).

(e) It remains to distinguish the two cases (ii)(a) and (ii)(b). Let us see in which cases an F. John critical point can fail to satisfy the KKT conditions. That concerns the case where  $\bar{t} = 0$ , and at the same time  $g(\bar{x}) \leq \gamma_\infty^2$ . But  $g(\bar{x}) < \gamma_\infty^2$  is impossible here, because the right-hand branch of  $F(\bar{x}; \bar{x})$  has to be active. Then it turns out that  $g(\bar{x}) = \gamma_\infty^2$  and  $0 \in \partial g(\bar{x})$  is the only case where KKT fails. It may be considered as the limiting case of a critical point  $\bar{x}$  of constraint violation. This settles all cases in statement (3).

(f) Finally, to prove statement (2), let  $\bar{x}$  satisfy the F. John necessary optimality conditions for (2.3). From (b) we immediately see that it also satisfies  $0 \in \partial_1 F(\bar{x}; \bar{x})$ .  $\square$

*Remark.* (1) Lemma 5.1 shows why we should search for points  $\bar{x}$  satisfying  $0 \in \partial_1 F(\bar{x}; \bar{x})$ . It also indicates that minimizing  $F$  leads to so-called phase I/phase II methods (see [42, section 2.6]). Namely, as long as iterates stay infeasible, the right-hand term in  $F$  is dominant, so reducing  $F$  reduces constraint violation. This corresponds to phase I. Once a feasible iterate has been found, phase I terminates successfully, and iterates will henceforth stay feasible. This is where phase II begins and  $f$  is optimized.

(2) Condition (i) above addresses the case where phase I fails because iterates get stuck at a limit point  $\bar{x}$  with value  $g(\bar{x}) > \gamma_\infty^2$ , which is a local minimum (a critical point) of  $g$  alone. A first-order method may get trapped at such points, and in classical mathematical programming second-order techniques are used to avoid them. Here we are working with a nonsmooth program, where second-order methods are difficult to come up with (see, however, [38], where such a method is discussed, and also [11, 39]). Fortunately, in  $H_2/H_\infty$  control, feasible iterates are usually available, so phase I can even be avoided. Notice also that case (ii)(b) may be considered the limiting case of (i).

(3) In [44] Sagastizábal and Solodov use a different progress function, referred to as an *improvement function*, which does not feature the penalty term  $\mu[g(x) - \gamma_\infty^2]_+$ . Since this term equals 0 in phase II, both criteria lead essentially to the same steps in phase II, and differences could occur only in phase I. Now observe that with the *improvement function*, every step has to be a descent step for both the objective  $f$  and the constraint  $g$ . In contrast, in our approach, when reducing constraint violation, a slight increase in  $f$  not exceeding  $\mu[g(x) - \gamma_\infty^2]_+$  is granted. This helps the algorithm in not being trapped at infeasible local minima of  $f$  alone, and is therefore a possible advantage. Naturally, the difficulty of local minima of  $g$  alone (local minima of constraint violation) remains with both criteria. We will come

back to this issue in section 7.5, where numerical results are discussed. It turns out that a sound choice of  $\mu$  is important and gives better numerical results.

**5.2. First local model.** In this section we introduce a local model for  $F$  in a neighborhood of the current iterate  $x$ . Let us first introduce an approximation of  $g$  in a neighborhood of  $x$  by linearizing the operator  $y \mapsto G(y, \omega)$  around  $x$ :

$$(5.2) \quad \begin{aligned} \tilde{g}(y; x) &= \max_{\omega \in [0, \infty]} \lambda_1 (G(x, \omega) + G'(x, \omega)(y - x)) \\ &= \max_{\omega \in [0, \infty]} \max_{Z \in \mathcal{C}} Z \bullet (G(x, \omega) + G'(x, \omega)(y - x)), \end{aligned}$$

where  $\mathcal{C} = \{Z \in \mathbb{S}^m : Z \succeq 0, \text{tr}(Z) = 1\}$ , and where the derivative  $G'(x, \omega)$  refers to the variable  $x$ . Notice that  $\tilde{g}(x; x) = g(x)$ . By Taylor's theorem we expect  $\tilde{g}(y; x)$  to be a good approximation of  $g(y)$  for  $y$  in a neighborhood of  $x$ .

We now obtain an approximation of  $F$  in a neighborhood of  $x$  by introducing the following:

$$(5.3) \quad \tilde{F}(y; x) = \max \{f'(x)(y - x) - \mu[g(x) - \gamma_\infty^2]_+; [\tilde{g}(y; x) - \gamma_\infty^2] - [g(x) - \gamma_\infty^2]_+\}.$$

Notice that  $\tilde{F}(x; x) = F(x; x)$ , and that  $\tilde{F}(y; x)$  is close to  $F(y; x)$  for  $y$  close to  $x$ . The following result renders these statements exact.

**LEMMA 5.2.** *Let  $B \subset \mathbb{R}^n$  be a bounded set. Then there exists  $L > 0$  such that for all  $x, y \in B$ ,*

$$|g(y) - \tilde{g}(y; x)| \leq L\|y - x\|^2 \quad \text{and} \quad |F(y; x) - \tilde{F}(y; x)| \leq L\|y - x\|^2.$$

*Proof.* By Weyl's theorem we have  $\lambda_m(E) \leq \lambda_1(A + E) - \lambda_1(A) \leq \lambda_1(E)$  for all matrices  $A, E \in \mathbb{S}^m$ . We apply this to  $A = G(y, \omega)$  and  $A + E = G(x, \omega) + G'(x, \omega)(y - x)$ . Then  $E = \mathcal{O}(\|y - x\|^2)$ , uniformly over  $x, y \in B$  and uniformly over  $\omega \in [0, \infty]$ , which is a compact set. Here we use the fact that the operators  $G(\cdot, \omega)$  are of class  $C^2$  in  $x$  and jointly continuous in  $(x, \omega)$ . More precisely

$$\sup_{\omega \in [0, \infty]} \sup_{z \in \text{co}(B)} \|G''(z, \omega)\| < \infty.$$

This proves  $|g(y) - \tilde{g}(y; x)| \leq L_1\|y - x\|^2$  for some  $L_1 > 0$  and all  $x, y \in B$ .

Moreover,  $f$  is of class  $C^2$ , so that by Taylor's formula there exists  $L_2 > 0$  such that  $|f(y) - f(x) - f'(x)(y - x)| \leq L_2\|y - x\|^2$  uniformly over  $x, y \in B$ . With  $L = \max\{L_1, L_2\}$  we obtain

$$\begin{aligned} |F(y; x) - \tilde{F}(y; x)| &\leq \max \{|f(y) - f(x) - f'(x)(y - x)|; |g(y) - \tilde{g}(y; x)|\} \\ &\leq L\|y - x\|^2. \quad \square \end{aligned}$$

It is convenient to represent the local model (5.2) differently. Let us introduce

$$\alpha(\omega, Z) = [Z \bullet G(x, \omega) - \gamma_\infty^2] - [g(x) - \gamma_\infty^2]_+ \in \mathbb{R}, \quad \phi(\omega, Z) = G'(x, \omega)^* Z \in \mathbb{R}^n,$$

where dependence on the point  $x$  is suppressed for convenience. Then the right-hand branch of  $\tilde{F}(y; x)$  may be written as the envelope of cutting planes,

$$[\tilde{g}(y; x) - \gamma_\infty^2] - [g(x) - \gamma_\infty^2]_+ = \sup_{\omega \in [0, \infty]} \sup_{Z \in \mathcal{C}} \alpha(\omega, Z) + \phi(\omega, Z)^T (y - x).$$

Adding the left-hand branch of  $\tilde{F}(y; x)$  by introducing

$$\alpha_0 = -\mu[g(x) - \gamma_\infty^2]_+, \quad \phi_0 = f'(x),$$

we can introduce

$$\mathcal{G} = \text{co}(\{(\alpha(\omega, Z), \phi(\omega, Z)) : \omega \in [0, \infty], Z \in \mathcal{C}\} \cup \{(\alpha_0, \phi_0)\}).$$

Then the local model  $\tilde{F}(y; x)$  may be written as

$$(5.4) \quad \tilde{F}(y; x) = \max\{\alpha + \phi^T(y - x) : (\alpha, \phi) \in \mathcal{G}\}.$$

The advantage of (5.4) over (5.3) is that elements  $(\alpha, \phi)$  of  $\mathcal{G}$  are easier to store than elements  $(\omega, Z) \in [0, \infty] \times \mathcal{C}$ . Also, as we shall see, it is more convenient to construct approximations  $\mathcal{G}_k$  of  $\mathcal{G}$ . This is addressed in the next section.

**5.3. Second local model and tangent program.** Suppose  $x$  is the current iterate of our algorithm to be designed. In order to generate trial steps away from  $x$ , we will recursively generate approximations  $\tilde{F}_k(y; x)$  of  $\tilde{F}(y; x)$ , referred to as the working models. Using (5.4), these will be of the form

$$(5.5) \quad \tilde{F}_k(y; x) = \max\{\alpha + \phi^T(y - x) : (\alpha, \phi) \in \mathcal{G}_k\},$$

where  $\mathcal{G}_k \subset \mathcal{G}$ . In particular,  $\tilde{F}_k(y; x) \leq \tilde{F}(y; x)$ , with exactness  $\tilde{F}_k(x; x) = \tilde{F}(x; x) = F(x; x) = 0$  at  $y = x$ . Moreover, our construction presented below ensures that  $\partial_1 \tilde{F}_k(x; x) \subset \partial_1 F(x; x)$  for all  $k$  and that the  $\tilde{F}_k$  get closer to  $\tilde{F}$  as  $k$  increases. In tandem with the proximity control management described in section 6, this will also ensure that the  $\tilde{F}_k$  get closer to the true  $F$ . Once the set  $\mathcal{G}_k$  is formed, a new trial step  $y^{k+1}$  is computed via the tangent program:

$$(5.6) \quad \min_{y \in \mathbb{R}^n} \tilde{F}_k(y; x) + \frac{\delta_k}{2} \|y - x\|^2.$$

Here  $\delta_k > 0$  is the so-called proximity control parameter, which is specified anew at each step. How this should be organized will be explained in section 6.

Notice that by convexity  $y^{k+1}$  is a solution of (5.6) as soon as

$$(5.7) \quad 0 \in \partial_1 \tilde{F}_k(y^{k+1}; x) + \delta_k(y^{k+1} - x).$$

The first question is, what happens if the solution of the program (5.6) is  $y^{k+1} = x$ ?

**LEMMA 5.3.** *Suppose  $y^{k+1} = x$  is the solution of the tangent program (5.6). Then  $0 \in \partial_1 F(x; x)$ .*

This is indeed clear in view of (5.7), because we get  $0 \in \partial_1 \tilde{F}_k(x; x)$ , which implies  $0 \in \partial_1 F(x; x)$  by the property  $\partial_1 \tilde{F}_k(x; x) \subset \partial_1 F(x; x)$  of a working model. The conclusion is that as soon as  $0 \notin \partial_1 F(x; x)$ , then  $0 \notin \partial_1 \tilde{F}_k(x; x)$ , and the trial step  $y^{k+1}$  will always offer something new. In particular, if  $0 \notin \partial_1 F(x; x)$ , then we know for sure that  $\tilde{F}_k(y^{k+1}; x) < \tilde{F}(x; x) = 0$ , so that there is always a progress predicted by  $\tilde{F}_k$ .

*Remark.* In light of Lemma 5.3 it may seem natural to confine the test  $0 \in \partial_1 \tilde{F}(x; x)$  (step 2 of the algorithm) to the first instance of the tangent program  $k = 1$ . Indeed, if  $0 \in \partial_1 \tilde{F}_1(x; x)$ , then the first tangent program will detect this and return  $y^2 = x$ , in which case we quit. However, notice that this does not work the other

way round. If  $0 \in \partial_1 F(x; x)$ , then the tangent program based on  $\tilde{F}_k$  may still find  $y^{k+1} \neq x$ , in which case we would not necessarily stop the inner loop. Only when  $\partial_1 \tilde{F}_k(x; x) = \partial_1 F(x; x)$  are we certain that  $y^{k+1} = x$ . In other words, if we wish to confine the test in step 2 of the algorithm to the first instance of the tangent program in step 4, we have to use the full subdifferential  $\partial_1 \tilde{F}_1(x; x) = \partial_1 F(x; x)$ . As soon as  $y^2 \neq x$ , then the inner loop is entered, and this condition is no longer required for the following  $\tilde{F}_k$ . In any case, letting  $\partial_1 \tilde{F}_k(x; x) = \partial_1 F(x; x)$  does not pose a numerical problem if  $\partial_1 F(x; x)$  is not exceedingly large.

From now on we assume  $0 \notin \partial_1 F(x, x)$ . The solution  $y^{k+1}$  of (5.6) is then predicting a decrease of the value of the progress function (5.1) at  $y^{k+1}$ . This gives  $y^{k+1}$  the option to improve over the current iterate  $x$  and become the new iterate  $x^+$ . For this to happen, we have to make sure that  $\tilde{F}_k$  is a good model of  $F$  in the neighborhood of  $x$ .

According to standard terminology, when  $y^{k+1}$  is accepted as the new iterate  $x^+$ , it is called a serious step, while trial points  $y^{k+1}$  which are rejected are called null steps. If  $y^{k+1}$  is a null step and has to be rejected, we use it to improve the model  $\mathcal{G}_{k+1}$  at the next sweep.

Let us now show in detail how to construct the sets  $\mathcal{G}_k$ . We choose them of the form

$$(5.8) \quad \mathcal{G}_k = \text{co}(\mathcal{G}_0 \cup \mathcal{G}_k^c \cup \mathcal{G}_k^*), \quad k = 1, 2, \dots,$$

where we refer to  $\mathcal{G}_0$  as the subgradient elements, to  $\mathcal{G}_k^c$  as the cutting planes, and to  $\mathcal{G}_k^*$  as the aggregate element. The first property concerns  $\mathcal{G}_0$ , which is held fixed during the iteration  $k$ .

LEMMA 5.4. *Let  $\omega_0 \in \Omega(x)$  be any of the active frequencies at  $x$ . Choose a normalized eigenvector  $e_0$  associated with the maximum eigenvalue  $g(x) = \lambda_1(G(x, \omega_0))$  of  $G(x, \omega_0)$ , and let  $Z_0 := e_0 e_0^T \in \mathcal{C}$ . If we let  $(\alpha_0, \phi_0) \in \mathcal{G}_0$  and  $(\alpha(\omega_0, Z_0), \phi(\omega_0, Z_0)) \in \mathcal{G}_0$ , and if  $\mathcal{G}_0 \subset \mathcal{G}_k$ , then we have  $\tilde{F}_k(x; x) = F(x; x) = 0$  at all times  $k$ .*

In practice it is useful to enrich the set  $\mathcal{G}_0$  so that it contains the subdifferential  $\partial_1 F(x; x)$  at  $x$ . This can be arranged in those cases where  $\Omega(x)$ , the set of active frequencies, is finite. For every  $\omega \in \Omega(x)$  let  $r_\omega \geq 1$  be the eigenvalue multiplicity of  $\lambda_1(G(x, \omega))$ . Let the  $r_\omega$  columns of  $Q_\omega$  be an orthonormal basis of the maximum eigenspace of  $G(x, \omega)$ . Then put

$$(5.9) \quad \mathcal{G}_0 = \text{co} \left( \{(\alpha(\omega, Z_\omega), \phi(\omega, Z_\omega)) : \omega \in \Omega(x), Z_\omega = Q_\omega^T Y_\omega Q_\omega, Y_\omega \in \mathbb{S}^{r_\omega}, Y_\omega \succeq 0, \text{Tr}(Y_\omega) = 1\} \cup \{(\alpha_0, \phi_0)\} \right).$$

We observe that this set is not finitely generated, but can be handled as a semidefinite programming constraint via the matrices  $Y_\omega$ . However, for our convergence proof it would be sufficient to keep just the one element required by Lemma 5.4 in  $\mathcal{G}_0$ .

Let us now look at the cutting plane sets  $\mathcal{G}_k^c$ . Here we use a recursive construction. Suppose the solution  $y^{k+1}$  of tangent program (5.6) based on the latest model  $\mathcal{G}_k$  is a null step. Then we need to improve the next model  $\mathcal{G}_{k+1}$ , and this is done by including a cutting plane in the new set  $\mathcal{G}_{k+1}^c$ , which cuts away the unsuccessful trial step  $y^{k+1}$ .

LEMMA 5.5. *Let  $y^{k+1}$  be the solution of tangent program (5.6) at stage  $k$  and suppose  $y^{k+1}$  is a null step. Suppose the right-hand branch of (5.3) is active at*

$y^{k+1}$ , and let  $\omega_{k+1} \in [0, \infty]$  and  $Z_{k+1} \in \mathcal{C}$  be one of the pairs where the maximum (5.2) is attained, that is,  $\tilde{g}(y^{k+1}; x) - \gamma_\infty^2 - [g(x) - \gamma_\infty^2]_+ = \alpha(\omega_{k+1}, Z_{k+1}) + \phi(\omega_{k+1}, Z_{k+1})^T(y^{k+1} - x)$ . If we keep  $(\alpha(\omega_{k+1}, Z_{k+1}), \phi(\omega_{k+1}, Z_{k+1})) \in \mathcal{G}_{k+1}^c$ , then

$$\tilde{F}_{k+1}(y^{k+1}; x) = \tilde{F}(y^{k+1}; x).$$

*Remark.* (1) Following standard terminology, we refer to this procedure as the cutting plane element. In fact, adding  $\omega_{k+1}$  and  $Z_{k+1}$  to the approximations at the next step  $k+1$  will cut away the unsuccessful null step  $y^{k+1}$ , paving the way for a better  $y^{k+2}$  at the next sweep.

(2) If the right-hand branch in (5.3) is not active, it suffices to have the pair  $(\alpha_0, \phi_0) \in \mathcal{G}_0$ . As we keep this in  $\mathcal{G}_0$  anyway, no action on cutting planes is required in this event; i.e., we may have  $\mathcal{G}_{k+1}^c = \emptyset$ .

In practice it will be useful to enrich the set  $\mathcal{G}_{k+1}^c$  by what we call anticipating cutting planes. Let us again consider the case of a finite set  $\Omega(x)$ . We select a finite extension  $\Omega_e(x)$  of  $\Omega(x)$  along the lines described in [5]. We let

(5.10)

$$\mathcal{G}_{k+1}^c = \text{co} \left( \{(\alpha(\omega_{k+1}, Z_{k+1}), \phi(\omega_{k+1}, Z_{k+1}))\} \cup \{(\alpha(\omega, Z_\omega), \phi(\omega, Z_\omega)) : \omega \in \Omega_e(x) \setminus \Omega(x), Z_\omega = Q_\omega^T Y_\omega Q_\omega, Y_\omega \succeq 0, \text{Tr}(Y_\omega) = 1\} \right),$$

where the columns of  $Q_\omega$  are an orthonormal basis of some invariant subspace of  $\lambda_1(G(x, \omega))$ . Notice that for  $\omega \in \Omega_e(x) \setminus \Omega(x)$ , the support planes belonging to  $(\alpha(\omega, Z_\omega), \phi(\omega, Z_\omega))$  are indeed different in nature from those retained in  $\mathcal{G}_0$ , because they will not be exact at  $y = x$ . We may have  $\alpha(\omega, Z_\omega) < 0$ , so these planes resemble cutting planes, which are exact at the null steps  $y^{k+1}$ .

Notice that convergence theory requires only  $(\alpha(\omega_{k+1}, Z_{k+1}), \phi(\omega_{k+1}, Z_{k+1})) \in \mathcal{G}_{k+1}^c$  for the element of Lemma 5.5.

*Remark.* Notice that the planes in  $\mathcal{G}_0$  are exact at  $x$ , while genuine cutting planes are exact at the null steps  $y^{k+1}$ . Anticipated cutting planes need not be exact anywhere, but we have observed that they often behave similarly to true cutting planes and can help to avoid a large number of unsuccessful null steps.

We need yet another process to improve the model  $\mathcal{G}_{k+1}$ , which in the nonsmooth terminology is referred to as aggregation, and which is needed in order to avoid storing an increasing number of cutting planes. Suppose that the solution  $y^{k+1}$  of the old tangent program (5.6) based on  $\mathcal{G}_k$  is a null step. By the optimality condition we have  $0 \in \partial_1 \tilde{F}_k(y^{k+1}; x) + \delta_k(y^{k+1} - x)$ . Using the representation (5.4) and the form (5.8), we find  $(\alpha_0, \phi_0) \in \mathcal{G}_0$ ,  $(\alpha_{k+1}, \phi_{k+1}) \in \mathcal{G}_k^c$ , and  $(\alpha_k^*, \phi_k^*) \in \mathcal{G}_k^*$  together with convex coefficients  $\tau_0 \geq 0$ ,  $\tau_{k+1} \geq 0$ ,  $\tau_k^* \geq 0$ ,  $\tau_0 + \tau_{k+1} + \tau_k^* = 1$ , such that

$$0 = \tau_0 \phi_0 + \tau_{k+1} \phi_{k+1} + \tau_k^* \phi_k^* + \delta_k(y^{k+1} - x).$$

We put  $\alpha_{k+1}^* = \tau_0 \alpha_0 + \tau_{k+1} \alpha_{k+1} + \tau_k^* \alpha_k^* \in \mathbb{R}$ ,  $\phi_{k+1}^* = \tau_0 \phi_0 + \tau_{k+1} \phi_{k+1} + \tau_k^* \phi_k^* \in \mathbb{R}^n$  and keep  $(\alpha_{k+1}^*, \phi_{k+1}^*) \in \mathcal{G}_{k+1}^*$ , calling it the aggregate element. Notice that we have  $(\alpha_{k+1}^*, \phi_{k+1}^*) \in \mathcal{G}$  by convexity. Altogether, this shows

$$(5.11) \quad 0 = \phi_{k+1}^* + \delta_k(y^{k+1} - x).$$

LEMMA 5.6. *Keeping the aggregate element  $(\alpha_{k+1}^*, \phi_{k+1}^*)$  in the new  $\mathcal{G}_{k+1}^*$  ensures that  $\tilde{F}_{k+1}(y^{k+1}; x) \geq \tilde{F}_k(y^{k+1}; x)$  and that (5.11) is satisfied.*

To conclude this section, let us outline how the tangent program based on the forms (5.4) and (5.8) is solved. Notice first that elements of  $\mathcal{G}_0 \cup \mathcal{G}_k^c$  have the same form  $(\alpha(\omega, Z_\omega), \phi(\omega, Z_\omega))$ , where  $\omega \in \Omega_e(x)$  for some finite extension of  $\Omega(x)$ , and  $Z_\omega = Q_\omega^T Y_\omega Q_\omega$  for some  $Y_\omega \succeq 0$ ,  $\text{Tr}(Y_\omega) = 1$ . To this we add the aggregate element  $(\alpha_k^*, \phi_k^*)$ , and the element  $(\alpha_0, \phi_0)$  coming from the left-hand branch of  $\tilde{F}$ . This means, after relabeling the finite set  $\Omega_e(x)$  as  $\{\omega_1, \dots, \omega_p\}$ , we can write (5.6) in the form

$$\min_{y \in \mathbb{R}^n} \max \left\{ \alpha_0 + \phi_0^T(y - x); \max_{r=1, \dots, p} \max_{Y_r \succeq 0, \text{Tr}(Y_r)=1} \alpha_r(Y_r) + \phi_r(Y_r)^T(y - x); \right. \\ \left. \alpha_{p+1} + \phi_{p+1}^T(y - x) \right\} + \frac{\delta_k}{2} \|y - x\|^2,$$

where  $\alpha_r(Y_r) = \alpha(\omega_r, Z_{\omega_r})$ , etc., and where the aggregate element  $(\alpha_k^*, \phi_k^*)$  is relabeled  $(\alpha_{p+1}, \phi_{p+1})$ . Replacing the maximum over the three branches by a maximum over the convex hull of the three does not change the value of this program. Using Fenchel duality, we may then swap the min and max operators. Then the inner minimum can be computed explicitly, which leads to the expression

$$y^{k+1} = x - \frac{1}{\delta_k} \left( \tau_0 \phi_0 + \sum_{r=1}^p \tau_r \phi_r(Y_r) + \tau_{p+1} \phi_{p+1} \right),$$

where  $(\tau, Y)$  is the dual variable. Substituting this back into the dual program, using linearity of  $\phi(Y)$  in  $Y$ , and rewriting  $\tau_r Y_r$  as a new matrix  $Y_r$  with  $\text{Tr}(Y_r) = \tau_r$  leads to the dual program

$$\begin{aligned} \text{maximize} \quad & \tau_0 \alpha_0 + \sum_{r=1}^p \alpha_r(Y_r) + \tau_{p+1} \alpha_{p+1} - \frac{1}{2\delta_k} \left\| \tau_0 \phi_0 + \sum_{r=1}^p \phi_r(Y_r) + \tau_{p+1} \phi_{p+1} \right\|^2 \\ \text{subject to} \quad & \tau_0 \geq 0, \tau_{p+1} \geq 0, Y_r \succeq 0, \text{ and } \tau_0 + \sum_{r=0}^{p+1} \text{Tr}(Y_r) + \tau_{p+1} = 1, \end{aligned}$$

which we recognize as the concave form of a semidefinite program (SDP), as soon as we write  $\phi_r(Y_r)$  in its original form  $G'(x, \omega_r)^* Q_{\omega_r}^T Y_r Q_{\omega_r}$ . The return formula becomes

$$(5.12) \quad y^{k+1} = x - \frac{1}{\delta_k} \left( \tau_0^* \phi_0 + \sum_{r=1}^p \phi_r(Y_r^*) + \tau_{p+1}^* \phi_{p+1} \right),$$

where the dual optimal solution is  $(\tau_0^*, Y_1^*, \dots, Y_p^*, \tau_{p+1}^*)$ . Notice that this SDP is usually of small size, so that solving a succession of these programs seems a satisfactory strategy.

To conclude, we consider the case of particular interest in which the eigenvalue multiplicity of all matrices involved is 1, or where we decide to keep only one eigenvector for each leading eigenvalue. If  $\lambda_1(G(x, \omega))$  has eigenvalue multiplicity  $r_\omega = 1$ , the matrices  $Q_\omega$  are just column vectors  $e_\omega$ , where  $e_\omega$  is the normalized eigenvector associated with  $\lambda_1(G(x, \omega))$  and  $Y_\omega = 1$ . Similarly, for the latest cutting plane we then have  $Q_\omega = e_\omega$  for the normalized eigenvector of  $\lambda_1(G(x, \omega) + G'(x, \omega)(y^{k+1} - x))$ . In this case the sets  $\mathcal{G}_0, \mathcal{G}_k^c$  are finite, and so  $\mathcal{G}_k$  itself is a polyhedron  $\text{co}\{(\alpha_0, \phi_0), \dots,$

$(\alpha_{p+1}, \phi_{p+1})\}$ , where  $\text{card}(\Omega_e(x)) = p$ . In this case the dual program is a convex quadratic program which can be solved very efficiently:

$$\begin{aligned} & \text{maximize} \quad \sum_{r=0}^{p+1} \tau_r \alpha_r - \frac{1}{2\delta_k} \left\| \sum_{r=0}^{p+1} \tau_r \phi_r \right\|^2 \\ & \text{subject to} \quad \tau_r \geq 0, r = 0, \dots, p+1, \text{ and } \sum_{r=0}^{p+1} \tau_r = 1, \end{aligned}$$

with dual optimal solution  $\tau^*$ , and the return formula is  $y^{k+1} = x - \frac{1}{\delta_k} \sum_{r=0}^{p+1} \tau_r^* \phi_r$ .

**5.4. The algorithm.** In this section we present the nonsmooth spectral bundle algorithm for program (2.3).

**6. Management of the proximity parameter.** In this section the convergence proof of Algorithm 1 will be given.

To begin with, let us explain the management of the proximity control parameter in steps 5 and 8. Notice that there are two control mechanisms, governed by the control parameters  $\rho_k$  and  $\tilde{\rho}_k$ . In step 5, test parameter  $\rho_k$  compares the current model  $\tilde{F}_k$  to the truth  $F$ . The ideal case would be  $\rho_k \approx 1$ , but we accept  $y^{k+1} = x^{j+1}$  much earlier, namely, if  $\rho_k \geq \gamma$ , where the reader might for instance imagine  $\gamma = \frac{1}{4}$ . Let us call  $y^{k+1}$  bad if  $\rho_k < \gamma$ . So null steps are bad, while serious steps are not bad. Imagine further that  $\Gamma = \frac{3}{4}$ ; then steps  $y^{k+1}$  with  $\rho_k > \Gamma$  are good steps. In the good case the model  $\tilde{F}_k$  seems very reliable, so we can relax proximity control a bit at the next outer step. This is arranged by memorizing  $\delta^+ = \delta_k/2$  in step 5 of the algorithm.

It is more intriguing to decide what we should do when  $\rho_k < \gamma$ , meaning that  $y^{k+1}$  is bad (a null step). Here we need the second control parameter  $\tilde{\rho}_k$  in step 8 to support our decision. Adopting the same terminology, we say that the agreement between  $\tilde{F}$  and  $\tilde{F}_k$  is bad if  $\tilde{\rho}_k < \tilde{\gamma}$ . If this is the case, we keep  $\delta_{k+1} = \delta_k$  unchanged, being reluctant to increase the  $\delta$ -parameter prematurely, and continue to rely on cutting planes and aggregation, hoping that this will drive  $\tilde{F}_k$  closer to  $\tilde{F}$  (and also to  $F$ ) and bring home the bacon in the end. On the other hand, if  $\tilde{\rho}_k \geq \tilde{\gamma}$ , then we have to accept that driving  $\tilde{F}_k$  closer to  $\tilde{F}$  alone will not do the job, simply because  $\tilde{F}$  itself is too far from the true  $F$ . Here we need to tighten proximity control by increasing  $\delta_{k+1} = 2\delta_k$  at the next sweep. This is done in step 8 and brings  $\tilde{F}$  closer to  $F$ .

*Remark.* Notice that the control parameters  $\rho_k$  and  $\tilde{\rho}_k$  in steps 5 and 8 are well defined because we enter the inner loop only when  $0 \notin \partial_1 F(x; x)$ , in which case we have  $\tilde{F}_k(y^{k+1}; x) < \tilde{F}_k(x; x) = 0$ .

**6.1. Finiteness of inner loop.** Let  $x$  be the current iterate of the outer loop. We start our convergence analysis by showing that the inner loop terminates after a finite number of updates  $k$  with a serious step  $y^{k+1} = x^+$ . This will be proved in the next three lemmas.

Recall that  $y^{k+1}$  is the solution of the tangent program (5.6) and may be obtained from the dual optimal solution by the return formula (5.12), which is of the form

$$y^{k+1} = x - \frac{1}{\delta_k} \left[ \tau_0 f'(x) + \sum_{\omega \in \Omega_e(x)} \tau_\omega G'(x, \omega)^* Z_\omega \right]$$

for a finite extension  $\Omega_e(x)$  of  $\Omega(x)$  and for certain  $Z_\omega \in \mathcal{C}$ . Since the sequence  $\delta_k$  in the inner loop is nondecreasing, we have the following lemma.

---

**Algorithm 1.** Proximity control algorithm for the  $H_2/H_\infty$  program (2.3).

---

**Parameters:**  $0 < \gamma < \tilde{\gamma} < \Gamma < 1$ .

- 1: **Initialize outer loop.** Find initial  $x^1$  such that  $f(x^1) < \infty$  and  $g(x^1) < \infty$ . Put outer loop counter  $j = 1$ .
- 2: **Outer loop.** At outer loop counter  $j$ , stop at the current iterate  $x^j$  if  $0 \in \partial_1 F(x^j; x^j)$ . Otherwise compute  $\Omega(x^j)$  and continue with inner loop.
- 3: **Initialize inner loop.** Choose approximation  $\mathcal{G}_1$  of  $\mathcal{G}$  as in (5.8), where  $\mathcal{G}_0$  contains  $(\alpha(\omega_0, Z_0), \phi(\omega_0, Z_0))$  for some fixed  $\omega_0 \in \Omega(x^j)$  and  $Z_0 = e_0 e_0^T$ , where  $e_0$  is a normalized eigenvector associated with  $\lambda_1(G(x^j, \omega_0))$ . Possibly enrich  $\mathcal{G}_0$  as in (5.9). Initialize  $\mathcal{G}_1^c = \emptyset$ ,  $\mathcal{G}_1^* = \emptyset$ , but possibly enrich using anticipated cutting planes (5.10). Initialize proximity parameter  $\delta_1 > 0$ . If memory element  $\delta^+$  for  $\delta$  is available, use it to initialize  $\delta_1$ . Put inner loop counter  $k = 1$ .
- 4: **Trial step.** At inner loop counter  $k$  for given approximation  $\mathcal{G}_k$  and proximity control parameter  $\delta_k > 0$ , solve tangent program:

$$\min_{y \in \mathbb{R}^n} \tilde{F}_k(y; x^j) + \frac{\delta_k}{2} \|y - x^j\|^2,$$

whose solution is  $y^{k+1}$ .

- 5: **Test of progress.** Check whether

$$\rho_k = \frac{F(y^{k+1}; x^j)}{\tilde{F}_k(y^{k+1}; x^j)} \geq \gamma.$$

If this is the case, accept trial step  $y^{k+1}$  as the new iterate  $x^{j+1}$  (serious step). Compute new memory element  $\delta^+$  as:

$$\delta^+ = \begin{cases} \frac{\delta_k}{2} & \text{if } \rho_k > \Gamma, \\ \delta_k & \text{otherwise.} \end{cases}$$

Increase outer loop counter  $j \rightarrow j + 1$ , and go back to step 2. If  $\rho_k < \gamma$ , continue inner loop with step 6 (null step).

- 6: **Cutting plane.** Select a frequency  $\omega_{k+1}$  where  $\tilde{g}(y^{k+1}, x^j)$  is active and pick a normalized eigenvector  $e_{k+1}$  associated with the maximum eigenvalue of  $G(x^j, \omega_{k+1}) + G'(x^j, \omega_{k+1})(y^{k+1} - x^j)$ . Put  $Z_{k+1} = e_{k+1} e_{k+1}^T$  and assure  $(\alpha(\omega_{k+1}, Z_{k+1}), \phi(\omega_{k+1}, Z_{k+1})) \in \mathcal{G}_{k+1}^c$ . Possibly enrich  $\mathcal{G}_{k+1}^c$  by anticipating cutting planes as in (5.10).
- 7: **Aggregation.** Keep aggregate pair  $(\alpha_{k+1}^*, \phi_{k+1}^*)$  as in (5.11) in  $\mathcal{G}_{k+1}^*$ .
- 8: **Proximity control.** Compute control parameter

$$\tilde{\rho}_k = \frac{\tilde{F}(y^{k+1}; x^j)}{\tilde{F}_k(y^{k+1}; x^j)}.$$

Update proximity parameter  $\delta_k$  as

$$\delta_{k+1} = \begin{cases} \delta_k & \text{if } \rho_k < \gamma \text{ and } \tilde{\rho}_k < \tilde{\gamma}, \\ 2\delta_k & \text{if } \rho_k < \gamma \text{ and } \tilde{\rho}_k \geq \tilde{\gamma}. \end{cases}$$

Increase inner loop counter  $k$  and go back to step 4.

---

LEMMA 6.1. *The solutions  $y^{k+1}$  of (5.6) satisfy*

$$(6.1) \quad \|y^{k+1}\| \leq \|x\| + \delta_1^{-1} \left( \|f'(x)\| + \max_{\omega \in [0, \infty]} \|G'(x, \omega)^*\| \right) < \infty.$$

We are now ready to prove finite termination of the inner loop. Our first step is the following.

LEMMA 6.2. *Suppose the inner loop turns forever and creates an infinite sequence  $y^{k+1}$  of null steps with  $\rho_k < \gamma$ . Then there must be an instant  $k_0$  such that the control parameter  $\tilde{\rho}_k$  satisfies  $\tilde{\rho}_k < \tilde{\gamma}$  for all  $k \geq k_0$ .*

*Proof.* Indeed, by assumption none of the trial steps  $y^{k+1}$  passes the acceptance test in step 5, so  $\rho_k < \gamma$  at all times  $k$ . Suppose now that  $\tilde{\rho}_k \geq \tilde{\gamma}$  for infinitely many times  $k$ . Then according to step 8 the proximity control parameter  $\delta_k$  is increased infinitely often, meaning  $\delta_k \rightarrow \infty$ .

Using the fact that  $y^{k+1}$  is the optimal solution of the tangent program (5.6) gives  $0 \in \partial_1 \tilde{F}_k(y^{k+1}; x) + \delta_k(y^{k+1} - x)$ . Using convexity of  $\tilde{F}_k(\cdot; x)$ , we deduce that

$$-\delta_k(y^{k+1} - x)^T(x - y^{k+1}) \leq \tilde{F}_k(x; x) - \tilde{F}_k(y^{k+1}; x).$$

Using  $\tilde{F}_k(x; x) = F(x; x) = 0$ , ensured by keeping  $(\alpha(\omega_0, Z_0), \phi(\omega_0, Z_0)) \in \mathcal{G}_0 \subset \mathcal{G}_k$  at all times (Lemma 5.4), we obtain

$$(6.2) \quad \frac{\delta_k \|y^{k+1} - x\|^2}{-\tilde{F}_k(y^{k+1}; x)} \leq 1.$$

Next, applying Lemma 5.2 to the bounded set  $B = \{y^{k+1} : k \in \mathbb{N}\} \cup \{x\}$  gives

$$(6.3) \quad \left| F(y^{k+1}; x) - \tilde{F}(y^{k+1}; x) \right| \leq L \|y^{k+1} - x\|^2$$

for some  $L > 0$  and every  $k \in \mathbb{N}$ . Now we expand the control parameters  $\rho_k$  and  $\tilde{\rho}_k$  as follows:

$$\begin{aligned} \tilde{\rho}_k &= \rho_k + \frac{F(y^{k+1}; x) - \tilde{F}(y^{k+1}; x)}{-\tilde{F}_k(y^{k+1}; x)} \\ &\leq \rho_k + \frac{L \|y^{k+1} - x\|^2}{-\tilde{F}_k(y^{k+1}; x)} \leq \rho_k + \frac{L}{\delta_k} \quad (\text{using (6.3) and then (6.2)}). \end{aligned}$$

Since  $L/\delta_k \rightarrow 0$ , we deduce  $\limsup \tilde{\rho}_k \leq \limsup \rho_k \leq \gamma < \tilde{\gamma}$ , which contradicts  $\tilde{\rho}_k > \tilde{\gamma}$  for infinitely many  $k$ .  $\square$

So far we know that if the inner loop turns forever, this implies  $\rho_k < \gamma$  and  $\tilde{\rho}_k < \tilde{\gamma}$  from some counter  $k_0$  onwards. Our next lemma shows that this cannot happen. We refer the interested reader to [18, Proposition 4.3], where essentially the same result is proved. For the sake of completeness and the coherence of notation we give our own proof below.

LEMMA 6.3. *Suppose the inner loop turns forever and produces iterates  $y^{k+1}$  with  $\rho_k < \gamma$  and  $\tilde{\rho}_k < \tilde{\gamma}$  for all  $k \geq k_0$ . Then  $0 \in \partial_1 F(x; x)$ .*

*Proof.* (1) Step 8 of the algorithm tells us that from counter  $k_0$  onwards we are in the case where the proximity parameter is no longer increased. We may therefore assume that it remains unchanged for  $k \geq k_0$ , that is,  $\delta := \delta_k$  for all  $k \geq k_0$ .

(2) For later use, let us introduce the function

$$\psi_k(y; x) = \tilde{F}_k(y; x) + \frac{\delta}{2} \|y - x\|^2.$$

As we have seen already, the necessary optimality condition for the tangent program implies

$$\delta \|y^{k+1} - x\|^2 \leq F(x; x) - \tilde{F}_k(y^{k+1}; x) = -\tilde{F}_k(y^{k+1}; x).$$

Now remember that in step 7 of the algorithm we keep the aggregate  $(\alpha_{k+1}^*, \phi_{k+1}^*) \in \mathcal{G}_{k+1}$ . Let us define the function

$$\psi_k^*(y; x) = \alpha_{k+1}^* + \phi_{k+1}^{*T}(y - x) + \frac{\delta}{2} \|y - x\|^2.$$

We claim that

$$(6.4) \quad \psi_k^*(y^{k+1}; x) = \psi_k(y^{k+1}; x) \quad \text{and} \quad \psi_k^*(y; x) \leq \psi_{k+1}(y; x).$$

Indeed, the inequality on the right is clear because  $(\alpha_{k+1}^*, \phi_{k+1}^*)$  is retained in  $\mathcal{G}_{k+1}$  and therefore contributes to the supremum building  $\psi_{k+1}$ . As for the equality on the left, observe that the aggregate subgradient  $\phi_k^*$  is the one which realizes the necessary optimality condition for tangent program (5.6) at stage  $k$ . Now  $\psi_k(\cdot; x)$  is just the objective of this program, so the function  $\psi_k^*(\cdot; x)$  must be exact at  $y^{k+1}$ .

We now prove the relationship

$$(6.5) \quad \psi_k^*(y; x) = \psi_k^*(y^{k+1}; x) + \frac{\delta}{2} \|y - y^{k+1}\|^2.$$

Indeed, notice that  $\psi_k^*$  is a quadratic function, so expanding it gives

$$\begin{aligned} \psi_k^*(y; x) &= \psi_k^*(y^{k+1}; x) + \nabla \psi_k^*(y^{k+1}; x)^T (y - y^{k+1}) \\ &\quad + \frac{1}{2} (y - y^{k+1})^T \nabla^2 \psi_k^*(y^{k+1}; x) (y - y^{k+1}). \end{aligned}$$

But  $\nabla^2 \psi_k^*(y^{k+1}; x) = \delta I$ , so in order to establish (6.5), we have but to show that  $\nabla \psi_k^*(y^{k+1}; x) = 0$ . To prove this observe that

$$\begin{aligned} \nabla \psi_k^*(y^{k+1}; x) &= \phi_{k+1}^* + \delta(y^{k+1} - x) \\ &= -\delta(y^{k+1} - x) + \delta(y^{k+1} - x) = 0 \end{aligned} \quad (\text{using (5.11)}),$$

so (6.5) is proved. Using this and the previous relations gives

$$\begin{aligned} \psi_k(y^{k+1}; x) &\leq \psi_k^*(y^{k+1}; x) + \frac{\delta}{2} \|y^{k+2} - y^{k+1}\|^2 && (\text{using (6.4) left}) \\ &= \psi_k^*(y^{k+2}; x) && (\text{using (6.5)}) \\ &\leq \psi_{k+1}(y^{k+2}; x) && (\text{using (6.4) right}) \\ &\leq \psi_{k+1}(x; x) && (y^{k+2} \text{ is minimizer of } \psi_{k+1}) \\ &= \tilde{F}_k(x; x) = F(x; x) = 0. \end{aligned}$$

This proves that the sequence  $\psi_k(y^{k+1}; x)$  is monotonically increasing and bounded above, so it converges to some limit  $\psi^* \leq F(x; x) = 0$ . Since the term  $\frac{\delta}{2} \|y^{k+2} - y^{k+1}\|^2$  is squeezed in between two terms with the same limit  $\psi^*$ , we deduce that

$$\frac{\delta}{2} \|y^{k+2} - y^{k+1}\|^2 \rightarrow 0.$$

Since the sequence  $y^{k+1}$  is bounded by Lemma 6.1, we deduce using a geometric argument that

$$(6.6) \quad \|y^{k+2} - x\|^2 - \|y^{k+1} - x\|^2 \rightarrow 0.$$

Recalling the relation  $\tilde{F}_k(y; x) = \psi_k(y; x) - \frac{\delta}{2}\|y - x\|^2$ , we finally obtain

$$(6.7) \quad \begin{aligned} & \tilde{F}_{k+1}(y^{k+2}; x) - \tilde{F}_k(y^{k+1}; x) \\ &= \psi_{k+1}(y^{k+2}; x) - \psi_k(y^{k+1}; x) - \frac{\delta}{2}\|y^{k+2} - x\|^2 + \frac{\delta}{2}\|y^{k+1} - x\|^2, \end{aligned}$$

which converges to 0 due to  $\psi_k(y^{k+1}; x) \rightarrow \psi^*$  proved above and property (6.6).

(3) Let  $(\alpha_{k+1}, \phi_{k+1})$  be the cutting plane element obtained from the null step  $y^{k+1}$  which we retain in  $\mathcal{G}_{k+1}$ . By construction this defines an affine support plane of  $\tilde{F}(\cdot; x)$  at  $y^{k+1}$ . But on the other hand the pair  $(\alpha_{k+1}, \phi_{k+1})$  also contributes to the building of the new model  $\tilde{F}_{k+1}(\cdot; x)$ ; thus the new model must be exact at  $y^{k+1}$ , because always  $\tilde{F}_{k+1} \leq \tilde{F}$ , so the value of  $\tilde{F}$  is the best  $\tilde{F}_{k+1}$  could possibly attain. In other words,  $\phi_{k+1}$  is also a subgradient of  $\tilde{F}_{k+1}(\cdot; x)$  at  $y^{k+1}$ . That means

$$\phi_{k+1}^T(y - y^{k+1}) \leq \tilde{F}_{k+1}(y; x) - \tilde{F}_{k+1}(y^{k+1}; x).$$

Using  $\tilde{F}_{k+1}(y^{k+1}; x) = \tilde{F}(y^{k+1}; x)$  we therefore have

$$(6.8) \quad \tilde{F}(y^{k+1}; x) + \phi_{k+1}^T(y - y^{k+1}) \leq \tilde{F}_{k+1}(y; x).$$

Now observe that

$$\begin{aligned} 0 & \leq \tilde{F}(y^{k+1}; x) - \tilde{F}_k(y^{k+1}; x) \\ &= \tilde{F}(y^{k+1}; x) + \phi_{k+1}^T(y^{k+2} - y^{k+1}) - \tilde{F}_k(y^{k+1}; x) - \phi_{k+1}^T(y^{k+2} - y^{k+1}) \\ &\leq \tilde{F}_{k+1}(y^{k+2}; x) - \tilde{F}_k(y^{k+1}; x) + \|\phi_{k+1}\| \|y^{k+2} - y^{k+1}\| \quad (\text{using (6.8)}), \end{aligned}$$

and this term tends to 0 because of (6.7) and the boundedness of  $\phi_{k+1}$ , and because  $y^{k+1} - y^{k+2} \rightarrow 0$ . We conclude that

$$(6.9) \quad \tilde{F}(y^{k+1}; x) - \tilde{F}_k(y^{k+1}; x) \rightarrow 0.$$

(4) We now show that  $\tilde{F}_k(y^{k+1}; x) \rightarrow F(x; x) = 0$ , and therefore by (6.9) also  $\tilde{F}(y^{k+1}; x) \rightarrow F(x; x) = 0$ . Suppose, contrary to the claim, that  $\eta := F(x; x) - \limsup \tilde{F}_k(y^{k+1}; x) > 0$ . Choose  $0 < \theta < (1 - \tilde{\gamma})\eta$ . It follows from (6.9) that there exists  $k_1 \geq k_0$  such that

$$\tilde{F}(y^{k+1}; x) - \theta \leq \tilde{F}_k(y^{k+1}; x)$$

for all  $k \geq k_1$ . Using  $\tilde{\rho}_k < \tilde{\gamma}$  for all  $k \geq k_1$  gives

$$\begin{aligned} \tilde{\gamma}(\tilde{F}_k(y^{k+1}; x) - F(x; x)) & \leq \tilde{F}(y^{k+1}; x) - F(x; x) \\ & \leq \tilde{F}_k(y^{k+1}; x) + \theta - F(x; x). \end{aligned}$$

Passing to the limit implies  $\tilde{\gamma}\eta \geq \eta - \theta$ , contradicting the choice of  $\theta$ . This proves  $\eta = 0$ , as claimed.

(5) Having shown  $\tilde{F}_k(y^{k+1}; x) \rightarrow F(x; x) = 0$ , we now argue that we must have  $y^{k+1} \rightarrow x$ . This follows from the definition of  $y^{k+1}$ , because

$$\psi_k(y^{k+1}; x) = \tilde{F}_k(y^{k+1}; x) + \frac{\delta}{2} \|y^{k+1} - x\|^2 \leq \psi_k(x; x) = F(x; x) = 0.$$

Since  $\tilde{F}_k(y^{k+1}; x) \rightarrow 0$  by part (4), we have indeed  $y^{k+1} \rightarrow x$ . To finish the proof, observe that  $0 \in \partial_1 \psi_k(y^{k+1}; x)$  implies

$$\begin{aligned} \delta(x - y^{k+1})^T(y - y^{k+1}) &\leq \tilde{F}_k(y; x) - \tilde{F}_k(y^{k+1}; x) \\ (6.10) \qquad \qquad \qquad &\leq \tilde{F}(y; x) - \tilde{F}_k(y^{k+1}; x) \end{aligned}$$

for every  $y$ . Passing to the limit gives

$$0 \leq \tilde{F}(y; x) - \tilde{F}(x; x),$$

because the left-hand side in (6.10) converges to 0 in view of  $y^{k+1} \rightarrow x$ , and since  $\tilde{F}_k(y^{k+1}; x) \rightarrow F(x; x)$  by (3) above. Since  $\partial_1 \tilde{F}(x; x) \subset \partial_1 F(x; x)$ , we are done.  $\square$

**6.2. Convergence of outer loop.** Let us consider the sequence  $(x^j)_{j \in \mathbb{N}}$  of serious steps generated by Algorithm 1. We want to show that  $0 \in \partial_1 F(\bar{x}; \bar{x})$  for every accumulation point  $\bar{x}$  of  $(x^j)_{j \in \mathbb{N}}$ . We start by proving that under reasonable hypotheses, the sequence of serious iterates of our algorithm is bounded.

LEMMA 6.4. *Suppose the following two hypotheses are satisfied:*

- (H<sub>1</sub>)  *$g$  is weakly coercive in the sense that if a sequence  $x^j$  satisfies  $\|x^j\| \rightarrow \infty$  and  $g(x^j) > \gamma_\infty^2$ , then  $g(x^j)$  is not strictly monotonically decreasing.*
- (H<sub>2</sub>)  *$f$  is weakly coercive on the level set  $\{x \in \mathbb{R}^n : g(x) \leq \gamma_\infty^2\}$  in the sense that if  $x^j$  is a sequence of feasible iterates with  $\|x^j\| \rightarrow \infty$ , then  $f(x^j)$  is not strictly monotonically decreasing.*

*Then the sequence  $x^j$  of serious iterates with starting point  $x^1$  generated by our algorithm is bounded.*

*Proof.* There are two cases to be discussed.

(a) Suppose the iterates are all infeasible  $g(x^j) > \gamma_\infty^2$ . In that case we use axiom (H<sub>1</sub>). Notice that in phase I we have  $g(x^{j+1}) - g(x^j) \leq F(x^{j+1}, x^j) < 0$ , so the sequence  $g(x^j)$  is strictly decreasing. Then  $x^j$  is bounded by axiom (H<sub>1</sub>).

(b) Suppose next that the iterates are feasible for  $j \geq j_0$ . In phase II we have  $F(x^{j+1}, x^j) = \max\{f(x^{j+1}) - f(x^j), g(x^{j+1}) - \gamma_\infty^2\} \leq 0$ , and hence  $f(x^{j+1}) < f(x^j)$  for  $j \geq j_0$ . Then by axiom (H<sub>2</sub>) the sequence  $x^j$  could not be unbounded.  $\square$

*Remark.* Notice that axiom (H<sub>2</sub>) is certainly satisfied if  $f$  is coercive in the usual sense on the feasible set, that is, if  $f(x^j) \rightarrow \infty$  for feasible iterates with  $\|x^j\| \rightarrow \infty$ . Similarly, (H<sub>1</sub>) could be replaced by the hypothesis that the set  $\{x \in \mathbb{R}^n : \gamma_\infty^2 < g(x) \leq g(x^1)\}$  is bounded.

We are now ready to prove convergence of the outer loop of Algorithm 1.

THEOREM 6.5. *Let axioms (H<sub>1</sub>) and (H<sub>2</sub>) be satisfied. Then every accumulation point  $\bar{x}$  of the sequence of serious steps  $x^j$  generated by the algorithm satisfies  $0 \in \partial_1 F(\bar{x}; \bar{x})$ . In particular,  $\bar{x}$  is either a critical point of constraint violation or an  $F$ . John critical point of the mixed  $H_2/H_\infty$  program (2.3).*

*Proof.* The second part of the statement follows from Lemma 5.1. Let us prove  $0 \in \partial_1 F(\bar{x}; \bar{x})$ .

(1) We first prove convergence  $F(x^{j+1}; x^j) \rightarrow 0$  ( $j \rightarrow \infty$ ). By construction, we know that  $F(x^{j+1}; x^j) \leq 0$  for every  $j \in \mathbb{N}$ . We now distinguish two cases.

Case 1: there exists  $j_0 \in \mathbb{N}$  such that  $g(x^{j_0}) \leq \gamma_\infty^2$ . From that index onwards we have

$$F(x^{j+1}; x^j) = \max \{ f(x^{j+1}) - f(x^j); g(x^{j+1}) - \gamma_\infty^2 \} \leq 0,$$

and hence  $f(x^{j+1}) \leq f(x^j)$  and  $g(x^j) \leq \gamma_\infty^2$ . That means the sequence  $(f(x^i))_{i \in \mathbb{N}}$  is monotone decreasing from  $j_0$  onwards. For any accumulation point  $\bar{x}$  of  $(x^j)_{j \in \mathbb{N}}$ , continuity of  $f$  shows that  $f(\bar{x})$  is an accumulation point of  $(f(x^i))_{i \in \mathbb{N}}$ , and by the monotone sequences theorem, this implies  $f(x^j) \rightarrow f(\bar{x})$ . Now for  $j \geq j_0$  we have

$$F(x^{j+1}; x^j) = \max \{ f(x^{j+1}) - f(x^j); g(x^{j+1}) - \gamma_\infty^2 \},$$

and hence  $\liminf_{j \rightarrow \infty} F(x^{j+1}; x^j) \geq \lim_{j \rightarrow \infty} f(x^{j+1}) - f(x^j) = 0$ . In tandem with  $F(x^{j+1}; x^j) \leq 0$  this clearly implies  $F(x^{j+1}; x^j) \rightarrow 0$  ( $j \rightarrow \infty$ ).

Case 2:  $g(x^j) > \gamma_\infty^2$  for all  $j \in \mathbb{N}$ . Here

$$F(x^{j+1}; x^j) = \max \{ f(x^{j+1}) - f(x^j) - \mu[g(x^j) - \gamma_\infty^2]; g(x^{j+1}) - g(x^j) \} \leq 0.$$

Hence  $(g(x^j))_{j \in \mathbb{N}}$  is monotonically decreasing. As in the first case, we prove that by continuity of  $g$ ,  $g(\bar{x})$  is an accumulation point and so a limit point of  $(g(x^j))_{j \in \mathbb{N}}$ . We deduce in the same way that  $F(x^{j+1}; x^j) \rightarrow 0$ .

(2) Suppose that at the  $j$ th stage of the outer loop the inner loop accepts a serious step at  $k = k_j$ . Then  $x^{j+1} = y^{k_j+1}$ . By the definition of  $y^{k_j+1}$  as minimizer of the tangent program (5.6), this means

$$\delta_{k_j} (x^j - x^{j+1}) \in \partial_1 \tilde{F}_{k_j}(x^{j+1}; x^j).$$

By the subgradient inequality this gives

$$\delta_{k_j} (x^j - x^{j+1})^T (x^j - x^{j+1}) \leq \tilde{F}_{k_j}(x^j; x^j) - \tilde{F}_{k_j}(x^{j+1}; x^j) = -\tilde{F}_{k_j}(x^{j+1}; x^j),$$

where  $\tilde{F}_{k_j}(x^j; x^j) = F(x^j; x^j) = 0$  by Lemma 5.4. Since  $x^{j+1} = y^{k_j+1}$  was accepted in step 4 of the algorithm, we have  $\rho_{k_j} \geq \gamma$ , i.e.,  $-\tilde{F}_{k_j}(x^{j+1}; x^j) \leq -\gamma^{-1}F(x^{j+1}; x^j)$ . Altogether

$$0 \leq \delta_{k_j} \|x^j - x^{j+1}\|^2 \leq -\gamma^{-1}F(x^{j+1}; x^j).$$

Since  $F(x^{j+1}; x^j)$  converges to 0 by part (1), we deduce  $\delta_{k_j} \|x^j - x^{j+1}\|^2 \rightarrow 0$ . We claim that this implies  $\phi_j = \delta_{k_j} (x^j - x^{j+1}) \rightarrow 0$  ( $j \rightarrow \infty$ ).

(3) Suppose on the contrary that there exists an infinite subsequence  $j \in \mathcal{N}$  of  $\mathbb{N}$  such that  $\|\phi_j\| = \delta_{k_j} \|x^j - x^{j+1}\| \geq \eta > 0$  for some  $\eta > 0$  and every  $j \in \mathcal{N}$ . Therefore

$$\delta_{k_j} \|x^j - x^{j+1}\|^2 \geq \eta \|x^j - x^{j+1}\| \geq 0$$

for  $j \in \mathcal{N}$ , which implies  $(x^j - x^{j+1})_{j \in \mathcal{N}} \rightarrow 0$ . That is possible only when  $(\delta_{k_j})_{j \in \mathcal{N}} \rightarrow \infty$ . We now argue that there exists yet another infinite subsequence  $\mathcal{N}'$  of  $\mathbb{N}$  with the property that  $\delta_{k_j} \rightarrow \infty$ , ( $j \in \mathcal{N}'$ ), and such that in addition for each  $j \in \mathcal{N}'$ , the doubling rule to increase  $\delta_k$  in step 7 of the algorithm was applied at least once before  $x^{j+1} = y^{k_j+1}$  was accepted by the inner loop. To construct  $\mathcal{N}'$ , we associate with every  $j \in \mathcal{N}$  the last outer-loop instant  $j' \leq j$  where the  $\delta$ -parameter was increased at least once while the inner loop was turning, and we let  $\mathcal{N}'$  consist of all these  $j'$ ,  $j \in \mathcal{N}$ . It could happen that  $j' = j$ , but in general we know only that

$$2\delta_{k_{j'-1}} \leq \delta_{k_{j'}} \quad \text{and} \quad \delta_{k_{j'}} \geq \delta_{k_{j'+1}} \geq \dots \geq \delta_{k_j}.$$

The latter ensures  $\delta_{k_{j'}} \rightarrow \infty$ ,  $j' \in \mathcal{N}'$ .

Let us say that for  $j \in \mathcal{N}'$ , the doubling rule was applied for the last time at  $k_j - \nu_j$  for some  $\nu_j \geq 1$ . That is, we have  $\delta_{k_j - \nu_j + 1} = 2\delta_{k_j - \nu_j}$ , while the  $\delta$ -parameter was frozen during the remaining steps before acceptance, i.e.,

$$(6.11) \quad \delta_{k_j} = \delta_{k_j - 1} = \cdots = \delta_{k_j - \nu_j + 1} = 2\delta_{k_j - \nu_j}.$$

Recall from step 7 of the algorithm that we have  $\rho_k < \gamma$  and  $\tilde{\rho}_k \geq \tilde{\gamma}$  for those  $k$ , where the step was not accepted and the doubling rule was applied. That is,

$$\rho_{k_j - \nu_j} = \frac{F(x^j; x^j) - F(y^{k_j - \nu_j + 1}; x^j)}{F(x^j; x^j) - \tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j)} = \frac{F(y^{k_j - \nu_j + 1}; x^j)}{\tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j)} < \gamma$$

and

$$\tilde{\rho}_{k_j - \nu_j} = \frac{F(x^j; x^j) - \tilde{F}(y^{k_j - \nu_j + 1}; x^j)}{F(x^j; x^j) - \tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j)} = \frac{\tilde{F}(y^{k_j - \nu_j + 1}; x^j)}{\tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j)} \geq \tilde{\gamma}.$$

By definition of  $y^{k_j - \nu_j + 1}$  and according to (6.11), we now have

$$\frac{1}{2}\delta_{k_j} (x^j - y^{k_j - \nu_j + 1}) \in \partial_1 \tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j).$$

Using  $\tilde{F}_{k_j - \nu_j}(x^j; x^j) = F(x^j; x^j) = 0$  and the subgradient inequality for  $\tilde{F}_{k_j - \nu_j}(\cdot; x^j)$  at  $y^{k_j - \nu_j + 1}$  gives

$$\begin{aligned} \frac{1}{2}\delta_{k_j} (x^j - y^{k_j - \nu_j + 1})^T (x^j - y^{k_j - \nu_j + 1}) &\leq \tilde{F}_{k_j - \nu_j}(x^j; x^j) - \tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j) \\ &\leq -\tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j). \end{aligned}$$

This could also be written as

$$(6.12) \quad \frac{\delta_{k_j} \|x^j - y^{k_j - \nu_j + 1}\|^2}{-\tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j)} \leq 2.$$

Now we know from Lemma 6.4 that the set of serious iterates  $x^j$  is bounded. In tandem with Lemma 6.1, which relates the norm of the null steps  $y^{k+1}$  to the norm of  $x^j$ , we deduce that the set  $B = \{x^j : j \in \mathbb{N}\} \cup \{y^{k+1} : k = 1, \dots, k_j, j \in \mathbb{N}\}$  is bounded. Then Lemma 5.2 provides  $L > 0$  such that

$$(6.13) \quad |F(y^{k_j - \nu_j + 1}; x^j) - \tilde{F}(y^{k_j - \nu_j + 1}; x^j)| \leq L \|y^{k_j - \nu_j + 1} - x^j\|^2$$

for all  $j \in \mathcal{N}'$ . Now expanding the expression  $\tilde{\rho}_{k_j - \nu_j}$  gives

$$\begin{aligned} \tilde{\rho}_{k_j - \nu_j} &= \rho_{k_j - \nu_j} + \frac{F(y^{k_j - \nu_j + 1}; x^j) - \tilde{F}(y^{k_j - \nu_j + 1}; x^j)}{-\tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j)} \\ &\leq \rho_{k_j - \nu_j} + \frac{L \|x^j - y^{k_j - \nu_j + 1}\|^2}{-\tilde{F}_{k_j - \nu_j}(y^{k_j - \nu_j + 1}; x^j)} \quad (\text{using (6.13)}) \\ &\leq \rho_{k_j - \nu_j} + \frac{2L}{\delta_{k_j}} \quad (\text{using (6.12)}). \end{aligned}$$

Since  $\rho_j < \gamma$  and  $L/2\delta_{k_j} \rightarrow 0$  for the infinite subsequence  $j \in \mathcal{N}'$ , we deduce  $\limsup_{j \in \mathcal{N}'} \tilde{\rho}_{k_j - \nu_j} \leq \limsup_{j \in \mathcal{N}'} \rho_{k_j - \nu_j} \leq \gamma < \tilde{\gamma}$ , contradicting  $\tilde{\rho}_j \geq \tilde{\gamma} > \gamma$  for the infinitely many  $j \in \mathcal{N}'$ . This proves that an infinite sequence  $j \in \mathcal{N}$  with  $\|\phi_j\| \geq \eta > 0$  could not exist. The conclusion is that  $(\phi_j)_{j \in \mathbb{N}} = (\delta_{k_j}(x^j - x^{j+1}))_{j \in \mathbb{N}}$  converges to 0.

(4) Let  $\bar{x}$  be an accumulation point of the sequence of serious steps  $x^j$  and pick a convergent subsequence  $x^j \rightarrow \bar{x}$ ,  $j \in \mathcal{N}$ . We have to prove  $0 \in \partial_1 F(\bar{x}; \bar{x})$ .

Since  $\phi_j = \delta_{k_j}(x^j - x^{j+1})$  is a subgradient of  $\tilde{F}_{k_j}(\cdot, x^j)$  at  $y^{k_j+1} = x^{j+1}$  we have

$$\begin{aligned} \phi_j^T h &\leq \tilde{F}_{k_j}(x^{j+1} + h; x^j) - \tilde{F}_{k_j}(x^{j+1}; x^j) \\ &\leq \tilde{F}(x^{j+1} + h; x^j) - \tilde{F}_{k_j}(x^{j+1}; x^j) \quad (\text{using } \tilde{F}_{k_j} \leq \tilde{F}) \end{aligned}$$

for every test vector  $h \in \mathbb{R}^n$ . Now we use the fact that  $y^{k_j+1} = x^{j+1}$  was accepted in step 4 of the algorithm. That means

$$-\tilde{F}_{k_j}(x^{j+1}; x^j) \leq -\gamma^{-1} F(x^{j+1}; x^j).$$

Combining these two estimates gives

$$(6.14) \quad \phi_j^T h \leq \tilde{F}(x^{j+1} + h; x^j) - \gamma^{-1} F(x^{j+1}; x^j)$$

for every test vector  $h$ . Now fix  $h' \in \mathbb{R}^n$  and choose the test vector  $h^j = x^j - x^{j+1} + h'$  for  $j \in \mathcal{N}'$ . Substituting this in (6.14) we obtain

$$(6.15) \quad \delta_{k_j} \|x^j - x^{j+1}\|^2 + \phi_j^T h' \leq \tilde{F}(x^j + h'; x^j) - \gamma^{-1} F(x^{j+1}; x^j).$$

Now observe that  $\delta_{k_j} \|x^j - x^{j+1}\|^2 \rightarrow 0$  by part (2), and  $\phi_j = \delta_{k_j}(x^j - x^{j+1}) \rightarrow 0$  by part (3). This means that the left-hand side of (6.15) converges to 0. As for the terms on the right, recall that  $F(x^{j+1}; x^j) \rightarrow 0$  by part (1) of the proof. Finally, by joint continuity of  $\tilde{F}(\cdot; \cdot)$ , the term  $\tilde{F}(x^j + h'; x^j)$  converges to  $\tilde{F}(\bar{x} + h'; \bar{x})$ . We conclude, passing to the limit  $j \in \mathcal{N}'$  in (6.15) and using  $\tilde{F}(\bar{x}; \bar{x}) = 0$ , that

$$0 \leq \tilde{F}(\bar{x} + h'; \bar{x}) = \tilde{F}(\bar{x} + h'; \bar{x}) - \tilde{F}(\bar{x}; \bar{x}).$$

As this works for every  $h' \in \mathbb{R}^n$ , we have shown  $0 \in \partial_1 \tilde{F}(\bar{x}; \bar{x})$ , and hence also  $0 \in \partial_1 F(\bar{x}; \bar{x})$ .  $\square$

**7. Implementation.** Algorithm 1 has been implemented for both structured and unstructured mixed synthesis, and we use the enriched versions of  $\mathcal{G}_0$  and  $\mathcal{G}_k^c$  to speed up convergence. Notice that in some of the examples in section 8, the controller has to be strictly proper to ensure well-posedness of the  $H_2$  norm. (Namely,  $D_K = 0$  in (2.2) when  $D_{2u}$  and  $D_{y2}$  are nonzero in the plant (2.1).) In those cases the data in (2.2) are no longer freely assigned, the parameterizations being  $K = \mathcal{K}(A_K, B_K, C_K)$  with a linear operator  $\mathcal{K}$ . More general types of parameterizations would equally well fit into our approach and are referred to as structural constraints on the controller.

**7.1. Stopping criteria.** Notice that Algorithm 1 is a first-order method, which may be slow in the neighborhood of a local solution of (2.3). As in [5], we have therefore implemented termination criteria, which avoid pointless computational efforts during the final phase, where iterates make minor progress. Our first stopping test checks criticality  $0 \in \partial_1 F(x; x)$  by computing

$$\inf\{\|h\| : h \in \partial_1 F(x; x)\} < \varepsilon_1.$$

FIG. 1.  $H_2/H_\infty$  optimal static controllers  $K(\gamma_\infty) = (K_1(\gamma_\infty), K_2(\gamma_\infty)) \in \mathbb{R}^2$  for the vehicular suspension control problem.  $[\|T_\infty(K_\infty)\|_\infty, \|T_\infty(K_2)\|_\infty] \ni \gamma_\infty \mapsto K(\gamma_\infty)$  continuously transforms the  $H_\infty$  optimal gain  $K_\infty$  into the  $H_2$  optimal gain  $K_2$ .

Notice that this program is similar (but easier) than the SDP discussed in section 5.3, because the linear terms in that cast are not needed.

A second test compares the progress of the local model around the current iterate:

$$(7.1) \quad |F(x^+; x)| \leq \varepsilon_2.$$

Our third test compares the relative step length to the controller gains:

$$(7.2) \quad \|x^+ - x\| \leq \varepsilon_3(1 + \|x\|).$$

For stopping, we require that either the first or the second and third to be satisfied.

**7.2. Choice of the performance level  $\gamma_\infty$ .** In all test examples we first compute (locally) optimal  $H_2$ - and  $H_\infty$ -controllers  $K_2$  and  $K_\infty$ . It is now trivial (see, e.g., [10]) that the performance level  $\gamma_\infty$  in program (2.3) has to satisfy

$$(7.3) \quad \|T_\infty(K_\infty)\|_\infty \leq \gamma_\infty < \|T_\infty(K_2)\|_\infty.$$

Indeed, the mixed  $H_2/H_\infty$  problem (2.3) is infeasible for  $\gamma_\infty < \|T_\infty(K_\infty)\|_\infty$ , while for  $\gamma_\infty \geq \|T_\infty(K_2)\|_\infty$  the optimal  $H_2$ -controller  $K_2$  is also optimal for (2.3). Disregarding complications due to (multiple) local minima, it would make sense, in a specific case study, to consider the entire one-parameter family  $K(\gamma_\infty)$  of solutions of (2.3) as a function of the gain value  $\gamma_\infty$  over the range (7.3), as this would transform  $K_\infty$  continuously into  $K_2$  (see, e.g., Figure 1). In our tests we only compute  $K(\gamma_\infty)$  for those values  $\gamma_\infty$  which allow comparison to previous results in the literature.

Table 1 reports the problem dimensions  $n_x, n_y, n_u$  and the synthesized controller orders  $n_K$ . Columns 5 and 6 report  $\|T_\infty(K_\infty)\|_\infty$  and  $\|T_\infty(K_2)\|_\infty$ , which are the bounds in (7.3), needed to choose  $\gamma_\infty$  correctly. In column 4 we report  $\|T_2(K_2)\|_2$ , because it gives a lower bound on the optimal value  $\|T_2(K(\gamma_\infty))\|_2$  of (2.3).

Notice that in columns  $\|T_2(K_2)\|_2$  and  $\|T_\infty(K_\infty)\|_\infty$  we would expect decreasing values for a fixed example as  $n_K$  increases. However, in CM4 the orders 0 and 50 give, respectively, 9.2645e-01 and 9.3844e-01, which is not as it should be, because the order 50 controller is worse than the static controller. This phenomenon is due

to the fact that in all cases  $n_K < n_x$ , we only compute local minima of the  $H_\infty$  program, and similarly, of the  $H_2$  program. As  $n_K$  increases, more local minima appear, and it may be very difficult to improve the situation. This is obviously very unsatisfactory, and appropriate procedures to initialize at a given order  $n_K$  are currently being investigated.

**7.3. Initialization by a stabilizing controller.** In all our test examples, we use the techniques in [11] to compute a closed-loop stabilizing initial  $K^0$ , which is not necessarily feasible for (2.3). This allows us to test phase I of our method.  $K_\infty$  may always be chosen as a feasible initial iterate, so that phase I could in principle be avoided, but we prefer to use various ways to initialize Algorithm 1. In the full-order case  $n_K = n_x$ ,  $K_2$  and  $K_\infty$  are computed by algebraic Riccati equations (AREs) as routinely available in the MATLAB control toolbox. In the reduced-order case  $n_K < n_x$ , things are more complicated, and minima are in general only local. The locally optimal  $H_\infty$ -controller  $K_\infty$  is computed by the method of [5], which uses the initial closed-loop stabilizing  $K^0$  to initialize the procedure. Methods to compute  $K_2$  in the reduced-order case  $n_K < n_x$  are discussed in [43]. Since the objective function  $f(K)$  is not defined everywhere, standard software for unconstrained programming may face difficulties, and we have implemented a Polak–Rivière conjugate gradient method (with a special safeguard to stay in the set  $D$  of exponentially stabilizing controllers) to compute  $K_2$ . An alternative is of course to use Algorithm 1 with  $\gamma_\infty$  so large that  $\gamma_\infty > \|T_\infty(K_2)\|_2$  can be ensured. But this is often slow, because Algorithm 1 is a first-order method. This confirms the observation of the authors of

FIG. 2. Full-order mixed  $H_2/H_\infty$  synthesis for the four disks problem: the values of the  $H_2$  norm in relation to the number of serious steps are shown for four different values of the penalty parameter  $\mu$ . Here we choose  $\mu \in \{0, 0.1, 0.5, 10\}$ . Vertical lines point out the instant at which the iterates become feasible.

[43], who report slow convergence for  $H_2$  synthesis based on first-order (gradient-type) methods and recommend using second-order methods instead.

**7.4. Stability constraint.** Notice that closed-loop stability of  $K$  is not a constraint in the usual sense of mathematical programming, because the set  $D$  of closed-loop exponentially stabilizing  $K$  is an open domain. In the program (2.3), closed-loop stability  $K \in D$  is a hidden constraint, which may cause problems because the functions  $f$  and  $g$  are not defined outside  $D$ . The strategy which we adopt here is to compute an initial closed-loop stabilizing controller  $K^0 \in D$  and ignore the hidden constraint during the optimization process. Since  $f(K^0) < \infty$  and  $g(K^0) < \infty$ , our algorithm produces iterates  $K^j$  with  $f(K^j) < \infty$  and  $g(K^j) < \infty$  at all times  $j$ , and most of the time this ensures that  $K^j$  remains closed-loop stabilizing, i.e.,  $K^j \in D$ .

**7.5. Choice of  $\mu$ .** In [42, section 2.6] a similar progress function is discussed for objectives which are maxima of finite or infinite families of smooth functions, but a line search method is obtained. In both cases convergence theory works for arbitrary values of the parameter  $\mu$ , so that no immediate insight into the choice of  $\mu$  is obtained. Yet in practice the choice of  $\mu$  may influence the actual performance of the algorithm.

Figure 2 and Table 2 present the numerical results of our nonsmooth algorithm for the four disks problem presented in section 8. After computing an initial stabilizing controller  $K_0$ , the nonsmooth algorithm is run with four different values of the penalty parameter  $\mu$ , including the case  $\mu = 0$  to compare with the improvement function of [44].

As we can see in Table 2, for  $\mu = 0$  the algorithm fails to reach a feasible point. This is indeed a case where we could identify the final  $K$  of phase I where  $g(K) > \gamma_\infty^2$  as a local minimum of  $f$  alone. Recall that when  $\mu = 0$ , every descent step of the improvement function is a descent step of both  $f$  and  $g$ , and the algorithm then gets trapped as soon as it reaches a local minimum of either  $f$  or  $g$ . Choosing  $\mu > 0$

TABLE 2

allows a possible increase of the objective  $f$  during phase I, so that being trapped at an infeasible local minimum of  $f$  alone can be avoided.

Among the choices  $\mu > 0$  we have noticed that when  $\mu$  is not too small, the number of iterations needed to reach a feasible point decreases as  $\mu$  increases. However, choosing too large a  $\mu$ , as shown by the two last columns in Table 2, does not give the best results either, so this trend seems to be true only for a certain range. Nothing decisive can be proposed to date, but  $\mu$  of the same order of magnitude as the progress function without the penalty term so far gave the best results in practice.

**7.6. Choice of  $\Gamma$ .** The last issue we address is the choice of  $\Gamma$ , which is crucial, because step 5 is the only place in the algorithm where the proximity parameter  $\delta_k$  can be reduced. Too large a  $\Gamma$  gives few reductions of  $\delta_k$ , and since the latter is often increased during the inner loop, this bears the risk of exceedingly large  $\delta_k$ , causing the algorithm to stop.

To illustrate this observation, we have run the four disks example in section 8 for three different values  $\Gamma \in \{0.4, 0.6, 0.8\}$ ; see Table 3. The results are illustrated in Figure 3 and Table 3. We observe that the number of iterations increases with the values of  $\Gamma$ . The best numerical results were obtained for  $\Gamma = 0.6$ , and this is the value we retained for all the numerical tests. At least over a certain range one can say that the larger  $\Gamma$ , the smaller the steps accepted as serious steps  $x \rightarrow x^+$ , and the more outer iterations are needed to reach the same  $H_2$  performance.

**8. Numerical experiments.** In this section we test our nonsmooth algorithm on a variety of  $H_2/H_\infty$  synthesis problems from the literature.

**8.1. Two academic examples.** We first present two academic examples whose models are described in [10] and [49, Example 1]. Notice that the first one is simple

FIG. 3. Full-order mixed  $H_2/H_\infty$  synthesis for the four disks problem: the values of the  $H_2$  norm versus the number of serious steps for three different values of the parameter  $\Gamma \in \{0.4, 0.6, 0.8\}$ .

enough to allow explicit computation of static output feedback controllers  $u = Ky$  for  $H_2$ ,  $H_\infty$ , and  $H_2/H_\infty$  synthesis. The problem data are given in Table 1.

Table 4 confirms that our proximity control algorithm successfully performs the  $H_2/H_\infty$  synthesis on the two considered examples. We not only improve the results computed by the LMI approaches in [10] and [49], we even obtain the theoretical values of the  $H_2$  and  $H_\infty$  norms.

**8.2. Vehicular suspension controller design.** The model of the vehicular suspension is described in [15] and [51]. We first focus on static  $H_2/H_\infty$  synthesis. The  $H_\infty$  performance level in (2.3) is chosen as  $\gamma_\infty = 5.225$  and the optimal solution we obtain is

$$K(\gamma_\infty) = [ 41600 \ 2393 ].$$

The  $H_2$  norm computed by our algorithm is  $\|T_2(K(\gamma_\infty))\|_2 = 34.446$ , compared to 35.8065 obtained in [51], which gives an improvement of 3.8%. Moreover, the  $H_\infty$  performance is  $\|T_\infty(K(\gamma_\infty))\|_\infty = 5.2250$ , compared to 5.0506 obtained in [51]. This shows that the  $H_\infty$  constraint is not active in the heuristic [51], highlighting the inevitable conservatism of the LMI approaches. In contrast, our method always attains the constraint within the numerical precision.

These results are shown in Table 5, which also gives the results of  $H_2/H_\infty$  synthesis for dynamic controllers of order  $n_K = 2, 4$ . Notice that in the first column of Table 5 by choosing the  $H_\infty$  performance level  $\gamma_\infty > \gamma_2 = \|T_\infty(K_2)\|_\infty$ , where  $\|T_\infty(K_2)\|_\infty$  is given in Table 1, the  $H_2/H_\infty$  solution is close to the solution of the  $H_2$  synthesis.

**8.3. Four disks.** The four disks model is originally described in [16] and has previously been studied to evaluate reduced-order design methods. The open loop plant is of order  $n_x = 8$  and has two stable poles.

We first focus on mixed  $H_2/H_\infty$  synthesis of full-order controllers in order to compare our nonsmooth algorithm to the original Riccati equation approach in [27]. The results are presented in Table 6. We also give results of  $H_2/H_\infty$  synthesis of reduced-order controllers in Table 7.

As can be seen in Table 6, our method gives significant improvement over the older results in [27] based on coupled Riccati equations. This highlights the reduction of conservatism of our approach compared to Riccati and LMI methods.

**8.4. COMPl<sub>e</sub>ib examples.** The models in this section are from the COMPl<sub>e</sub>ib collection [34]: aircraft model AC14, distillation tower BDT2, heat flow in a thin rod

TABLE 6

HF1, and cable mass model CM4. They are originally designed for  $H_\infty$  synthesis, so an  $H_2$  channel was added as suggested by Leibfritz [33, 34]. The same channel is used for both  $H_2$  and  $H_\infty$  performance in example AC14, while we choose  $B_2 = B_\infty$  and  $D_{y2} = 0$  for the three other models. This way the  $H_2$  norm is well-posed.

In each example, we first choose the  $H_\infty$  performance level  $\gamma_\infty$  larger than  $\|T_\infty(K_2)\|_\infty$ . In doing this we have to obtain an estimate of the optimal  $H_2$  performance  $\|T_2(K_2)\|_2$  given in Table 1. Numerical results are in Tables 8 and 9.

As an illustration, Figures 4 and 5 show the evolution of the  $H_2$  and  $H_\infty$  norms, for example, BDT2, during the first iterations.

In Figure 4 we observe phases I and II of the algorithm. As long as iterates remain infeasible, descent steps to reduce constraint violation are generated, sometimes causing the objective to increase. As soon as the feasible domain  $g(x) \leq \gamma_\infty^2$  is reached, descent of the objective  $f$  begins, and iterates stay feasible.

Figure 5 shows the frequency plot  $\omega \mapsto \lambda_1(T_\infty(K_i, j\omega)^H T_\infty(K_i, j\omega))$  of the  $H_\infty$  constraint during the first 6 iterations (serious steps)  $K_i$ ,  $i = 1, \dots, 6$ , along with the second eigenvalue  $\lambda_2$ . As can be seen, the maximum  $\|T_\infty(K_i)\|_\infty^2$  is sometimes attained at a single marked peak  $\omega$ , while other cases feature rather a flat plateau in the low frequency band. Multiple peaks appear usually at the end of the process, but cannot be ruled out at any moment, as shown by the lower right plot, which has a plateau where  $\lambda_1$  and  $\lambda_2$  are close. Stars indicate frequencies kept in the extended set  $\Omega_e(K_i)$ .

**9. Conclusion.** We have studied and tested a nonlinear mathematical programming approach to the mixed  $H_2/H_\infty$ -controller synthesis problem. The importance of this problem was recognized in the late 1980s, but approaches based on AREs could not be brought to work satisfactorily. It is possible to characterize the optimal  $H_2/H_\infty$ -controller by way of the Q-parameterization, but as soon as the controller has to satisfy additional structural constraints, such as, for instance, reduced-order  $n_K < n_x$ , an analytic solution does not exist. In that situation convexity methods based on LMIs and AREs are no longer suitable, and finding the globally optimal solution is known to be NP-hard. As a consequence, we propose a strategy based on local optimization, which comes with a weaker certificate, but has the benefit of working in practice. The problem being nonconvex, nonsmooth, and semi-infinite, we have

FIG. 4. Example BDT2:  $H_2$  norm during the first 50 iterations.

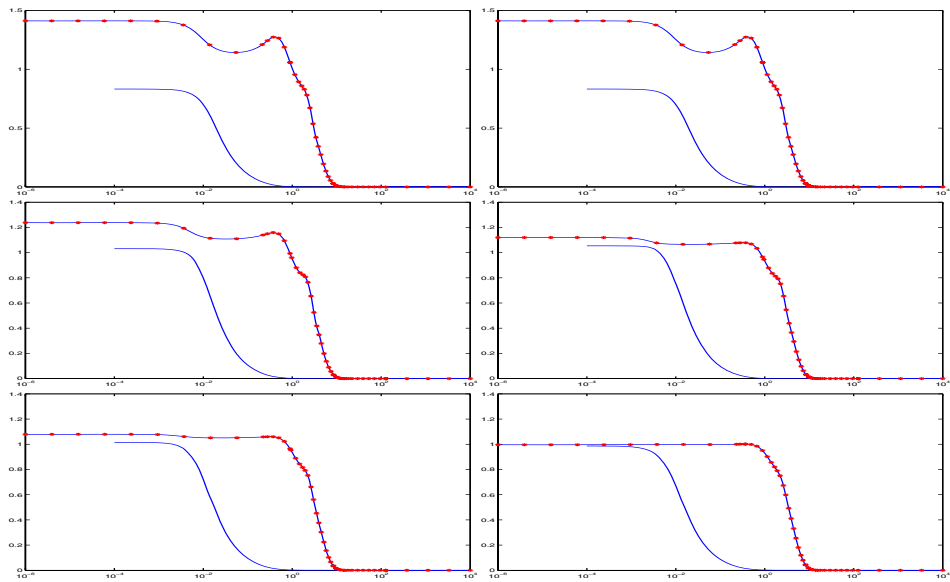

FIG. 5. Example BDT2: Largest and second largest eigenvalues versus frequency in logarithmic scale, the first 6 iterations. Observe that the second eigenvalue  $\lambda_2$  is strictly below the first one on the range  $\omega \leq 10^4$ , except for the bottom right plot, where coalescence on a low frequency band seems to occur.

developed a nonsmooth constrained programming technique suited for the  $H_2/H_\infty$  problem and other programs of a similar structure. The new method has been tested on several benchmark studies and shown to perform better than existing methods.

# GENERALIZED $\mathcal{S}$ -PROCEDURE FOR INEQUALITY CONDITIONS ON ONE-VECTOR-LOSSLESS SETS AND LINEAR SYSTEM ANALYSIS\*

YOSHIO EBIHARA<sup>†</sup>, KATSUTOSHI MAEDA<sup>†</sup>, AND TOMOMICHI HAGIWARA<sup>†</sup>

**Abstract.** The generalized version of the  $\mathcal{S}$ -procedure, recently introduced by Iwasaki and co-authors and Scherer independently, has proved to be very useful for robustness analysis and synthesis of control systems. In particular, this procedure provides a nonconservative way to convert specific inequality conditions on lossless sets into numerically verifiable conditions represented by linear matrix inequalities (LMIs). In this paper, we introduce a new notion, one-vector-lossless sets, and propose a generalized  $\mathcal{S}$ -procedure to reduce inequality conditions on one-vector-lossless sets into LMIs without any conservatism. By means of the proposed generalized  $\mathcal{S}$ -procedure, we can examine various properties of matrix-valued functions over some regions on the complex plane. To illustrate the usefulness, we show that full rank property analysis problems of polynomial matrices over some specific regions on the complex plane can be reduced into LMI feasibility problems. It turns out that many existing results such as Lyapunov's inequalities and LMIs for state-feedback controller synthesis readily follow from the suggested generalized  $\mathcal{S}$ -procedure.

**Key words.**  $\mathcal{S}$ -procedure, one-vector-lossless set, linear matrix inequalities

**1. Introduction.** Recently, the generalized version of the  $\mathcal{S}$ -procedure has been introduced independently by Iwasaki and Hara [7, 8], Iwasaki, Meinsma, and Fu [9], Iwasaki and Shibata [10], and Scherer [14, 15, 16, 17]. Basically speaking, this procedure enables us to convert intractable semi-infinite parametrized linear matrix inequalities into numerically verifiable finite-dimensional linear matrix inequalities (LMIs). The scope of its application is wide and includes a variety of robustness analysis and synthesis problems in linear control system theory.

Among these recent papers, in [9, 8], the following inequality condition with respect to a Hermitian matrix  $\Theta$  and a subset  $\mathcal{S}$  of Hermitian matrices is discussed:

$$(1.1) \quad \zeta^* \Theta \zeta > 0 \quad \forall \zeta \in \mathcal{G}, \quad \mathcal{G} := \{\zeta \in \mathbb{C}^n : \zeta \neq 0, \quad \zeta^* S \zeta \geq 0 \quad \forall S \in \mathcal{S}\}.$$

It can be easily seen that a sufficient condition for (1.1) is given by

$$(1.2) \quad \exists S \in \mathcal{S} \text{ such that } \Theta \succ S.$$

The procedure to replace (1.1) by (1.2) is called the generalized  $\mathcal{S}$ -procedure in [9, 8]. Generally, this replacement introduces conservatism; the condition (1.2) is only sufficient for (1.1) and may not be necessary. The significance of the studies in [9, 8] lies in the fact that the generalized  $\mathcal{S}$ -procedure has been proved to be nonconservative if the set  $\mathcal{S}$  is *lossless*<sup>1</sup> [9, 8]. If the set  $\mathcal{S}$  is lossless, then the set  $\mathcal{S}$  is convex and hence

<sup>1</sup>In the paper [8], the terminology “rank-one separable” is used in place of “lossless.”

the LMI condition (1.2) can be verified numerically via sophisticated interior-point methods [1, 4].

When we deal with linear system analysis and synthesis problems by working with the generalized  $\mathcal{S}$ -procedure in [9, 8], the underlying idea is that inequality conditions on matrix-valued functions  $G(\lambda)$  over *curves*  $\lambda \in \Lambda$  ( $\Lambda \subset \mathbf{C}$ ) can be reformulated into a conformable form to the condition (1.1) by considering an appropriate Hermitian matrix  $\Theta$  and a lossless set  $\mathcal{S}$  [9, 8]. When dealing with a linear system, its various properties can be characterized by inequality conditions on their transfer functions in the frequency domain [1, 20, 21]. In [9, 8], those frequency domain inequalities are reformulated in the form of (1.1) so that the generalized  $\mathcal{S}$ -procedure can be applied. It follows that we can verify various properties of linear systems without introducing any conservatism by solving LMIs resulting from the generalized  $\mathcal{S}$ -procedure.

For linear system analysis and synthesis, however, we also need to verify inequality conditions on matrix-valued functions  $G(\lambda)$  over *region*  $\lambda \in \mathcal{D}$  ( $\mathcal{D} \subset \mathbf{C}$ ). For example, full rank property analysis of polynomial matrices over some specific regions on the complex plane forms an important basis for the stability analysis of linear systems [1, 6]. In view of these facts, it should be quite natural to pose the following question: Can we verify various properties of matrix-valued functions  $G(\lambda)$  over *region*  $\lambda \in \mathcal{D}$  ( $\mathcal{D} \subset \mathbf{C}$ ) by following similar lines to the generalized  $\mathcal{S}$ -procedure?

To answer this question, in this paper, we first introduce a new notion, *one-vector-lossless sets*, and provide a nonconservative generalized  $\mathcal{S}$ -procedure for inequality conditions on this set. More precisely, by taking account of the fact that the properties of lossless sets are fully used to represent *curves* on the complex plane [9, 8], we first consider to relax the requirements for the lossless sets and define one-vector-lossless sets, which enables us to represent *regions* on the complex plane. Then, we clarify under what condition the generalized  $\mathcal{S}$ -procedure for inequality conditions on this set is nonconservative. It follows that we can provide a counterpart result of [9, 8] in the case of the one-vector-lossless sets.

To illustrate the usefulness of the proposed generalized  $\mathcal{S}$ -procedure, we show that full rank property analysis problems of polynomial matrices over some regions  $\mathcal{D} \subset \mathbf{C}$  can be reduced into LMI feasibility problems. It turns out that the well-known results such as Lyapunov's inequalities for stability analysis of linear systems [1, 5] and LMIs for state-feedback controller synthesis [1, 18] follow immediately from the full rank property analysis by means of the proposed generalized  $\mathcal{S}$ -procedure. Thus, in conjunction with the results in [8, 16], the present paper reveals that most LMI results in linear system theory can be captured in a unified fashion within the framework of the generalized  $\mathcal{S}$ -procedure.

We use the following notation in this paper. For a matrix  $A$ , its transpose and complex conjugate transpose are denoted by  $A^T$  and  $A^*$ , respectively. For a matrix  $A \in \mathbf{C}^{n \times m}$  with  $\text{rank}(A) = r < n$ ,  $A^\perp \in \mathbf{C}^{(n-r) \times n}$  is a matrix such that  $A^\perp A = 0$  and  $A^\perp (A^\perp)^* \succ 0$ . The symbols  $\mathbf{H}_n$  and  $\mathbf{P}_n$  denote the sets of  $n \times n$  Hermitian matrices and positive-definite Hermitian matrices, respectively. For matrices  $\Psi$  and  $P$ , we denote by  $\Psi \otimes P$  their Kronecker product. For  $\lambda \in \mathbf{C}$  and  $\Psi \in \mathbf{H}_2$ , we define a function  $\sigma : \mathbf{C} \times \mathbf{H}_2 \rightarrow \mathbf{R}$  by

$$\sigma(\lambda, \Psi) := \begin{bmatrix} \lambda \\ 1 \end{bmatrix}^* \Psi \begin{bmatrix} \lambda \\ 1 \end{bmatrix}.$$

**2. Generalized  $\mathcal{S}$ -procedure for inequality conditions on one-vector-lossless sets.** The notion of *one-vector-lossless sets* plays an important role in this

paper. In this section, we first describe its precise definition and provide a nonconservative generalized  $\mathcal{S}$ -procedure for inequality conditions on this set.

**DEFINITION 2.1** (one-vector-lossless sets). *A subset  $\mathcal{S} \subset \mathbf{H}_n$  is said to be one-vector-lossless if it has the following properties:*

- (a)  $\mathcal{S}$  is convex.
- (b)  $S \in \mathcal{S} \Rightarrow \tau S \in \mathcal{S} \ \forall \tau > 0$ .
- (c) For each nonzero matrix  $H \in \mathbf{C}^{n \times n}$  with rank  $r$  that satisfies

$$(2.1) \quad H = H^* \succeq 0, \quad \text{trace}(SH) \geq 0 \quad \forall S \in \mathcal{S},$$

there exist vectors  $\zeta_i \in \mathbf{C}^n$  ( $i = 1, \dots, r$ ) such that  $H = \sum_{i=1}^r \zeta_i \zeta_i^*$  and the condition  $\zeta_j^* S \zeta_j \geq 0$  ( $\forall S \in \mathcal{S}$ ) holds for at least one index  $j$ .

This definition has been introduced by relaxing the requirements for the *lossless* sets given in [9]. Indeed, Definition 2.1 becomes the requirements for the lossless sets by replacing (c) by (c') given in the following:

- (c') For each nonzero matrix  $H \in \mathbf{C}^{n \times n}$  with rank  $r$  that satisfies (2.1), there exist vectors  $\zeta_i \in \mathbf{C}^n$  ( $i = 1, \dots, r$ ) such that

$$H = \sum_{i=1}^r \zeta_i \zeta_i^*, \quad \zeta_i^* S \zeta_i \geq 0 \quad \forall i, \quad \forall S \in \mathcal{S}.$$

This property is referred to as *rank-one separable* in [8]. Detailed analysis on this property can also be found in [13].

By comparing the conditions (c) and (c'), we see that the condition  $\zeta_j^* S \zeta_j \geq 0$  ( $\forall S \in \mathcal{S}$ ) is required only for one index  $j$  in the definition of the one-vector-lossless sets. Hence, it is obvious that a lossless set is one-vector-lossless.

In the case where the set  $\mathcal{S}$  is lossless, the condition (1.1) can be converted into (1.2) without introducing any conservatism. The following theorem gives a counterpart of this result in the case where the set  $\mathcal{S}$  is one-vector-lossless.

**THEOREM 2.2** (the generalized  $\mathcal{S}$ -procedure for inequality conditions on one-vector-lossless sets). *Let  $\Theta \in \mathbf{H}_n$  and a one-vector-lossless set  $\mathcal{S} \subset \mathbf{H}_n$  be given. If  $\Theta = \Theta^* \succeq 0$ , then the following statements are equivalent:*

- (i)  $\zeta^* \Theta \zeta > 0 \ \forall \zeta \in \mathcal{G}$ ,  $\mathcal{G} := \{\zeta \in \mathbf{C}^n : \zeta \neq 0, \zeta^* S \zeta \geq 0 \ \forall S \in \mathcal{S}\}$ .
- (ii) There exists  $S \in \mathcal{S}$  such that  $\Theta \succ S$ .

*Proof.* (ii)  $\Rightarrow$  (i). Suppose (ii) holds. Then, there exists  $S_0 \in \mathcal{S}$  such that  $\zeta^* (\Theta - S_0) \zeta > 0$  ( $\forall \zeta \neq 0$ ). This inequality implies that

$$\zeta^* \Theta \zeta > 0 \quad \forall \zeta \in \mathcal{G}_0, \quad \mathcal{G}_0 := \{\zeta \in \mathbf{C}^n : \zeta \neq 0, \quad \zeta^* S_0 \zeta \geq 0\}.$$

Since  $\mathcal{G} \subset \mathcal{G}_0$ , we can conclude that the condition (ii) implies (i).

(i)  $\Rightarrow$  (ii). Suppose (ii) does not hold, i.e., there is no  $S \in \mathcal{S}$  such that  $\Theta \succ S$ . Then, since  $\mathcal{S}$  is convex, it follows from the separating hyperplane theorem [11] that there exists a nonzero matrix  $H \in \mathbf{C}^{n \times n}$  such that

$$(2.2) \quad H = H^* \succeq 0, \quad \text{trace}((\Theta - S)H) \leq 0 \quad \forall S \in \mathcal{S}.$$

In view of the property (b) of the one-vector-lossless set, we see that the following conditions are necessary for the second condition in (2.2) to hold:

$$(2.3) \quad \text{trace}(\Theta H) \leq 0, \quad \text{trace}(SH) \geq 0 \quad \forall S \in \mathcal{S}.$$

Since  $\mathcal{S}$  is one-vector-lossless, it follows from the property (c) of Definition 2.1 that the second condition from (2.3) implies the existence of the vectors  $\zeta_i$  ( $i = 1, \dots, r$ ) such that  $H = \sum_{i=1}^r \zeta_i \zeta_i^*$  and  $\zeta_j^* S \zeta_j \geq 0$  ( $\forall S \in \mathcal{S}$ ) for some  $j$ , where  $r$  is the rank of  $H$ . For those vectors  $\zeta_i$ , the first condition in (2.3) implies  $\zeta_i^* \Theta \zeta_i = 0$  ( $i = 1, \dots, r$ ) due to the assumption  $\Theta = \Theta^* \succeq 0$ . These facts in particular imply that  $\zeta_j^* \Theta \zeta_j = 0$  and  $\zeta_j \in \mathcal{G}$  for at least one index  $j$ . This clearly contradicts the condition (i).  $\square$

We note that, in comparison with the case where the set  $\mathcal{S}$  is lossless [9], an additional condition  $\Theta = \Theta^* \succeq 0$  has been imposed in Theorem 2.2. This could be regarded as a price to pay for relaxing the requirements on the set  $\mathcal{S}$  from a lossless one to a one-vector-lossless one.

By means of the generalized  $\mathcal{S}$ -procedure in Theorem 2.2, we can convert the semi-infinite inequality condition (i) into the numerically verifiable LMI condition in (ii). Hence, when we deal with control system analysis and synthesis problems at hand, a crucial step is to reduce those problems into a form conformable to the condition (i). This step is not obvious in general. When exploring such reduction, it is indispensable to see concretely what sets are indeed one-vector-lossless. In the next theorem, we will show a class of one-vector-lossless sets that is relevant to control system analysis and synthesis.

**THEOREM 2.3.** *Let  $\Psi \in \mathbf{H}_2$  with  $\det(\Psi) < 0$  and  $\Gamma \in \mathbf{C}^{2n \times l}$  be given. Define a subset of Hermitian matrices by*

$$(2.4) \quad \mathcal{S} := \{\Gamma^*(\Psi \otimes P)\Gamma : P \in \mathbf{P}_n\}.$$

*Then the set  $\mathcal{S}$  is one-vector-lossless.*

*Proof.* The proof is rather technical and thus given in the appendix.  $\square$

It is meaningful to examine the property of one-vector-lossless set  $\mathcal{S}$  given by (2.4) in comparison with the lossless set  $\mathcal{S}_1$  discussed in [8], where

$$\mathcal{S}_1 := \{\Gamma^*(\Psi \otimes P)\Gamma : P \in \mathbf{H}_n\}.$$

To see a significant difference between these two sets, let us take  $\Psi = \text{diag}(-1, 1)$  and  $\Gamma = I_{2n}$  for simplicity and consider the following set that concerns the condition (i) in Theorem 2.2:

$$(2.5) \quad \mathcal{G} := \left\{ \begin{bmatrix} f_1 \\ f_0 \end{bmatrix} \in \mathbf{C}^{2n} : f_0, f_1 \in \mathbf{C}^n, \begin{bmatrix} f_1 \\ f_0 \end{bmatrix} \neq 0, \begin{bmatrix} f_1 \\ f_0 \end{bmatrix}^* S \begin{bmatrix} f_1 \\ f_0 \end{bmatrix} \geq 0 \quad \forall S \in \mathcal{S} \right\}.$$

Then, we can show that the above set defined from the one-vector-lossless set  $\mathcal{S}$  coincides with

$$(2.6) \quad \mathcal{L} := \left\{ \begin{bmatrix} f_1 \\ f_0 \end{bmatrix} \in \mathbf{C}^{2n} : f_1 = s f_0 \text{ for some } s \in \overline{\mathbf{D}} \right\},$$

where  $\overline{\mathbf{D}}$  denotes the closure of the open unit disc  $\mathbf{D}$  on the complex plane. On the other hand, if we replace the one-vector-lossless set  $\mathcal{S}$  in (2.5) by the lossless set  $\mathcal{S}_1$ , then the resulting set  $\mathcal{G}_1$  coincides with the set  $\mathcal{L}_1$  obtained by replacing  $\overline{\mathbf{D}}$  in (2.6) by  $\partial\mathbf{D}$ . These observations clearly indicate that the lossless sets are related to *curves* on the complex plane, while the one-vector-lossless sets are related to *regions* on the complex plane. This is the key observation to develop the generalized  $\mathcal{S}$ -procedure for inequality conditions on the one-vector-lossless sets. We show in the next section that full rank property analysis problems of polynomial matrices over some regions on the complex plane can be dealt with by the proposed generalized  $\mathcal{S}$ -procedure.

**3. Linear system analysis using generalized  $\mathcal{S}$ -procedure.** For given complex matrices  $M_k \in \mathbf{C}^{n \times m}$  ( $k = 0, \dots, N$ ) with  $n \geq m$ , let us consider the  $n \times m$  complex polynomial matrix represented by  $M(s) = \sum_{k=0}^N s^k M_k$ . We assume that the normal rank of  $M(s)$  is  $m$ . Following the discussions in [6, 19], we define a (finite) zero of  $M(s)$  as a complex value  $z \in \mathbf{C}$  for which the rank of  $M(s)$  drops from its normal value, i.e.,  $\text{rank}(M(z)) < m$ . In linear system analysis and synthesis, it is of great importance to determine whether the zeros of given polynomial matrix  $M(s)$  belong to a specific region  $\mathcal{D} \subset \mathbf{C}$ . This can be restated equivalently in the way that the polynomial matrix  $M(s)$  is of full-column rank for all  $s \in \mathcal{D}^c$ , where  $\mathcal{D}^c$  denotes the complement of the region  $\mathcal{D}$  in  $\mathbf{C}$ . In the subsequent discussions, we restrict our attention to the regions defined below.

**DEFINITION 3.1.** For given  $\Psi \in \mathbf{H}_2$  with  $\det(\Psi) < 0$ , we define a set  $\mathcal{D}_\Psi$  and its complement  $\mathcal{D}_\Psi^c$  by

$$(3.1) \quad \mathcal{D}_\Psi := \{\lambda \in \mathbf{C} : \sigma(\lambda, \Psi) < 0\}, \quad \mathcal{D}_\Psi^c := \{\lambda \in \mathbf{C} : \sigma(\lambda, \Psi) \geq 0\}.$$

By selecting the Hermitian matrix  $\Psi$  in (3.1) appropriately, we can obtain several important regions in linear system analysis and synthesis. In particular, by letting

$$(3.2) \quad \Psi_c := \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad \Psi_d := \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix},$$

we see that  $\mathcal{D}_{\Psi_c}$  and  $\mathcal{D}_{\Psi_d}$  coincide with the open left half plane  $\mathbf{C}_-$  and the open unit disc  $\mathbf{D}$ , respectively. These regions are particularly important for stability analysis of continuous- and discrete-time linear systems.

We are now in the right position to show that the full rank property analysis problems of polynomial matrices can be reduced into LMI feasibility problems by means of the proposed generalized  $\mathcal{S}$ -procedure. We note that such reduction into LMIs is also investigated in the preceding studies, and similar results to the next theorem can also be found in the literature; see, for example, [6].

**THEOREM 3.2.** Let complex matrices  $M_k \in \mathbf{C}^{n \times m}$  ( $k = 0, \dots, N$ ) with  $n \geq m$  and  $\Psi = \begin{bmatrix} \psi_{11} & \psi_{12} \\ \psi_{12}^* & \psi_{22} \end{bmatrix} \in \mathbf{H}_2$  with  $\det(\Psi) < 0$  be given, and define  $M(s) := \sum_{k=0}^N s^k M_k$ ,  $\mathcal{M} := [M_N \cdots M_0]$ . Suppose either of the following assumptions holds:

1.  $M_N$  is of full-column rank.
2.  $\psi_{11} < 0$ .

Then, the following conditions are equivalent:

- (i) The polynomial matrix  $M(s)$  is of full-column rank for all  $s \in \mathcal{D}_\Psi^c$ .
- (ii)

$$\begin{aligned} & f^* \mathcal{M}^* \mathcal{M} f > 0 \quad \forall f \in \mathcal{L}, \\ & \mathcal{L} := \{f \in \mathbf{C}^{(N+1)m} : f \neq 0, \quad f^* S f \geq 0 \quad \forall S \in \mathcal{S}_W\}, \\ & \mathcal{S}_W := \{W^*(\Psi \otimes P)W : P \in \mathbf{P}_{Nm}\}, \\ & W := \begin{bmatrix} W_1 \\ W_2 \end{bmatrix}, \quad W_1 := \begin{bmatrix} I_{Nm} \\ 0_{m, Nm} \end{bmatrix}^*, \quad W_2 := \begin{bmatrix} 0_{m, Nm} \\ I_{Nm} \end{bmatrix}^*. \end{aligned}$$

- (iii) There exists  $P \in \mathbf{P}_{Nm}$  such that

$$(3.3) \quad \mathcal{M}^* \mathcal{M} - W^*(\Psi \otimes P)W \succ 0.$$

If the matrices  $M_k$  ( $k = 0, \dots, N$ ) and  $\Psi$  are all real, then the equivalence still holds when we restrict  $P$  to be real.

*Proof.* The proof for the equivalence of (i) and (ii) is given in the appendix. The main step of the proof, the equivalence of (ii) and (iii), follows immediately from Theorems 2.2 and 2.3. Indeed, the set  $\mathcal{S}_W$  is one-vector-lossless by Theorem 2.3 while it is clear that  $\mathcal{M}^*\mathcal{M} \succeq 0$ . Hence the generalized  $\mathcal{S}$ -procedure in Theorem 2.2 establishes the equivalence of (ii) and (iii). Noting that the real case results can be shown by following similar arguments to [9], we complete the proof.  $\square$

From this theorem, we see that full rank property of polynomial matrices can be assessed by simply solving the LMI (3.3), provided that either assumption 1 or 2 is satisfied. From the definition of  $\mathcal{D}_\Psi^c$  in (3.1), we see that the assumption  $\psi_{11} < 0$  enforces the region  $\mathcal{D}_\Psi^c$  to be bounded. To put it another way, our assumption requires that the matrix  $M_N$  is of full-column rank if the region  $\mathcal{D}_\Psi^c$  is unbounded. When studying the full rank property of polynomial matrices over unbounded regions, it is well-known that we have to take a special care on zeros at infinity [2, 3, 6, 19], and the assumption 1 is surely a sufficient condition for the absence of the zeros at infinity. Hence, under the assumption 1, delicate problems stemming from zeros at infinity have been excluded from our discussions.

It is obvious that the result in Theorem 3.2 forms an important basis for dealing with stability related issues in linear system analysis. In particular, the (generalized) Lyapunov's inequality [1, 5] is surely a special case of (3.3). In addition, existing LMI results for  $\mathcal{D}$ -stabilizability also follow from Theorem 3.2, where a matrix pair  $A \in \mathbf{C}^{n \times n}$ ,  $B \in \mathbf{C}^{n \times m}$  is said to be  $\mathcal{D}$ -stabilizable iff there exists  $K \in \mathbf{C}^{m \times n}$  such that  $sI - (A + BK)$  is nonsingular for all  $s \in \mathcal{D}^c$ . From the Popov–Belevitch–Hautus (PBH) tests [20, 21], this condition can be restated equivalently as  $[sI - A \quad B]^*$  is of full-column rank for all  $s \in \mathcal{D}^c$ . Hence, for the region  $\mathcal{D}_\Psi$ , we can conclude from Theorem 3.2 that the pair  $(A, B)$  is  $\mathcal{D}_\Psi$ -stabilizable iff there exists  $P \in \mathbf{P}_n$  such that

$$\begin{bmatrix} I_n & -A^* \\ 0_{m,n} & B^* \end{bmatrix}^* \begin{bmatrix} I_n & -A^* \\ 0_{m,n} & B^* \end{bmatrix} - \Psi^T \otimes P \succ 0.$$

From Finsler's lemma [1], this LMI can be rewritten as

$$(3.4) \quad B^\perp \begin{bmatrix} A & I \end{bmatrix} (\Psi^T \otimes P) \begin{bmatrix} A^* \\ I \end{bmatrix} (B^\perp)^* \prec 0.$$

The condition (3.4) is known as the *elimination-of-variables* type LMI condition for state-feedback stabilizing controller synthesis with respect to the stability region  $\mathcal{D}_\Psi$  [18]. In this way, we can derive existing stability-related LMI conditions straightforwardly by means of the generalized  $\mathcal{S}$ -procedure for inequality conditions on one-vector-lossless set.

**4. Conclusion.** In this paper, we first introduced a new notion, one-vector-lossless sets, and provided a nonconservative generalized  $\mathcal{S}$ -procedure for inequality conditions on the one-vector-lossless sets. We next showed that full rank property analysis problems of polynomial matrices over some regions on the complex plane can be reduced into LMI feasibility problems by means of the proposed generalized  $\mathcal{S}$ -procedure. It turned out that many existing results such as Lyapunov's inequalities for stability analysis of linear systems and LMIs for state-feedback controller synthesis can be viewed as particular cases of this result. To summarize, in conjunction with [8, 16], this paper clarified that most LMI results in linear control system theory can be grasped within the unified framework of the generalized  $\mathcal{S}$ -procedure.

## 5. Appendix.

**5.1. Proof of Theorem 2.3.** We need the following lemma for the proof.

LEMMA 5.1. For given  $F, G \in \mathbf{C}^{n \times m}$ , and  $\Psi = \begin{bmatrix} \psi_{11} & \psi_{12} \\ \psi_{12}^* & \psi_{22} \end{bmatrix} \in \mathbf{H}_2$  with  $\det(\Psi) < 0$ , suppose

$$(5.1) \quad \psi_{11}FF^* + \psi_{12}^*FG^* + \psi_{12}GF^* + \psi_{22}GG^* \succeq 0.$$

Then, there exists a unitary matrix  $U \in \mathbf{C}^{m \times m}$  such that

$$(5.2) \quad \psi_{11}\tilde{f}_1\tilde{f}_1^* + \psi_{12}^*\tilde{f}_1\tilde{g}_1^* + \psi_{12}\tilde{g}_1\tilde{f}_1^* + \psi_{22}\tilde{g}_1\tilde{g}_1^* \succeq 0,$$

where

$$(5.3) \quad [\tilde{f}_1 \ \cdots \ \tilde{f}_m] := FU, \quad [\tilde{g}_1 \ \cdots \ \tilde{g}_m] := GU, \quad \tilde{f}_i, \tilde{g}_i \in \mathbf{C}^n \ (i = 1, \dots, m).$$

*Proof.* We give the proof only for the case  $\psi_{11} > 0$ . Other cases can be proved similarly. If  $\psi_{11} > 0$ , then the condition (5.1) can be rewritten equivalently as

$$\left(F + \frac{\psi_{12}}{\psi_{11}}G\right) \left(F + \frac{\psi_{12}}{\psi_{11}}G\right)^* \succeq -\psi_{11}^{-2}\det(\Psi)GG^*.$$

From [12], this condition holds iff there exists a matrix  $W \in \mathbf{C}^{m \times m}$  such that

$$(5.4) \quad \sqrt{-\psi_{11}^{-2}\det(\Psi)}G = \left(F + \frac{\psi_{12}}{\psi_{11}}G\right)W, \quad \|W\| \leq 1.$$

Since  $\|W\| \leq 1$ , for each eigenvalue  $\lambda$  of  $W$  and its associated eigenvector  $\xi$ , we have  $W\xi = \lambda\xi$ ,  $|\lambda| \leq 1$ ,  $\xi^*\xi = 1$ . Taking one such  $\xi$ , we can construct a unitary matrix  $U$  of the form  $U = \begin{bmatrix} \xi & \bar{U} \end{bmatrix}$ ,  $\bar{U} \in \mathbf{C}^{m \times (m-1)}$ . Then, we see from (5.4) that the vectors  $\tilde{f}_1$  and  $\tilde{g}_1$  defined by (5.3) with this unitary matrix  $U$  satisfy

$$\sqrt{-\psi_{11}^{-2}\det(\Psi)}\tilde{g}_1 = \left(\tilde{f}_1 + \frac{\psi_{12}}{\psi_{11}}\tilde{g}_1\right)\lambda \quad (|\lambda| \leq 1).$$

This implies (5.2).  $\square$

Now we are ready to prove Theorem 2.3.

*Proof.* It is obvious that the set  $\mathcal{S}$  given in (2.4) has the properties (a) and (b) in Definition 2.1. To prove the property (c), let  $H \in \mathbf{C}^{l \times l}$  be a nonzero matrix that satisfies (2.1). In addition, we denote the full rank factorization of  $H$  by

$$(5.5) \quad H = LL^*, \quad L \in \mathbf{C}^{l \times r}, \quad r := \text{rank}(H).$$

With this  $L$ , define

$$(5.6) \quad \begin{bmatrix} F \\ G \end{bmatrix} := \Gamma L, \quad F, G \in \mathbf{C}^{n \times r}.$$

Then, the second condition in (2.1) can be rewritten as

$$\text{trace}((\psi_{11}FF^* + \psi_{12}^*FG^* + \psi_{12}GF^* + \psi_{22}GG^*)P) \geq 0 \quad \forall P \in \mathbf{P}_n.$$

It can be seen that this condition holds iff (5.1) holds. Hence, from Lemma 5.1, there exists a unitary matrix  $U \in \mathbf{C}^{r \times r}$  that satisfies (5.2) with  $\tilde{f}_i, \tilde{g}_i \in \mathbf{C}^n$  ( $i = 1, \dots, m$ ) given by (5.3). Here, note that (5.2) is equivalent to

$$(5.7) \quad \text{trace}((\psi_{11}\tilde{f}_1\tilde{f}_1^* + \psi_{12}^*\tilde{f}_1\tilde{g}_1^* + \psi_{12}\tilde{g}_1\tilde{f}_1^* + \psi_{22}\tilde{g}_1\tilde{g}_1^*)P) \geq 0 \quad \forall P \in \mathbf{P}_n.$$

By defining  $[\zeta_1 \ \cdots \ \zeta_r] := LU$ , we have  $H = \sum_{i=1}^r \zeta_i \zeta_i^*$ . On the other hand, from (5.6) and (5.3), it is apparent that  $[\tilde{f}_1^* \ \tilde{g}_1^*]^* = \Gamma \zeta_1$ . Hence, we see from (5.7) that the

condition  $\zeta_1^* \Gamma^*(\Psi \otimes P) \Gamma \zeta_1 \geq 0$  ( $\forall P \in \mathbf{P}_n$ ) holds or, equivalently,  $\zeta_1^* S \zeta_1 \geq 0$  ( $\forall S \in \mathcal{S}$ ). This clearly shows that the set  $\mathcal{S}$  satisfies the property (c) of Definition 2.1.  $\square$

**5.2. Proof of the equivalence of (i) and (ii) in Theorem 3.2.** The condition (i) can be restated equivalently as

$$\begin{aligned} & f^* \mathcal{M}^* \mathcal{M} f > 0 \quad \forall f \in \mathcal{K}, \\ \mathcal{K} := \{ & f = [f_N^* \cdots f_0^*]^* \in \mathbf{C}^{(N+1)m} : f_0 \neq 0, \\ & \exists s \in \mathcal{D}_{\Psi}^c \text{ such that } f_{k+1} = s f_k \ (k = 0, \dots, N-1) \}. \end{aligned}$$

Hence, to prove the equivalence of (i) and (ii), it suffices to show that  $\mathcal{K} = \mathcal{L}$ . To this end, we first note that  $\mathcal{K} = \mathcal{L}'$ , where

$$\begin{aligned} \mathcal{L}' := \{ & f = [f_N^* \cdots f_0^*]^* \in \mathbf{C}^{(N+1)m} : \\ & f_k \in \mathbf{C}^m \ (k = 0, \dots, N), \\ & f_0 \neq 0, \quad f^* S f \geq 0 \quad \forall S \in \mathcal{S}_W \}. \end{aligned}$$

To see this, suppose  $f = [f_N^* \cdots f_0^*]^* \in \mathcal{K}$ , and define  $f_u, f_l \in \mathbf{C}^{Nm}$  by

$$(5.8) \quad f_u := [f_N^* \cdots f_1^*]^* = W_1 f, \quad f_l := [f_{N-1}^* \cdots f_0^*]^* = W_2 f.$$

Then, from the definition of  $\mathcal{K}$ , the following inequality holds for all  $P \in \mathbf{P}_{Nm}$ :

$$\begin{aligned} f^* W^* (\Psi \otimes P) W f &= \begin{bmatrix} f_u \\ f_l \end{bmatrix}^* (\Psi \otimes P) \begin{bmatrix} f_u \\ f_l \end{bmatrix} \\ &= \begin{bmatrix} s f_l \\ f_l \end{bmatrix}^* (\Psi \otimes P) \begin{bmatrix} s f_l \\ f_l \end{bmatrix} = \sigma(s, \Psi) f_l^* P f_l \geq 0. \end{aligned}$$

This shows that  $f \in \mathcal{L}'$ , and hence  $\mathcal{K} \subset \mathcal{L}'$ . On the other hand, suppose  $f = [f_N^* \cdots f_0^*]^* \in \mathcal{L}'$ , and define  $f_u$  and  $f_l$  by (5.8). Then, from the definition of  $\mathcal{L}'$ , we have

$$\text{trace}((\psi_{11} f_u f_u^* + \psi_{12}^* f_u f_l^* + \psi_{12} f_l f_u^* + \psi_{22} f_l f_l^*) P) \geq 0 \quad \forall P \in \mathbf{P}_{Nm}.$$

It can be easily seen that the above condition implies

$$(5.9) \quad \psi_{11} f_u f_u^* + \psi_{12}^* f_u f_l^* + \psi_{12} f_l f_u^* + \psi_{22} f_l f_l^* \succeq 0.$$

Moreover, under the assumption  $f_0 \neq 0$ , we have  $f_l \neq 0$ , and hence (5.9) holds iff  $f_u = s f_l$  for some  $s \in \mathcal{D}_{\Psi}^c$  [12]. This clearly shows that  $f \in \mathcal{K}$  and hence  $\mathcal{L}' \subset \mathcal{K}$ . Thus we can conclude  $\mathcal{K} = \mathcal{L}'$ .

To complete the proof, note that  $\mathcal{L} = \mathcal{L}' \cup \mathcal{J}'$ , where

$$\begin{aligned} \mathcal{J}' := \{ & f = [f_N^* \cdots f_0^*]^* \in \mathbf{C}^{(N+1)m} : \\ & f_k \in \mathbf{C}^m \ (k = 0, \dots, N), \quad f \neq 0, \quad f_0 = 0, \quad f^* S f \geq 0 \quad \forall S \in \mathcal{S}_W \}. \end{aligned}$$

Moreover, we can show that the set  $\mathcal{J}'$  is equivalent to

$$\begin{aligned} \mathcal{J} := \{ & f = [f_N^* \cdots f_0^*]^* \in \mathbf{C}^{(N+1)m} : \\ & f_k \in \mathbf{C}^m \ (k = 0, \dots, N), \\ & f_N \neq 0, \quad f_k = 0 \ (k = 0, \dots, N-1), \quad f^* S f \geq 0 \quad \forall S \in \mathcal{S}_W \}. \end{aligned}$$

To see the equivalence of  $\mathcal{J}'$  and  $\mathcal{J}$ , let us take a vector  $f \in \mathcal{J}'$ . Furthermore, define  $f_u$  and  $f_l$  by (5.8) and suppose  $f_l \neq 0$ . Then, the vectors  $f_u$  and  $f_l$  should satisfy

(5.9), and thus  $f_u = sf_l$  holds for some  $s \in \mathcal{D}_\Psi^c$ . Since  $f_0 = 0$ , however,  $f_u = sf_l$  implies  $f_l = 0$ . This clearly contradicts the assumption  $f_l \neq 0$ . Hence, we have  $f_l = 0$  and thus  $f \in \mathcal{J}$ . This shows that  $\mathcal{J}' \subset \mathcal{J}$ . On the other hand, it is apparent that  $\mathcal{J} \subset \mathcal{J}'$ , and hence we have  $\mathcal{J}' = \mathcal{J}$ .

Summarizing the above arguments,  $\mathcal{L} = \mathcal{K} \cup \mathcal{J}$  holds. Hence, the equivalence of (i) and (ii) can be verified by showing that the condition  $f^* \mathcal{M}^* \mathcal{M} f > 0$  holds for all  $f \in \mathcal{J}$  under either assumption 1 or 2. If  $\psi_{11} < 0$ , however, it can be easily seen that the set  $\mathcal{J}$  is empty. On the other hand, if  $\psi_{11} \geq 0$ , then we have  $M_N^* M_N \succ 0$  from the assumption. This indicates that  $f^* \mathcal{M}^* \mathcal{M} f = f_N^* M_N^* M_N f_N > 0$  ( $\forall f \in \mathcal{J}$ ). Hence, we can conclude that the conditions (i) and (ii) are equivalent under either assumption 1 or 2. This completes the proof.  $\square$

## ON SECOND ORDER SHAPE OPTIMIZATION METHODS FOR ELECTRICAL IMPEDANCE TOMOGRAPHY\*

L. AFRAITES<sup>†</sup>, M. DAMBRINE<sup>†</sup>, AND D. KATEB<sup>†</sup>

**Abstract.** This paper is devoted to the analysis of a second order method for recovering the a priori unknown shape of an inclusion  $\omega$  inside a body  $\Omega$  from boundary measurement. This inverse problem—known as electrical impedance tomography—has many important practical applications and hence has been the focus of much attention during the past few years. However, to the best of our knowledge, no work has yet considered a second order approach for this problem. This paper aims to fill that void: We investigate the existence of second order derivative of the state  $u$  with respect to perturbations of the shape of the interface  $\partial\omega$ . Then we choose a cost function in order to recover the geometry of  $\partial\omega$  and derive the expression of the derivatives needed to implement the corresponding Newton method. We then investigate the stability of the process and explain why this inverse problem is severely ill-posed by proving the compactness of the Hessian at the global minimizer.

**Key words.** inverse conductivity problem, shape optimization, second order method

**DOI.** 10.1137/070687438

**1. Introduction.** Let  $\Omega$  be a bounded open set with smooth boundary in  $\mathbb{R}^N$ , with  $N \geq 3$ . Consider an  $L^\infty$  function  $\sigma$  such that there exists a real  $c$  with  $\sigma(x) \geq c > 0$ . Consider the elliptic equation

$$(1) \quad -\operatorname{div}(\sigma(x)\nabla u) = 0 \text{ in } \Omega,$$

with the Dirichlet boundary condition

$$(2) \quad u = f \text{ on } \partial\Omega.$$

Define the Dirichlet-to-Neumann map as

$$\Lambda_\sigma : f \mapsto \sigma(\partial_{\mathbf{n}}u)|_{\partial\Omega},$$

where  $u$  solves (1), (2) and  $\mathbf{n}$  is the outer unit normal vector to  $\partial\Omega$ . The inverse conductivity problem of Calderón is to determine  $\sigma$  from  $\Lambda_\sigma$ . Electrical impedance tomography aims to form an image of the conductivity distribution  $\sigma$  from the knowledge of  $\Lambda_\sigma$ . When  $\sigma$  is smooth enough, one can reconstruct  $\sigma$  from  $\Lambda_\sigma$  (see the works of Sylvester and Uhlmann [23], Nachman [16, 17], and Novikov [18]). When the conductivity distribution is only  $L^\infty$ , Astala and Päivärinta have recently shown in [4] that, in dimension two, the map  $\Lambda_\sigma$  determines  $\sigma \in L^\infty(\Omega)$ .

We are interested in a particular case of that problem: when a body is inserted inside a given object with a distinct conductivity, the question of determining its shape from boundary measurement arises in many fields of modern technology. In the context of the inverse problem of conductivity of Calderón, we restrict the range

<sup>†</sup>Laboratoire de Mathématiques Appliquées de Compiègne, Université de Technologie de Compiègne (lekhir.afraites@utc.fr, marc.dambrine@utc.fr, djalil.kateb@utc.fr).

of admissible conductivity distributions to the family of piecewise constant functions which take only two distinct values,  $\sigma_1, \sigma_2 > 0$ , which are assumed to be known. The conductivity distribution is then defined by an open subset  $\omega$  as

$$(3) \quad \sigma = \sigma_1 \chi_{\Omega \setminus \omega} + \sigma_2 \chi_{\omega}.$$

Here, the only unknown of the problem is  $\omega$ , a subdomain of  $\Omega$  with a smooth boundary  $\partial\omega$ ; its outer unit normal vector is denoted by  $\mathbf{n}$ . The notation  $\chi_{\omega}$  (respectively,  $\chi_{\Omega \setminus \omega}$ ) denotes the characteristic function of  $\omega$  (respectively,  $\Omega \setminus \omega$ ). The second main difference arises from practical considerations: it is unrealistic from the point of view of applications to know the full graph of Dirichlet-to-Neumann. Therefore, we will assume that one has access to a single point in that graph. This nondestructive testing problem is usually written from a numerical point of view as the minimization of a cost function: typically a least-squares matching criterion. Many authors have investigated the steepest descent method for this problem [13, 8, 11, 20, 3] with the methods of shape optimization since the unknown parameter is a geometrical domain.

This work is devoted to the study of second order methods for this problem, which has only been considered before for simplified models in [6, 2]. By introducing second order methods, one aims to reach two distinct objectives.

- On one hand, we provide all the needed material to design a Newton algorithm. By Newton algorithm, we mean the usual second order scheme of optimization. We will give differentiability results for the state function and for the objective that we have chosen to study in this work. Nevertheless, we point out that the discretization of a Newton method for this problem turns out to be very delicate; this is why, in the present paper, we will neither discuss this problem nor present numerical examples. Some simulations in the bidimensional case are presented in [1].
- On the other hand, we analyze rigorously the well-posedness of the optimization method. This is justified by the huge numerical literature devoted to the numerical study of this question in the field of inverse problems; the numerical experiments insist on the ill-posedness of this problem. We will explain the instability in the continuous settings in terms of shape optimization. We show that the shape Hessian is not coercive. In fact, its Riesz operator is compact. This property explains the instability of the minimization process.

**2. Statement of the results.** Let us describe the precise problem under consideration and the notation. We consider a bounded domain  $\Omega \subset \mathbb{R}^N$  with a  $\mathcal{C}^2$  boundary. It is filled with a material whose conductivity is  $\sigma_1$  and with an unknown inclusion  $\omega$  in  $\Omega$  of conductivity  $\sigma_2 \neq \sigma_1$ . We search to reconstruct the shape of  $\omega$  by measuring  $\partial\Omega$ , the input voltage, and the corresponding output current. In what follows, we fix  $d_0 > 0$  and consider inclusions  $\omega$  such that  $\omega \subset\subset \Omega_{d_0} = \{x \in \Omega, d(x, \partial\Omega) > d_0\}$ . We also assume that the boundary  $\partial\omega$  is of class  $\mathcal{C}^{4,\alpha}$ . The inverse problem arises when one has access to the normal vector derivative of the potential  $u$  that solves (1), (2) when the conductivity distribution is defined by (3). Assume that one knows

$$(4) \quad \sigma_1 \partial_{\mathbf{n}} u = g \text{ on } \partial\Omega.$$

Then the problem (1), (2), (4) is overdetermined. The electrical impedance tomography problem we consider is to recover the shape of  $\omega$  from the knowledge of the single Cauchy pair  $(f, g)$ .

In order to recover the shape of the inclusion  $\omega$ , an usual strategy is to minimize a cost function. Many choices are possible; however, it turns out that a Kohn

and Vogelius-type objective leads to a minimization problem with nicer properties than the least-squares fitting approaches (we refer to [3] for a comparison of different objectives with order one methods, and to [2] for the case of a perfectly insulated inclusion). Therefore, we study such a cost function in this work.

Let us define this criterion. Its distinctive feature is to involve two state functions,  $u_d$  and  $u_n$ : the state  $u_d$  solves (1), (2), while  $u_n$  solves (1), (4). The Kohn–Vogelius objective  $J_{KV}$  is then defined as

$$(5) \quad J_{KV}(\omega) = \int_{\Omega} \sigma |\nabla(u_d - u_n)|^2.$$

Let us sum up the results of this paper concerning the minimization of this objective. We first prove differentiability results for the state  $u_d$ . In what follows, we use the convention that a bold character denotes a vector. If  $\mathbf{h}$  denotes a deformation field, it can be written as  $\mathbf{h} = \mathbf{h}_\tau + h_n \mathbf{n}$  on  $\partial\omega$ . Note also that in the following lines,  $\mathbf{n}$  denotes the outer normal field to  $\partial\omega$  pointing into  $\Omega \setminus \bar{\omega}$ . Hence, for  $x \in \partial\omega$ , we define, when the limit exists,  $u^\pm(x)$  (respectively,  $(\partial_n u)^\pm(x)$ ) as the limit of  $u(x \pm t\mathbf{n}(x))$  (respectively,  $\langle \nabla u(x \pm t\mathbf{n}(x)), \mathbf{n}(x) \rangle$ ) when  $t > 0$  tends to 0. Note that  $\mathbf{h}_\tau$  is a vector while  $h_n$  is a scalar quantity.

The admissible deformation fields have to preserve  $\partial\Omega$  and the regularity of the boundaries: therefore the space of admissible fields is

$$\mathcal{H} = \{\mathbf{h} \in \mathcal{C}^{4,\alpha}(\mathbb{R}^d, \mathbb{R}^d), \text{Supp}(\mathbf{h}) \subset \Omega_{d_0}\}.$$

The following result concerns the first order derivative of the state functions  $u_d$  and  $u_n$ . It was derived in [8, 20, 3].

**THEOREM 1.** *Let  $\Omega$  be an open smooth subset of  $\mathbb{R}^N$  and let  $\omega$  be an element of  $\Omega_{d_0}$  with a boundary of class  $\mathcal{C}^{4,\alpha}$ . Then the state functions  $u_d$  and  $u_n$  are shape differentiable; furthermore their shape derivatives  $u'_d$  and  $u'_n$  belong to  $H^1(\Omega \setminus \bar{\omega}) \cup H^1(\omega)$  and satisfy*

$$(6) \quad \left\{ \begin{array}{l} \Delta u'_d = 0 \text{ in } \Omega \setminus \bar{\omega} \text{ and in } \omega, \\ [u'_d] = h_n \frac{[\sigma]}{\sigma_1} \partial_{\mathbf{n}} u_d^- \text{ on } \partial\omega, \\ [\sigma \partial_n u'_d] = [\sigma] \text{div}_\tau(h_n \nabla_\tau u_d) \text{ on } \partial\omega, \\ u'_d = 0 \text{ on } \partial\Omega. \end{array} \right.$$

$$(7) \quad \left\{ \begin{array}{l} \Delta u'_n = 0 \text{ in } \Omega \setminus \bar{\omega} \text{ and in } \omega, \\ [u'_n] = h_n \frac{[\sigma]}{\sigma_1} \partial_{\mathbf{n}} u_n^- \text{ on } \partial\omega, \\ [\sigma \partial_n u'_n] = [\sigma] \text{div}_\tau(h_n \nabla_\tau u_n) \text{ on } \partial\omega, \\ \partial u'_n = 0 \text{ on } \partial\Omega. \end{array} \right.$$

The first main result of this work concerns the second order derivative. It is given in the following theorem.

**THEOREM 2.** *Let  $\Omega$  be an open smooth subset of  $\mathbb{R}^N$  and let  $\omega$  be an element of  $\Omega_{d_0}$  with a  $\mathcal{C}^{4,\alpha}$  boundary. Let  $\mathbf{h}_1$  and  $\mathbf{h}_2$  be two deformation fields in  $\mathcal{H}$ . Then the*

state  $u_d$  has a second order shape derivative  $u_d'' \in H^1(\Omega \setminus \bar{\omega}) \cup H^1(\omega)$  that solves

$$(8) \quad \left\{ \begin{array}{l} \Delta u_d'' = 0 \text{ in } \Omega \setminus \bar{\omega} \text{ and in } \omega, \\ [u_d''] = (h_{1,n}h_{2,n}H - \mathbf{h}_{1\tau} \cdot (D\mathbf{n} \mathbf{h}_{2\tau})) [\partial_{\mathbf{n}} u_d] - (h_{1,n}[\partial_{\mathbf{n}}(u_d)']_2 + h_{2,n}[\partial_{\mathbf{n}}(u_d)']_1) \\ \quad + (\mathbf{h}_{1\tau} \cdot \nabla h_{2,n} + \mathbf{h}_{2\tau} \cdot \nabla h_{1,n}) [\partial_{\mathbf{n}} u_d] \text{ on } \partial\omega, \\ [\sigma \partial_{\mathbf{n}} u_d''] = \operatorname{div}_{\tau} \left( h_{2,n} [\sigma \nabla_{\tau}(u_d)']_1 + h_{1,n} [\sigma \nabla_{\tau}(u_d)']_2 + \mathbf{h}_{1\tau} \cdot (D\mathbf{n} \mathbf{h}_{2\tau}) [\sigma \nabla_{\tau} u_d] \right) \\ \quad - \operatorname{div}_{\tau} ((\mathbf{h}_{1\tau} \cdot \nabla_{\tau} h_{2,n} + \nabla_{\tau} h_{1,n} \cdot \mathbf{h}_{2\tau}) [\sigma \nabla_{\tau} u_d]) \\ \quad - \operatorname{div}_{\tau} (h_{2,n} h_{1,n} (2D\mathbf{n} - HI) [\sigma \nabla_{\tau} u_d]) \text{ on } \partial\omega, \\ u_d'' = 0 \text{ on } \partial\Omega. \end{array} \right.$$

Here,  $(u_d)'_i$  denotes the first order derivative of  $u$  in the direction of  $h_i$  as given in (6),  $D\mathbf{n}$  stands for the second fundamental form of the manifold  $\partial\omega$ , and  $H$  stands for the mean curvature of  $\partial\omega$ . Note that  $H$  is then the sum of the main curvatures and not the scaled version (divided by  $n - 1$ ) in dimension  $n$ .

The twin result concerning  $u_n$  is an easy adaption of Theorem 2. Once the differentiability of the state function has been established, one can consider the objectives. In [3], we have shown the first order result.

**THEOREM 3.** *Let  $\Omega$  be an open smooth subset of  $\mathbb{R}^N$  and let  $\omega$  be an element of  $\Omega_{d_0}$  with a  $C^{4,\alpha}$  boundary. Let  $\mathbf{h}_1$  and  $\mathbf{h}_2$  be two deformation fields in  $\mathcal{H}$ . The Kohn–Vogelius objective is differentiable with respect to the shape, and its derivative in the direction of a deformation field  $\mathbf{h}$  is given by*

$$(9) \quad DJ_{KV}(\omega)\mathbf{h} = [\sigma] \int_{\partial\omega} \left[ \frac{\sigma_1}{\sigma_2} (|\partial_{\mathbf{n}} u_d^+|^2 - |\partial_{\mathbf{n}} u_n^+|^2) + |\nabla_{\tau} u_d|^2 - |\nabla_{\tau} u_n|^2 \right] h_n.$$

We now give the second order derivative of the Kohn–Vogelius criterion.

**THEOREM 4.** *Let  $\Omega$  be an open smooth subset of  $\mathbb{R}^N$  and  $\omega$  an element of  $\Omega_{d_0}$  with a  $C^{4,\alpha}$  boundary. Let  $\mathbf{h}_1$  and  $\mathbf{h}_2$  be two deformation fields in  $\mathcal{H}$ . The Kohn–Vogelius objective is twice differentiable with respect to the shape, and its second derivative in the directions  $\mathbf{h}_1$  and  $\mathbf{h}_2$  is given by*

$$(10) \quad \begin{aligned} D^2 J_{KV}(\omega)(\mathbf{h}_1, \mathbf{h}_2) &= \int_{\partial\omega} [\sigma |\nabla v|^2] (\mathbf{h}_{1\tau} \cdot \nabla_{\tau}(h_{2,n}) + \mathbf{h}_{2\tau} \cdot \nabla_{\tau}(h_{1,n}) - \mathbf{h}_{2\tau} \cdot (D\mathbf{n} \mathbf{h}_{1\tau})) \\ &\quad - \int_{\partial\omega} \partial_{\mathbf{n}} \left( [\sigma |\nabla v|^2] \right) h_{1,n} h_{2,n} + 2 [\sigma \nabla v \cdot (h_{1,n} \nabla v'_2 + h_{2,n} \nabla v'_1)] \\ &\quad + \int_{\partial\omega} \left[ \sigma \left( \partial_{\mathbf{n}}(u_n)'_1 v'_2 + \partial_{\mathbf{n}}(u_n)'_2 v'_1 - \partial_{\mathbf{n}} v'_1 (u_d)'_2 - \partial_{\mathbf{n}} v'_2 (u_d)'_1 \right) \right] \\ &\quad + 2 \int_{\partial\omega} v \left[ \sigma \partial_{\mathbf{n}}(u_n)''_{1,2} \right] - \sigma_1 \partial_{\mathbf{n}} v^+ [(u_d)''_{1,2}], \end{aligned}$$

where we have set  $v = u_d - u_n$ .

To investigate the properties of stability of this cost function, we are led to consider an admissible inclusion  $\omega^*$  to solve both (1), (2) and (1), (4) in order to obtain the corresponding measurements  $f^*$  and  $g^*$ . It is obvious that the domain  $\omega^*$  realizes the absolute minimum of the criterion  $J_{KV}$  since, by construction, we can write

$u_d = u_n$  in  $\Omega$  and hence  $J_{KV}(\omega^*) = 0$ . We will check that the Euler equation

$$DJ_{KV}(\omega^*)(\mathbf{h}) = 0$$

holds. We will also prove that

$$(11) \quad D^2 J_{KV}(\omega^*)(\mathbf{h}, \mathbf{h}) = \int_{\Omega} \sigma |\nabla v'|^2.$$

Moreover, if  $h_n \neq 0$ , then  $D^2 J_{KV}(\omega^*)(\mathbf{h}, \mathbf{h}) > 0$  holds. Nevertheless, (11) does not mean that the minimization problem is well-posed. In fact, the second important result is the following theorem that explains the instability of standard minimization algorithms.

**THEOREM 5.** *Assume that  $\omega^*$  is a critical shape of  $J_{KV}$  for which the additional condition  $u_n = u_d$  holds. Then the Riesz operator corresponding to  $D^2 J_{KV}(\omega^*)$  defined from  $H^{1/2}(\partial\omega^*)$  with values in  $H^{-1/2}(\partial\omega^*)$  is compact. Moreover, the minimization problem is severely ill-posed in the following sense: if the target domain is  $\mathcal{C}^\infty$  and if  $\lambda_n$  denotes the  $n$ th eigenvalue of  $D^2 J_{KV}(\omega^*)$ , then  $\lambda_n = o(n^{-s})$  for all  $s > 0$ .*

Theorem 5 has two main consequences. First, the shape Hessian at the global minimizer is not coercive. This means that this minimizer may not be a local strict minimum of the criterion. Moreover, the criterion provides no control of the distance between the parameter  $\omega$  and the target  $\omega^*$ . The second consequence concerns any numerical scheme used to obtain this optimal domain  $\omega^*$ . One has to face this difficulty, and this explains why frozen Newton or Levenberg–Marquard schemes have been used to solve numerically this problem [8, 3].

The paper is organized as follows. In a first section, we state some preliminary results on shape derivatives. Some are well-known facts in shape optimization and will be recalled without proof for the sake of readability. Some of them (e.g., the derivatives of a Laplace–Beltrami operator and the tangential regularity of the solution to (1), (2) along the discontinuity of the conductivity distribution) are less known and will be proved thanks to potential layer methods. Hence we will tackle the computations in section 4 that we consider as the core of this work: it is essentially devoted to proving Theorem 2. After a first part where we prove the existence of a second order derivative for the state, we propose two distinct methods to find the boundary value problem solved by this second order derivative. The method presented in the core of the paper consists in a direct differentiation of the boundary conditions. Section 5 is devoted to the analysis of the criterion, and we establish Theorems 4 and 5. We explain their consequences on the stability of critical shapes.

In the final section, we present some appendices. Section 6.1 is devoted to proving tangential regularity along the interface for solution of (1), (2). In section 6.2, we consider the bidimensional case that requires an additional size assumption on the inclusion. Section 6.3 deals gives a second proof of Theorem 2. It follows along the lines of classical proofs of shape differentiability by differentiating the weak formulation of problem (1), (2) and interpreting the result in terms of differential operator and boundary conditions.

**3. Elements of shape calculus.** Before entering the proof of Theorem 2, we recall without proof some basic facts from shape optimization (see [7] for references). Let  $\mathbf{h}$  be a deformation field in  $\mathcal{C}^2(\Omega, \mathbb{R}^d)$  with  $\|\mathbf{h}\|_{\mathcal{C}^2} < 1$ . We set  $T_t(h, \cdot) = \text{Id} + t\mathbf{h}$  and denote by  $\Omega_t$  the transported domain  $\Omega_t = T_t(\Omega)$ . To avoid heavy notations, we will use the notation  $T_t$  instead of  $T_t(h, \cdot)$ .

**Material and shape derivatives.** Classically, in the mechanics of continuous media, the material derivative is defined as being a positive limit. In our context, for any vector field  $\mathbf{h} \in \mathcal{H}$ , we define the material derivative of the domain functional  $y = y(\Omega)$  at  $\Omega$  in an admissible direction  $\mathbf{h}$  as the limit:

$$(12) \quad \dot{y}(\Omega; \mathbf{h}) = \lim_{t \rightarrow 0} \frac{y(\Omega_t) \circ T_t - y(\Omega)}{t}.$$

Similarly, one can define the material derivative  $\dot{y}(\partial\Omega, \mathbf{h})$  for any domain functional  $y = y(\partial\Omega)$  which depends on  $\partial\Omega$ . Another kind of derivative occurs, called the shape derivative of  $y(\Omega, \mathbf{h})$ . It is viewed as a first local variation. Its definition is given by the following definition.

DEFINITION 1. *The shape derivative  $y' = y'(\Omega; \mathbf{h})$  of a functional  $y(\Omega)$  at  $\Omega$  in the direction of a vector field  $\mathbf{h}$  is given by*

$$(13) \quad y' = \dot{y} - \mathbf{h} \cdot \nabla y.$$

For more details on these derivations, the reader can consult [22, 7].

**Elements of tangential derivatives.** In what follows, we will need to manipulate the tangential differential operators on a manifold. For the reader's convenience, we recall from [5, 7] some definitions and also some useful rules of calculus.

DEFINITION 2. *The tangential divergence of a vector field  $\mathbf{V} \in C^1(\mathbb{R}^d, \mathbb{R}^d)$  is given by*

$$(14) \quad \operatorname{div}_\tau(\mathbf{V}) = \operatorname{div}(\mathbf{V}) - D\mathbf{V} \cdot \mathbf{n}, \mathbf{n},$$

where the notation  $D\mathbf{V}$  denotes the Jacobian matrix of  $\mathbf{V}$ . When the vector  $\mathbf{V} \in C^1(\partial\Omega, \mathbb{R}^d)$  is defined on  $\partial\Omega$ , then the following notation is used to define the tangential divergence:

$$(15) \quad \operatorname{div}_\tau(\mathbf{V}) = \operatorname{div}(\tilde{\mathbf{V}}) - (D\tilde{\mathbf{V}} \cdot \mathbf{n}) \cdot \mathbf{n},$$

where  $\tilde{\mathbf{V}}$  stands for an arbitrary  $C^1$  extension of  $\mathbf{V}$  on an open neighborhood of  $\partial\Omega$ .

We introduce now the notion of tangential gradient  $\nabla_\tau$  of any smooth scalar function  $f$  in  $C^1(\partial\Omega, \mathbb{R}^d)$ .

DEFINITION 3. *Let an element  $f \in C^1(\partial\Omega, \mathbb{R}^d)$  be given and let  $\tilde{f}$  be an extension of  $f$  in the sense that  $\tilde{f} \in C^1(U)$  and  $\tilde{f}|_{\partial\Omega} = f$  and where  $U$  is an open neighborhood of  $\partial\Omega$ . Then the following notation is used to define the tangential gradient:*

$$(16) \quad \nabla_\tau f = \nabla \tilde{f}|_{\partial\Omega} - \nabla \tilde{f} \cdot \mathbf{n} \, \mathbf{n} \text{ on } \partial\Omega.$$

The details for the existence of such an extension can be found in [5]. Let us remark that these definitions do not depend on the choice of the extension. Furthermore, one can show the important relation

$$(17) \quad \int_{\partial\Omega} \nabla_\tau f \cdot \mathbf{F} = - \int_{\partial\Omega} f \operatorname{div}_\tau(\mathbf{F})$$

for all elements  $f \in C^1(\partial\Omega)$  and all vector fields  $F \in C^1(\partial\Omega, \mathbb{R}^d)$  satisfying  $F_n = \langle F, \mathbf{n} \rangle = 0$ .

**Integration by parts on  $\partial\Omega$ .** In general, the condition above,  $F_n = 0$ , is not always satisfied. We are then led to find another formula to extend the formula to the general case. The extension of this integration by parts formula to fields with a normal vector component involves curvature.

First, we point out that the curvature is connected to the normal vector via the tangential divergence operator. Recall that the mean curvature of  $\partial\Omega$  is defined as  $H = \operatorname{div}_\tau(\mathbf{n})$ . Making use of the form of  $\operatorname{div}_\tau(\mathbf{n})$  on the boundary, one shows straightforwardly the following statement.

**PROPOSITION 1.** *Let  $\Omega$  be an open subset of  $\mathbb{R}^N$  with a  $\mathcal{C}^2$  boundary. For any unitary extension  $\mathcal{N}$  of  $\mathbf{n}$  on a neighborhood of  $\partial\Omega$ , one has*

$$\operatorname{div}(\mathcal{N}) = H \text{ on } \partial\Omega.$$

Assume that the manifold  $\partial\Omega$  has no borders. If  $\mathbf{F} \in H^2(\partial\Omega)^3$  and  $f \in H^2(\partial\Omega)$ , then we have

$$(18) \quad \int_{\partial\Omega} \nabla_\tau f \cdot \mathbf{F} + f \operatorname{div}_\tau(\mathbf{F}) = \int_{\partial\Omega} (\nabla f \cdot \mathbf{n} + Hf) \mathbf{F} \cdot \mathbf{n}.$$

We assume now that the domain  $\Omega$  has a  $\mathcal{C}^3$  boundary. The simplest second order derivative is the Laplace–Beltrami operator; it is defined as follows (see [5, 7]), thanks to the following usual chain rule.

**DEFINITION 4.** *Let  $f \in H^2(\partial\Omega)$ . The Laplace–Beltrami  $\Delta_\tau$  of  $f$  is defined as*

$$(19) \quad \Delta_\tau f = \operatorname{div}_\tau(\nabla_\tau f).$$

There is a relation connecting the Laplace operator and the Laplace–Beltrami operator. Let us denote  $\partial_{nn}^2 f = (D^2 f \cdot \mathbf{n}) \cdot \mathbf{n}$ , where  $D^2 f$  stands for the Hessian of  $f$ .

**PROPOSITION 2.** *Let  $\Omega$  be a domain with a boundary  $\partial\Omega$  of class  $\mathcal{C}^3$ . For all functions  $f \in H^3(\Omega)$ , it holds that*

$$(20) \quad \Delta f = \Delta_\tau f + H \partial_{nn} f + \partial_{nn}^2 f \text{ on } \partial\Omega.$$

**Some useful derivatives.** We need to compute shape and material derivatives of special vector fields: the outer unit normal vector  $\mathbf{n}$ , the tangential gradient, and the Laplace–Beltrami operator applied to a function. While the derivative of the normal vector is obtained by a straightforward calculus, we have to transport from  $\partial\Omega_t$  to  $\partial\Omega$  the Laplace–Beltrami operator and the tangential gradient in order to compute the other derivatives.

*Derivatives of the normal vector.* We describe the material and shape derivatives of the normal vector. We will denote by  $\mathbf{n}$  the gradient of the signed distance to  $\partial\Omega$ . This is a unitary extension of the unitary normal vector  $\mathbf{n}$  at  $\partial\Omega$  which is smooth in the vicinity of  $\partial\Omega$ . This extension furnishes a symmetric Jacobian  $D\mathbf{n}$  that satisfies  $D\mathbf{n}\mathbf{n} = 0$  on  $\partial\Omega$ . The direction  $\mathbf{h}$  will be supposed to be in  $\mathcal{C}^2(\mathbb{R}^d, \mathbb{R}^d)$  or in  $\mathcal{C}^2(\partial\Omega, \mathbb{R}^d)$ .

**PROPOSITION 3.** *The material derivative  $\dot{\mathbf{n}}$  of the normal vector  $\mathbf{n}$  at  $\Omega$  in the direction of a vector field  $\mathbf{h} \in \mathcal{C}^1(\mathbb{R}^d, \mathbb{R}^d)$  is given by*

$$\dot{\mathbf{n}} = -\nabla_\tau(\mathbf{h} \cdot \mathbf{n}) + D\mathbf{n}\mathbf{h}_\tau,$$

where  $\mathbf{h}_\tau = \mathbf{h} - \mathbf{h} \cdot \mathbf{n} \mathbf{n}$ .

Concerning its shape derivative defined as  $\mathbf{n}' = (\partial_t \mathbf{n}_t)|_{t=0}$ , where  $\mathbf{n}_t$  is any smooth unitary extension of  $\mathbf{n}$  to  $\partial\Omega_t$ , we obtain the following.

**PROPOSITION 4.** *The shape derivative  $\mathbf{n}'$  in the direction of  $\mathbf{h}$  is given by*

$$\mathbf{n}' = -\nabla_\tau(\mathbf{h} \cdot \mathbf{n}).$$

*Derivative of the tangential gradient.* For  $f \in H^3(\partial\Omega)$ , we compute the material derivative of  $\nabla_\tau f$ .

PROPOSITION 5. *For all functions  $f \in C^2(\mathbb{R}^3)$  and directions  $\mathbf{h} \in C^2(\partial\Omega, \mathbb{R}^3)$ , one has*

$$\overline{\dot{\nabla}_\tau f} = \nabla_\tau f' + (D^2 f \mathbf{h})_\tau - \nabla f \cdot \mathbf{n} \dot{\mathbf{n}} - \nabla f \cdot \dot{\mathbf{n}} \mathbf{n}.$$

*Proof.* We differentiate  $\nabla f$  and  $\nabla f \cdot \mathbf{n} \mathbf{n}$  and obtain

$$\overline{\dot{\nabla} f} = \nabla f' + D^2 f \mathbf{h},$$

while

$$\overline{\dot{\nabla f \cdot \mathbf{n} \mathbf{n}}} = \nabla f \cdot \dot{\mathbf{n}} \mathbf{n} + \nabla f \cdot \mathbf{n} \dot{\mathbf{n}} + \nabla f' \cdot \mathbf{n} \mathbf{n} + (D^2 f \mathbf{h}) \cdot \mathbf{n} \mathbf{n}.$$

The two former equations give the desired result.  $\square$

*Derivative of the Laplace–Beltrami operator.* Now, we want to compute the material derivative  $\overline{\dot{\Delta}_\tau f}$ . We begin to study how to transport the Laplace–Beltrami operator when one works on  $\partial\Omega_t$ . Let  $\Delta_{\tau,t}$  denote the Laplace–Beltrami operator on the manifold  $\partial\Omega_t$ . To compute the derivative of a Laplace–Beltrami operator, we need the following proposition, which we quote from [22].

PROPOSITION 6. *Let  $f \in H^{5/2}(\mathbb{R}^d)$ . Then*

$$(21) \quad \int_{\partial\Omega} \left[ (\Delta_{\tau,t} f) \circ T_t \gamma_\tau(t) \right] \phi \\ = - \int_{\partial\Omega} \left[ C(t) \left( \nabla(f \circ T_t) - (B(t) \mathbf{n}) \cdot \nabla(f \circ T_t) \right) \right] \cdot \nabla \phi \quad \forall \phi \in \mathcal{D}(\mathbb{R}^d).$$

In the former proposition, we set

$$(22) \quad \begin{aligned} \gamma(t) &= \det DT_t, \\ \gamma_\tau(t) &= \gamma(t) \|(DT_t^{-1})^T \cdot \mathbf{n}\|_{\mathbb{R}^d}, \\ B(t) &= \frac{D(T_t^{-1})(D(T_t)^{-1})^T}{\|(DT_t^{-1})^T \cdot \mathbf{n}\|_{\mathbb{R}^d}^2}, \\ C(t) &= \gamma_\tau(t) D(T_t^{-1})(D(T_t)^{-1})^T. \end{aligned}$$

A straightforward computation gives

$$(23) \quad \begin{aligned} \gamma'(0) &= \operatorname{div}_\tau(\mathbf{h}), \\ \gamma'_\tau(0) &= \operatorname{div}_\tau(\mathbf{h}) = \operatorname{div}_\tau(\mathbf{h}_\tau) + H\mathbf{h}_n, \\ B'(0) &= 2(D\mathbf{h}\mathbf{n}) \cdot \mathbf{n}I - (D\mathbf{h} + (D\mathbf{h})^T), \\ C'(0) &= \operatorname{div}_\tau(\mathbf{h})I - (D\mathbf{h} + (D\mathbf{h})^T). \end{aligned}$$

We then have the following result.

THEOREM 6. *Let  $f \in \mathcal{D}(\mathbb{R}^d)$ . The material derivative of  $\Delta_\tau f$  in the direction  $\mathbf{h}$  is given by*

$$(24) \quad \begin{aligned} \overline{\dot{\Delta}_\tau f} &= \Delta_\tau \dot{f} + \nabla_\tau f \cdot \nabla_\tau [\operatorname{div}_\tau(\mathbf{h}_\tau)] \\ &\quad + \nabla_\tau(H\mathbf{h}_n) \cdot \nabla_\tau f - \operatorname{div}_\tau \left( \left( (D\mathbf{h} + (D\mathbf{h})^T) \nabla_\tau f \right)_\tau \right). \end{aligned}$$

*Proof.* Formula (24) is shown in a weak sense. For each test function  $\phi \in \mathcal{C}^\infty(\partial\Omega)$ , there exists an extension  $\tilde{\phi} \in \mathcal{D}(\mathbb{R}^d)$  such that  $\partial_{\mathbf{n}}\tilde{\phi} = 0$ ; this can be done by extending  $\phi$  as a constant along the orbits of the gradient of the signed distance function to  $\partial\Omega$  and through the use of a cut-off function. For  $f \in \mathcal{D}(\mathbb{R}^d)$ , we set

$$A(t) = \int_{\partial\Omega} \frac{(\Delta_{\tau,t}f) \circ T_t - \Delta_{\tau}f}{t} \gamma_{\tau}(t) \phi.$$

After an integration by parts on  $\partial\Omega$ , we obtain

$$\begin{aligned} A(t) &= \int_{\partial\Omega} \frac{1 - \gamma_{\tau}(t)}{t} (\Delta_{\tau,t}f) \circ T_t \phi + \int_{\partial\Omega} \frac{\gamma_{\tau}}{t} ((\Delta_{\tau,t}f) \circ T_t \phi) + \frac{1}{t} \nabla_{\tau}f \cdot \nabla_{\tau}\phi, \\ &= \int_{\partial\Omega} \frac{1 - \gamma_{\tau}(t)}{t} (\Delta_{\tau,t}f) \circ T_t \phi \\ &\quad + \int_{\partial\Omega} \frac{1}{t} \left( [\nabla_{\tau}f - C(t)\nabla(f \circ T_t)] \cdot \nabla\tilde{\phi} + [(B(t)\mathbf{n} \cdot \nabla(f \circ T_t))] C(t) \mathbf{n} \cdot \nabla\tilde{\phi} \right). \end{aligned}$$

Since  $\partial_{\mathbf{n}}\tilde{\phi} = 0$  and  $C(0) = I$ , we get

$$\begin{aligned} A(t) &= \int_{\partial\Omega} \frac{1 - \gamma_{\tau}(t)}{t} (\Delta_{\tau,t}f) \circ T_t \phi + \int_{\partial\Omega} \frac{\nabla_{\tau}(f - f \circ T_t)}{t} \cdot \nabla_{\tau}\tilde{\phi} \\ &\quad + \int_{\partial\Omega} \frac{C(0) - C(t)}{t} \nabla(f \circ T_t) \cdot \nabla_{\tau}\tilde{\phi}. \end{aligned}$$

When  $t \rightarrow 0$ , then

$$\begin{aligned} \int_{\partial\Omega} \overline{\Delta_{\tau}f} \phi &= - \int_{\partial\Omega} \gamma'_{\tau}(t) \Delta_{\tau}f \phi + \nabla_{\tau}f \cdot \nabla_{\tau}\phi + (C'(0) \cdot \nabla f) \cdot \nabla_{\tau}\phi, \\ &= \int_{\partial\Omega} \left( \Delta_{\tau}f - \operatorname{div}_{\tau}(\mathbf{h}) \Delta_{\tau}f \right) \phi + \left( D\mathbf{h} + (D\mathbf{h})^T - \operatorname{div}_{\tau}(\mathbf{h}) I \right) \nabla f \cdot \nabla_{\tau}\phi, \\ &= \int_{\partial\Omega} \left[ \Delta_{\tau}f - \operatorname{div}_{\tau}(\mathbf{h}) \Delta_{\tau}f + \operatorname{div}_{\tau}(\operatorname{div}_{\tau}(h) \nabla_{\tau}f) \right. \\ &\quad \left. - \operatorname{div}_{\tau} \left( \left( (D\mathbf{h} + (D\mathbf{h})^T) \nabla f \right)_{\tau} \right) \right] \phi. \end{aligned}$$

Expanding the double divergence term, we obtain

$$\overline{\Delta_{\tau}f} = \Delta_{\tau}f + \nabla_{\tau}f \cdot \nabla_{\tau} \operatorname{div}_{\tau}(\mathbf{h}) - \operatorname{div}_{\tau} \left( \left( (D\mathbf{h} + (D\mathbf{h})^T) \nabla f \right)_{\tau} \right).$$

In order to make these derivatives explicit, we let the curvatures of  $\partial\Omega$  appear by means of

$$\nabla_{\tau}f \cdot \nabla_{\tau} \operatorname{div}_{\tau}(\mathbf{h}) = \nabla_{\tau}f \cdot \nabla_{\tau} [\operatorname{div}_{\tau}(\mathbf{h}_{\tau}) + H\mathbf{h}_n],$$

and this ends the proof of Theorem 6.  $\square$

**Structure of second order shape derivatives.** Since the fundamental work of J. Hadamard, domain derivatives of order one are well known to depend only on the normal component of the deformation field  $\mathbf{h}$ : It is written as  $l_1(\mathbf{h} \cdot \mathbf{n})$ . The reason for this is that, if the field  $\mathbf{h}$  is tangent to  $\Omega$ , then its flow preserves for small time at order one the domain  $\Phi_t(\Omega) = \Omega + o(t)$ , with abuse of notation.

This property is lost for second order derivatives as illustrated by Theorem 5.9.2 of [7]. As shown in [19], the second order derivative of a function  $E$  can be written as

$$D^2 E(\mathbf{h}_1, \mathbf{h}_2) = l_2(\mathbf{h}_1 \cdot \mathbf{n}, \mathbf{h}_2 \cdot \mathbf{n}) + l_1(Z),$$

where  $Z$  denotes

$$Z = (D_\tau \mathbf{n} \mathbf{h}_{1\tau}) \cdot \mathbf{h}_{2\tau} - \nabla_\tau(\mathbf{h}_1 \cdot \mathbf{n}) \cdot \mathbf{h}_{2\tau} - \nabla_\tau(\mathbf{h}_2 \cdot \mathbf{n}) \cdot \mathbf{h}_{1\tau}.$$

The important point is that a second order shape derivative also depends on the tangential component of the deformation fields and that this dependence disappears at critical shapes.

**4. Existence of the second order derivative of the state. Proof of Theorem 2.** This section is devoted to the proof of Theorem 2. We follow the usual strategy to derive existence in shape optimization. In the first step, we will write the weak formulation of the problem, then transport it on the reference domain, pass to the limit, and obtain existence of the material derivative. In the second step, we will seek a boundary value problem solved by the material derivative. This will provide a characterization of the second order shape derivative. Two strategies, which we will detail, are possible: The first one, explored in section 6.1, consists in working on the variational formulation, while the second one uses the tangential differential calculus by differentiating the boundary conditions. The latter approach will be presented in section 4. Both approaches require that the trace on the interface of discontinuity  $\partial\omega$  of the solution to the boundary value problem have tangential derivatives. For the sake of readability, we postponed all the needed justifications until section 6.2.

*Preliminary results.* In what follows, we will use some technical formulae. To preserve the readability of the proof of the main result, we state them in this paragraph. The tools needed for proving these results can be found in [22]. Given a smooth vector field  $\mathbf{h}$ , we denote

$$A_{\mathbf{h}} = D\mathbf{h} + D\mathbf{h}^T - \operatorname{div}(\mathbf{h}) I.$$

We begin with the following formula.

LEMMA 1. *It holds that*

$$(25) \quad \nabla u \cdot A_{\mathbf{h}} \nabla v = \nabla(\mathbf{h} \cdot \nabla u) \cdot \nabla v + \nabla(\mathbf{h} \cdot \nabla v) \cdot \nabla u - \operatorname{div}((\nabla u \cdot \nabla v) \mathbf{h}).$$

Given two smooth vector fields  $\mathbf{h}_1$  and  $\mathbf{h}_2$ , we set

$$(26) \quad \mathfrak{A} = D\mathbf{h}_2 A_{\mathbf{h}_1} + A_{\mathbf{h}_1} D\mathbf{h}_2^T - A_{\mathbf{h}_1} \operatorname{div}(\mathbf{h}_2) - (A_{\mathbf{h}_1})'(\mathbf{h}_2)$$

and

$$b = (\mathbf{h}_2 \cdot \nabla u) A_{\mathbf{h}_1} \nabla v + (\mathbf{h}_2 \cdot \nabla v) A_{\mathbf{h}_1} \nabla u - ((A_{\mathbf{h}_1} \nabla u) \cdot \nabla v) \mathbf{h}_2.$$

Here, the notation  $(A_{\mathbf{h}_1})'(\mathbf{h}_2)$  stands for the matrix defined by its elements:

$$((A_{\mathbf{h}_1})'(\mathbf{h}_2))_{k,l} = \nabla(((A_{\mathbf{h}_1})')_{k,l}) \cdot \mathbf{h}_2.$$

LEMMA 2. *One has*

$$(27) \quad \nabla u \cdot \mathfrak{A} \nabla v = \operatorname{div}(b) - (\mathbf{h}_2 \cdot \nabla u) \operatorname{div}((A_{\mathbf{h}_1} \nabla v)) - (\mathbf{h}_2 \cdot \nabla v) \operatorname{div}((A_{\mathbf{h}_1} \nabla u)).$$

We need the following crucial result.

LEMMA 3. *If  $u$  is harmonic, then*

$$(28) \quad \operatorname{div}(A_{\mathbf{h}_1} \nabla u) = \Delta(\mathbf{h}_1 \cdot \nabla u).$$

*Proof.* For any harmonic function  $u$  in  $\Omega$  and for every test function  $\phi \in \mathcal{D}(\Omega)$ , we can write

$$\int_{\Omega} \nabla \dot{u} \nabla \phi = \int_{\Omega} A_{\mathbf{h}} \nabla u \cdot \nabla \phi.$$

Then

$$\int_{\Omega} \Delta \dot{u} \cdot \phi = \int_{\Omega} \operatorname{div}(A_{\mathbf{h}} \nabla u) \cdot \phi.$$

Since  $\dot{u} = u' + \mathbf{h} \cdot \nabla u$  and since  $u'$  is harmonic in  $\Omega$ , we obtain the result.  $\square$

We follow Hettlich and Rundell [9] and Simon [21] to define the second order derivative of an operator with respect to a domain. We compute the second derivative by considering two admissible deformations fields,  $\mathbf{h}_1, \mathbf{h}_2 \in \mathcal{H}$ , that will describe the small variations of  $\partial\omega$ . Simon showed that the second derivative  $F''(\partial\omega; \mathbf{h}_1, \mathbf{h}_2)$  of  $F(\partial\omega)$  is defined as a bounded bilinear operator satisfying

$$(29) \quad F''(\partial\omega; \mathbf{h}_1, \mathbf{h}_2) = \left( F'(\partial\omega; \mathbf{h}_1) \right)' \mathbf{h}_2 - F'(\partial\omega; D\mathbf{h}_1 \mathbf{h}_2).$$

For more details, the reader can consult the appendix on page 613 of [9].

*Step 1: Existence of the second order derivative.* Let us begin the proof. Let  $\mathbf{h}_1, \mathbf{h}_2 \in \mathcal{H}$  be two vector fields. The direction  $\mathbf{h}_1$  being fixed, we consider  $\dot{u}_{1, \mathbf{h}_2}$  the variation of  $u_1$  with respect to the direction  $\mathbf{h}_2$ . We recall from [3] that the material derivative  $\dot{u}_1$  of  $u$  in the direction  $\mathbf{h}_1$  satisfies

$$\forall v \in H_0^1(\Omega), \quad \int_{\Omega} \sigma \nabla \dot{u}_1 \cdot \nabla v = \int_{\Omega} \sigma \nabla u \cdot A_{\mathbf{h}_1} \nabla v.$$

Let  $\phi_2 : \Omega \mapsto \Omega$  be the diffeomorphism defined by  $\phi_2(x) = x + \mathbf{h}_2(x)$ , and set  $\psi_2 = \phi_2^{-1}$ . Setting  $\omega_{\mathbf{h}_2} = \{x + \mathbf{h}_2(x), x \in \omega\}$ ,  $\Omega_{\mathbf{h}_2} = \{x + \mathbf{h}_2(x), x \in \Omega\} = \Omega$ , and  $\sigma_{\mathbf{h}_2} = \sigma \circ \phi_2$ , we get

$$(30) \quad \int_{\Omega_{\mathbf{h}_2}} \sigma_{\mathbf{h}_2} \nabla \dot{u}_{1, \mathbf{h}_2} \cdot \nabla v = \int_{\Omega_{\mathbf{h}_2}} \sigma_{\mathbf{h}_2} \nabla u_{\mathbf{h}_2} \cdot A_{\mathbf{h}_1} \nabla v,$$

where  $u_{\mathbf{h}_2}$  is the solution of the original problem with  $\omega_{\mathbf{h}_2}$  instead of  $\omega$ . Making the change of variables  $x = \phi_2(X)$ , we get the integral identity on the fixed domain  $\Omega$ :

$$(31) \quad \begin{aligned} \int_{\Omega} \sigma \nabla \tilde{u}_{1, \mathbf{h}_2} \cdot \left( D\psi_2 (D\psi_2)^T \det(D\phi_2) \right) \nabla v \\ = \int_{\Omega} \sigma \nabla \tilde{u}_{\mathbf{h}_2} \cdot \left( D\psi_2 \widetilde{A_{\mathbf{h}_1}} (D\psi_2)^T \det(D\phi_2) \right) \nabla v, \end{aligned}$$

with the notation  $\tilde{u} = u \circ \phi_2$  and  $\widetilde{A_{\mathbf{h}_1}} = A_{\mathbf{h}_1} \circ \phi_2$ . Since the material derivative  $\dot{u}_1$  of  $u$  with respect to the direction  $\mathbf{h}_1$  satisfies

$$\int_{\Omega} \sigma \nabla \dot{u}_1 \cdot \nabla v = \int_{\Omega} \sigma \nabla u \cdot A_{\mathbf{h}_1} \nabla v,$$

the difference of (30) and (31) gives

$$\begin{aligned} \int_{\Omega} \sigma \nabla (\tilde{u}_{1, \mathbf{h}_2} - \dot{u}_1) \cdot \nabla v &= \int_{\Omega} \sigma \nabla \tilde{u}_{1, \mathbf{h}_2} \cdot \left( I - D\psi_2 (D\psi_2)^T \det(D\phi_2) \right) \nabla v \\ &\quad + \int_{\Omega} \sigma \nabla \tilde{u}_{\mathbf{h}_2} \cdot \left( D\psi_2 \widetilde{A_{\mathbf{h}_1}} (D\psi_2)^T \det(D\phi_2) - A_{\mathbf{h}_1} \right) \nabla v \\ &\quad + \int_{\Omega} (\nabla \tilde{u}_{\mathbf{h}_2} - \nabla u) \cdot A_{\mathbf{h}_1} \nabla v. \end{aligned}$$

We quote from [13] and [9] the following asymptotic formulae:

$$\begin{aligned} \|\det(D\phi_i) - 1 - \operatorname{div}(\mathbf{h}_i)\|_{\infty} &= O(\|\mathbf{h}_i\|_{\mathcal{C}^2}^2), \\ \|D\psi_i (D\psi_i)^T \det(D\phi_i) - I + A_{\mathbf{h}_i}\|_{\infty} &= O(\|\mathbf{h}_i\|_{\mathcal{C}^2}^2), \\ \|D\psi_2 \widetilde{A_{\mathbf{h}_1}} (D\psi_2)^T \det(D\phi_2) - A_{\mathbf{h}_1} + D\mathbf{h}_2 A_{\mathbf{h}_1} \\ &\quad + A_{\mathbf{h}_1} (D\mathbf{h}_2)^T - \operatorname{div}(\mathbf{h}_2) A_{\mathbf{h}_1} - (A_{\mathbf{h}_1})'(\mathbf{h}_2)\|_{\infty} = O(\|\mathbf{h}_2\|_{\mathcal{C}^2}^2). \end{aligned}$$

Making the adequate substitutions, we easily check that the material derivative of  $\dot{u}_1$  with respect to  $\mathbf{h}_2$  exists. This derivative, denoted by  $\ddot{u}_1$ , satisfies

$$(32) \quad \int_{\Omega} \sigma \nabla \ddot{u}_1 \cdot \nabla v \, dx = \int_{\Omega} \sigma [\nabla \dot{u}_1 \cdot A_{\mathbf{h}_2} \nabla v + \nabla \dot{u}_2 \cdot A_{\mathbf{h}_1} \nabla v - \nabla u \cdot \mathfrak{A} \nabla v],$$

where  $\mathfrak{A}$  is defined in (26).

*Step 2: Derivation of (8) by differentiation of the boundary conditions on  $\partial\omega$ .* The aim of this section is to compute the second order shape derivative of the state by differentiating the boundary conditions. We start with the expression of the flux jump  $[\sigma \partial_{\mathbf{n}} u'']$  by computing the normal derivatives of each of the expressions  $\overline{[\sigma \nabla u'] \cdot \mathbf{n}}$  and  $\overline{\operatorname{div}_{\tau}(h_{1,n}[\sigma \nabla_{\tau} u])}$ . Since

$$[\sigma \nabla u'] \cdot \mathbf{n} = \operatorname{div}_{\tau}(h_{1,n}[\sigma \nabla_{\tau} u]) = h_{1,n}[\sigma \Delta_{\tau} u] + \nabla_{\tau} h_{1,n} \cdot [\sigma \nabla_{\tau} u],$$

then we get

$$\begin{aligned} (33) \quad \overline{[\sigma \nabla u'] \cdot \mathbf{n}} &= \overline{\operatorname{div}_{\tau}(h_{1,n}[\sigma \nabla_{\tau} u])} \\ &= \overline{h_{1,n}[\sigma \Delta_{\tau} u]} + h_{1,n} \overline{[\sigma \Delta_{\tau} u]} + \overline{\nabla_{\tau} h_{1,n}} \cdot [\sigma \nabla_{\tau} u] + \nabla_{\tau} h_{1,n} \cdot \overline{[\sigma \nabla_{\tau} u]}. \end{aligned}$$

In order to avoid lengthy computations, we shall concentrate on each normal derivative appearing in the above formula. Some of the results are straightforward and their proofs will be left to the reader. Combining Propositions 3 and 5, we conclude that

$$\overline{\nabla_{\tau} h_{1,n}} = -\nabla_{\tau}(\mathbf{h}_1 \cdot \nabla_{\tau} h_{2,n}) + (D^2 h_{1,n} \cdot \mathbf{h}_2)_{\tau} - \nabla h_{1,n} \cdot \dot{\mathbf{n}} \, \mathbf{n} - \nabla h_{1,n} \cdot \mathbf{n} \, \dot{\mathbf{n}}.$$

In the same manner, we also get

$$\overline{[\sigma \nabla_\tau u]} = [\sigma \nabla_\tau u'_2] + ([\sigma D^2 u] \cdot \mathbf{h}_2)_\tau - [\sigma \nabla_\tau u] \cdot \dot{\mathbf{n}} \mathbf{n} - [\sigma \nabla_\tau u] \mathbf{n} \dot{\mathbf{n}}.$$

We use Proposition 3 and obtain

$$\begin{aligned} \overline{\mathbf{h}_1 \cdot \dot{\mathbf{n}}} &= \dot{\mathbf{h}}_1 \cdot \mathbf{n} + \mathbf{h}_1 \cdot \dot{\mathbf{n}} \\ &= \mathbf{h}_2 \cdot \nabla h_{1,n} - \nabla_\tau h_{2,n} \cdot \mathbf{h}_{1\tau}. \end{aligned}$$

Formula (33) becomes

$$\begin{aligned} (34) \quad \overline{\operatorname{div}_\tau (h_{1,n} [\sigma \nabla_\tau u])} &= \overline{h_{1,n} [\sigma \Delta_\tau u]} + h_{1,n} \overline{[\sigma \Delta_\tau u]} + \overline{\nabla_\tau h_{1,n}} \cdot [\sigma \nabla_\tau u] + \nabla_\tau h_{1,n} \cdot \overline{[\sigma \nabla_\tau u]} \\ &= \left( -\nabla_\tau (\mathbf{h}_1 \cdot \nabla_\tau h_{2,n}) + (D^2 h_{1,n} \cdot \mathbf{h}_2)_\tau - \nabla h_{1,n} \cdot \dot{\mathbf{n}} \mathbf{n} \right) [\sigma \nabla_\tau u] \\ &\quad + \nabla_\tau h_{1,n} \left( [\sigma \nabla_\tau u'_2] + ([\sigma D^2 u] \cdot \mathbf{h}_2)_\tau \right) \\ &\quad + (\mathbf{h}_2 \cdot \nabla h_{1,n} - \nabla_\tau h_{2,n} \cdot \mathbf{h}_{1\tau}) \cdot [\sigma \Delta_\tau u] + h_{1,n} \overline{[\sigma \Delta_\tau u]}. \end{aligned}$$

Let us pose  $A = [\sigma (D^2 u \cdot \mathbf{h}_2)_\tau] \cdot \nabla_\tau h_{1,n}$  and  $B = [\sigma \nabla_\tau u] \cdot (D^2 h_{1,n} \cdot \mathbf{h}_2)_\tau$ ; by formula (73), we simplify  $A$  and  $B$  as follows:

$$\begin{aligned} A &= -[\sigma \nabla_\tau u] \cdot (D \mathbf{n} \nabla_\tau h_{1,n}) h_{2,n} + [\sigma D^2 u] \mathbf{h}_{2\tau} \cdot \nabla_\tau h_{1,n}, \\ B &= (D^2 h_{1,n} \cdot \mathbf{h}_{2\tau}) \cdot [\sigma \nabla_\tau u] + \nabla_\tau (\partial_n h_{1,n}) \cdot [\sigma \nabla_\tau u] h_{2,n} - [\sigma \nabla_\tau u] \cdot (D \mathbf{n} \nabla_\tau h_{1,n}) h_{2,n}. \end{aligned}$$

After this computation and the formula of  $\dot{\mathbf{n}}$ , (34) becomes

$$\begin{aligned} (35) \quad \overline{\operatorname{div}_\tau (h_{1,n} [\sigma \nabla_\tau u])} &= (-\nabla_\tau (\mathbf{h}_{1\tau} \cdot \nabla_\tau h_{2,n})) \cdot [\sigma \nabla_\tau u] - \partial_n h_{1,n} (D \mathbf{n} \mathbf{h}_{2\tau} - \nabla_\tau h_{2,n}) [\sigma \nabla_\tau u] \\ &\quad + (D^2 h_{1,n} \cdot \mathbf{h}_{2\tau}) \cdot [\sigma \nabla_\tau u] + \nabla_\tau (\partial_n h_{1,n}) \cdot [\sigma \nabla_\tau u] h_{2,n} \\ &\quad - 2[\sigma \nabla_\tau u] \cdot (D \mathbf{n} \nabla_\tau h_{1,n}) h_{2,n} \\ &\quad + \nabla_\tau h_{1,n} [\sigma \nabla_\tau u'_2] + [\sigma D^2 u] \mathbf{h}_{2\tau} \cdot \nabla_\tau h_{1,n} \\ &\quad + (h_{2,n} \partial_n (h_{1,n}) - \nabla_\tau h_{2,n} \cdot \mathbf{h}_{1\tau}) \cdot [\sigma \Delta_\tau u] \\ &\quad + \mathbf{h}_{2\tau} \cdot \nabla_\tau h_{1,n} [\sigma \Delta_\tau u] + h_{1,n} \overline{[\sigma \Delta_\tau u]}. \end{aligned}$$

We tackle the computation of  $(\partial_n u)'$ . For the sake of clarity, we subdivide the work into several steps.

*First step.* We simplify the quantity  $\overline{\operatorname{div}_\tau (h_{1,n} [\sigma \nabla_\tau u])}$ . According to (35), and by using the formula of divergence and by adding and cutting the quantity  $[\sigma \Delta_\tau u'_2]$ , we obtain

$$\begin{aligned} (36) \quad \overline{\operatorname{div}_\tau (h_{1,n} [\sigma \nabla_\tau u])} &= \operatorname{div}_\tau \left( h_{1,n} [\sigma \nabla_\tau u'_2] + (h_{2,n} \partial_n h_{1,n} - \nabla_\tau h_{2,n} \cdot \mathbf{h}_{1\tau}) [\sigma \nabla_\tau u] \right) \\ &\quad + [\sigma \Delta_\tau u] \nabla_\tau h_{1,n} \cdot \mathbf{h}_{2\tau} \\ &\quad - \partial_n h_{1,n} [\sigma \nabla_\tau u] \cdot (D \mathbf{n} \mathbf{h}_{2\tau}) + [\sigma \nabla_\tau u] \cdot (D^2 h_{1,n} \cdot \mathbf{h}_{2\tau}) \\ &\quad - 2h_{2,n} [\sigma \nabla_\tau u] \cdot (D \mathbf{n} \nabla_\tau h_{1,n}) \\ &\quad + [\sigma D^2 u] \mathbf{h}_{2\tau} \cdot \nabla_\tau h_{1,n} + h_{1,n} \left( \overline{[\sigma \Delta_\tau u]} - [\sigma \Delta_\tau u'_2] \right). \end{aligned}$$

*Second step.* We compute  $\overline{[\sigma \partial_{\mathbf{n}} u'_1]}$ . From the expression of  $\dot{\mathbf{n}}$ , we get after some straightforward computations

$$(37) \quad \begin{aligned} \overline{[\sigma \partial_{\mathbf{n}} u'_1]} &= \overline{[\sigma \nabla u'_1]} \cdot \mathbf{n} + [\sigma \nabla u'_1] \cdot \dot{\mathbf{n}} \\ &= [\sigma \partial_{\mathbf{n}}(u'_1)_2] + ([\sigma D^2 u'_1] \mathbf{h}_2) \cdot \mathbf{n} + [\sigma \nabla_{\tau} u'_1] \cdot (D\mathbf{n} \mathbf{h}_{2\tau} - \nabla_{\tau} h_{2,n}). \end{aligned}$$

*Third step.* We compute  $\sigma \partial_{\mathbf{n}}(u'_1)'_2$ . From the jump condition on the flux of the derivative (6) and from (36) and (37), we obtain

$$\begin{aligned} [\sigma \partial(u'_1)'_2] &= \overline{\operatorname{div}_{\tau}(h_{1,n}[\sigma \nabla_{\tau} u])} - ([\sigma D^2 u'_1] \mathbf{h}_2) \cdot \mathbf{n} - [\sigma \nabla_{\tau} u'_1] \cdot (D\mathbf{n} \mathbf{h}_{2\tau} - \nabla_{\tau} h_{2,n}) \\ &= \operatorname{div}_{\tau} \left( h_{1,n}[\sigma \nabla_{\tau} u'_2] + (h_{2,n} \partial_{\mathbf{n}} h_{1,n} - \nabla_{\tau} h_{2,n} \cdot \mathbf{h}_{1\tau}) [\sigma \nabla_{\tau} u] \right) \\ &\quad - ([\sigma D^2 u'_1] \mathbf{h}_2) \cdot \mathbf{n} + [\sigma \nabla_{\tau} u'_1] \cdot (\nabla_{\tau} h_{2,n} - D\mathbf{n} \mathbf{h}_{2\tau}) - \partial_{\mathbf{n}} h_{1,n} [\sigma \nabla_{\tau} u] \cdot (D\mathbf{n} \mathbf{h}_{2\tau}) \\ &\quad + (D^2 h_{1,n} \mathbf{h}_{2\tau}) \cdot [\sigma \nabla_{\tau} u] + [\sigma D^2 u] \mathbf{h}_{2\tau} \cdot \nabla_{\tau} h_{1,n} - 2h_{2,n} (D\mathbf{n} [\sigma \nabla_{\tau} u]) \cdot \nabla_{\tau} h_{1,n} \\ &\quad + \nabla_{\tau} h_{1,n} \cdot \mathbf{h}_{2\tau} [\sigma \Delta_{\tau} u] + h_{1,n} \left( \overline{[\sigma \Delta_{\tau} u]} - [\sigma \Delta_{\tau} u'_2] \right). \end{aligned}$$

Taking into account the calculation

$$\begin{aligned} &- ([\sigma D^2 u'_1] \mathbf{h}_2) \cdot \mathbf{n} + [\sigma \nabla_{\tau} u'_1] \cdot \nabla_{\tau} h_{2,n} \\ &= - \left( h_{2,n} [\sigma D^2 u'_1] \mathbf{n} + [\sigma D^2 u'_1] \mathbf{h}_{2\tau} \right) \cdot \mathbf{n} + [\sigma \nabla_{\tau} u'_1] \cdot \nabla_{\tau} h_{2,n}, \\ &= h_{2,n} \left( [\sigma \Delta_{\tau} u'_1] + H [\sigma \partial_{\mathbf{n}} u'_1] \right) + [\sigma \nabla_{\tau} u'_1] \cdot \nabla_{\tau} h_{2,n} - ([\sigma D^2 u'_1] \mathbf{h}_{2\tau}) \cdot \mathbf{n}, \\ &= \operatorname{div}_{\tau} \left( h_{2,n} [\sigma \nabla_{\tau} u'_1] \right) + H h_{2,n} [\sigma \partial_{\mathbf{n}} u'_1] - ([\sigma D^2 u'_1] \mathbf{h}_{2\tau}) \cdot \mathbf{n}, \end{aligned}$$

we get

$$(38) \quad \begin{aligned} [\sigma \partial_{\mathbf{n}}(u'_1)'_2] &= \operatorname{div}_{\tau} \left( h_{1,n} [\sigma \nabla_{\tau} u'_2] + h_{2,n} [\sigma \nabla_{\tau} u'_1] \right. \\ &\quad \left. + (h_{2,n} \partial_{\mathbf{n}} h_{1,n} - \nabla_{\tau} h_{2,n} \cdot \mathbf{h}_{1\tau}) [\sigma \nabla_{\tau} u] \right) \\ &\quad + [\sigma \Delta_{\tau} u] \nabla_{\tau} h_{1,n} \cdot \mathbf{h}_{2\tau} + H h_{2,n} [\sigma \partial_{\mathbf{n}} u'_1] - ([\sigma D^2 u'_1] \mathbf{h}_{2\tau}) \cdot \mathbf{n} \\ &\quad - \left( [\sigma \nabla_{\tau} u'_1] + \partial_{\mathbf{n}} h_{1,n} [\sigma \nabla_{\tau} u] \right) \cdot (D\mathbf{n} \mathbf{h}_{2\tau}) + (D^2 h_{1,n} \mathbf{h}_{2\tau}) \cdot [\sigma \nabla_{\tau} u] \\ &\quad - 2h_{2,n} \nabla_{\tau} h_{1,n} \cdot (D\mathbf{n} [\sigma \nabla_{\tau} u]) + [\sigma D^2 u] \mathbf{h}_{2\tau} \cdot \nabla_{\tau} h_{1,n} \\ &\quad \left. + h_{1,n} \left( \overline{[\sigma \Delta_{\tau} u]} - [\sigma \Delta_{\tau} u'_2] \right) \right). \end{aligned}$$

This formula remains hard to handle. To get a more convenient one, we decide to derive, tangentially to the direction  $\mathbf{h}_2$ , the boundary identity

$$[\sigma \partial_{\mathbf{n}} u'_1] = h_{1,n} [\sigma \Delta_{\tau} u] + \nabla_{\tau} h_{1,n} \cdot [\sigma \nabla_{\tau} u].$$

This leads to

$$\begin{aligned} &([\sigma D^2 u'_1] \mathbf{h}_{2\tau}) \cdot \mathbf{n} + (D\mathbf{n} \mathbf{h}_{2\tau}) \cdot [\sigma \nabla_{\tau} u'_1] \\ &= \nabla_{\tau} h_{1,n} \cdot \mathbf{h}_{2\tau} [\sigma \Delta_{\tau} u] + h_{1,n} \nabla_{\tau} [\sigma \Delta_{\tau} u] \cdot \mathbf{h}_{2\tau} \\ &\quad + (D^2 h_{1,n} \mathbf{h}_{2\tau}) \cdot [\sigma \nabla_{\tau} u] - \partial_{\mathbf{n}} h_{1,n} [\sigma \nabla_{\tau} u] \cdot (D\mathbf{n} \mathbf{h}_{2\tau}) + [\sigma D^2 u] \mathbf{h}_{2\tau} \cdot \nabla_{\tau} h_{1,n}. \end{aligned}$$

The preceding formula enables us to simplify the expression (38):

$$\begin{aligned}
 [\sigma \partial_{\mathbf{n}}(u'_1)'_2] &= \operatorname{div}_{\tau} \left( h_{1,n} [\sigma \nabla_{\tau} u'_2] + h_{2,n} [\sigma \nabla_{\tau} u'_1] + (h_{2,n} \partial_{\mathbf{n}} h_{1,n} - \nabla_{\tau} h_{2,n} \cdot \mathbf{h}_{1\tau}) [\sigma \nabla_{\tau} u] \right) \\
 &\quad + H h_{2,n} [\sigma \partial_{\mathbf{n}} u'_1] - 2 h_{2,n} \nabla_{\tau} h_{1,n} \cdot (D\mathbf{n} [\sigma \nabla_{\tau} u]) \\
 (39) \quad &\quad - h_{1,n} \nabla_{\tau} [\sigma \Delta_{\tau} u] \cdot \mathbf{h}_{2\tau} + h_{1,n} \left( \overline{[\sigma \Delta_{\tau} u]} - [\sigma \Delta_{\tau} u'_2] \right).
 \end{aligned}$$

From (24)

$$\begin{aligned}
 \overline{[\sigma \Delta_{\tau} u]} &= [\sigma \Delta_{\tau} \dot{u}] + \nabla_{\tau} \operatorname{div}_{\tau} (\mathbf{h}_{2\tau}) \cdot [\sigma \nabla_{\tau} u] + \nabla_{\tau} (H \mathbf{h}_{2,n}) \cdot [\sigma \nabla_{\tau} u] \\
 (40) \quad &\quad - \operatorname{div}_{\tau} \left( \left( (D\mathbf{h}_2 + (D\mathbf{h}_2)^T) [\sigma \nabla_{\tau} u] \right)_{\tau} \right),
 \end{aligned}$$

and we have

$$[\sigma \Delta_{\tau} \dot{u}] = [\sigma \Delta_{\tau} u'] + \Delta_{\tau} ([\sigma \nabla u] \cdot \mathbf{h}_2).$$

That gives

$$\begin{aligned}
 (41) \quad \left( \overline{[\sigma \Delta_{\tau} u]} - [\sigma \Delta_{\tau} u'_2] \right) &= \Delta_{\tau} ([\sigma \nabla u] \cdot \mathbf{h}_2) + \nabla_{\tau} \operatorname{div}_{\tau} (\mathbf{h}_{2\tau}) \cdot [\sigma \nabla_{\tau} u] \\
 &\quad + \nabla_{\tau} (H \mathbf{h}_{2,n}) \cdot [\sigma \nabla_{\tau} u] - \operatorname{div}_{\tau} \left( \left( (D\mathbf{h}_2 + (D\mathbf{h}_2)^T) [\sigma \nabla_{\tau} u] \right)_{\tau} \right).
 \end{aligned}$$

We break up  $\mathbf{h}_2$  into normal and tangential components and use the formula of divergence; then expression (39) becomes

$$\begin{aligned}
 &[\sigma \partial_{\mathbf{n}}(u'_1)'_2] \\
 &= \operatorname{div}_{\tau} \left( h_{1,n} [\sigma \nabla_{\tau} u'_2] + h_{2,n} [\sigma \nabla_{\tau} u'_1] + (h_{2,n} \partial_{\mathbf{n}} h_{1,n} - \nabla_{\tau} h_{2,n} \cdot \mathbf{h}_{1\tau}) [\sigma \nabla_{\tau} u] \right) \\
 &\quad + \operatorname{div}_{\tau} (h_{1,n} h_{2,n} (H I - 2 D\mathbf{n}) \cdot [\sigma \nabla_{\tau} u]) - h_{1,n} (\nabla_{\tau} [\sigma \Delta_{\tau} u] \cdot \mathbf{h}_{2\tau} - \Delta_{\tau} [\sigma \nabla_{\tau} u] \cdot \mathbf{h}_{2\tau}) \\
 &\quad + h_{1,n} \left( \nabla_{\tau} \operatorname{div}_{\tau} (\mathbf{h}_{2\tau}) \cdot [\sigma \nabla_{\tau} u] - \operatorname{div}_{\tau} \left( \left( (D\mathbf{h}_{2\tau} + (D\mathbf{h}_{2\tau})^T) [\sigma \nabla_{\tau} u] \right)_{\tau} \right) \right).
 \end{aligned}$$

LEMMA 4. *We have*

$$\begin{aligned}
 &-\nabla_{\tau} [\sigma \Delta_{\tau} u] \cdot \mathbf{h}_{2\tau} + \Delta_{\tau} [\sigma \nabla_{\tau} u] \cdot \mathbf{h}_{2\tau} \\
 &+ \nabla_{\tau} \operatorname{div}_{\tau} (\mathbf{h}_{2\tau}) \cdot [\sigma \nabla_{\tau} u] - \operatorname{div}_{\tau} \left( \left( (D\mathbf{h}_{2\tau} + (D\mathbf{h}_{2\tau})^T) [\sigma \nabla_{\tau} u] \right)_{\tau} \right) = 0.
 \end{aligned}$$

*Proof.* By using the relation between the material and shape derivatives, we obtain

$$\overline{[\sigma \Delta_{\tau} u]} = [\sigma \Delta_{\tau} u'] + \nabla ([\sigma \Delta_{\tau} u]) \cdot \mathbf{h}_2 \quad \text{and} \quad [\sigma \Delta_{\tau} \dot{u}] = [\sigma \Delta_{\tau} u'] + \Delta_{\tau} ([\sigma \nabla u] \cdot \mathbf{h}_2).$$

Let us inject these relations in (40) and while applying for the direction  $\mathbf{h}_{2\tau}$ , we obtain

$$\begin{aligned} \Delta_\tau([\sigma \nabla_\tau u] \cdot \mathbf{h}_{2\tau}) + \nabla_\tau \operatorname{div}_\tau (\mathbf{h}_{2\tau}) \cdot [\sigma \nabla_\tau u] \\ = \nabla_\tau [\sigma \Delta_\tau u] \cdot \mathbf{h}_{2\tau} + \operatorname{div}_\tau \left( \left( (D\mathbf{h}_{2\tau} + (D\mathbf{h}_{2\tau})^T) [\sigma \nabla_\tau u] \right)_\tau \right). \end{aligned}$$

This completes the proof.  $\square$

According to Lemma 4, we obtain

$$\begin{aligned} [\sigma \partial_{\mathbf{n}}(u'_1)'_2] = \operatorname{div}_\tau \left( h_{1,n} [\sigma \nabla_\tau u'_2] + h_{2,n} [\sigma \nabla_\tau u'_1] + (h_{2,n} \partial_{\mathbf{n}} h_{1,n} - \nabla_\tau h_{2,n} \cdot \mathbf{h}_{1\tau}) [\sigma \nabla_\tau u] \right) \\ + \operatorname{div}_\tau (h_{1,n} h_{2,n} (HI - 2D\mathbf{n}) \cdot [\sigma \nabla_\tau u]). \end{aligned}$$

As a conclusion, we use the relation of second derivative

$$[\sigma \partial_{\mathbf{n}} u''_{1,2}] = [\sigma \partial_{\mathbf{n}}(u'_1)'_2] - [\sigma \partial_{\mathbf{n}} u'_{D\mathbf{h}_1 \mathbf{h}_2}] = [\sigma \partial_{\mathbf{n}}(u'_1)'_2] - \operatorname{div}_\tau (D\mathbf{h}_1 \mathbf{h}_2 \cdot \mathbf{n} [\sigma \nabla_\tau u]).$$

Let us split the field  $\mathbf{h}_2$  in two parts:  $D\mathbf{h}_1 \mathbf{h}_2 \cdot \mathbf{n} = h_{2,n} \mathbf{n} \cdot D\mathbf{h}_1 \mathbf{n} + D\mathbf{h}_1 \mathbf{h}_{2\tau} \cdot \mathbf{n}$ . In the spirit of (73), we obtain

$$(42) \quad D\mathbf{h}_1 \mathbf{h}_{2\tau} \cdot \mathbf{n} = \nabla_\tau h_{1,n} \cdot \mathbf{h}_{2\tau} - \mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{h}_{2\tau}.$$

Thanks to (72), the jump  $[\sigma \partial_{\mathbf{n}} u'_{D\mathbf{h}_1 \mathbf{h}_2}]$  can then be written in the form

$$[\sigma \partial_{\mathbf{n}} u'_{D\mathbf{h}_1 \mathbf{h}_2}] = \operatorname{div}_\tau ((h_{2,n} \mathbf{n} \cdot \nabla_\tau h_{1,n} + \nabla_\tau h_{1,n} \cdot \mathbf{h}_{2\tau} - \mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{h}_{2\tau}) [\sigma \nabla_\tau u]).$$

Gathering all the terms, simplifications occur and we obtain the desired result:

$$\begin{aligned} [\sigma \partial_{\mathbf{n}} u''_{1,2}] = \operatorname{div}_\tau \left( h_{2,n} [\sigma \nabla_\tau u'_1] + h_{1,n} [\sigma \nabla_\tau u'_2] \right) \\ - \operatorname{div}_\tau ((\mathbf{h}_{1\tau} \cdot \nabla_\tau h_{2,n} + \nabla_\tau h_{1,n} \cdot \mathbf{h}_{2\tau}) [\sigma \nabla_\tau u]) \\ - \operatorname{div}_\tau (h_{2,n} h_{1,n} (2D\mathbf{n} - HI) [\sigma \nabla_\tau u]) + \operatorname{div}_\tau (\mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{h}_{2\tau}) [\sigma \nabla_\tau u]. \end{aligned}$$

To get the jumps of the potential, we use (29) and (68):

$$\begin{aligned} [u''_{1,2}] = [(u'_1)'_2] - [u'_{D\mathbf{h}_1 \mathbf{h}_2}] = -\mathbf{h}_1 \cdot [\nabla u'_2] - \mathbf{h}_2 \cdot [\nabla u_1] - [u'_{D\mathbf{h}_1 \mathbf{h}_2}] \\ = -h_{2,n} [\partial_{\mathbf{n}} u'_1] - h_{1,n} [\partial_{\mathbf{n}} u'_2] - \mathbf{h}_{2\tau} \cdot [\nabla_\tau u'_1] - \mathbf{h}_{1\tau} \cdot [\nabla_\tau u'_2] \\ - h_{2,n} \mathbf{n} \cdot [\nabla(\mathbf{h}_1 \cdot \nabla u)] - h_{1,n} \mathbf{n} \cdot [\nabla(\mathbf{h}_2 \cdot \nabla u)] - [u'_{D\mathbf{h}_1 \mathbf{h}_2}]. \end{aligned}$$

Thanks to the jump of the potential for the first order shape derivative given in (6), we obtain

$$\mathbf{h}_{2\tau} \cdot [\nabla_\tau u'_1] = -\mathbf{h}_{2\tau} \cdot [\nabla(\mathbf{h}_1 \cdot \nabla u)] \quad \text{and} \quad \mathbf{h}_{1\tau} \cdot [\nabla_\tau u'_2] = -\mathbf{h}_{1\tau} \cdot [\nabla(\mathbf{h}_2 \cdot \nabla u)]$$

and then

$$\begin{aligned} (43) \quad [u''_{1,2}] = -h_{2,n} [\partial_{\mathbf{n}} u'_1] - h_{1,n} [\partial_{\mathbf{n}} u'_2] - h_{2,n} \mathbf{n} \cdot [\nabla(\mathbf{h}_1 \cdot \nabla u)] \\ + \mathbf{h}_{1\tau} \cdot [\nabla(\mathbf{h}_2 \cdot \nabla u)] - [u'_{D\mathbf{h}_1 \mathbf{h}_2}]. \end{aligned}$$

Computing the other jumps that appeared in the former expression, we get

$$\begin{aligned}
 [\nabla(\mathbf{h}_2 \cdot \nabla u)] &= (D\mathbf{h}_2)^T [\nabla u] + [D^2 u] \mathbf{h}_2, \\
 \mathbf{h}_{1\tau} \cdot [\nabla(\mathbf{h}_2 \cdot \nabla u)] &= \mathbf{n} \cdot D\mathbf{h}_2 \mathbf{h}_{1\tau} [\partial_{\mathbf{n}} u] + h_{2,n} \mathbf{h}_{1\tau} \cdot [D^2 u] \mathbf{n} + \mathbf{h}_{1\tau} \cdot [D^2 u] \mathbf{h}_{2\tau}, \\
 h_{2,n} \mathbf{n} \cdot [\nabla(\mathbf{h}_1 \cdot \nabla u)] &= h_{2,n} [\partial_{\mathbf{n}} u] \mathbf{n} \cdot D\mathbf{h}_1 \mathbf{n} + h_{2,n} h_{1,n} \mathbf{n} \cdot [D^2 u] \mathbf{n} + h_{2,n} \mathbf{n} \cdot [D^2 u] \mathbf{h}_{1\tau}, \\
 [u'_{D\mathbf{h}_1 \mathbf{h}_2}] &= -D\mathbf{h}_1 \mathbf{h}_2 \cdot \mathbf{n} [\partial_{\mathbf{n}} u] = - (h_{2,n} \mathbf{n} \cdot D\mathbf{h}_1 \mathbf{n} + \mathbf{n} \cdot D\mathbf{h}_1 \mathbf{h}_{2\tau}) [\partial_{\mathbf{n}} u].
 \end{aligned}$$

With the help of formula (42), we obtain

$$\begin{aligned}
 &-h_{2,n} \mathbf{n} \cdot [\nabla(\mathbf{h}_1 \cdot \nabla u)] + \mathbf{h}_{1\tau} \cdot [\nabla(\mathbf{h}_2 \cdot \nabla u)] - [u'_{D\mathbf{h}_1 \mathbf{h}_2}] \\
 &= (\nabla_{\tau} h_{1,n} \cdot \mathbf{h}_{2\tau} + \nabla_{\tau} h_{2,n} \cdot \mathbf{h}_{1\tau}) [\partial_{\mathbf{n}} u] \\
 &\quad - 2\mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{h}_{2\tau} [\partial_{\mathbf{n}} u] + \mathbf{h}_{1\tau} \cdot [D^2 u] \mathbf{h}_{2\tau} - h_{2,n} h_{1,n} \mathbf{n} \cdot [D^2 u] \mathbf{n}, \\
 \mathbf{n} \cdot [D^2 u] \mathbf{n} &= -[\Delta_{\tau} u] - H [\partial_{\mathbf{n}} u] = -H [\partial_{\mathbf{n}} u], \\
 \mathbf{h}_{1\tau} \cdot [D^2 u] \mathbf{h}_{2\tau} &= \mathbf{h}_{1\tau} \cdot D([\nabla u]) \mathbf{h}_{2\tau} = \mathbf{h}_{1\tau} \cdot D([\partial_{\mathbf{n}} u] \mathbf{n}) \mathbf{h}_{2\tau} = [\partial_{\mathbf{n}} u] \mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{h}_{2\tau}.
 \end{aligned}$$

Finally, we gather the results of these computations to write

$$\begin{aligned}
 (44) \quad [u''_{1,2}] &= - \left( h_{2,n} [\partial_{\mathbf{n}} u'_1] + h_{1,n} [\partial_{\mathbf{n}} u'_2] \right) + (\nabla_{\tau} h_{1,n} \cdot \mathbf{h}_{2\tau} + \nabla_{\tau} h_{2,n} \cdot \mathbf{h}_{1\tau}) [\partial_{\mathbf{n}} u] \\
 &\quad + (h_{2,n} h_{1,n} H - \mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{h}_{2\tau}) [\partial_{\mathbf{n}} u].
 \end{aligned}$$

**Case of Neumann boundary conditions.** Since the admissible deformation fields have a support with no intersection points with the outer boundary, it is a straightforward application of the preceding computations to show that the  $u_n$  solution to (1), (4) is twice differentiable with respect to the shape. Furthermore, its second order derivative  $u''_n$  belongs to  $H^1(\Omega \setminus \bar{\omega}) \cup H^1(\omega)$  and solves

$$(45) \quad \left\{ \begin{array}{l} \Delta u''_n = 0 \text{ in } \omega \setminus \bar{\omega} \text{ and in } \omega, \\ [u''_n] = (h_{1,n} h_{2,n} H - \mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{h}_{2\tau}) [\partial_{\mathbf{n}} u_n] - (h_{1,n} [\partial_{\mathbf{n}}(u_n)'_2] + h_{2,n} [\partial_{\mathbf{n}}(u_n)'_1]) \\ \quad + (\mathbf{h}_{1\tau} \cdot \nabla h_{2,n} + \mathbf{h}_{2\tau} \cdot \nabla h_{1,n}) [\partial_{\mathbf{n}} u_n] \text{ on } \partial\omega, \\ [\sigma \partial_n u''_n] = \operatorname{div}_{\tau} \left( h_{2,n} [\sigma \nabla_{\tau}(u_n)'_1] + h_{1,n} [\sigma \nabla_{\tau}(u_n)'_2] + \mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{h}_{2\tau} [\sigma \nabla_{\tau} u_n] \right) \\ \quad - \operatorname{div}_{\tau} ((\mathbf{h}_{1\tau} \cdot \nabla_{\tau} h_{2,n} + \nabla_{\tau} h_{1,n} \cdot \mathbf{h}_{2\tau} \\ \quad + h_{2,n} h_{1,n} (2D\mathbf{n} - HI)) [\sigma \nabla_{\tau} u_n]) \text{ on } \partial\omega, \\ \partial_n u''_n = 0 \text{ on } \partial\Omega, \end{array} \right.$$

where we use the notation of Theorem 2.

### 5. Second order derivatives for the criterion.

**5.1. Proof of Theorem 4.** The differentiability of the objective is a direct application of Theorem 2. The computation we make here is based on the relation

$$(46) \quad D^2 J_{KV}(\omega)(\mathbf{h}_1, \mathbf{h}_2) = D(DJ_{KV}(\omega)\mathbf{h}_1)\mathbf{h}_2 - DJ_{KV}(\omega)D\mathbf{h}_1\mathbf{h}_2.$$

To obtain (10), we compute in the first step the shape gradient in the direction  $\mathbf{h}_1$ . Then, in the second step, we differentiate the obtained expression in the direction of  $\mathbf{h}_2$ . In what follows, we adopt the notation  $v = u_d - u_n$  to obtain concise expressions.

$$\begin{aligned} DJ_{KV}(\omega)\mathbf{h}_1 &= \sigma_1 \int_{\Omega \setminus \bar{\omega}} \operatorname{div}(|\nabla v|^2 \mathbf{h}_1) + 2\nabla v \cdot \nabla v'_1 + \sigma_2 \int_{\omega} \operatorname{div}(|\nabla v|^2 \mathbf{h}_1) + 2\nabla v \cdot \nabla v'_1 \\ &= \sigma_1(A_1 + 2B_1) + \sigma_2(A_2 + 2B_2), \end{aligned}$$

where

$$\begin{aligned} A_1 &= \int_{\Omega \setminus \bar{\omega}} \operatorname{div}(|\nabla v|^2 \mathbf{h}_1), & B_1 &= \int_{\Omega \setminus \bar{\omega}} \nabla v \cdot \nabla v'_1, \\ A_2 &= \int_{\omega} \operatorname{div}(|\nabla v|^2 \mathbf{h}_1), & B_2 &= \int_{\omega} \nabla v \cdot \nabla v'_1. \end{aligned}$$

Now, we use the classical formulae to differentiate a domain integral:

$$\begin{aligned} DA_1(\omega)\mathbf{h}_2 &= \int_{\Omega \setminus \bar{\omega}} \operatorname{div} \left( \operatorname{div}(|\nabla v|^2 \mathbf{h}_1) \mathbf{h}_2 \right) + 2 \operatorname{div}(\nabla v \cdot \nabla v'_1 \mathbf{h}_2) \\ &= - \int_{\partial\omega} \operatorname{div}(|\nabla v|^2 \mathbf{h}_1) h_{2,n} + 2\nabla v^+ \cdot \nabla (v'_1)^+ h_{1,n}, \\ DA_2(\omega)\mathbf{h}_2 &= \int_{\partial\omega} \operatorname{div}(|\nabla v|^2 \mathbf{h}_1) h_{2,n} + 2\nabla v^- \cdot \nabla (v'_1)^- h_{1,n}. \end{aligned}$$

The terms  $DB_i$ ,  $i = 1, 2$ , require more precision. First, we write

$$\begin{aligned} DB_1(\omega)\mathbf{h}_2 &= \int_{\Omega \setminus \bar{\omega}} \operatorname{div}(\nabla v \cdot \nabla v'_1 \mathbf{h}_2) + \nabla v'_1 \cdot \nabla v'_2 + \nabla v \cdot \nabla (v'_1)'_2 \\ &= - \int_{\partial\omega} \nabla v^+ \cdot \nabla (v'_1)^+ h_{2,n} + \partial_{\mathbf{n}} v^+ ((v'_1)^+)'_2 \\ &\quad + \frac{1}{2} \left( \partial_{\mathbf{n}} (v'_1)^+ (v'_2)^+ + \partial_{\mathbf{n}} (v'_2)^+ (v'_1)^+ \right) \\ &\quad - \int_{\partial\Omega} \partial_{\mathbf{n}} v ((u_n)'_1)'_2 + \frac{1}{2} \left( \partial_{\mathbf{n}} (u_d)'_1 (u_n)'_2 + \partial_{\mathbf{n}} (u_d)'_2 (u_n)'_1 \right). \end{aligned}$$

Note that we used the Green formula twice to keep the symmetry in  $\mathbf{h}_1$  and  $\mathbf{h}_2$ . We also use the fact that the derivatives  $(u_d)'_i$  are harmonic in  $\Omega \setminus \bar{\omega}$  to transform the boundary integral on the exterior boundary into an integral on the moving boundary. We obtain

$$\begin{aligned} DB_1(\omega)\mathbf{h}_2 &= - \int_{\partial\omega} \nabla v^+ \cdot \nabla (v'_1)^+ \mathbf{h}_{2,n} + \partial_{\mathbf{n}} v^+ (((u_d)'_1)'_2)^+ - v \partial_{\mathbf{n}} (((u_n)'_1)'_2)^+ \\ &\quad - \int_{\partial\omega} \frac{1}{2} \left( \partial_{\mathbf{n}} (v'_1)^+ ((u_d)'_2)^+ + \partial_{\mathbf{n}} (v'_2)^+ ((u_d)'_1)^+ \right. \\ &\quad \left. - \partial_{\mathbf{n}} ((u_n)'_1)^+ (v'_2)^+ - \partial_{\mathbf{n}} ((u_n)'_2)^+ (v'_1)^+ \right). \end{aligned}$$

By the same methods, we get

$$\begin{aligned} DB_2(\omega)\mathbf{h}_2 &= \int_{\partial\omega} \nabla v^- \cdot \nabla (v'_1)^- h_{2,n} + \partial_{\mathbf{n}} v^- ((v'_1)'_2)^- \\ &\quad + \frac{1}{2} \left( \partial_{\mathbf{n}} (v'_1)^- (v'_2)^- + \partial_{\mathbf{n}} (v'_2)^- (v'_1)^- \right). \end{aligned}$$

We regroup the different terms, and after some straightforward computations, we obtain

$$\begin{aligned} D(DJ_{KV}(\omega)\mathbf{h}_1)(\omega)\mathbf{h}_2 &= - \int_{\partial\omega} \operatorname{div} \left( \left[ \sigma |\nabla v|^2 \mathbf{h}_1 \right] \right) + 2 \left[ \sigma \nabla v \cdot \left( h_{1,n} \nabla v'_2 + h_{2,n} \nabla v'_1 \right) \right] \\ &\quad - \int_{\partial\omega} \left[ \sigma \left( (u_d)'_2 \partial_{\mathbf{n}} v'_1 + (u_d)'_1 \partial_{\mathbf{n}} v'_2 - \partial_{\mathbf{n}} (u_n)'_2 v'_1 - \partial_{\mathbf{n}} (u_n)'_1 v'_2 \right) \right] \\ &\quad + 2 \int_{\partial\omega} v \left[ \sigma \partial_{\mathbf{n}} ((u_n)'_1)'_2 \right] - \sigma_1 \partial_{\mathbf{n}} v^+ \left[ ((u_d)'_1)'_2 \right]. \end{aligned}$$

In order to compute  $D^2 J_{KV}(\omega)(\mathbf{h}_1, \mathbf{h}_2)$ , the first order derivative of the Kohn–Vogelius objective is needed. It can be written as follows:

$$DJ_{KV}(\omega)\mathbf{h} = - \int_{\partial\omega} \left[ \sigma |\nabla v|^2 \right] h_n + 2 \int_{\partial\omega} v \left[ \sigma \partial_{\mathbf{n}} (u_n)' \right] - \sigma_1 \partial_{\mathbf{n}} v^+ \left[ (u_d)' \right].$$

Gathering (46) with the jump relations for the second order derivatives, we write the second derivative of the Kohn–Vogelius criterion as

$$\begin{aligned} D^2 J_{KV}(\omega)(\mathbf{h}_1, \mathbf{h}_2) &= - \int_{\partial\omega} \operatorname{div} \left( \left[ \sigma |\nabla v|^2 \mathbf{h}_1 \right] \right) - \left[ \sigma |\nabla v|^2 \right] (D\mathbf{h}_1 \mathbf{h}_2) \cdot \mathbf{n} \\ &\quad - \int_{\partial\omega} \left[ \sigma \left( (u_d)'_2 \partial_{\mathbf{n}} v'_1 + (u_d)'_1 \partial_{\mathbf{n}} v'_2 - \partial_{\mathbf{n}} (u_n)'_2 v'_1 - \partial_{\mathbf{n}} (u_n)'_1 v'_2 \right) \right] \\ &\quad + 2 \int_{\partial\omega} \left[ \sigma \nabla v \cdot \left( h_{1,n} \nabla v'_2 + h_{2,n} \nabla v'_1 \right) \right] + v \left[ \sigma \partial_{\mathbf{n}} (u_n)''_{1,2} \right] - \sigma_1 \partial_{\mathbf{n}} v^+ \left[ (u_d)''_{1,2} \right]. \end{aligned}$$

Let us give a simplified version for the first term. We decompose the field  $\mathbf{h}_2$  into normal vector and tangential parts and use (42). After some elementary computations, we obtain

$$\begin{aligned} &- \int_{\partial\omega} \operatorname{div} \left( \left[ \sigma |\nabla v|^2 \mathbf{h}_1 \right] \right) - \left[ \sigma |\nabla v|^2 \right] (D\mathbf{h}_1 \mathbf{h}_2) \cdot \mathbf{n} \\ &= \int_{\partial\omega} \left[ \sigma |\nabla v|^2 \right] (\mathbf{h}_{1\tau} \cdot \nabla_{\tau} h_{2,n} + \mathbf{h}_{2\tau} \cdot \nabla_{\tau} h_{1,n} - \mathbf{h}_{2\tau} \cdot D\mathbf{n} \mathbf{h}_{1\tau}) \\ &\quad - \int_{\partial\omega} \partial_{\mathbf{n}} \left( \left[ \sigma |\nabla v|^2 \right] \right) h_{1,n} h_{2,n}. \end{aligned}$$

Finally, the second order derivative of the Kohn–Vogelius objective becomes

(47)

$$\begin{aligned} D^2 J_{KV}(\omega)(\mathbf{h}_1, \mathbf{h}_2) &= \int_{\partial\omega} [\sigma |\nabla v|^2] (\mathbf{h}_{1\tau} \cdot \nabla_\tau h_{2,n} + \mathbf{h}_{2\tau} \cdot \nabla_\tau h_{1,n} - \mathbf{h}_{2\tau} \cdot D\mathbf{n} \mathbf{h}_{1\tau}) \\ &\quad - \int_{\partial\omega} \partial_{\mathbf{n}} \left( [\sigma |\nabla v|^2] \right) h_{1,n} h_{2,n} + 2 \left[ \sigma \nabla v \cdot (h_{1,n} \nabla v'_2 + h_{2,n} \nabla v'_1) \right] \\ &\quad - \int_{\partial\omega} \left[ \sigma \left( (u_d)'_2 \partial_{\mathbf{n}} v'_1 + (u_d)'_1 \partial_{\mathbf{n}} v'_2 - \partial_{\mathbf{n}} (u_n)'_2 v'_1 - \partial_{\mathbf{n}} (u_n)'_1 v'_2 \right) \right] \\ &\quad + 2 \int_{\partial\omega} v \left[ \sigma \partial_{\mathbf{n}} (u_n)''_{1,2} \right] - \sigma_1 \partial_{\mathbf{n}} v^+ \left[ (u_d)''_{1,2} \right]. \end{aligned}$$

**5.2. Analysis of stability. Proof of Theorem 5.** Now, we specify the domain  $\omega$  that is assumed to be a critical shape for  $J_{KV}$ . Moreover, we assume that the additional condition  $u_d = u_n$  holds. To emphasize that we deal with such a special domain, we will denote it  $\omega^*$ . The assumptions mean that the measurements are compatible and that  $\omega^*$  is a global minimum of the criterion. From the necessary condition of order two at a minimum, the shape Hessian is positive at such a point.

Let us notice that only the normal component of  $\mathbf{h}$  appears. Let us also emphasize that there is no hope to get  $\mathbf{h} = 0$  from the structure theorem for the second order shape derivative (see [7]). The deformation field  $\mathbf{h}$  appears in  $D^2 J_{KV}(\omega^*)(\mathbf{h}, \mathbf{h})$  only through its normal component  $h_n$  since  $\omega^*$  is a critical point for  $J_{KV}$ . This remark explains why we consider in the statement of Theorem 5 the scalar Sobolev space corresponding to the normal components of the deformation field.

We now prove Theorem 5. From (47), we deduce

$$\begin{aligned} (48) \quad D^2 J_{KV}(\omega^*)[h, h] &= -2 \int_{\partial\omega^*} \left[ \sigma \left( u_d' \partial_{\mathbf{n}} v' - \partial_{\mathbf{n}} u_n' v' \right) \right] \\ &= 2 [\sigma] \int_{\partial\omega^*} \left( (u_d'^+ - u_n'^+) \operatorname{div}_\tau (h_n \nabla_\tau u_d) - \frac{\sigma_1}{\sigma_2} \partial_{\mathbf{n}} u_d^+ h_n \partial_{\mathbf{n}} (u_d' - u_n')^+ \right) \\ &= 2 [\sigma] \left( \left\langle u_d'^+ - u_n'^+, \operatorname{div}_\tau (h_n \nabla_\tau u_d) \right\rangle - \frac{\sigma_1}{\sigma_2} \left\langle \partial_{\mathbf{n}} u_d h_n, \partial_{\mathbf{n}} (u_d' - u_n')^+ \right\rangle \right), \end{aligned}$$

where  $\langle \cdot, \cdot \rangle$  denotes the duality between  $H^{1/2}(\partial\omega^*) \times H^{-1/2}(\partial\omega^*)$ . Let us introduce the operators

$$\begin{aligned} T_1 : H^{1/2}(\partial\omega^*) &\rightarrow H^{-1/2}(\partial\omega^*), & \mathbf{h} &\mapsto \operatorname{div}_\tau (h_n \nabla_\tau u_d), \\ M_1 : H^{1/2}(\partial\omega^*) &\rightarrow H^{1/2}(\partial\omega^*), & \mathbf{h} &\mapsto u_d'^+ - u_n'^+, \\ T_2 : H^{1/2}(\partial\omega^*) &\rightarrow H^{1/2}(\partial\omega^*), & \mathbf{h} &\mapsto h_n \partial_{\mathbf{n}} u_d^+, \\ M_2 : H^{1/2}(\partial\omega^*) &\rightarrow H^{-1/2}(\partial\omega^*), & \mathbf{h} &\mapsto \partial_{\mathbf{n}} (u_d'^+ - u_n'^+). \end{aligned}$$

The Hessian can then be written in the form

$$D^2 J_{KV}(\omega^*)(\mathbf{h}, \mathbf{h}) = 2 [\sigma] \left( \left\langle M_1(\mathbf{h}), T_1(\mathbf{h}) \right\rangle - \frac{\sigma_1}{\sigma_2} \left\langle T_2(\mathbf{h}), M_2(\mathbf{h}) \right\rangle \right).$$

From the classical results of Maz'ya and Shaposhnikova on multipliers [15, 24], we get easily that  $T_1$  and  $T_2$  are continuous operators. In fact, the compactness of the Hessian is a consequence of the fact that both operators  $M_1$  and  $M_2$  are compact. We use a regularity argument and remark that  $M_1$  is the composition of the operators

$$\begin{aligned} R_1 : H^{1/2}(\partial\omega^*) &\rightarrow H_\diamond^{1/2}(\partial\Omega) & \text{and} & & R_2 : H_\diamond^{1/2}(\partial\Omega) &\rightarrow H^{1/2}(\partial\omega^*) \\ \mathbf{h} &\mapsto -u'_n & & & \phi &\mapsto \psi, \end{aligned}$$

where  $\psi$  is the trace on  $\partial\omega^*$  of the  $\Psi$  solution of

$$(49) \quad \begin{cases} -\Delta\Psi = 0 \text{ in } \Omega \setminus \overline{\omega^*} \text{ and in } \omega^*, \\ [\Psi] = 0 \text{ on } \partial\omega^*, \\ [\sigma\partial_{\mathbf{n}}\Psi] = 0 \text{ on } \partial\omega^*, \\ \Psi = \phi \text{ on } \partial\Omega. \end{cases}$$

While  $R_1$  is a continuous operator, we prove that  $R_2$  is compact. Let us express  $u|_{\partial\omega^*} = \psi$ . We use the integral representation formula. The definition of the layer operators and all the justifications are postponed until section 6.1 for the lightness of the presentation. If  $u$  solves the boundary value problem (49), then it also solves the following system of integral equations:

$$\begin{bmatrix} \frac{1}{2}I + \mu K_{\omega^*} & \frac{\sigma_1}{\sigma_2 + \sigma_1} S_{\partial\Omega\partial\omega^*} \\ \mu K_{\partial\omega^*\partial\Omega} & \frac{\sigma_1}{\sigma_2 + \sigma_1} S_{\Omega} \end{bmatrix} \begin{bmatrix} (u)|_{\partial\omega^*} \\ (\partial_{\mathbf{n}}u)|_{\partial\Omega} \end{bmatrix} = \frac{\sigma_1}{\sigma_1 + \sigma_2} \begin{bmatrix} K_{\partial\Omega\partial\omega^*}\phi \\ \left(-\frac{1}{2} + K_{\Omega}\right)\phi \end{bmatrix}.$$

The matrix operator arising in this equation appears also in (55). It has a continuous inverse thanks to Theorem 7, proved in section 6.1. Let us express  $u|_{\partial\omega^*} = \psi$ :

$$\begin{aligned} (50) \quad & \left[ \left( \frac{1}{2}I + \mu K_{\omega^*} \right) - \mu S_{\partial\Omega\partial\omega^*} S_{\Omega}^{-1} K_{\partial\omega^*\partial\Omega} \right] \psi \\ &= \frac{\sigma_1}{\sigma_1 + \sigma_2} \left[ K_{\partial\Omega\partial\omega^*} - S_{\partial\Omega\partial\omega^*} S_{\Omega}^{-1} \left( \frac{1}{2}I - K_{\Omega} \right) \right] \phi. \end{aligned}$$

Since the operators  $K_{\partial\Omega\partial\omega^*}$  and  $S_{\partial\Omega\partial\omega^*}$  are compact, the operator  $R_2$  is compact, and hence  $M_1$  is compact. The proof of compactness of  $M_2$  is similar. Let us mention that a similar strategy of proof can be found in [6].

The natural question is then as to how this optimization problem is ill-posed. This question is related directly to the rate at which the singular values of the Hessian operator are decreasing. Equation (50) shows that this rate is that of the operators  $K_{\partial\Omega\partial\omega^*}$ , and  $S_{\partial\Omega\partial\omega^*}$ . Now, since for every  $u \in H^{1/2}(\partial\Omega)$ , the functions  $K_{\partial\Omega\partial\omega^*}u$  and  $S_{\partial\Omega\partial\omega^*}u$  are harmonic outside of  $\partial\Omega$  and therefore in  $\Omega$ , their restrictions on  $\partial\omega^*$  are as smooth as  $\partial\omega^*$ . We conclude that if  $\partial\omega^*$  is  $\mathcal{C}^\infty$ , then the restriction belongs to each  $H^s(\partial\omega^*)$  for  $s > 1/2$ , and that if  $\lambda_n$  denotes the  $n$ th eigenvalue of  $D^2 J_{KV}(\omega^*)$ , then  $\lambda_n = o(n^{-s})$  for all  $s > 0$ .

## 6. Appendices.

**6.1. An auxiliary boundary value problem.** We have to justify rigorously that the right-hand sides of (6)–(8) make sense. They involve tangential derivatives of  $u_n$  and  $u_d$  along the interface  $\partial\omega$  up to order three. The existence of these derivatives is not clear a priori since the gradient of the solution has a discontinuity along this interface. Our first aim is to make the tangential regularity precise along the interface  $\partial\omega$  of the solution  $u$  of (1) with either Dirichlet or Neumann boundary conditions. Our strategy is to find an integral equation solved by this trace and to use known properties on the layers operators to obtain regularity on the solution of the integral equation.

We should have access to the trace of  $u$  on the interface  $\partial\omega$ . To that end, we introduce for any  $\alpha \in H^{1/2}(\partial\omega)$  and  $\beta \in H^{-1/2}(\partial\omega)$  the following boundary value problems:

(51)

$$(D) \left\{ \begin{array}{l} \Delta v = 0 \text{ in } \Omega \setminus \bar{\omega} \text{ and in } \omega, \\ [v] = \alpha \text{ on } \partial\omega, \\ [\sigma \partial_n v] = \beta \text{ on } \partial\omega, \\ v = f_1 \text{ on } \partial\Omega, \end{array} \right. \quad (N) \left\{ \begin{array}{l} \Delta v = 0 \text{ in } \Omega \setminus \bar{\omega} \text{ and in } \omega, \\ [v] = \alpha \text{ on } \partial\omega, \\ [\sigma \partial_n v] = \beta \text{ on } \partial\omega, \\ \partial_n v = g_1 \text{ on } \partial\Omega, \end{array} \right.$$

where  $(f_1, g_1) \in H^{1/2}(\partial\Omega) \times H^{-1/2}(\partial\Omega)$ . Note that for  $\alpha = 0$ ,  $\beta = 0$ , and  $(f_1, g_1) = (f, g)$ , then  $(u_d)$  and  $u_n$  solve, respectively, (D) and (N); furthermore the choice of

$$(52) \quad \alpha = \frac{[\sigma]}{\sigma_2} h_n \partial_n u^+ \quad \text{and} \quad \beta = [\sigma] \operatorname{div}_\tau (h_n \nabla_\tau u)$$

leads to (6) and (7) when we take  $(f_1, g_1) = (0, 0)$ .

*Existence of solutions to (D) and (N).* To study these problems, we use the integral representation in terms of layer potentials.

In the first step, we recall some definitions. The fundamental solution to the Laplace equation  $\Gamma$  is defined as

$$\Gamma(x, y) = -\frac{1}{4\pi} \frac{1}{|x - y|} \quad \text{if } n = 3.$$

The integral equations applying to the direct problem will be obtained from a study of the classical single- and double-layer potentials. We begin to introduce the following operators:

$$\begin{aligned} S_{\partial\Omega\partial\omega} : u &\mapsto S_{\partial\Omega\partial\omega}u(x) := \int_{\partial\Omega} \Gamma(x, y)u(y) \, d\sigma(y), \quad x \in \partial\omega; \\ S_{\partial\omega\partial\Omega} : u &\mapsto S_{\partial\omega\partial\Omega}u(x) := \int_{\partial\omega} \Gamma(x, y)u(y) \, d\sigma(y), \quad x \in \partial\Omega; \\ K_{\partial\Omega\partial\omega} : u &\mapsto K_{\partial\Omega\partial\omega}u(x) := \int_{\partial\Omega} \partial_n \Gamma(x, y)u(y) \, d\sigma(y), \quad x \in \partial\omega; \\ K_{\partial\omega\partial\Omega} : u &\mapsto K_{\partial\omega\partial\Omega}u(x) := \int_{\partial\omega} \partial_n \Gamma(x, y)u(y) \, d\sigma(y), \quad x \in \partial\Omega. \end{aligned}$$

Note that all these operators have a smooth kernel since the boundaries  $\partial\omega$  and  $\partial\Omega$  are assumed to have no common point. We also denote

$$\begin{aligned} S_\Omega : u &\mapsto S_\Omega u(x) := \int_{\partial\Omega} \Gamma(x, y) u(y) \, d\sigma(y), \quad x \in \partial\Omega; \\ K_\Omega : u &\mapsto K_\Omega u(x) := \int_{\partial\Omega} \partial_{\mathbf{n}} \Gamma(x, y) u(y) \, d\sigma(y), \quad x \in \partial\Omega; \\ S_\omega : u &\mapsto S_\omega u(x) := \int_{\partial\omega} \Gamma(x, y) u(y) \, d\sigma(y), \quad x \in \partial\omega; \\ K_\omega : u &\mapsto K_\omega u(x) := \int_{\partial\omega} \partial_{\mathbf{n}} \Gamma(x, y) u(y) \, d\sigma(y), \quad x \in \partial\omega. \end{aligned}$$

We obtain some systems of integral equations to compute the state function and their shape derivatives. Since  $v$  is harmonic in  $\Omega \setminus \bar{\omega}$  and for all  $x \in \partial\Omega \cup \partial\omega$ , it has the classical boundary representation:

$$(53) \quad \begin{aligned} \frac{1}{2}v(x) &= \int_{\partial\Omega} \partial_{\mathbf{n}} \Gamma(x, y) v(y) - \int_{\partial\omega} \partial_{\mathbf{n}} \Gamma(x, y) v(y) \\ &\quad - \int_{\partial\Omega} \Gamma(x, y) \partial_{\mathbf{n}} v(y) + \int_{\partial\omega} \Gamma(x, y) \partial_{\mathbf{n}} v(y). \end{aligned}$$

Similarly since  $v$  is harmonic in  $\omega$ , for all  $x \in \partial\omega$  we can write

$$(54) \quad \frac{1}{2}v(x) = \int_{\partial\omega} \partial_{\mathbf{n}} \Gamma(x, y) v(y) - \int_{\partial\omega} \Gamma(x, y) \partial_{\mathbf{n}} v(y).$$

Let us denote by  $v_d$  the solution of the boundary value problem (D) in (51). Let us show how to compute their restrictions and also their normal vector derivatives on the boundaries. Incorporating the jump conditions, a straightforward computation leads to the boundary integral equations

$$(55) \quad \begin{aligned} &\begin{bmatrix} \frac{1}{2}I + \mu K_\omega & \frac{\sigma_1}{\sigma_2 + \sigma_1} S_{\partial\Omega\partial\omega} \\ \mu K_{\partial\omega\partial\Omega} & \frac{\sigma_1}{\sigma_2 + \sigma_1} S_\Omega \end{bmatrix} \begin{bmatrix} (v_d^+)_{|\partial\omega} \\ (\partial_{\mathbf{n}} v_d)_{|\partial\Omega} \end{bmatrix} \\ &= \frac{1}{\sigma_1 + \sigma_2} \begin{bmatrix} \sigma_2 \left( \frac{1}{2}I - K_\omega \right) & S_\omega \\ -\sigma_2 K_{\partial\omega\partial\Omega} & S_{\partial\omega\partial\Omega} \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix} + \frac{\sigma_1}{\sigma_1 + \sigma_2} \begin{bmatrix} K_{\partial\Omega\partial\omega} f_1 \\ \left( -\frac{1}{2} + K_\Omega \right) f_1 \end{bmatrix}, \end{aligned}$$

where  $\mu = [\sigma]/(\sigma_1 + \sigma_2)$ . Thanks to (54), the quantity  $(\partial_{\mathbf{n}} v_d)^+$  is then given by

$$S_\omega (\partial_{\mathbf{n}} v_d)_{|\partial\omega}^+ = \frac{\sigma_2}{\sigma_1} \left( -\frac{1}{2}I + K_\omega \right) \left( v_d^+(x)_{|\partial\omega} - \alpha \right) + \frac{1}{\sigma_1} S_\omega \beta.$$

Concerning  $v_n$ , the solution of the Neumann problem (N) in (51), the same kind of

computation gives

$$(56) \quad \begin{bmatrix} \frac{1}{2}I + \mu K_\omega & -\frac{\sigma_1}{\sigma_2 + \sigma_1} K_{\partial\Omega\partial\omega} \\ \mu K_{\partial\omega\partial\Omega} & -\frac{\sigma_1}{\sigma_2 + \sigma_1} \left( -\frac{1}{2}I + K_\Omega \right) \end{bmatrix} \begin{bmatrix} (v_n^+)_{|\partial\omega} \\ (v_n)_{|\partial\Omega} \end{bmatrix} \\ = \frac{1}{\sigma_1 + \sigma_2} \begin{bmatrix} \sigma_2 \left( \frac{1}{2}I - K_\omega \right) & S_\omega \\ -\sigma_2 K_{\partial\omega\partial\Omega} & S_{\partial\omega\partial\Omega} \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix} - \frac{\sigma_1}{\sigma_1 + \sigma_2} \begin{bmatrix} S_{\partial\Omega\partial\omega} g_1 \\ S_\Omega g_1 \end{bmatrix}.$$

Finally, the computation of  $(\partial_{\mathbf{n}} v_n)_{|\partial\omega}^+$  is given by

$$S_\omega (\partial_{\mathbf{n}} v_n)_{|\partial\omega}^+ = \frac{\sigma_2}{\sigma_1} \left( -\frac{1}{2}I + K_\omega \right) (v_n^+(x)_{|\partial\omega} - \alpha) + \frac{1}{\sigma_1} S_\omega \beta.$$

Concerning the well-posedness of (55), we can state the following result.

**THEOREM 7.** *The linear system of integral equations (55) has a unique solution in  $H^{1/2}(\partial\omega) \times H^{-1/2}(\partial\Omega)$ .*

*Proof.* Let  $A$  be the matrix operator defined on  $H^{1/2}(\partial\omega) \times H^{-1/2}(\partial\Omega)$  as

$$(57) \quad A = \begin{bmatrix} \frac{1}{2}I + \mu K_\omega & \frac{\sigma_1}{\sigma_2 + \sigma_1} S_{\partial\Omega\partial\omega} \\ \mu K_{\partial\omega\partial\Omega} & \frac{\sigma_1}{\sigma_1 + \sigma_2} S_\Omega \end{bmatrix}.$$

The main argument of the proof is based on the Fredholm alternative. We have to show that the adjoint operator  $A^*$  is injective. Since the boundaries are bounded, the adjoint operator  $A^*$  defined on  $H^{-1/2}(\partial\omega) \times H^{1/2}(\partial\Omega)$  can be written in the form

$$(58) \quad A^* = \begin{bmatrix} \frac{1}{2}I + \mu K_\omega^* & \mu K_{\partial\Omega\partial\omega}^* \\ \frac{\sigma_1}{\sigma_2 + \sigma_1} S_{\partial\omega\partial\Omega} & \frac{\sigma_1}{\sigma_2 + \sigma_1} S_\Omega \end{bmatrix}.$$

Let  $(u, v) \in H^{-1/2}(\partial\omega) \times H^{1/2}(\partial\Omega)$  be in the kernel of  $A^*$ . Consider the potential  $W$  defined for each  $x \in \mathbb{R}^d$  by

$$(59) \quad W(x) = \frac{\sigma_1}{\sigma_2 + \sigma_1} \left( \int_{\partial\omega} \Gamma(x, y) u(y) + \int_{\partial\Omega} \Gamma(x, y) v(y) \right).$$

In the first step, we show that  $W = 0$ . The function  $W$  satisfies  $\Delta W = 0$  in  $\mathbb{R}^d \setminus (\partial\omega \cup \partial\Omega)$  by construction. We check that  $W|_{\partial\Omega} = 0$  from the equation corresponding to the second line of  $A^*$ . By the properties of the single-layer potential,  $[W] = 0$  on  $\partial\omega$ . Furthermore, it holds that  $[\sigma \partial_{\mathbf{n}} W] = 0$  on  $\partial\omega$ . Indeed, we can have [14]

$$\partial_{\mathbf{n}} W^+ = \frac{\sigma_1}{\sigma_1 + \sigma_2} \left( \left( \frac{1}{2} + K_\omega^* \right) u + K_{\partial\Omega\partial\omega}^* v \right)$$

and

$$\partial_{\mathbf{n}} W^- = \frac{\sigma_1}{\sigma_1 + \sigma_2} \left( \left( -\frac{1}{2} + K_{\omega}^* \right) v + K_{\partial\Omega\partial\omega}^* v \right),$$

and hence

$$\sigma_1 \partial_{\mathbf{n}} W^+ - \sigma_2 \partial_{\mathbf{n}} W^- = \sigma_1 \left( \left( \frac{1}{2} I + \mu K_{\omega}^* \right) u + \mu K_{\partial\Omega\partial\omega}^* v \right).$$

This corresponds to the first line of  $A^*(u, v)$ . Then  $W$  solves the Laplace equation (1) with homogeneous Dirichlet boundary conditions. By the uniqueness of the solution, we get  $W = 0$  in  $\Omega$ .

In the second step, we deduce that  $u = v = 0$ . Since  $W = 0$  in  $\Omega$ , we see that  $[\partial_{\mathbf{n}} W] = 0$  on  $\partial\omega$ . Since  $[\partial_{\mathbf{n}} W] = \sigma_1 u / (\sigma_1 + \sigma_2)$  on  $\partial\omega$ , we deduce  $u = 0$ . From the second line of  $A^*(u, v) = 0$ , we see that  $S_{\Omega} v = 0$  on  $\partial\Omega$ . Since the single-layer potential operator  $S_{\Omega} : H^{-1/2}(\partial\Omega) \mapsto H^{1/2}(\partial\Omega)$  is an isomorphism,  $v = 0$  holds. The injectivity of  $A^*$  is proved. Since  $2A = I + C$ , where  $C$  is a compact operator, we conclude that  $A$  has a continuous inverse thanks to the Fredholm alternative.  $\square$

In a similar way, the problem (56) is well-posed under some additional assumptions. We define the adequate space

$$H_{\diamond}^{1/2}(\partial\Omega) = \left\{ \phi \in H^{1/2}(\partial\Omega) : \int_{\partial\Omega} \phi = 0 \right\}.$$

We can state the following result.

**THEOREM 8.** *If we impose the normalizing condition*

$$\int_{\partial\Omega} v_n = \int_{\partial\Omega} f_1,$$

*then there exists one unique couple  $((v_n)_{|\partial\omega}, (v_n)_{|\partial\Omega}) \in H^{1/2}(\partial\omega) \times H_{\diamond}^{1/2}(\partial\Omega)$  solution of (56).*

*Proof.* Set

$$(60) \quad B = \begin{bmatrix} \frac{1}{2}I + \mu K_{\omega} & -\frac{\sigma_1}{\sigma_2 + \sigma_1} K_{\partial\Omega\partial\omega} \\ \mu K_{\partial\omega\partial\Omega} & -\frac{\sigma_1}{\sigma_1 + \sigma_2} \left( -\frac{1}{2}I + K_{\Omega} \right) \end{bmatrix}$$

as the operator defined on  $H^{1/2}(\partial\omega) \times H_{\diamond}^{1/2}(\partial\Omega)$ . The adjoint  $B^*$  can be written in the form

$$(61) \quad B^* = \begin{bmatrix} \frac{1}{2}I + \mu K_{\omega}^* & \mu K_{\partial\Omega\partial\omega}^* \\ -\frac{\sigma_1}{\sigma_1 + \sigma_2} K_{\partial\omega\partial\Omega}^* & -\frac{\sigma_1}{\sigma_1 + \sigma_2} \left( -\frac{1}{2}I + K_{\Omega}^* \right) \end{bmatrix}.$$

We begin to show that  $B^*$  is injective. Let  $(u, v) \in H^{1/2}(\partial\omega) \times H^{1/2}(\partial\Omega)$  be in the kernel of  $B^*$ . We introduce the potential

$$Z(x) = -\frac{\sigma_1}{\sigma_1 + \sigma_2} \left( \int_{\partial\omega} \Gamma(x, y)u(y) + \int_{\partial\Omega} \Gamma(x, y)v(y) \right), \quad x \in \mathbb{R}^d.$$

We can see that  $Z$  is a harmonic function in  $\mathbb{R}^d \setminus (\partial\omega \cup \partial\Omega)$ , satisfying  $\partial_n Z = 0$  on  $\partial\Omega$ . By the properties of the single-layer potential,  $[Z] = 0$ . Furthermore, a straightforward calculation shows that  $[\sigma \partial_n Z] = 0$  on  $\partial\omega$ . Hence,  $Z$  solves the boundary value problem

$$-\operatorname{div}(\sigma \nabla Z) = 0 \text{ in } \Omega,$$

$$\partial_n Z = 0 \text{ on } \partial\Omega.$$

The function is therefore constant in  $\Omega$ . Writing  $[\partial_n Z] = 0$  on  $\partial\omega$ , we get easily  $u = 0$  and then  $(-\frac{1}{2} + K_\Omega^*)v = 0$ . Since the operator  $\lambda I - K_\Omega^*$  is one-to-one on  $H_\diamond^{1/2}(\partial\Omega)$ , we deduce that  $v = 0$ . We conclude the proof thanks to the Fredholm alternative.  $\square$

*Tangential regularity results.* In order to give a sense to the jump conditions arising in (6)–(8), we need to work in the space of functions of higher regularity. We choose the framework of Hölder spaces. We quote [12] to make the behavior of the layer potentials on these spaces precise.

THEOREM 9 (Kirsch [12]).

1. If  $\partial\omega$  is of class  $C^{2,\alpha}$ ,  $0 < \alpha < 1$ , then the operators  $S_\omega$  and  $K_\omega$  map  $C^\beta(\partial\omega)$  continuously into  $C^{1,\beta}$  for all  $0 < \beta \leq \alpha$ .
2. Let  $k \in \mathbb{N}$  with  $k \neq 0$ . If  $\partial\omega$  is of class  $C^{k+1,\alpha}$  with  $0 < \alpha < 1$ , then the operators  $S_\omega$  and  $K_\omega$  map  $C^{k,\beta}(\partial\omega)$  continuously into  $C^{k+1,\beta}(\partial\omega)$  for all  $0 < \beta \leq \alpha$ .
3. Let  $k$  be an integer. If  $\partial\omega$  is of class  $C^{k+2,\alpha}$ , then  $K_\omega^*$  maps  $C^{k,\beta}$  continuously into  $C^{k+1,\beta}(\partial\omega)$  for all  $0 < \beta \leq \alpha$ .

PROPOSITION 7. Assume that  $\partial\omega$  is of class  $C^{4,\alpha}$ . Then the trace of  $u_d$  solution of the boundary value problem (1), (2) belongs to  $C^{3,\alpha}(\partial\omega, \mathbb{R})$ , while  $\partial_n u_d \in C^{2,\alpha}(\partial\omega, \mathbb{R})$ .

*Proof.* We consider now the particular case where both  $\alpha$  and  $\beta$  are the zero function and  $(f_1, g_1) = (f, g)$ , where  $f$  and  $g$  are, respectively, the Dirichlet and Neumann boundary data. To recover the tangential regularity of the solution  $u$  along  $\partial\omega$ , we look at the first line of (55) to deduce that

$$(62) \quad \left[ \frac{1}{2}I + \mu K_\omega \right] (u_d)|_{\partial\omega} = -\frac{\sigma_1}{\sigma_2 + \sigma_1} S_{\partial\Omega\partial\omega} \partial_n u_d|_{\partial\Omega} + \frac{\sigma_1}{\sigma_1 + \sigma_2} K_{\partial\Omega\partial\omega} f$$

and

$$(63) \quad S_\omega(\partial_n u_d)|_{\partial\omega}^+ = \frac{\sigma_2}{\sigma_1} \left( -\frac{1}{2}I + K_\omega \right) u_d^+(x)|_{\partial\omega}.$$

It is easy to deduce that  $(u_d)|_{\partial\omega} \in C^{3,\alpha}(\partial\omega)$ . Indeed, from (62), which we consider as an equation in  $(u_d)|_{\partial\omega}$  with data  $f$  and  $(\partial_n u_d)|_{\partial\Omega} = g$ , we see that  $(f, (\partial_n u_d)|_{\partial\Omega})$  belongs to  $H^{1/2}(\partial\Omega) \times H^{-1/2}(\partial\Omega)$ , thanks to Theorem 7.

Since the two boundaries have no intersection point and since  $\partial\omega$  is of class  $C^{4,\alpha}$ , it follows that the right-hand side of the former equation is of class  $C^{3,\alpha}(\partial\omega)$ . We then conclude that the solution of (62) will be of class  $C^{3,\alpha}$  since the operator  $1/2I + \mu K_\omega$  is an isomorphism from  $C^{3,\alpha}(\partial\omega)$  into itself. With the same arguments, we show straightforwardly that  $(\partial_n u_n)|_{\partial\omega}^+ \in C^{2,\alpha}$ .  $\square$

**About the regularity of the jumps of the second derivative.** The equations giving the jump conditions  $[u'_d]$  and  $[\partial u'_d]$  show obviously that  $[u'_d]$  and  $[\partial_n u'_d]$  belong, respectively, to  $C^{2,\alpha}(\partial\omega)$  and  $C^{1,\alpha}(\partial\omega)$ . Hence, it comes straightforwardly that  $[u''_d] \in \mathcal{C}^{1,\alpha}$ . With the same arguments, we show that  $[\partial_n u''_d] \in \mathcal{C}^{0,\alpha}$  (see [22] for more details) and then that all the formal computations to get the equations describing the second derivative make sense.

**Remark on the interest of (51) for numerical schemes.** In view of a numerical discretization of the state equation, one has to emphasize that the choice of a finite elements method seems inappropriate: one should extract a tangential derivative of high order on the interface  $\partial\omega$ . The obtained numerical accuracy is not sufficient to incorporate the results in an optimization scheme. On the contrary, the systems of boundary integral equations (55) and (56) are well suited for this kind of computation. Any numerical discretization needs to compute the state, its derivatives with respect to the shape, and the normal derivatives along the interface  $\partial\omega$ . This can be done for both  $u_d$  and  $u'_d$  with just a change in the right-hand side of the same system. Nevertheless, a discussion of adapted schemes should be precise and is out of the scope of this manuscript.

**6.2. The bidimensional case.** The results obtained in the three-dimensional case can be extended to the bidimensional up to the additional assumption:

(H) *The diameter of the outer domain  $\Omega$  is strictly less than 1.*

In fact, the proofs extends to the bidimensional case on every step except the following fact: for a bidimensional domain  $D$ , the single-layer potential  $S_D$  is not in general an isomorphism from  $H^s(\partial D)$  into  $H^{s+1}(\partial D)$  for  $s \in \mathbb{R}$ . However, Hsiao and Wendland have shown in [10] that, provided that  $\text{diam}(D) < 1$ , the single-layer potential is an isomorphism from  $H^s(\partial D)$  into  $H^{s+1}(\partial D)$  for all  $s \in \mathbb{R}$ . In the previously presented results, we used the inverse of  $S_\Omega$  in the proof of Theorem 5, and the inverse of  $S_\omega$  in the proof of Theorem 7, and assumption (H) ensures that  $S_\Omega$  and  $S_\omega$  are both invertible.

The diverse notions of curvatures coincide in dimension two. Hence the expression of the second order derivative is simpler in dimension two. For example, the state  $u_d$  has a second order shape derivative  $u''_d \in H^1(\Omega \setminus \bar{\omega}) \cup H^1(\omega)$  that solves

(64)

$$\left\{ \begin{array}{l} \Delta u''_d = 0 \text{ in } \Omega \setminus \bar{\omega} \text{ and in } \omega, \\ [u''_d] = \left( (h_{1,n}h_{2,n} - h_{1,\tau}h_{2,\tau})H \right) [\partial_n u_d] - (h_{1,n}[\partial_n(u_d)'_2] + h_{2,n}[\partial_n(u_d)'_1]) \\ \quad + (\mathbf{h}_{1\tau} \cdot \nabla h_{2,n} + \mathbf{h}_{2\tau} \cdot \nabla h_{1,n}) [\partial_n u_d] \text{ on } \partial\omega, \\ [\sigma \partial_n u''_d] = \text{div}_\tau \left( h_{2,n} [\sigma \nabla_\tau(u_d)'_1] + h_{1,n} [\sigma \nabla_\tau(u_d)'_2] \right. \\ \quad \left. + (h_{1,\tau}h_{2,\tau} - h_{1,n}h_{2,n})H[\sigma \nabla_\tau u_d] \right) \\ \quad - \text{div}_\tau \left( (\mathbf{h}_{1\tau} \cdot \nabla_\tau h_{2,n} + \nabla_\tau h_{1,n} \cdot \mathbf{h}_{2\tau}) [\sigma \nabla_\tau u_d] \right) \text{ on } \partial\omega, \\ u''_d = 0 \text{ on } \partial\Omega. \end{array} \right.$$

**6.3. Another derivation of (8).** As usual in the derivation of boundary conditions satisfied by shape derivatives, two strategies are at hand. First, one can differentiate the boundary conditions satisfied by the state equation. This choice, presented in section 4, is the shortest solution but requires dealing with tangential derivations. One can alternatively deal with the weak form of the state equation

and perform as many integrations by parts as required to transform the volume integral into surface integrals that can be seen as boundary conditions. This second method will be presented now. It uses more elementary mathematical tools but requires lengthy computations. These computations are presented here only for the completeness of the presentation.

We want to make explicit the problem solved by  $(u')'$ . To achieve this, we should write the right-hand side of (32),

$$F = \int_{\Omega} \sigma \left[ \nabla \dot{u}_1 \cdot A_{\mathbf{h}_2} \nabla v + \nabla \dot{u}_2 \cdot A_{\mathbf{h}_1} \nabla v - \nabla u \cdot \mathfrak{A} \nabla v \right],$$

as the sum of an integral with  $\nabla v$  in factor and an integral of a divergence to identify the jump conditions on  $\partial\omega$ . To that end, we will use algebraic identities that involve second order derivatives of  $u, \dot{u}_i$  and of the test function  $v \in \mathcal{D}(\Omega)$ . Using Lemma 1, we obtain

$$\begin{aligned} \int_{\Omega} \sigma \nabla \dot{u}_1 \cdot A_{\mathbf{h}_2} \nabla v &= \int_{\Omega} \sigma \left[ \nabla (\mathbf{h}_2 \cdot \nabla \dot{u}_1) \cdot \nabla v + \nabla (\mathbf{h}_2 \cdot \nabla v) \cdot \nabla \dot{u}_1 - \operatorname{div} ((\nabla \dot{u}_1 \cdot \nabla v) \mathbf{h}_2) \right], \\ \int_{\Omega} \sigma \nabla \dot{u}_2 \cdot A_{\mathbf{h}_1} \nabla v &= \int_{\Omega} \sigma \left[ \nabla (\mathbf{h}_1 \cdot \nabla \dot{u}_2) \cdot \nabla v + \nabla (\mathbf{h}_1 \cdot \nabla v) \cdot \nabla \dot{u}_2 - \operatorname{div} ((\nabla \dot{u}_2 \cdot \nabla v) \mathbf{h}_1) \right]. \end{aligned}$$

Concerning the remaining terms, we use Lemma 2 to get

$$\begin{aligned} \int_{\Omega} \sigma \nabla u \cdot \mathfrak{A} \nabla v &= \int_{\Omega} \sigma \operatorname{div} ((\mathbf{h}_2 \cdot \nabla u) A_{\mathbf{h}_1} \nabla v + (\mathbf{h}_2 \cdot \nabla v) A_{\mathbf{h}_1} \nabla u - (A_{\mathbf{h}_1} \nabla u \cdot \nabla v) \mathbf{h}_2) \\ &\quad - \sigma \left[ (\mathbf{h}_2 \cdot \nabla u) \operatorname{div} (A_{\mathbf{h}_1} \nabla v) + (\mathbf{h}_2 \cdot \nabla v) \operatorname{div} (A_{\mathbf{h}_1} \nabla u) \right]. \end{aligned}$$

We apply Lemma 3 and gather the expressions obtained for  $F$ .

$$\begin{aligned} (65) \quad F &= \int_{\Omega} \sigma \left[ \nabla (\mathbf{h}_1 \cdot \nabla \dot{u}_2 + \mathbf{h}_2 \cdot \nabla \dot{u}_1) \cdot \nabla v + \nabla (\mathbf{h}_2 \cdot \nabla v) \cdot \nabla \dot{u}_1 + \nabla (\mathbf{h}_1 \cdot \nabla v) \cdot \nabla \dot{u}_2 \right] \\ &\quad + \int_{\Omega} \sigma \operatorname{div} ((A_{\mathbf{h}_1} \nabla u \cdot \nabla v - \nabla \dot{u}_1 \cdot \nabla v) \mathbf{h}_2 - (\nabla \dot{u}_2 \cdot \nabla v) \mathbf{h}_1) \\ &\quad + \int_{\Omega} \sigma \left[ (\mathbf{h}_2 \cdot \nabla v) \Delta (\mathbf{h}_1 \cdot \nabla u) - \operatorname{div} ((\mathbf{h}_2 \cdot \nabla v) A_{\mathbf{h}_1} \nabla u) - \nabla (\mathbf{h}_2 \cdot \nabla u) \cdot A_{\mathbf{h}_1} \nabla v \right]. \end{aligned}$$

Using (25), we remove the dependency on  $A_{\mathbf{h}_1} \nabla v$ :

$$\begin{aligned} \nabla (\mathbf{h}_2 \cdot \nabla u) \cdot A_{\mathbf{h}_1} \nabla v &= \nabla (\mathbf{h}_1 \cdot \nabla (\mathbf{h}_2 \cdot \nabla u)) \cdot \nabla v \\ &\quad + \nabla (\mathbf{h}_1 \cdot \nabla v) \cdot \nabla (\mathbf{h}_2 \cdot \nabla u) - \operatorname{div} ((\nabla (\mathbf{h}_2 \cdot \nabla u) \cdot \nabla v) \mathbf{h}_1). \end{aligned}$$

Therefore, we write  $F = F_1 + F_2$ , where

(66)

$$\begin{aligned} F_1 &= \int_{\Omega} \sigma \left[ \nabla (\mathbf{h}_1 \cdot \nabla \dot{u}_2 + \mathbf{h}_2 \cdot \nabla \dot{u}_1) - \nabla (\mathbf{h}_1 \cdot \nabla (\mathbf{h}_2 \cdot \nabla u)) \right] \cdot \nabla v, \\ F_2 &= \int_{\Omega} \sigma \left[ \nabla (\mathbf{h}_1 \cdot \nabla v) \cdot \nabla (\dot{u}_2 - \mathbf{h}_2 \cdot \nabla u) + \nabla (\mathbf{h}_2 \cdot \nabla v) \cdot \nabla \dot{u}_1 + (\mathbf{h}_2 \cdot \nabla v) \Delta (\mathbf{h}_1 \cdot \nabla u) \right] \\ &\quad + \int_{\Omega} \sigma \operatorname{div} \left( (A_{\mathbf{h}_1} \nabla u \cdot \nabla v - \nabla \dot{u}_1 \cdot \nabla v) \mathbf{h}_2 \right. \\ &\quad \left. + (\nabla (\mathbf{h}_2 \cdot \nabla u) \cdot \nabla v - \nabla \dot{u}_2 \cdot \nabla v) \mathbf{h}_1 - (\mathbf{h}_2 \cdot \nabla v) A_{\mathbf{h}_1} \nabla u \right). \end{aligned}$$

The connection between second order material and shape derivatives is given by

$$\ddot{u}_1 = (u'_1)'_2 + \mathbf{h}_1 \cdot \nabla \dot{u}_2 + \mathbf{h}_2 \cdot \nabla \dot{u}_1 - \mathbf{h}_1 \cdot \nabla (\mathbf{h}_2 \cdot \nabla u).$$

Incorporating this expression into (66), we rewrite (32) as

$$(67) \quad \forall v \in H_0^1(\Omega), \quad \int_{\Omega} \sigma \nabla (u'_1)'_2 \cdot \nabla v = F_2.$$

Testing it against  $v \in \mathcal{D}(\Omega \setminus \partial\omega)$ , we get  $\Delta (u'_1)'_2 = 0$  in  $\Omega \setminus \overline{\omega}$  and in  $\omega$ . We now deduce the jump conditions for  $(u'_1)'_2$ . To obtain the jump of the potential, we simply write that  $\ddot{u}_1 \in H_0^1(\Omega)$ , hence  $[\ddot{u}_1] = 0$  on  $\partial\omega$ , and then

$$(68) \quad [(u'_1)'_2] = -\mathbf{h}_1 \cdot [\nabla u'_2] - \mathbf{h}_2 \cdot [\nabla \dot{u}_1].$$

To express the jump of the flux, we then apply the Gauss formula in (67) to get

$$(69) \quad - \int_{\partial\omega} [\sigma \partial_{\mathbf{n}} (u'_1)'_2] v = F_2.$$

The second term  $F_2$  contains all the jumps of the flux on the interface  $\partial\omega$ .

**A simplified expression of  $F_2$ .** To get a simplified formula for  $F_2$  under a boundary integral, some lengthy but straightforward calculations are needed. We summarize the result by means of the following lemma.

LEMMA 5. *One has*

(70)

$$\begin{aligned} F_2 &= \int_{\partial\omega} \operatorname{div}_{\tau} (2h_{2,n} h_{1,n} D\mathbf{n} [\sigma \nabla_{\tau} u] - h_{2,n} \mathbf{n} \cdot \nabla h_{1,n} [\sigma \nabla_{\tau} u] + h_{2,n} \mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{n} [\sigma \nabla_{\tau} u]) v \\ &\quad + \int_{\partial\omega} \operatorname{div}_{\tau} (\mathbf{h}_{1\tau} \cdot \nabla_{\tau} (h_{2,n}) [\sigma \nabla_{\tau} u] - h_{1,n} h_{2,n} H [\sigma \nabla_{\tau} u]) v \\ &\quad - \int_{\partial\omega} \left( \operatorname{div}_{\tau} (h_{2,n} [\sigma \nabla_{\tau} u'_1]) + \operatorname{div}_{\tau} (h_{1,n} [\sigma \nabla_{\tau} u'_2]) \right) v. \end{aligned}$$

*Proof.* First, write

$$\begin{aligned} \int_{\Omega} \sigma \nabla (\mathbf{h}_1 \cdot \nabla v) \cdot \nabla (\dot{u}_2 - \mathbf{h}_2 \cdot \nabla u) &= \sigma_1 \int_{\Omega \setminus \overline{\omega}} \nabla (\mathbf{h}_1 \cdot \nabla v) \cdot \nabla u'_2 + \sigma_2 \int_{\omega} \nabla (\mathbf{h}_1 \cdot \nabla v) \cdot \nabla u'_2 \\ &= - \int_{\partial\omega} [\sigma \partial_{\mathbf{n}} u'_2] (\mathbf{h}_1 \cdot \nabla v). \end{aligned}$$

Note that the normal vector is oriented from  $\omega$  to  $\Omega \setminus \bar{\omega}$ . In the same spirit, we write

$$\begin{aligned} \nabla(\mathbf{h}_2 \cdot \nabla v) \cdot \nabla \dot{u}_1 + (\mathbf{h}_2 \cdot \nabla v) \Delta(\mathbf{h}_1 \cdot \nabla u) &= \nabla(\mathbf{h}_2 \cdot \nabla v) \cdot \nabla(\dot{u}_1 - \mathbf{h}_1 \cdot \nabla u) \\ &\quad + \operatorname{div}((\mathbf{h}_2 \cdot \nabla v) \cdot \nabla(\mathbf{h}_1 \cdot \nabla u)). \end{aligned}$$

By an argument of symmetry, we then can write

$$\int_{\Omega} \sigma \nabla(\mathbf{h}_2 \cdot \nabla v) \cdot \nabla(\dot{u}_1 - \mathbf{h}_1 \cdot \nabla u) = - \int_{\partial\omega} [\sigma \partial_{\mathbf{n}} u'_1](\mathbf{h}_2 \cdot \nabla v).$$

To drop the dependency in  $A_{\mathbf{h}_1}$ , we use (25) and get after expansion

$$\begin{aligned} \operatorname{div}((A_{\mathbf{h}_1} \nabla u \cdot \nabla v) \mathbf{h}_2) &= \operatorname{div}((\nabla(\mathbf{h}_1 \cdot \nabla v) \cdot \nabla u + \nabla(\mathbf{h}_1 \cdot \nabla u) \nabla v) \mathbf{h}_2) \\ &\quad - \operatorname{div}(\operatorname{div}((\nabla u \cdot \nabla v) \mathbf{h}_1) \mathbf{h}_2), \\ \operatorname{div}((\mathbf{h}_2 \cdot \nabla v) A_{\mathbf{h}_1} \nabla u) &= \nabla(\mathbf{h}_2 \cdot \nabla v) \cdot A_{\mathbf{h}_1} \nabla u + (\mathbf{h}_2 \cdot \nabla v) \operatorname{div}(A_{\mathbf{h}_1} \nabla u) \\ &= \nabla(\mathbf{h}_1 \cdot \nabla(\mathbf{h}_2 \cdot \nabla v)) \cdot \nabla u + \nabla(\mathbf{h}_1 \cdot \nabla u) \nabla(\mathbf{h}_2 \cdot \nabla v) \\ &\quad + (\mathbf{h}_2 \cdot \nabla v) \Delta(\mathbf{h}_1 \cdot \nabla u) - \operatorname{div}((\nabla(\mathbf{h}_2 \cdot \nabla v) \cdot \nabla u) \mathbf{h}_1) \\ &= \nabla(\mathbf{h}_1 \cdot \nabla(\mathbf{h}_2 \cdot \nabla v)) \cdot \nabla u \\ &\quad + \operatorname{div}((\mathbf{h}_2 \cdot \nabla v) \nabla(\mathbf{h}_1 \cdot \nabla u) - (\nabla(\mathbf{h}_2 \cdot \nabla v) \cdot \nabla u) \mathbf{h}_1). \end{aligned}$$

After integrating by parts, we conclude, thanks to the state equation, with

$$\int_{\Omega} \sigma \nabla(\mathbf{h}_1 \cdot \nabla(\mathbf{h}_2 \cdot \nabla v)) \cdot \nabla u = - \int_{\Omega} (\mathbf{h}_1 \cdot \nabla(\mathbf{h}_2 \cdot \nabla v)) \operatorname{div}(\sigma \nabla u) = 0.$$

We substitute the shape derivative  $u'$  to the material derivative  $\dot{u}$ :

$$\begin{aligned} F_2 &= - \int_{\partial\omega} [\sigma \partial_{\mathbf{n}} u'_1](\mathbf{h}_2 \cdot \nabla v) + [\sigma \partial_{\mathbf{n}} u'_2](\mathbf{h}_1 \cdot \nabla v) - \int_{\Omega} \sigma \operatorname{div}(\operatorname{div}((\nabla u \cdot \nabla v) \mathbf{h}_1) \mathbf{h}_2) \\ &\quad + \int_{\Omega} \sigma \operatorname{div}\left(\left((\nabla(\mathbf{h}_1 \cdot \nabla v) \cdot \nabla u) \mathbf{h}_2 + (\nabla(\mathbf{h}_2 \cdot \nabla v) \cdot \nabla u) \mathbf{h}_1\right) \right. \\ &\quad \left. - ((\nabla u'_2 \cdot \nabla v) \mathbf{h}_1 + (\nabla u'_1 \cdot \nabla v) \mathbf{h}_2)\right). \end{aligned}$$

First, we use the continuity of the flux on  $\partial\omega$ , then we integrate by parts on  $\partial\omega$ , and finally we incorporate the expressions of the jumps of the shape derivatives  $u'$  to obtain

$$\begin{aligned} &\int_{\Omega} \sigma \operatorname{div}(\mathbf{h}_1 \cdot (\nabla(\mathbf{h}_2 \cdot \nabla v) \cdot \nabla u)) \\ &= - \int_{\partial\omega} [\sigma \nabla u \cdot \nabla(\mathbf{h}_2 \cdot \nabla v)] h_{1,n} = - \int_{\partial\omega} [\sigma \nabla_{\tau} u] h_{1,n} \nabla_{\tau}(\mathbf{h}_2 \cdot \nabla v) \\ &= \int_{\partial\omega} \operatorname{div}_{\tau}([\sigma \nabla_{\tau} u] h_{1,n}) \mathbf{h}_2 \cdot \nabla v = \int_{\partial\omega} [\sigma \partial_{\mathbf{n}} u'_1] \mathbf{h}_2 \cdot \nabla v. \end{aligned}$$

This leads to a simplified expression for  $F_2$ :

$$F_2 = - \int_{\Omega} \sigma \operatorname{div} \left( \operatorname{div} ((\nabla u, \nabla v) \mathbf{h}_1) \mathbf{h}_2 + \left( (\nabla u'_1, \nabla v) \mathbf{h}_2 + (\nabla u'_2, \nabla v) \mathbf{h}_1 \right) \right).$$

Let us study each term of this sum. Using the Gauss formula and integrating by parts on the manifold  $\partial\omega$ , we obtain

$$\begin{aligned} & \int_{\Omega} \sigma \operatorname{div} \left( (\nabla u'_1, \nabla v) \mathbf{h}_2 \right) \\ &= - \int_{\partial\omega} h_{2,n} [\sigma \nabla u'_1, \nabla v] = - \int_{\partial\omega} h_{2,n} [\sigma \partial_{\mathbf{n}} u'_1] \partial_{\mathbf{n}} v - \int_{\partial\omega} h_{2,n} [\sigma \nabla_{\tau} u'_1] \nabla_{\tau} v \\ &= - \int_{\partial\omega} h_{2,n} [\sigma \partial_{\mathbf{n}} u'_1] \partial_{\mathbf{n}} v + \int_{\partial\omega} \operatorname{div}_{\tau} \left( h_{2,n} [\sigma \nabla_{\tau} u'_1] \right) v. \end{aligned}$$

By symmetry, we also get

$$\int_{\Omega} \sigma \operatorname{div} \left( (\nabla u'_2, \nabla v) \mathbf{h}_1 \right) = - \int_{\partial\omega} h_{1,n} [\sigma \partial_{\mathbf{n}} u'_2] \partial_{\mathbf{n}} v + \int_{\partial\omega} \operatorname{div}_{\tau} \left( h_{1,n} [\sigma \nabla_{\tau} u'_2] \right) v.$$

We now turn to the term with a double divergence. We first write it as a boundary integral thanks to the Gauss formula:

$$\int_{\Omega} \sigma \operatorname{div} \left( \operatorname{div} ((\nabla u, \nabla v) \mathbf{h}_1) \mathbf{h}_2 \right) = - \int_{\partial\omega} h_{2,n} \operatorname{div} \left( \mathbf{h}_1 [\sigma (\nabla u, \nabla v)] \right).$$

Then we use (14) to introduce the tangential operators:

$$\begin{aligned} \int_{\Omega} \sigma \operatorname{div} \left( \operatorname{div} ((\nabla u, \nabla v) \mathbf{h}_1) \mathbf{h}_2 \right) &= - \int_{\partial\omega} h_{2,n} \operatorname{div}_{\tau} \left( \mathbf{h}_1 [\sigma (\nabla u, \nabla v)] \right) \\ &\quad - \int_{\partial\omega} h_{2,n} D \left( \mathbf{h}_1 [\sigma (\nabla u, \nabla v)] \right) \mathbf{n} \cdot \mathbf{n}. \end{aligned}$$

We study each of these terms, starting with the one involving tangential derivatives: we expand the tangential divergence to incorporate the jump relation for the state  $u$ :

$$\begin{aligned} \operatorname{div}_{\tau} \left( \mathbf{h}_1 [\sigma (\nabla u, \nabla v)] \right) &= \operatorname{div}_{\tau} (\mathbf{h}_1) [\sigma (\nabla u, \nabla v)] + \mathbf{h}_1 \cdot \nabla_{\tau} [\sigma \nabla u, \nabla v] \\ &= \operatorname{div}_{\tau} (\mathbf{h}_1) [\sigma \nabla_{\tau} u] \cdot \nabla_{\tau} v + \mathbf{h}_1 \cdot \nabla_{\tau} [\sigma \nabla_{\tau} u, \nabla_{\tau} v]. \end{aligned}$$

Then the first term becomes

$$\begin{aligned} \int_{\partial\omega} h_{2,n} \operatorname{div}_{\tau} \left( \mathbf{h}_1 [\sigma (\nabla u, \nabla v)] \right) &= \int_{\partial\omega} h_{2,n} \operatorname{div}_{\tau} (\mathbf{h}_1) [\sigma \nabla_{\tau} u] \cdot \nabla_{\tau} v \\ &\quad + \int_{\partial\omega} h_{2,n} \mathbf{h}_1 \cdot \nabla_{\tau} [\sigma \nabla_{\tau} u, \nabla_{\tau} v]. \end{aligned}$$

We use the integration by parts formula (18) to get

$$\begin{aligned} & \int_{\partial\omega} h_{2,n} \operatorname{div}_{\tau} \left( \mathbf{h}_1 [\sigma (\nabla u, \nabla v)] \right) \\ &= \int_{\partial\omega} h_{1,n} h_{2,n} H [\sigma \nabla_{\tau} u] \cdot \nabla_{\tau} v - \operatorname{div}_{\tau} \left( \operatorname{div}_{\tau} (\mathbf{h}_1) h_{2,n} [\sigma \nabla_{\tau} u] \right) v \\ &\quad - \operatorname{div}_{\tau} (\mathbf{h}_1 h_{2,n}) [\sigma \nabla_{\tau} u] \cdot \nabla_{\tau} v \\ &= \int_{\partial\omega} \operatorname{div}_{\tau} \left( \left( \operatorname{div}_{\tau} (\mathbf{h}_1 h_{2,n}) - \operatorname{div}_{\tau} (\mathbf{h}_1) h_{2,n} - h_{1,n} h_{2,n} H \right) [\sigma \nabla_{\tau} u] \right) v. \end{aligned}$$

Expanding

$$\begin{aligned} & \operatorname{div}_\tau \left( \operatorname{div}_\tau (\mathbf{h}_1 h_{2,n}) [\sigma \nabla_\tau u] \right) v \\ &= \operatorname{div}_\tau \left( \operatorname{div}_\tau (\mathbf{h}_1) h_{2,n} [\sigma \nabla_\tau u] + \mathbf{h}_1 \cdot \nabla_\tau (h_{2,n}) [\sigma \nabla_\tau u] \right) v \\ &= \operatorname{div}_\tau \left( \operatorname{div}_\tau (\mathbf{h}_1) h_{2,n} [\sigma \nabla_\tau u] \right) v + \operatorname{div}_\tau (\mathbf{h}_1 \cdot \nabla_\tau h_{2,n} [\sigma \nabla_\tau u]) v, \end{aligned}$$

we obtain the new expression:

$$(71) \quad \int_{\partial\omega} h_{2,n} \operatorname{div}_\tau \left( \mathbf{h}_1 [\sigma (\nabla u \cdot \nabla v)] \right) = \int_{\partial\omega} \operatorname{div}_\tau \left( (\mathbf{h}_1 \cdot \nabla_\tau h_{2,n} - h_{1,n} h_{2,n} H) [\sigma \nabla_\tau u] \right) v.$$

Now, we consider the term involving normal components. We have

$$(72) \quad \begin{aligned} \mathbf{n} \cdot D(\mathbf{h}_1 [\sigma (\nabla u \cdot \nabla v)]) \mathbf{n} &= \mathbf{n} \cdot \nabla (h_{1,n} [\sigma \nabla u \cdot \nabla v]) - [\sigma \nabla u \cdot \nabla v] \mathbf{h}_{1,\tau} \cdot D\mathbf{n} \mathbf{n} \\ &= \mathbf{n} \cdot \nabla (h_{1,n}) [\sigma \nabla_\tau u] \nabla_\tau v + h_{1,n} \mathbf{n} \cdot \nabla ([\sigma \nabla u \cdot \nabla v]). \end{aligned}$$

Then we get

$$\begin{aligned} & \int_{\partial\omega} h_{2,n} D(\mathbf{h}_1 [\sigma (\nabla u \cdot \nabla v)]) \mathbf{n} \cdot \mathbf{n} \\ &= \int_{\partial\omega} h_{2,n} \mathbf{n} \cdot \nabla (h_{1,n}) [\sigma \nabla_\tau u] \cdot \nabla_\tau v + h_{2,n} h_{1,n} \mathbf{n} \cdot \nabla ([\sigma \nabla u \cdot \nabla v]) \\ &= \int_{\partial\omega} -\operatorname{div}_\tau (h_{2,n} \mathbf{n} \cdot \nabla (h_{1,n}) [\sigma \nabla_\tau u]) v + h_{2,n} h_{1,n} \mathbf{n} \cdot \nabla ([\sigma \nabla u \cdot \nabla v]). \end{aligned}$$

A straightforward calculus leads to

$$\begin{aligned} \mathbf{n} \cdot \nabla ([\sigma \nabla u \cdot \nabla v]) &= \mathbf{n} \cdot \left( [\sigma D^2 u \nabla v] + D^2 v [\sigma \nabla u] \right) \\ &= \mathbf{n} \cdot \left( \partial_{\mathbf{n}} v [\sigma D^2 u] \mathbf{n} + [\sigma D^2 u] \nabla_\tau v + D^2 v [\sigma \nabla_\tau u] \right) \\ &= \partial_{\mathbf{n}} v \left[ \sigma \frac{\partial^2 u}{\partial n^2} \right] + \mathbf{n} \cdot [\sigma D^2 u] \nabla_\tau v + \mathbf{n} \cdot D^2 v [\sigma \nabla_\tau u], \end{aligned}$$

where  $D^2 u$  is the Hessian matrix of  $u$ . From (20) and from the jump conditions for the state  $u$ , we deduce that

$$\left[ \sigma \frac{\partial^2 u}{\partial n^2} \right] = -[\sigma \Delta_\tau u].$$

When one differentiates the relation expressing the continuity of the flux for the state along the tangential direction  $\nabla_\tau v$ , one gets (see [7, p. 235])

$$0 = \nabla [\sigma \partial_{\mathbf{n}} u] \cdot \nabla_\tau v = [\sigma D^2 u] \nabla_\tau v \cdot \mathbf{n} + [\sigma \nabla u] \cdot (D\mathbf{n} \nabla_\tau v).$$

In the same spirit, it comes that

$$(73) \quad \nabla \partial_{\mathbf{n}} v \cdot [\sigma \nabla_\tau u] = D^2 v [\sigma \nabla_\tau u] \cdot \mathbf{n} + \nabla v \cdot (D\mathbf{n} [\sigma \nabla_\tau u]).$$

Since  $D\mathbf{n}$  is a symmetric matrix and  $D\mathbf{n}\mathbf{n} = 0$ , one checks  $\nabla v \cdot (D\mathbf{n}[\sigma\nabla_\tau u]) = [\sigma\nabla u] \cdot (D\mathbf{n}\nabla_\tau v)$ . Then

$$\mathbf{n} \cdot \nabla ([\sigma\nabla u \cdot \nabla v]) = -[\sigma\Delta_\tau u] \partial_{\mathbf{n}} v - 2D\mathbf{n}[\sigma\nabla_\tau u] \cdot \nabla_\tau v + [\sigma\nabla_\tau u] \nabla_\tau \partial_{\mathbf{n}} v.$$

We integrate this expression on  $\partial\omega$  and obtain after some integration by parts

$$\begin{aligned} & \int_{\partial\omega} h_{2,n} h_{1,n} \mathbf{n} \cdot \nabla ([\sigma\nabla u \cdot \nabla v]) \\ &= - \int_{\partial\omega} h_{2,n} h_{1,n} [\sigma\Delta_\tau u] \partial_{\mathbf{n}} v + \int_{\partial\omega} h_{2,n} h_{1,n} [\sigma\nabla_\tau u] \nabla_\tau \partial_{\mathbf{n}} v \\ & \quad - 2 \int_{\partial\omega} h_{2,n} h_{1,n} D\mathbf{n} [\sigma\nabla_\tau u] \cdot \nabla_\tau v, \\ &= - \int_{\partial\omega} \left[ h_{2,n} h_{1,n} [\sigma\Delta_\tau u] + \operatorname{div}_\tau (h_{2,n} h_{1,n} [\sigma\nabla_\tau u]) \right] \partial_{\mathbf{n}} v \\ & \quad + 2 \int_{\partial\omega} \operatorname{div}_\tau (h_{2,n} h_{1,n} D\mathbf{n} [\sigma\nabla_\tau u]) v. \end{aligned}$$

Hence

$$\begin{aligned} & \int_{\partial\omega} h_{2,n} D(\mathbf{h}_1 [\sigma(\nabla u \cdot \nabla v)]) \mathbf{n} \cdot \mathbf{n} \\ &= - \int_{\partial\omega} \left[ h_{2,n} h_{1,n} [\sigma\Delta_\tau u] + \operatorname{div}_\tau (h_{2,n} h_{1,n} [\sigma\nabla_\tau u]) \right] \partial_{\mathbf{n}} v \\ & \quad + \int_{\partial\omega} \operatorname{div}_\tau (2h_{2,n} h_{1,n} D\mathbf{n} [\sigma\nabla_\tau u] - h_{2,n} \mathbf{n} \cdot \nabla_\tau h_{1,n} [\sigma\nabla_\tau u]) v, \\ & \int_{\Omega} \sigma \operatorname{div} \left( \operatorname{div} ((\nabla u \cdot \nabla v) \mathbf{h}_1) \mathbf{h}_2 \right) \\ &= \int_{\partial\omega} \left[ h_{2,n} h_{1,n} [\sigma\Delta_\tau u] + \operatorname{div}_\tau (h_{2,n} h_{1,n} [\sigma\nabla_\tau u]) \right] \partial_{\mathbf{n}} v \\ & \quad - \int_{\partial\omega} \operatorname{div}_\tau (2h_{2,n} h_{1,n} D\mathbf{n} [\sigma\nabla_\tau u] - h_{2,n} \mathbf{n} \cdot \nabla h_{1,n} [\sigma\nabla_\tau u]) v \\ & \quad - \int_{\partial\omega} \operatorname{div}_\tau (\mathbf{h}_{1\tau} \cdot \nabla_\tau (h_{2,n}) [\sigma\nabla_\tau u] - h_{1,n} h_{2,n} H [\sigma\nabla_\tau u]) v. \end{aligned}$$

Gathering all the terms, we write  $F_2$  as

$$\begin{aligned} F_2 &= \int_{\partial\omega} \operatorname{div}_\tau \left( 2h_{2,n} h_{1,n} D\mathbf{n} [\sigma\nabla_\tau u] \right. \\ & \quad \left. + (\mathbf{h}_{1\tau} \cdot \nabla_\tau (h_{2,n}) - h_{2,n} \mathbf{n} \cdot \nabla h_{1,n} - h_{1,n} h_{2,n} H) [\sigma\nabla_\tau u] \right) v \\ & \quad - \int_{\partial\omega} \left( \operatorname{div}_\tau \left( h_{2,n} [\sigma\nabla_\tau u'_1] \right) + \operatorname{div}_\tau \left( h_{1,n} [\sigma\nabla_\tau u'_2] \right) \right) \\ & \quad - \int_{\partial\omega} \left( h_{2,n} h_{1,n} [\sigma\Delta_\tau u] + \operatorname{div}_\tau (h_{2,n} h_{1,n} [\sigma\nabla_\tau u]) \right) \partial_{\mathbf{n}} v \\ & \quad + \int_{\partial\omega} \left( h_{1,n} \operatorname{div}_\tau (h_{2,n} [\sigma\nabla_\tau u]) + h_{2,n} \operatorname{div}_\tau (h_{1,n} [\sigma\nabla_\tau u]) \right) \partial_{\mathbf{n}} v. \end{aligned}$$

We end the proof after expanding the tangential divergence of the last term of  $F_2$ .  $\square$

Let us return to the weak formulation (69) of the derivative. By identification, we get

$$\begin{aligned} [\sigma \partial_{\mathbf{n}}(u'_1)_2] &= \operatorname{div}_{\tau} \left( h_{2,n} [\sigma \nabla_{\tau} u'_1] \right) + \operatorname{div}_{\tau} \left( h_{1,n} [\sigma \nabla_{\tau} u'_2] \right) \\ &\quad - \operatorname{div}_{\tau} (h_{2,n} h_{1,n} (2D\mathbf{n} - HI) [\sigma \nabla_{\tau} u]) \\ &\quad - \operatorname{div}_{\tau} (\mathbf{h}_{1\tau} \cdot \nabla_{\tau} (h_{2,n}) [\sigma \nabla_{\tau} u]) \\ &\quad - h_{2,n} \mathbf{n} \cdot \nabla h_{1,n} [\sigma \nabla_{\tau} u] + h_{2,n} \mathbf{h}_{1\tau} \cdot D\mathbf{n} \mathbf{n} [\sigma \nabla_{\tau} u]. \end{aligned}$$

Finally, we conclude the expression giving the jump of the flux for the second order derivative by relation (29).

## A VIABILITY THEOREM FOR MORPHOLOGICAL INCLUSIONS\*

THOMAS LORENZ†

**Abstract.** The aim of this paper is to adapt the viability theorem from differential inclusions (governing the evolution of vectors in a finite-dimensional space) to so-called morphological inclusions (governing the evolution of nonempty compact subsets of the Euclidean space). In this morphological framework, the evolution of compact subsets of  $\mathbb{R}^N$  is described by means of flows along bounded Lipschitz vector fields (similarly to the velocity method (a.k.a. speed method) in shape analysis). Now for each compact subset, more than just one vector field is admitted—correspondingly to the set-valued map of a differential inclusion in finite dimensions. We specify sufficient conditions on the given data such that for every initial compact set, at least one of these compact-valued evolutions satisfies fixed state constraints in addition. The proofs follow an approximative track similar to the standard approach for differential inclusions in  $\mathbb{R}^N$ , but they use tools about weak compactness and weak convergence of Banach-valued functions. Finally an application to shape optimization under state constraints is sketched.

**Key words.** shape evolutions with state constraints, velocity method (speed method), morphological equations, Nagumo’s theorem, viability condition, Clarke’s generalized shape derivative

**1. Introduction.** State constraints provide challenging questions in any form of dynamic system. For the problem of finding sufficient and necessary conditions on the state constraints, the first complete answer for ordinary differential equations was given by Nagumo [26] in 1942, and this characterization (using Bouligand tangent cones) has been rediscovered many times during previous decades.

If solutions of any given initial value problem are not unique, then two versions of this question are to be distinguished from each other: we demand that either *all* solutions have their values in the fixed set of constraints or that (just) *at least one* solution with this property exists. In the first case, the corresponding set of constraints is called *invariant* and, in the latter case, it is *viable* or *weakly invariant*.

For autonomous differential inclusions in  $\mathbb{R}^N$ , the results are presented in Aubin’s monograph *Viability Theory* [2], for example.

The main goal of this paper is a sufficient characterization of viability for shapes.

To be more precise, we leave the familiar Euclidean space  $\mathbb{R}^N$  and consider evolutions of nonempty compact subsets of  $\mathbb{R}^N$  instead. Correspondingly, the solution  $x : [0, T] \rightarrow \mathbb{R}^N$  (of a differential inclusion) is now replaced by a curve  $K : [0, T] \rightarrow \mathcal{K}(\mathbb{R}^N)$ , with  $\mathcal{K}(\mathbb{R}^N)$  denoting the set of nonempty compact subsets of  $\mathbb{R}^N$  usually supplied with the Pompeiu–Hausdorff distance

$$\begin{aligned} d(K_1, K_2) &:= \sup_{\substack{x \in K_2, \\ y \in K_1}} \max \left\{ \text{dist}(x, K_1), \text{dist}(y, K_2) \right\} \\ &= \sup_{z \in \mathbb{R}^N} |\text{dist}(z, K_1) - \text{dist}(z, K_2)|. \end{aligned}$$

†Interdisciplinary Center for Scientific Computing (IWR), Ruprecht–Karls–University of Heidelberg, Im Neuenheimer Feld 294, 69120 Heidelberg, Germany (thomas.lorenz@iwr.uni-heidelberg.de).

The state constraints are again formulated as a subset, i.e., now  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  (instead of  $V \subset \mathbb{R}^N$  for differential inclusions).

**Lipschitz vector fields for specifying time derivatives of curves in  $(\mathcal{K}(\mathbb{R}^N), \mathcal{d})$ .** For formulating the viability problem in the metric space  $(\mathcal{K}(\mathbb{R}^N), \mathcal{d})$ , we have to specify how compact subsets of  $\mathbb{R}^N$  are “deformed.” The so-called *velocity method* or *speed method* has led C  a, Delfour, Zol  sio, and others to remarkable results about shape optimization (see, e.g., [9, 12, 11, 33, 38] and the references there). It is based on prescribing a vector field  $v : \mathbb{R}^N \times [0, T] \longrightarrow \mathbb{R}^N$  such that the corresponding ordinary differential equation  $\frac{d}{dt} x(\cdot) = v(x(\cdot), \cdot)$  induces a unique flow on  $\mathbb{R}^N$ . Indeed, supposing  $v$  to be sufficiently smooth, the Cauchy problem

$$\frac{d}{dt} x(\cdot) = v(x(\cdot), \cdot) \text{ in } [0, T], \quad x(0) = x_0 \in \mathbb{R}^N$$

is always well-posed, and any compact initial set  $K \subset \mathbb{R}^N$  is deformed to

$$\vartheta_v(t, K) := \left\{ x(t) \mid \exists x(\cdot) \in C^1([0, t], \mathbb{R}^N) : \frac{d}{dt} x(\cdot) = v(x(\cdot), \cdot) \text{ in } [0, t], \ x(0) \in K \right\}$$

after an arbitrary time  $t \geq 0$ . As a key advantage, this concept of set evolution does not require any regularity conditions on the compact set  $K$  or its topological boundary (but only on the vector field  $v$ ). In other words,  $v$  can be interpreted as a “direction of deformation” for  $(\mathcal{K}(\mathbb{R}^N), \mathcal{d})$ . So it is “possible to define directional derivatives and speak of shape gradient and shape Hessian with respect to (w.r.t.) the associated vector space of velocities. This second approach has been known in the literature as the *velocity method*” [12, Chapter 1, section 6]. (The “first” approach mentioned there in [12] refers to perturbations of the identity map and applying techniques of differential geometry.)

Aubin seized this notion for extending ordinary differential equations to this metric space of compact subsets. The so-called *morphological equations* are sketched in [3] and then presented in [5, 4] in more detail. (They seem to be closer to ordinary differential equations in  $\mathbb{R}^N$  than Panasyuk’s concept of “quasi-differential equations” [29, 28, 27]. In contrast to [1], morphological equations dispense with any aspects of affine-linear structure.)

For a given curve  $K(\cdot) : [0, T] \longrightarrow \mathcal{K}(\mathbb{R}^N)$ , autonomous Lipschitz vector fields  $\mathbb{R}^N \longrightarrow \mathbb{R}^N$  are used for specifying the counterparts of time derivatives. To be more precise, a Lipschitz continuous field  $g : \mathbb{R}^N \longrightarrow \mathbb{R}^N$  represents a first-order approximation of  $K(\cdot)$  at time  $t \in [0, T[$  if

$$(*) \quad \limsup_{h \downarrow 0} \frac{1}{h} \cdot \mathcal{d}(K(t+h), \vartheta_g(h, K(t))) = 0$$

(see Figure 1.1). Obviously, this limit superior being equal to 0 is even a limit because distances are always nonnegative by definition. Of course, such a field  $g(\cdot)$  does not have to be unique, and thus *all* bounded Lipschitz vector fields with property  $(*)$  form the so-called *mutation*  $\overset{\circ}{K}(t)$  of  $K(\cdot)$  at time  $t \in [0, T[$ . In particular, the mutation is a *subset* of all bounded Lipschitz functions  $\mathbb{R}^N \longrightarrow \mathbb{R}^N$  and extends the time derivative to curves in the metric space  $(\mathcal{K}(\mathbb{R}^N), \mathcal{d})$ .

**Solving a morphological equation with state constraints: Aubin’s adaptation of Nagumo’s theorem.** The step from specifying a time derivative (of a

FIG. 1.1.

curve) to formulating a (generalized) differential equation is rather small. It is based just on prescribing the time derivative as a function of the current state. In connection with nonempty compact subsets of  $\mathbb{R}^N$ , a function  $f : \mathcal{K}(\mathbb{R}^N) \rightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  is given with  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  denoting the set of all bounded and Lipschitz continuous functions  $\mathbb{R}^N \rightarrow \mathbb{R}^N$ .

For any initial set  $K_0 \in \mathcal{K}(\mathbb{R}^N)$ , we are looking for  $K(\cdot) : [0, T] \rightarrow \mathcal{K}(\mathbb{R}^N)$  satisfying the following:

1.  $K(\cdot)$  is Lipschitz continuous w.r.t. the Pompeiu–Hausdorff distance  $\mathcal{d}$ ;
2.  $f(K(t)) \in \mathring{K}(t)$  for a.e.  $t \in [0, T]$ , i.e.,  $\lim_{h \downarrow 0} \frac{1}{h} \cdot \mathcal{d}(K(t+h), \vartheta_{f(K(t))}(h, K(t))) = 0$ ;
3.  $K(0) = K_0$ .

Then  $K(\cdot)$  is called a *solution* of the (autonomous) *morphological equation*  $\mathring{K}(\cdot) \ni f(K(\cdot))$  in  $[0, T]$  with initial value  $K_0$ .

At first glance, the symbol  $\ni$  here seems to be contradictory to the term “equation.” The mutation  $\mathring{K}(t)$ , however, is defined as a *subset* of all transitions providing a first-order approximation of  $K(t + \cdot)$ , and so the “right-hand side”  $f(K(t)) \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  should be one of its elements. (In the classical framework of differentiable functions and vector spaces, the mutation consists of just one vector.)

Considering now additional state constraints, the question about existence of a solution has been answered completely by Aubin in [4, Theorem 0.1]. In particular, the assumptions about state constraints and  $f(\cdot)$  justify its interpretation as a counterpart of Nagumo’s theorem. Some applications and further studies are presented in [19, 17, 21]. The asymptotic condition related to the term “contingent” here is explained in more detail in the subsequent remarks after Definition 2.9 and Theorem 2.10.

**PROPOSITION 1.1** (Nagumo’s theorem for morphological equations [5, 4]). *Suppose  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  to be nonempty and closed w.r.t.  $\mathcal{d}$ .*

*Let  $f : (\mathcal{K}(\mathbb{R}^N), \mathcal{d}) \rightarrow (\text{Lip}(\mathbb{R}^N, \mathbb{R}^N), \|\cdot\|_\infty)$  be a continuous function satisfying*

1. *the uniform bound of Lipschitz constants:  $\sup_{M \in \mathcal{K}(\mathbb{R}^N)} \text{Lip } f(M) < \infty$ ;*
2. *the uniform bound of supremum norms:  $\sup_{M \in \mathcal{K}(\mathbb{R}^N)} \|f(M)\|_\infty < \infty$ .*

*For any  $M \in \mathcal{V}$ , let  $f(M) \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  be contingent to  $\mathcal{V}$  at  $M$  in the sense that*

$$\begin{aligned} 0 &= \liminf_{h \downarrow 0} \frac{1}{h} \cdot \text{dist}(\vartheta_{f(M)}(h, M), \mathcal{V}) \\ &\stackrel{\text{Def.}}{=} \liminf_{h \downarrow 0} \frac{1}{h} \cdot \inf_{C \in \mathcal{V}} \mathcal{d}(\vartheta_{f(M)}(h, M), C). \end{aligned}$$

*Then from any  $K_0 \in \mathcal{V}$  starts a solution  $K(\cdot) : [0, \infty[ \rightarrow \mathcal{K}(\mathbb{R}^N)$  of the morphological equation  $\mathring{K}(\cdot) \ni f(K(\cdot))$  which is viable in  $\mathcal{V}$ , i.e.,  $K(t) \in \mathcal{V}$  for all  $t$ .*

**The new step to morphological inclusions.** This paper focuses on the corresponding conditions (of viability) if more than one Lipschitz field is admitted for each compact set, i.e., the single-valued function  $f : \mathcal{K}(\mathbb{R}^N) \longrightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  is replaced by a set-valued map  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ . This modification of given data leads directly to the following definition: A Lipschitz continuous curve  $K(\cdot) : [0, T] \longrightarrow (\mathcal{K}(\mathbb{R}^N), d)$  is called a *solution* of the *morphological inclusion*

$$\overset{\circ}{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset \quad \text{in } [0, T[$$

with starting value  $K(0) \subset \mathbb{R}^N$  if  $\mathcal{F}(K(t)) \cap \overset{\circ}{K}(t) \neq \emptyset$  for almost every  $t \in [0, T[$ ; i.e., there exists  $w \in \mathcal{F}(K(t)) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  with

$$\lim_{h \downarrow 0} \frac{1}{h} \cdot d(K(t+h), \vartheta_w(h, K(t))) = 0.$$

Obviously, every morphological equation can be regarded as a morphological inclusion (just with single-valued  $\mathcal{F}$ ). So this step provides a real extension.

Considering now additional state constraints on  $K(\cdot)$ , we note that Doyen [16] has given sufficient and some necessary conditions on  $\mathcal{F}(\cdot)$  and  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  for the *invariance* of  $\mathcal{V}$  (i.e., *all continuous* solutions starting in  $\mathcal{V}$  stay in  $\mathcal{V}$ ). His key notion is first to extend Filippov's existence theorem from differential inclusions (in  $\mathbb{R}^N$ ) to morphological inclusions in  $\mathcal{K}(\mathbb{R}^N)$  [16, Theorem 7.1] and then to verify  $\text{dist}(K(t), \mathcal{V}) = 0$  for all  $t \in [0, T[$  (under the assumption that the values of  $\mathcal{F}(\cdot)$  are always contained in the corresponding *contingent cone* to  $\mathcal{V}$ ) [16, Theorem 8.2].

The main result here concerns sufficient conditions on  $\mathcal{F}(\cdot)$  and  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  for the *viability* of  $\mathcal{V}$ ; i.e., *at least one* Lipschitz continuous solution has to stay in  $\mathcal{V}$ . This question (in a more general environment) was pointed out as open in [5, section 2.3.3] and, to the best of my knowledge, has not been answered even for the special case of morphological inclusions in any article submitted before.

In fact, the following statement is very similar to the viability theorem for differential inclusions in  $\mathbb{R}^N$  (as it is discussed in [2, Theorems 3.3.2 and 3.3.4] and quoted here in Theorem 3.3). Roughly speaking,  $\mathcal{F}$  is supposed to be upper semicontinuous with closed convex values—after specifying a suitable topology on  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  in a moment—and we require (at least) one “contingent direction” in the value  $\mathcal{F}(K) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  for each  $K \in \mathcal{V}$ .

**THEOREM 1.2** (viability theorem for morphological inclusions). *Let  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  be a set-valued map and  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  a nonempty closed subset satisfying the following:*

1. *all values of  $\mathcal{F}$  are nonempty and convex (i.e., for any  $\lambda \in [0, 1]$  and  $g_1, g_2 \in \mathcal{F}(K) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , the function  $\lambda \cdot g_1 + (1 - \lambda) \cdot g_2 \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  also belongs to  $\mathcal{F}(K)$ );*
2.  *$\sup_{M \in \mathcal{K}(\mathbb{R}^N)} \sup_{f \in \mathcal{F}(M)} \text{Lip } f < \infty$  (uniformly bounded Lipschitz constants),  $\sup_{M \in \mathcal{K}(\mathbb{R}^N)} \sup_{f \in \mathcal{F}(M)} \|f\|_\infty < \infty$  (uniformly bounded supremum norms);*
3. *the graph of  $\mathcal{F}$  is closed (w.r.t. locally uniform convergence in  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ );*
4. *for each  $K \in \mathcal{V}$ , some  $w \in \mathcal{F}(K) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  is contingent to  $\mathcal{V}$  at  $K$  in the sense that  $0 = \liminf_{h \downarrow 0} \frac{1}{h} \cdot \text{dist}(\vartheta_w(h, K), \mathcal{V})$ .*

*Then for every initial compact set  $K_0 \in \mathcal{V}$ , there exists at least one solution  $K(\cdot) : [0, 1] \longrightarrow \mathcal{K}(\mathbb{R}^N)$  of the morphological inclusion  $\overset{\circ}{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset$  with  $K(0) = K_0$  and  $K(t) \in \mathcal{V}$  for all  $t \in [0, 1]$ .*

The new analytical aspects are closely related to the proof of this theorem. Indeed, Haddad and others realized the theorem of Alaoglu as a powerful tool for constructing

solutions of differential inclusions in  $\mathbb{R}^N$  under state constraints. The counterparts of time derivatives here, however, form a bounded sequence in  $L^\infty([0, 1], \text{Lip}(\mathbb{R}^N, \mathbb{R}^N))$  which cannot be identified with a dual space in an obvious way. So results of Ülger [34] and Kisielewicz [23] come now into play for characterizing weakly compact subsets of the Bochner integrable functions  $[0, 1] \rightarrow X$  (denoted by  $L^1([0, 1], X)$ ) and the set  $C^0(K, X)$  of continuous functions  $K \rightarrow X$  with a real Banach space  $X$  and a nonempty compact set  $K \subset \mathbb{R}^N$ .

### Sketching an application to shape optimization under state constraints.

In shape optimization, the essential aim is to detect a minimizer of a given functional  $J : \mathcal{K}(\mathbb{R}^N) \rightarrow \mathbb{R}$  evaluating each nonempty compact set via a real number (see, e.g., [12, 11, 24, 33]). An additional set of constraints,  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$ , makes the problem rather complicated in general.

As an application of our viability theorem, Theorem 1.2, we suggest a set-valued map  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , with the objective that every solution  $K(\cdot) : [0, \infty[ \rightarrow \mathcal{K}(\mathbb{R}^N)$  of the morphological inclusion  $\dot{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset$  satisfy the following two conditions and thus provide candidates (for the wanted minimizer):

- (i)  $J \circ K : [0, \infty[ \rightarrow \mathbb{R}$ ,  $t \mapsto J(K(t))$  is nonincreasing, and
- (ii) every compact set  $C$  being the limit of  $(K(t_n))_{n \in \mathbb{N}}$  in  $\mathcal{V}$  in the sense of Painlevé–Kuratowski for some sequence  $t_n \nearrow \infty$  satisfies a necessary condition on minimizers (in the form of Fermat’s rule).

Then Theorem 1.2 provides sufficient conditions on  $\mathcal{F}$  and  $\mathcal{V}$  for the existence of at least one solution  $K(\cdot)$  with all its values in  $\mathcal{V}$  (see Proposition 4.6).

This introduction (section 1) reflects the structure of the paper: Aubin’s theory of morphological equations is summarized in section 2; in particular, we mention the counterparts of Filippov’s and Nagumo’s theorems for evolutions in the metric space  $(\mathcal{K}(\mathbb{R}^N), d)$ . Then section 3 provides the step to morphological inclusions. It starts with the viability theorem about differential inclusions (in section 3.1), collects the tools for Banach-valued functions (in section 3.2), and verifies the viability theorem for morphological inclusions (in section 3.3). Finally, in section 4, we present the analytical details of the application to shape optimization.

**2. A brief outline of morphological equations.** Morphological equations provide typical geometric examples of so-called mutational equations. First presented in [3] and elaborated in [4, 5], mutational equations extend ordinary differential equations to a metric space  $(E, d)$ . In a word, the key idea is to describe derivatives by means of continuous maps (called *transitions*)  $\vartheta : [0, 1] \times E \rightarrow E$ ,  $(h, x) \mapsto \vartheta(h, x)$  instead of affine-linear maps  $(h, x) \mapsto x + h v$  (which are usually used in *vector spaces*). Strictly speaking, such a transition specifies the point  $\vartheta(t, x) \in E$  to which any initial point  $x \in E$  has been moved after time  $t \in [0, 1]$ .

It can be interpreted as a first-order approximation of a curve  $\xi : [0, T[ \rightarrow E$  at time  $t \in [0, T[$  if

$$\lim_{h \downarrow 0} \frac{1}{h} \cdot d(\xi(t+h), \vartheta(h, \xi(t))) = 0.$$

So-called *morphological equations* apply this concept to the set  $\mathcal{K}(\mathbb{R}^N)$  of nonempty compact subsets of  $\mathbb{R}^N$  supplied with the Pompeiu–Hausdorff distance  $d$ ,

$$\begin{aligned} d(K_1, K_2) &:= \sup_{\substack{x \in K_2, \\ y \in K_1}} \max \left\{ \text{dist}(x, K_1), \text{dist}(y, K_2) \right\} \\ &= \inf \left\{ \rho > 0 \mid K_1 \subset K_2 + \rho \mathbb{B}_1, K_2 \subset K_1 + \rho \mathbb{B}_1 \right\}. \end{aligned}$$

Here  $\mathbb{B}_1$  always denotes the closed unit ball in  $\mathbb{R}^N$ , i.e.,  $\mathbb{B}_1 := \{x \in \mathbb{R}^N \mid |x| \leq 1\}$ . This is a very general starting point for geometric evolution problems as there are no a priori restrictions in regard to the regularity of sets and their boundaries. Motivated by the velocity method (often used in shape optimization; see, e.g., [9, 12, 11, 33, 38]), ordinary differential equations are here to lay the basis for transitions.

DEFINITION 2.1.  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  consists of all bounded and Lipschitz continuous functions  $\mathbb{R}^N \longrightarrow \mathbb{R}^N$ .

DEFINITION 2.2. Choosing any function  $f : \mathbb{R}^N \times [0, T] \longrightarrow \mathbb{R}^N$ , the so-called reachable set  $\vartheta_f(t, K)$  of the initial set  $K \in \mathcal{K}(\mathbb{R}^N)$  at time  $t \in [0, T]$  is defined as

$$\vartheta_f(t, K) := \left\{ x(t) \in \mathbb{R}^N \mid \exists x(\cdot) \in W^{1,1}([0, t], \mathbb{R}^N) : x(0) \in K, \right. \\ \left. \frac{d}{d\tau} x(\tau) = f(x(\tau), \tau) \text{ for a.e. } \tau \in [0, t] \right\}$$

(and correspondingly for an autonomous function  $f : \mathbb{R}^N \longrightarrow \mathbb{R}^N$ ).

The special case of constant functions  $f(\cdot) \equiv v$  (with an arbitrary vector  $v \in \mathbb{R}^N$ ) leads to the Minkowski sum  $\vartheta_f(t, K) = K + h \cdot v \subset \mathbb{R}^N$ , and for an initial set  $K = \{x\}$  with just one element, in particular, we return to the familiar affine-linear map  $(h, x) \longmapsto x + h \cdot v$  that has already been mentioned as motivation.

An essential contribution of Aubin was to specify appropriate continuity conditions on the maps  $\vartheta : [0, 1] \times E \longrightarrow E$ ,  $(h, x) \longmapsto \vartheta(h, x)$  so that the familiar track of ordinary differential equations can be followed in a metric space  $(E, d)$ . Here we quote his definition introduced in the monograph [5] (emphasizing the local features slightly more than his original version in [4]). Reachable sets of every function  $f \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  satisfy these conditions in the metric space  $(\mathcal{K}(\mathbb{R}^N), \mathcal{d})$ .

DEFINITION 2.3 (see [5, Definition 1.1.2]). Let  $(E, d)$  be a metric space. A map  $\vartheta : [0, 1] \times E \longrightarrow E$  is called a transition on  $(E, d)$  if it satisfies the following conditions:

1.  $\vartheta(0, x) = x$  for all  $x \in E$ ;
2.  $\lim_{h \downarrow 0} \frac{1}{h} \cdot d(\vartheta(t+h, x), \vartheta(h, \vartheta(t, x))) = 0$  for all  $x \in E$ ,  $t \in [0, 1[$ ;
3.  $\alpha(\vartheta) := \max(0, \sup_{x \neq y} \limsup_{h \downarrow 0} \frac{d(\vartheta(h, x), \vartheta(h, y)) - d(x, y)}{h \cdot d(x, y)}) < \infty$ ;
4.  $\beta(\vartheta) := \sup_{x \in E} \limsup_{h \downarrow 0} \frac{1}{h} \cdot d(x, \vartheta(h, x)) < \infty$ .

For any two transitions  $\vartheta_1, \vartheta_2 : [0, 1] \times E \longrightarrow E$  on the same metric space  $(E, d)$ , the transitional distance between  $\vartheta_1$  and  $\vartheta_2$  is defined by

$$d_\Lambda(\vartheta_1, \vartheta_2) := \sup_{x \in E} \limsup_{h \downarrow 0} \frac{1}{h} \cdot d(\vartheta_1(h, x), \vartheta_2(h, x)).$$

Compact reachable sets of ordinary differential equations supplied with metric  $\mathcal{d}$  satisfy all these conditions on transitions—as a consequence of the classical Cauchy–Lipschitz theorem (about solutions of ordinary differential equations).

LEMMA 2.4. For every  $f \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , the map  $\vartheta_f : [0, 1] \times \mathcal{K}(\mathbb{R}^N) \longrightarrow \mathcal{K}(\mathbb{R}^N)$ ,  $(h, K) \longmapsto \vartheta_f(h, K)$  of reachable sets (as introduced in Definition 2.2) is a well-defined transition on the metric space  $(\mathcal{K}(\mathbb{R}^N), \mathcal{d})$  according to Definition 2.3.

To be more precise, the reachable sets satisfy the following for all initial sets  $K, K_1, K_2 \in \mathcal{K}(\mathbb{R}^N)$ , vector fields  $f, g \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , and times  $t, h \geq 0$ :

$$\begin{aligned} \vartheta_f(0, K) &= K, \\ \vartheta_f(t+h, K) &= \vartheta_f(h, \vartheta_f(t, K)), \\ \mathcal{d}(\vartheta_f(h, K_1), \vartheta_f(h, K_2)) &\leq \mathcal{d}(K_1, K_2) \cdot e^{\text{Lip } f \cdot h}, \\ \mathcal{d}(\vartheta_f(h, K), \vartheta_g(h, K)) &\leq \|f - g\|_\infty \cdot h \cdot e^{\text{Lip } f \cdot h}, \\ \mathcal{d}(\vartheta_f(t, K), \vartheta_f(t+h, K)) &\leq \|f\|_\infty \cdot h. \end{aligned}$$

Thus,  $\alpha(\vartheta_f) \leq \text{Lip } f$ ,  $\beta(\vartheta_f) \leq \|f\|_\infty$ ,  $d_\Lambda(\vartheta_f, \vartheta_g) \leq \|f - g\|_\infty \stackrel{\text{Def.}}{=} \sup_{x \in \mathbb{R}^N} |f(x) - g(x)|$ .

In particular,  $d(\vartheta_f(h, K_1), \vartheta_g(h, K_2)) \leq e^{\text{Lip } f \cdot h} (d(K_1, K_2) + h \cdot \|f - g\|_\infty)$ .

The proof is presented in [5, Proposition 3.5.3]. In particular, this lemma justifies calling  $\vartheta_f$  a *shape transition* on  $(\mathcal{K}(\mathbb{R}^N), d)$  (or *morphological transition*, in accordance with [5, Definition 3.7.2]). For the sake of simplicity,  $f \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  is sometimes identified with its shape transition  $\vartheta_f$ .

These reachable sets provide the tools for specifying (generalized) shape derivatives of a compact-valued tube  $K(\cdot) : [0, T[ \rightsquigarrow \mathbb{R}^N$ , i.e., a curve  $K(\cdot) : [0, T[ \rightarrow \mathcal{K}(\mathbb{R}^N)$ . So the next step will be to solve equations prescribing an element of the shape mutation.

**DEFINITION 2.5** (see [5, section 3.5.4]). *For any compact-valued tube  $K(\cdot) : [0, T[ \rightsquigarrow \mathbb{R}^N$ , the shape mutation  $\mathring{K}(t)$  at time  $t \in [0, T[$  consists of all  $f \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  satisfying*

$$\lim_{h \downarrow 0} \frac{1}{h} \cdot d(\vartheta_f(h, K(t)), K(t+h)) = 0.$$

**DEFINITION 2.6.** *For any given function  $f : \mathcal{K}(\mathbb{R}^N) \times [0, T[ \rightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , a compact-valued  $K(\cdot) : [0, T[ \rightsquigarrow \mathbb{R}^N$  is called a solution of the morphological equation*

$$\mathring{K}(\cdot) \ni f(K(\cdot), \cdot)$$

if

1.  $K(\cdot) : [0, T[ \rightsquigarrow \mathbb{R}^N$  is Lipschitz continuous with respect to  $d$ , and
2. for almost every  $t \in [0, T[$ ,  $f(K(t), t) \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  belongs to  $\mathring{K}(t)$  or, equivalently,  $\lim_{h \downarrow 0} \frac{1}{h} \cdot d(\vartheta_{f(K(t), t)}(h, K(t)), K(t+h)) = 0$ .

These conditions on a solution are in accordance with [5, Definition 1.3.1] being formulated for the autonomous case (i.e.,  $f$  not depending on time explicitly).

As an essential result of [5, 4], the Euler algorithm can be applied in the framework of morphological equations, and so the Cauchy–Lipschitz theorem (about ordinary differential equations) has the following counterpart that is proved in [5, Theorem 4.1.2] for the more general case that the values of  $f$  are bounded Lipschitz continuous *set-valued* maps.

**THEOREM 2.7.** *Suppose  $f : (\mathcal{K}(\mathbb{R}^N), d) \rightarrow (\text{Lip}(\mathbb{R}^N, \mathbb{R}^N), \|\cdot\|_\infty)$  to be Lipschitz continuous with Lipschitz constant  $\lambda$  and  $M := \sup_{K \in \mathcal{K}(\mathbb{R}^N)} \text{Lip } f(K) < \infty$ .*

*For every initial set  $K_0 \in \mathcal{K}(\mathbb{R}^N)$  and time  $T > 0$ , there exists a unique compact-valued solution  $K(\cdot) : [0, T[ \rightsquigarrow \mathbb{R}^N$  of the morphological equation  $\mathring{K}(\cdot) \ni f(K(\cdot))$  with  $K(0) = K_0$ .*

*Furthermore every Lipschitz compact-valued tube  $Q : [0, \infty[ \rightsquigarrow \mathbb{R}^N$  with  $\mathring{Q}(t) \neq \emptyset$  for every  $t \geq 0$  satisfies the following estimate at each time  $t \geq 0$ :*

$$d(K(t), Q(t)) \leq d(K_0, Q(0)) \cdot e^{(M+\lambda)t} + \int_0^t e^{(M+\lambda)(t-s)} \cdot \inf_{g \in \mathring{Q}(s)} \|f(Q(s)) - g\|_\infty ds.$$

*In particular, the solution  $K(\cdot)$  depends on the initial set  $K_0$  and the right-hand side  $f$  in a Lipschitz continuous way.*

Existence under (additional) state constraints proves to be a very interesting question for many applications. In the particular case of ordinary differential equations, Nagumo's theorem gives a necessary and sufficient condition on the set of constraints  $\mathcal{V}$  for existence of local solutions. It uses the contingent cone (in the sense of Bouligand) and has served as a key motivation for viability theory (see, e.g., [2]).

DEFINITION 2.8 (see [2, Definition 1.1.3]). *Let  $X$  be a normed vector space, let  $V \subset X$  be nonempty, and let  $x \in V$ . The contingent cone to  $V$  at  $x$  (in the sense of Bouligand) is*

$$T_V(x) := \left\{ u \in X \mid \liminf_{h \downarrow 0} \frac{1}{h} \cdot \text{dist}(x + hu, V) = 0 \right\}.$$

This classical definition of contingent cone in a normed vector space is now extended to the metric space  $(\mathcal{K}(\mathbb{R}^N), \mathbf{d})$  by using the shape transitions of  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  (instead of affine-linear maps as in vector spaces).

DEFINITION 2.9 (see [5, Definition 1.5.2]). *For nonempty  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  and  $K \in \mathcal{V}$ ,*

$$T_{\mathcal{V}}(K) := \left\{ f \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N) \mid \liminf_{h \downarrow 0} \frac{1}{h} \cdot \text{dist}(\vartheta_f(h, K), \mathcal{V}) = 0 \right\}$$

*is called a contingent transition set of  $\mathcal{V}$  at  $K$ .*

*Remark.* Considering here the metric space  $(\mathcal{K}(\mathbb{R}^N), \mathbf{d})$  (instead of a normed vector space as in Definition 2.8) has an immediate consequence: By definition of the distance from a subset  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$ ,

$$\text{dist}(\vartheta_F(h, K), \mathcal{V}) \stackrel{\text{Def.}}{=} \inf_{C \in \mathcal{V}} \mathbf{d}(\vartheta_f(h, K), C),$$

with the Pompeiu–Hausdorff metric  $\mathbf{d}$  on the right-hand side. In particular, we cannot expect any trivial identities of the contingent cone to a compact subset  $V \subset \mathbb{R}^N$  and the contingent transition set to  $\mathcal{V} := \{V\} \subset \mathcal{K}(\mathbb{R}^N)$ . Furthermore, Theorem 2.10 below and the main result of this paper, i.e., Theorem 3.11, become definitely incorrect if the Pompeiu–Hausdorff distance  $\mathbf{d}$  is replaced by the one-sided distance part called Pompeiu–Hausdorff excess (as defined in [5, section 3.2.1]). A counterexample is given in the remark after Theorem 2.10.

*Remark.* The “geometric” background of reachable sets implies an additional property of shape transitions in  $T_{\mathcal{V}}(K) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ . Indeed, for any  $f \in T_{\mathcal{V}}(K)$ , every function  $g \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  with  $f(\cdot) = g(\cdot)$  in a neighborhood of  $\partial K$  is also contained in  $T_{\mathcal{V}}(K)$  because the Cauchy–Lipschitz theorem about ordinary differential equations ensures  $\partial \vartheta_f(t, K) = \vartheta_f(t, \partial K) = \vartheta_g(t, \partial K) = \partial \vartheta_g(t, K)$  for small  $t \geq 0$ . So in other words, the criterion of  $T_{\mathcal{V}}(K)$  depends only on an arbitrarily small neighborhood of the boundary  $\partial K$ .

In fact, Nagumo’s theorem also holds for morphological equations, as shown in [5, Theorem 4.1.7] (again for the more general case that  $f$  is a *single-valued* function whose values are uniformly bounded Lipschitz continuous *set-valued* maps  $\mathbb{R}^N \rightsquigarrow \mathbb{R}^N$ ).

THEOREM 2.10 (Nagumo theorem for morphological equations [5, Theorem 4.1.7]). *Suppose  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  to be nonempty and closed w.r.t.  $\mathbf{d}$ .*

*Let  $f : (\mathcal{K}(\mathbb{R}^N), \mathbf{d}) \longrightarrow (\text{Lip}(\mathbb{R}^N, \mathbb{R}^N), \|\cdot\|_{\infty})$  be a continuous function satisfying*

1.  $\sup_{M \in \mathcal{K}(\mathbb{R}^N)} \text{Lip } f(M) < \infty$ ,
2.  $\sup_{M \in \mathcal{K}(\mathbb{R}^N)} \|f(M)\|_{\infty} < \infty$ .

*Then from any initial state  $K_0 \in \mathcal{V}$  starts at least one Lipschitz solution  $K(\cdot) : [0, T[ \longrightarrow \mathcal{K}(\mathbb{R}^N)$  of  $\dot{K}(\cdot) \ni f(K(\cdot))$  viable in  $\mathcal{V}$  (i.e.,  $K(t) \in \mathcal{V}$  for all  $t$ ) if and only if  $\mathcal{V}$  is a viability domain of  $f$  in the sense of  $f(M) \in T_{\mathcal{V}}(M)$  for each  $M \in \mathcal{V}$ .*

*Remark.* A simple example proves that the one-sided Hausdorff distance—a.k.a. Pompeiu–Hausdorff excess—as defined in [5, section 3.2.1]), namely,

$$h^{\sharp}(K_1, K_2) := \sup_{x \in K_1} \inf_{y \in K_2} |x - y| \quad \text{for } K_1, K_2 \in \mathcal{K}(\mathbb{R}^N),$$

must not replace the Pompeiu–Hausdorff metric in Definition 2.9 of the contingent transition set. Consider  $\mathcal{V} := \{\mathbb{B}_1\}$  with the closed unit ball  $\mathbb{B}_1 \subset \mathbb{R}^N$  and the constant map  $f(\cdot) \equiv f_0$  with  $f_0 : \mathbb{R}^N \rightarrow \mathbb{R}^N$ ,  $x \mapsto \frac{-x}{1+|x|}$ . Indeed, the flow along  $f_0$  makes the unit ball shrink strictly, and thus  $\vartheta_{f_0}(t, \mathbb{B}_1) \subset \mathbb{R}^N$  is contained in the interior of the unit ball  $\mathbb{B}_1$  for any  $t > 0$ , i.e.,  $\vartheta_{f_0}(t, \mathbb{B}_1) \notin \mathcal{V}$  and  $h^\#(\vartheta_{f_0}(t, \mathbb{B}_1), \mathbb{B}_1) = 0$ .

$h^\#$  can be useful, however, for other types of viability problems, such as those examples discussed in [30].

**3. The step to morphological inclusions.** The main goal now is to prove a similar viability theorem for morphological *inclusions*; i.e., the single-valued function  $f : \mathcal{K}(\mathbb{R}^N) \rightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  of the right-hand side is to be replaced by a set-valued map  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ . Correspondingly to Definition 2.6, we introduce the solution of a morphological inclusion in the following way.

**DEFINITION 3.1.** *For any given function  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , a compact-valued  $K(\cdot) : [0, T[ \rightsquigarrow \mathbb{R}^N$  is called a solution of the morphological inclusion*

$$\mathring{K}(\cdot) \cap \mathcal{F}(K(\cdot), \cdot) \neq \emptyset$$

if

1.  $K(\cdot) : [0, T[ \rightsquigarrow \mathbb{R}^N$  is Lipschitz continuous w.r.t.  $d$ , and
2.  $\mathcal{F}(K(t)) \cap \mathring{K}(t) \neq \emptyset$  for almost every  $t$ ; i.e., some  $w \in \mathcal{F}(K(t)) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  belongs to  $\mathring{K}(t)$  or, equivalently,  $\lim_{h \downarrow 0} \frac{1}{h} \cdot d(K(t+h), \vartheta_w(h, K(t))) = 0$ .

**3.1. The (well-known) viability theorem for differential inclusions.** The situation has already been investigated extensively for differential inclusions in  $\mathbb{R}^N$  (see, e.g., [2, 6]). For clarifying the new aspects of morphological inclusions, we now quote the corresponding result from [2, Theorems 3.3.2 and 3.3.5] after specifying the required terms.

**DEFINITION 3.2** (see [2, Definition 2.2.4]). *Let  $X$  and  $Y$  be normed vector spaces. A set-valued map  $F : X \rightsquigarrow Y$  is called a Marchaud map if it has the following properties:*

1.  $F$  is nontrivial, i.e.,  $\text{Graph } F \neq \emptyset$ ;
2.  $F$  is upper semicontinuous; i.e., for any  $x \in X$ , neighborhood  $V \supset F(x)$ ,  $\exists$  neighborhood  $U \subset X$  of  $x$  s.t.  $F(U) \subset V$ ;
3.  $F$  has compact convex values;
4.  $F$  has linear growth, i.e.,  $\sup_{y \in F(x)} |y| \leq C(1 + |x|)$  for all  $x \in X$ .

**THEOREM 3.3** (viability theorem for differential inclusions [2, Theorems 3.3.2 and 3.3.5]). *Consider a Marchaud map  $F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$  and a nonempty closed subset  $V \subset \mathbb{R}^N$  with  $F(x) \neq \emptyset$  for all  $x \in V$ .*

*Then for any  $T \in ]0, \infty[$ , the following two statements are equivalent:*

1. *For every point  $x_0 \in V$ , there is at least one solution  $x(\cdot) \in W^{1,1}([0, T], \mathbb{R}^N)$  of  $x'(\cdot) \in F(x(\cdot))$  (almost everywhere) with  $x(0) = x_0$  and  $x(t) \in V$  for all  $t$ .*
2.  *$F(x) \cap T_V(x) \neq \emptyset$  for all  $x \in V$ .*

The implication (1.)  $\implies$  (2.) is rather obvious. For proving (2.)  $\implies$  (1.), a standard approach uses an “approximating” sequence  $(x_n(\cdot))_{n \in \mathbb{N}}$  in  $W^{1,\infty}([0, 1], \mathbb{R}^N)$  such that  $\sup_t \text{dist}(x_n(t), V) \rightarrow 0$  ( $n \rightarrow \infty$ ) and  $(x_n(t), \frac{d}{dt} x_n(t))$  is close to  $\text{Graph } F \subset \mathbb{R}^N \times \mathbb{R}^N$  for almost every  $t$ . Then the theorems of Arzelà–Ascoli and Alaoglu provide a subsequence  $(x_{n_j}(\cdot))_{j \in \mathbb{N}}$  and limits  $x(\cdot) \in C^0([0, 1], \mathbb{R}^N)$ ,  $w(\cdot) \in L^\infty([0, 1], \mathbb{R}^N)$  with

$$x_{n_j}(\cdot) \rightarrow x(\cdot) \text{ uniformly, } \quad \frac{d}{dt} x_{n_j}(\cdot) \rightarrow w(\cdot) \text{ weakly}^* \text{ in } L^\infty([0, 1], \mathbb{R}^N).$$

Due to the continuous embedding  $L^\infty([0, 1], \mathbb{R}^N) \subset L^1([0, 1], \mathbb{R}^N)$ , we even obtain the convergence  $\frac{d}{dt} x_{n_j}(\cdot) \longrightarrow w(\cdot)$  weakly in  $L^1([0, 1], \mathbb{R}^N)$ . Thus,  $w(\cdot)$  is the weak derivative of  $x(\cdot)$ , and  $x(\cdot)$  is Lipschitz continuous. Finally Mazur's lemma quoted in Proposition 3.5 below implies

$$w(t) \in \bigcap_{\varepsilon > 0} \overline{\text{co}} \left( \bigcup_{z \in \mathbb{B}_\varepsilon(x(t))} F(z) \right) = F(x(t)) \quad \text{for a.e. } t.$$

Considering now morphological inclusions on  $(\mathcal{K}(\mathbb{R}^N), d)$  (instead of differential inclusions), an essential aspect changes: The derivative of a curve is no longer represented as a function in  $L^1([0, 1], \mathbb{R}^N)$ , but rather as a function  $[0, 1] \longrightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ . So the classical theorems of Arzelà–Ascoli, Alaoglu, and Mazur might have to be replaced by their counterparts concerning functions with their values in a Banach space (instead of  $\mathbb{R}^N$ ).

**3.2. Tools for functions with values in metric or Banach spaces.** Before adapting this concept for finite-dimensional differential inclusions to Banach-valued functions, we collect briefly the main tools in this framework. They consist mainly of (particularly weakly sequential) compactness criteria for both Bochner-integrable functions on a probabilistic space and continuous functions on a compact Hausdorff space.

First of all, the theorems of Arzelà–Ascoli and Mazur do not change significantly. Indeed, we always use the following general versions in this paper.

**PROPOSITION 3.4** (Arzelà–Ascoli in metric spaces [22]). *Let  $(E_1, d_1)$ ,  $(E_2, d_2)$  be precompact metric spaces; i.e., for any  $\varepsilon > 0$ , each set  $E_i$  ( $i = 1, 2$ ) can be covered by finitely many  $\varepsilon$ -balls w.r.t. metric  $d_i$ . Moreover, suppose the sequence  $(f_n)_{n \in \mathbb{N}}$  of functions  $E_1 \longrightarrow E_2$  to be uniformly equicontinuous (i.e., with a common modulus of continuity in  $E_1$ ).*

*Then there exists a subsequence  $(f_{n_j})_{j \in \mathbb{N}}$  that is a Cauchy sequence w.r.t. uniform convergence. If  $(E_2, d_2)$  is complete in addition, then  $(f_{n_j})_{j \in \mathbb{N}}$  converges uniformly to a continuous function  $E_1 \longrightarrow E_2$ .*

**PROPOSITION 3.5** (Mazur's lemma [36, section V.1, Theorem 2]). *For any weakly converging sequence  $(x_n)_{n \in \mathbb{N}}$  in a normed vector space, its weak limit is contained in the closed convex hull of  $\{x_n \mid n \in \mathbb{N}\}$ .*

The so-called Bochner integral extends the familiar concept of integration from real-valued functions to Banach-valued functions on the basis of “simple” functions.

**DEFINITION 3.6** (see [15]). *Let  $(\Omega, \Sigma, \mu)$  be a finite measure space and  $X$  a Banach space. A function  $f : \Omega \longrightarrow X$  is called simple if there exist  $x_1, x_2, \dots, x_n \in X$  and  $E_1, E_2, \dots, E_n \in \Sigma$  such that  $f = \sum_{j=1}^n x_j \chi_{E_j}$ , with  $\chi_{E_j} : \Omega \longrightarrow \{0, 1\}$  denoting the characteristic function of  $E_j \subset \Omega$ .*

*A function  $f : \Omega \longrightarrow X$  is called  $\mu$ -measurable if there exists a sequence  $(f_n)_{n \in \mathbb{N}}$  of simple functions  $\Omega \longrightarrow X$  with  $\|f - f_n\|_X \longrightarrow 0$   $\mu$ -almost everywhere for  $n \rightarrow \infty$ .*

*A  $\mu$ -measurable function  $f : \Omega \longrightarrow X$  is called Bochner integrable if there exists a sequence  $(f_n)_{n \in \mathbb{N}}$  of simple functions  $\Omega \longrightarrow X$  such that*

$$\lim_{n \rightarrow \infty} \int_{\Omega} \|f - f_n\|_X \, d\mu = 0.$$

*Then the Bochner integral of  $f$  over  $E \in \Sigma$  is defined by  $\int_E f \, d\mu := \lim_{n \rightarrow \infty} \int_E f_n \, d\mu$ . Let  $L^1(\mu, X)$  denote the Banach space of Bochner integrable functions  $\Omega \longrightarrow X$  equipped with its usual  $L^1$  norm.*

In the nineties, Ülger proved that restricting the values of Bochner integrable functions to a weakly compact subset of  $X$  implies the relative weak compactness of these functions in  $L^1(\mu, X)$ . For real-valued Lebesgue integrable functions, this is closely related with Alaoglu's theorem and a compact embedding.

**PROPOSITION 3.7** (see [34, Proposition 7]). *Let  $(\Omega, \Sigma, \mu)$  be a probabilistic space and  $X$  an arbitrary Banach space. For any weakly compact subset  $W \subset X$ , the set*

$$\{h \in L^1(\mu, X) \mid h(\omega) \in W \text{ for } \mu\text{-a.e. } \omega \in \Omega\}$$

*is relatively weakly compact in  $L^1(\mu, X)$ .*

An earlier version of this result is presented in [13], and [14] considers weak compactness of Bochner integrable functions with values in an arbitrary Banach space under weaker assumptions (see also [8]). The next proposition of Ülger provides a “weakly pointwise” characterization of weakly convergent sequences in  $L^1(\mu, X)$ .

**PROPOSITION 3.8** (see [34, Corollary 5]). *Let  $(\Omega, \Sigma, \mu)$  be a probabilistic space and  $X$  an arbitrary Banach space as in Proposition 3.7.*

*Set  $W := \{g \in L^1(\mu, X) \mid |g(\omega)| \leq 1 \text{ for } \mu\text{-almost every } \omega \in \Omega\}$ .*

*A sequence  $(g_n(\cdot))_{n \in \mathbb{N}}$  in  $W \subset L^1(\mu, X)$  converges weakly to  $g \in L^1(\mu, X)$  if and only if, for any subsequence  $(g_{n_k}(\cdot))_{k \in \mathbb{N}}$  given, there exists a sequence  $(h_k(\cdot))_{k \in \mathbb{N}}$  with  $h_k \in \text{co}\{g_{n_k}, g_{n_{k+1}}, \dots\}$  such that for  $\mu$ -almost every  $\omega \in \Omega$ ,*

$$h_k(\omega) \longrightarrow g(\omega) \quad (k \longrightarrow \infty) \quad \text{weakly in } X.$$

In fact, the classical theorem of Scorza-Dragoni [32] has a counterpart for Banach-valued functions as shown by Ricceri and Villani [31]. A so-called Carathéodory function depends on two arguments, and it is measurable w.r.t. the first one and continuous w.r.t. the second one. The key point of Scorza-Dragoni is to ensure continuity w.r.t. both arguments on “almost” the whole domain in the following sense.

**PROPOSITION 3.9** (see [31, Theorem 1]). *Let  $S$  be a compact Hausdorff topological space,  $\mu$  a Radon measure on  $S$ , and  $X, Y$  metric spaces. Suppose  $X$  to be separable.*

*Then every Carathéodory function  $g : S \times X \longrightarrow Y$  satisfies the so-called Scorza-Dragoni property; i.e., for every  $\varepsilon > 0$ , there exists a closed subset  $S_\varepsilon \subset S$  with  $\mu(S \setminus S_\varepsilon) < \varepsilon$  such that the restriction  $g|_{S_\varepsilon \times X}$  is continuous.*

So this proposition can be regarded as a counterpart of the well-known Lusin theorem (relating measurability to continuity almost everywhere)—but for functions with two arguments.

Last but not least, we quote a result of Kisielewicz characterizing weakly converging sequences of continuous functions on a compact Hausdorff space (like  $[0, T] \subset \mathbb{R}$ ).

**PROPOSITION 3.10** (see [23, Theorem 3]). *Let  $S$  be a compact Hausdorff space and  $X$  an arbitrary Banach space.  $C^0(S, X)$  denotes the Banach space of continuous functions  $S \longrightarrow X$  supplied with the supremum norm  $\|\cdot\|_\infty$ .*

*A sequence  $(g_n(\cdot))_{n \in \mathbb{N}}$  in  $C^0(S, X)$  converges weakly to  $g \in C^0(S, X)$  if and only if*

$$\bigwedge \left\{ \begin{array}{ll} \sup_n \|g_n\|_\infty < \infty & \text{and} \\ g_n(s) \longrightarrow g(s) & \text{weakly in } X \quad (n \longrightarrow \infty) \quad \text{for every } s \in S. \end{array} \right.$$

**3.3. Adapting this concept to morphological inclusions.** Now  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  and a set of constraints  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  are given.

Correspondingly to Theorem 3.3 about differential inclusions, we focus on the so-called *viability condition*, demanding from each compact set  $K \in \mathcal{V}$  that the value

$\mathcal{F}(K)$  and the contingent transition set  $T_{\mathcal{V}}(K) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  have at least one transition in common. Lacking a concrete counterpart of the Aumann integral in the metric space  $(\mathcal{K}(\mathbb{R}^N), \mathbf{d})$ , the question of its necessity (for the existence of solutions “viable in  $\mathcal{V}$ ”) is more complicated than for differential inclusions in  $\mathbb{R}^N$ , and thus we skip it here deliberately.

The main contribution of this paper is that in combination with appropriate assumptions about  $\mathcal{F}(\cdot)$  and  $\mathcal{V}$ , the viability condition is *sufficient*.

**THEOREM 3.11.** *Let  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  be a set-valued map and  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  a nonempty closed subset satisfying the following:*

1. *all values of  $\mathcal{F}$  are nonempty and convex;*
2.  *$A := \sup_{M \in \mathcal{K}(\mathbb{R}^N)} \sup_{f \in \mathcal{F}(M)} \text{Lip } f < \infty$ ,  $B := \sup_{M \in \mathcal{K}(\mathbb{R}^N)} \sup_{f \in \mathcal{F}(M)} \|f\|_{\infty} < \infty$ ;*
3. *the graph of  $\mathcal{F}$  is closed (w.r.t. locally uniform convergence in  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ );*
4.  *$T_{\mathcal{V}}(M) \cap \mathcal{F}(M) \neq \emptyset$  for all  $M \in \mathcal{V}$ .*

*Then for every initial compact set  $K_0 \in \mathcal{V}$ , there exists at least one compact-valued Lipschitz continuous solution  $K(\cdot) : [0, 1] \rightsquigarrow \mathbb{R}^N$  of the morphological inclusion  $\mathring{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset$  with  $K(0) = K_0$  and  $K(t) \in \mathcal{V}$  for all  $t \in [0, 1]$ .*

The proof is given in several steps using the notation of Theorem 3.11 (about constants  $A, B$ ). It is based on approximative solutions.

**LEMMA 3.12** (constructing approximative solutions). *Choose any  $\varepsilon > 0$ .*

*Under the assumptions of the viability theorem, Theorem 3.11, there exist a  $B$ -Lipschitz continuous function  $K_{\varepsilon}(\cdot) : [0, 1] \rightarrow \mathcal{K}(\mathbb{R}^N)$  and a piecewise constant function  $f_{\varepsilon}(\cdot) : [0, 1[ \rightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  satisfying the following with  $R_{\varepsilon} := \varepsilon e^A$ :*

- (a)  $K_{\varepsilon}(0) = K_0$ ;
- (b)  $\text{dist}(K_{\varepsilon}(t), \mathcal{V}) \leq R_{\varepsilon}$  for all  $t \in [0, 1]$ ;
- (c)  $f_{\varepsilon}(t) \in \mathring{K}_{\varepsilon}(t) \cap \mathcal{F}(\mathbb{B}_{R_{\varepsilon}}(K_{\varepsilon}(t))) \neq \emptyset$  for all  $t \in [0, 1[$ .

*Proof.* The proof follows the same track as [5, Lemma 1.6.5] and uses Zorn’s lemma: For  $\varepsilon > 0$  fixed, let  $\mathcal{A}_{\varepsilon}(K_0)$  denote the set of all tuples  $(\tau_K, K(\cdot), f(\cdot))$  consisting of some  $\tau_K \in [0, 1]$ , a  $B$ -Lipschitz continuous function  $K(\cdot) : [0, \tau_K] \rightarrow (\mathcal{K}(\mathbb{R}^N), \mathbf{d})$ , and some piecewise constant function  $f(\cdot) : [0, 1[ \rightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  such that

- (a)  $K(0) = K_0$ ;
- (b') (1)  $\text{dist}(K(\tau_K), \mathcal{V}) \leq r_{\varepsilon}(\tau_K)$  with  $r_{\varepsilon}(t) := \varepsilon e^{At}$ ,  
(2)  $\text{dist}(K(t), \mathcal{V}) \leq R_{\varepsilon}$  for all  $t \in [0, \tau_K]$ ;
- (c)  $f(t) \in \mathring{K}(t) \cap \mathcal{F}(\mathbb{B}_{R_{\varepsilon}}(K(t))) \neq \emptyset$  for all  $t \in [0, \tau_K[$ .

Obviously,  $\mathcal{A}_{\varepsilon}(K_0)$  is not empty since it contains  $(0, K(\cdot) \equiv K_0, f(\cdot) \equiv z_0)$  with the zero function  $z_0 \equiv 0 \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ . Moreover, an order relation  $\preceq$  on  $\mathcal{A}_{\varepsilon}(K_0)$  is specified by

$$(\tau_K, K(\cdot), f(\cdot)) \preceq (\tau_M, M(\cdot), g(\cdot)) :\Longleftrightarrow \tau_K \leq \tau_M, M|_{[0, \tau_K]} = K, g|_{[0, \tau_K]} = f.$$

So Zorn’s lemma provides a maximal element  $(\tau, K_{\varepsilon}(\cdot), f_{\varepsilon}(\cdot)) \in \mathcal{A}_{\varepsilon}(K_0)$ .

As all considered functions with values in  $\mathcal{K}(\mathbb{R}^N)$  have been supposed to be  $B$ -Lipschitz continuous,  $K_{\varepsilon}(\cdot)$  is also  $B$ -Lipschitz continuous in  $[0, \tau[$ . In particular,  $K_{\varepsilon}(\cdot)$  can always be extended to the closed interval  $[0, \tau] \subset [0, 1]$  in a unique way.

Assuming  $\tau < 1$  for a moment, we obtain a contradiction if  $K_{\varepsilon}(\cdot), f_{\varepsilon}(\cdot)$  can be extended to a larger interval  $[0, \tau + \delta] \subset [0, 1]$  ( $\delta > 0$ ) preserving conditions (b’), (c).

Since closed bounded balls of  $(\mathcal{K}(\mathbb{R}^N), \mathbf{d})$  are compact, the closed set  $\mathcal{V}$  contains an element  $Z \in \mathcal{K}(\mathbb{R}^N)$  with  $\mathbf{d}(K_{\varepsilon}(\tau), Z) = \text{dist}(K_{\varepsilon}(\tau), \mathcal{V}) \leq r_{\varepsilon}(\tau)$ , and assumption 4

of Theorem 3.11 provides an element

$$g \in T_V(Z) \cap \mathcal{F}(Z) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N).$$

Due to Definition 2.9 of the contingent transition set  $T_V(Z)$ , there is a sequence  $h_m \downarrow 0$  in  $]0, 1 - \tau[$  such that  $\text{dist}(\vartheta_g(h_m, Z), V) \leq \varepsilon h_m$  for all  $m \in \mathbb{N}$ . Now set

$$K_\varepsilon(t) := \vartheta_g(t - \tau, K_\varepsilon(\tau)), \quad f_\varepsilon(t) := g \quad \text{for each } t \in [\tau, \tau + h_1].$$

Obviously, Lemma 2.4 implies  $g \in \mathring{K}_\varepsilon(t)$  for all  $t \in [\tau, \tau + h_1[$ . Moreover, it leads to

$$\begin{aligned} d(K_\varepsilon(t), Z) &\leq d(\vartheta_g(t - \tau, K_\varepsilon(\tau)), K_\varepsilon(\tau)) + d(K_\varepsilon(\tau), Z) \\ &\leq B \cdot (t - \tau) + \varepsilon e^{A\tau} \tau \leq R_\varepsilon \end{aligned}$$

for every  $t \in [\tau, \tau + \delta[$  with  $\delta := \min\{h_1, \varepsilon e^{A\frac{1-\tau}{1+B}}\}$ ; i.e., conditions (b')(2) and (c) hold in the interval  $[\tau, \tau + \delta]$ . For any index  $m \in \mathbb{N}$  with  $h_m < \delta$ ,

$$\begin{aligned} \text{dist}(K_\varepsilon(\tau + h_m), V) &\leq d(\vartheta_g(h_m, K_\varepsilon(\tau)), \vartheta_g(h_m, Z)) + \text{dist}(\vartheta_g(h_m, Z), V) \\ &\leq d(K_\varepsilon(\tau), Z) \cdot e^{Ah_m} + \varepsilon \cdot h_m \\ &\leq \varepsilon e^{A\tau} \tau \cdot e^{Ah_m} + \varepsilon \cdot h_m \leq r_\varepsilon(\tau + h_m); \end{aligned}$$

i.e., condition (b')(1) is also satisfied at time  $t = \tau + h_m$  with any large  $m \in \mathbb{N}$ .

So  $K_\varepsilon(\cdot)|_{[0, \tau+h_m]}$  and  $f_\varepsilon(\cdot)|_{[0, \tau+h_m]}$  provide the wanted contradiction, and thus  $\tau = 1$ .  $\square$

Using the abbreviation  $\tilde{K}_j := \mathbb{B}_{j+B}(K_0) \stackrel{\text{Def.}}{=} \{x \in \mathbb{R}^N \mid \text{dist}(x, K_0) \leq j + B\}$  ( $j \in \mathbb{N}$ ) for (arbitrarily large) compact neighborhoods of the initial set  $K_0$ , we obtain the following.

**LEMMA 3.13** (selecting an approximative subsequence). *Under the assumptions of the viability theorem, Theorem 3.11, there are sequences  $K_n(\cdot) : [0, 1] \rightarrow \mathcal{K}(\mathbb{R}^N)$ ,  $f_n(\cdot) : [0, 1[ \rightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  ( $n \in \mathbb{N}$ ) and functions  $K(\cdot) : [0, 1] \rightarrow \mathcal{K}(\mathbb{R}^N)$ ,  $f(\cdot) : [0, 1[ \rightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  such that for every  $j, n \in \mathbb{N}$ ,*

- (a)  $K_0 = K_n(0) = K(0)$ ;
- (b)  $K(\cdot)$  and  $K_n(\cdot)$  are  $B$ -Lipschitz continuous w.r.t.  $d$ ;
- (c)  $f_n(\cdot)$  is piecewise constant,  $\sup_{t \in [0, 1[} \text{Lip } f_n(t) \leq A < \infty$ ,  
 $\sup_{t \in [0, 1[} \|f_n(t)\|_\infty \leq B < \infty$ ;
- (d)  $\text{dist}(K_n(t), V) \leq \frac{1}{n}$  for all  $t \leq 1$ ;
- (e)  $f_n(t) \in \mathring{K}_n(t) \cap \mathcal{F}(\mathbb{B}_{1/n}(K_n(t))) \neq \emptyset$  for all  $t < 1$ ;
- (f)  $d(K_m(\cdot), K(\cdot)) \rightarrow 0$  uniformly in  $[0, 1]$  for  $m \rightarrow \infty$ ;
- (g)  $f_m(\cdot)|_{\tilde{K}_j} \rightarrow f(\cdot)|_{\tilde{K}_j}$  weakly in  $L^1([0, 1], C^0(\tilde{K}_j, \mathbb{R}^N))$  for  $m \rightarrow \infty$ ;
- (h)  $\text{Lip } f(t)(\cdot) \leq A$ ,  $\|f(t)(\cdot)\|_\infty \leq B$  for almost every  $t < 1$ .

*Proof.* The proof is based on the approximative solutions of Lemma 3.12, of course.

Indeed, for each index  $n \in \mathbb{N}$ , Lemma 3.12 provides  $K_n(\cdot) : [0, 1] \rightarrow \mathcal{K}(\mathbb{R}^N)$  and  $f_n(\cdot) : [0, 1[ \rightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  corresponding to  $\varepsilon := \frac{1}{n} e^{-A}$ . Obviously, they satisfy the properties (a)–(e) claimed here.

In particular, these features stay correct whenever we consider subsequences instead and again abbreviate them as  $(K_n(\cdot))_{n \in \mathbb{N}}$ ,  $(f_n(\cdot))_{n \in \mathbb{N}}$ , respectively.

For property (f) about uniform convergence of  $(K_n(\cdot))$  w.r.t.  $d$ . The  $B$ -Lipschitz continuity of each  $K_n(\cdot)$  has two important consequences:

1. all  $K_n(\cdot) : [0, 1] \rightarrow (\mathcal{K}(\mathbb{R}^N), d)$  ( $n \in \mathbb{N}$ ) are equicontinuous, and

2.  $\bigcup_{\substack{n \in \mathbb{N} \\ t \in [0,1]}} \{K_n(t)\}$  is contained in the compact subset  $\mathbb{B}_B(K_0)$  of  $(\mathcal{K}(\mathbb{R}^N), \mathcal{d})$ .

So, Proposition 3.4 of Arzelà–Ascoli provides a subsequence (again denoted by)  $(K_n(\cdot))_n$  converging uniformly to a continuous function  $K(\cdot) : [0, 1] \longrightarrow (\mathcal{K}(\mathbb{R}^N), \mathcal{d})$ . In particular,  $K(\cdot)$  is also  $B$ -Lipschitz continuous with  $K(0) = K_0$ ; i.e., properties (a)–(f) are fulfilled completely.

For property (g) about weak convergence of  $f_n(\cdot)|_{\tilde{K}}$  with fixed compact  $\tilde{K} \subset \mathbb{R}^N$ . We can no longer follow the same track as for differential inclusions. Indeed, the functions  $f_n(\cdot)$  of shape transitions have their values in  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , which cannot be regarded as a dual space in an obvious way. So Alaoglu’s theorem (stating that closed balls of dual Banach spaces are weakly\* compact) cannot be applied similarly to differential inclusions.

Alternatively, we restrict our considerations to a compact neighborhood  $\tilde{K}$  of  $\bigcup_{\substack{n \in \mathbb{N} \\ t \in [0,1]}} K_n(t) \subset \mathbb{R}^N$  and use a sufficient condition on relatively weakly compact sets in  $L^1([0, 1], C^0(\tilde{K}, \mathbb{R}^N))$ . Here  $C^0(\tilde{K}, \mathbb{R}^N)$  (supplied with the supremum norm  $\|\cdot\|_\infty$ ) denotes the Banach space of all continuous functions  $\tilde{K} \longrightarrow \mathbb{R}^N$ .

In fact, the set  $\{f_n(t) \mid n \in \mathbb{N}, t \in [0, 1]\} \subset C^0(\mathbb{R}^N, \mathbb{R}^N)$  is uniformly bounded by  $B$  and equicontinuous (due to property (c)). So according to Proposition 3.4 of Arzelà–Ascoli, the set of their restrictions to  $\tilde{K}$

$$W := \left\{ f_n(t)|_{\tilde{K}} \mid n \in \mathbb{N}, t \in [0, 1] \right\} \subset C^0(\tilde{K}, \mathbb{R}^N)$$

is relatively compact w.r.t.  $\|\cdot\|_\infty$ . Thus,  $\{f_n(\cdot)|_{\tilde{K}} \mid n \in \mathbb{N}\}$  is relatively weakly compact in  $L^1([0, 1], C^0(\tilde{K}, \mathbb{R}^N))$  according to Proposition 3.7, and we obtain a subsequence (again denoted by)  $(f_n(\cdot))_{n \in \mathbb{N}}$  and some  $g(\cdot) \in L^1([0, 1], C^0(\tilde{K}, \mathbb{R}^N))$  with  $f_n(\cdot)|_{\tilde{K}} \longrightarrow g(\cdot)$  weakly in  $L^1([0, 1], C^0(\tilde{K}, \mathbb{R}^N))$ .

Obviously, both the subsequence and  $g(\cdot)$  depend on  $\tilde{K}$ , however.

For property (g) about  $f_n(\cdot)|_{\tilde{K}_j}$  with every compact  $\tilde{K}_j \subset \mathbb{R}^N$  ( $j \in \mathbb{N}$ ). Now this construction of subsequences is applied to the compact subsets  $\tilde{K}_j \stackrel{\text{def.}}{=} \mathbb{B}_{j+B}(K_0)$  of  $\mathbb{R}^N$  for  $j = 1, 2, 3 \dots$  successively. By means of Cantor’s diagonal construction, we obtain a subsequence (again denoted by)  $(f_n(\cdot))_{n \in \mathbb{N}}$  and a function  $g_j(\cdot) \in L^1([0, 1], C^0(\tilde{K}_j, \mathbb{R}^N))$  (for each  $j \in \mathbb{N}$ ) such that for each  $j \in \mathbb{N}$ ,

$$f_n(\cdot)|_{\tilde{K}_j} \longrightarrow g_j(\cdot) \quad (n \longrightarrow \infty) \quad \text{weakly in } L^1([0, 1], C^0(\tilde{K}_j, \mathbb{R}^N)).$$

As restrictions to  $\tilde{K}_j$  of one and the same subsequence  $(f_n(\cdot))_{n \in \mathbb{N}}$  converge weakly for each  $j \in \mathbb{N}$ , the inclusion  $\tilde{K}_j \subset \tilde{K}_{j+1}$  implies that for any indices  $j < k$

$$g_j(t)(\cdot) = g_k(t)(\cdot)|_{\tilde{K}_j} \in C^0(\tilde{K}_j, \mathbb{R}^N) \quad \text{for a.e. } t \in [0, 1],$$

and so  $(g_j(\cdot))_{j \in \mathbb{N}}$  induces a single function  $f : [0, 1] \longrightarrow C^0(\mathbb{R}^N, \mathbb{R}^N)$  defined as

$$f(t)(x) := g_j(t)(x) \quad \text{for } x \in \tilde{K}_j \text{ and a.e. } t \in [0, 1].$$

For property (h) about Lipschitz continuity and bounds of limit function  $f(\cdot)$ . Finally, we verify  $f(t) \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ ,  $\text{Lip } f(t) \leq A$ , and  $\|f(t)\|_\infty \leq B$  for almost every  $t \in [0, 1]$ . Indeed, as in the case of differential inclusions (section 3.1), Mazur’s lemma in Proposition 3.5 ensures here for each  $j \in \mathbb{N}$  (fixed) that

$$f(\cdot)|_{\tilde{K}_j} \in \bigcap_{n \in \mathbb{N}} \overline{\text{co}} \{f_n(\cdot)|_{\tilde{K}_j}, f_{n+1}(\cdot)|_{\tilde{K}_j} \dots\} \quad \text{in } L^1([0, 1], C^0(\tilde{K}_j, \mathbb{R}^N)).$$

Thus,  $f(\cdot)|_{\widetilde{K}_j}$  can be approximated by convex combinations of  $\{f_1(\cdot)|_{\widetilde{K}_j}, f_2(\cdot)|_{\widetilde{K}_j}, \dots\}$  w.r.t. the  $L^1$  norm. A further subsequence (of these convex combinations) converges to  $f(\cdot)|_{\widetilde{K}_j}$  almost everywhere in  $[0, 1]$ . So, for almost every  $t \in [0, 1]$ ,  $f(t)|_{\widetilde{K}_j}$  belongs to the same compact convex subset of  $(C^0(\widetilde{K}_j, \mathbb{R}^N), \|\cdot\|_\infty)$  as  $f_1(t)|_{\widetilde{K}_j}, f_2(t)|_{\widetilde{K}_j}, \dots$ , namely,  $\{w \in \text{Lip}(\widetilde{K}_j, \mathbb{R}^N) \mid \text{Lip } w \leq A, \|w\|_\infty \leq B\}$ .  $\square$

LEMMA 3.14 (the limit function is a solution). *Under the assumptions of the viability theorem, Theorem 3.11, consider both  $K_n(\cdot), K(\cdot) : [0, 1] \longrightarrow \mathcal{K}(\mathbb{R}^N)$  ( $n \in \mathbb{N}$ ) and  $f_n(\cdot), f(\cdot) : [0, 1] \longrightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  specified in Lemma 3.13.*

*Then  $K(\cdot)$  is a solution of the morphological inclusion  $\dot{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset$  with  $K(0) = K_0$  and  $K(t) \in \mathcal{V}$  for all  $t \in [0, 1]$ .*

*Proof.*  $K(t) \in \mathcal{V}$  for all  $t \in [0, 1]$  results directly from properties (d) and (f) of Lemma 3.13 because  $\mathcal{V}$  is assumed to be a closed subset of  $(\mathcal{K}(\mathbb{R}^N), \mathcal{d})$ .

So it remains to prove  $f(t) \in \dot{K}(\cdot) \cap \mathcal{F}(K(\cdot))$  for Lebesgue-almost every  $t \in [0, 1]$ .

The Carathéodory property of each  $f_n(\cdot)$  and every  $K_n(\cdot)$  is a reachable set. As each  $f_n : [0, 1] \longrightarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  from Lemma 3.13 is piecewise constant, it can be regarded as a measurable/Lipschitz function  $[0, 1] \times \mathbb{R}^N \longrightarrow \mathbb{R}^N$ ,  $(t, x) \longmapsto f_n(t)(x)$  in the sense of [7, Definition 9.5.1], i.e.,

$$\begin{aligned} f_n(\cdot)(x) : [0, 1] &\longrightarrow \mathbb{R}^N \quad \text{is Lebesgue measurable} && \text{for every } x \in \mathbb{R}^N, \\ f_n(t)(\cdot) : \mathbb{R}^N &\longrightarrow \mathbb{R}^N \quad \text{is } A\text{-Lipschitz continuous} && \text{for every } t \in [0, 1]. \end{aligned}$$

In addition,  $\|f_n(t)(\cdot)\|_\infty \leq B$  for every  $t \in [0, 1]$ ,  $n \in \mathbb{N}$ .

Moreover, each compact set  $K_n(t) \subset \mathbb{R}^N$  coincides with the reachable set

$$\vartheta_{f_n}(t, K_0) \stackrel{\text{Def.}}{=} \{x(t) \mid \exists x \in W^{1,1}([0, t], \mathbb{R}^N) : x'(s) = f_n(s)(x(s)) \text{ for a.e. } s, x(0) \in K_0\}$$

of the initial set  $K_0$  and the function  $f_n(\cdot)(\cdot) : [0, 1] \times \mathbb{R}^N \longrightarrow \mathbb{R}^N$ . Indeed, consider a subinterval  $[s_1, s_2] \subset [0, 1]$  in which  $f_n(\cdot)$  is constant, i.e.,  $f_n(\cdot)|_{[s_1, s_2]} \equiv g \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , and assume  $K_n(s_1) = \vartheta_{f_n}(s_1, K_0)$  (with subsequent induction in mind). Then both  $K_n(\cdot)$  and the reachable set  $\vartheta_{f_n}(\cdot, K_0)$  satisfy the morphological equation  $\dot{Q}(\cdot) \ni g$  in  $[s_1, s_2]$  and are  $B$ -Lipschitz continuous. So due to Theorem 2.7,  $K_n(\cdot) \equiv \vartheta_{f_n}(\cdot, K_0)$  in  $[s_1, s_2]$ . By means of induction, we conclude  $K_n(\cdot) \equiv \vartheta_{f_n}(\cdot, K_0)$  in  $[0, 1]$ .

For characterizing  $K(t)$  as a reachable set of  $f(\cdot)$ .  $K(t) \subset \vartheta_f(t, K_0)$  for every  $t$ . Indeed, Lemma 3.13 (f) implies the characterization as a limit with respect to  $\mathcal{d}$  (or, equivalently for compact sets here, in the sense of Painlevé–Kuratowski):

$$K(t) = \lim_{n \rightarrow \infty} K_n(t) = \lim_{n \rightarrow \infty} \vartheta_{f_n}(t, K_0).$$

For every  $x \in K(t)$ , there is a sequence  $(x_n(\cdot))_{n \in \mathbb{N}}$  of functions in  $W^{1,1}([0, t], \mathbb{R}^N)$  satisfying

$$\begin{cases} x'_n(s) = f_n(s)(x_n(s)) & \text{for a.e. } s \in [0, t], \\ x_n(0) \in K_0, \\ x_n(s) \in \vartheta_{f_n}(s, K_0) \subset \mathbb{B}_{1+B}(K_0) \stackrel{\text{Def.}}{=} \widetilde{K}_1 & \text{for each } s \in [0, t], \\ x_n(t) \longrightarrow x & \text{for } n \longrightarrow \infty. \end{cases}$$

Seizing the notions of [2, Convergence Theorem 2.4.4], the theorems of Arzelà–Ascoli and Alaoglu provide a subsequence  $(x_{n_j}(\cdot))_{j \in \mathbb{N}}$  and functions  $x(\cdot) \in C^0([0, t], \mathbb{R}^N)$ ,  $v(\cdot) \in L^1([0, t], \mathbb{R}^N)$  such that

$$x_{n_j}(\cdot) \longrightarrow x(\cdot) \quad \text{uniformly in } [0, t], \quad x'_{n_j}(\cdot) \longrightarrow v(\cdot) \quad \text{weakly in } L^1([0, t], \mathbb{R}^N),$$

implying the absolute continuity of  $x(\cdot)$  with  $x'(\cdot) = v(\cdot)$ .

For verifying  $x'(\cdot) = f(\cdot)(x(\cdot))$  (almost everywhere), we now prove  $f_{n_j}(\cdot)(x_{n_j}(\cdot)) \longrightarrow f(\cdot)(x(\cdot))$  weakly in  $L^1([0, t], \mathbb{R}^N)$  for  $j \longrightarrow \infty$ . For any  $g \in L^\infty([0, t], \mathbb{R}^N) \cong (L^1([0, t], \mathbb{R}^N))^*$ , the  $A$ -Lipschitz continuity of each  $f_{n_j}(s)$  implies

$$\int_0^t g(s)^T f_{n_j}(s)(x_{n_j}(s)) \, ds \in \int_0^t g(s)^T f_{n_j}(s)(x(s)) \, ds + c \|x(\cdot) - x_{n_j}(\cdot)\|_\infty \mathbb{B}_1.$$

As  $L^1([0, 1], C^0(\tilde{K}_1, \mathbb{R}^N)) \longrightarrow \mathbb{R}$ ,  $h \longmapsto \int_0^t g(s)^T h(s)(x(s)) \, ds$  is continuous,

$$\int_0^t g(s)^T f_{n_j}(s)(x_{n_j}(s)) \, ds \longrightarrow \int_0^t g(s)^T f(s)(x(s)) \, ds \text{ for } j \longrightarrow \infty.$$

Thus,  $x = x(t) \in \vartheta_f(t, K_0)$ .

For characterizing  $K(t)$  as a reachable set of  $f(\cdot)$ .  $\vartheta_f(t, K_0) \subset K(t)$  for every  $t$ . The next step is to verify that the tube  $K(\cdot) : [0, 1] \rightsquigarrow \mathbb{R}^N$  is invariant under  $f$ ; i.e., for every initial point  $x \in K(t)$  (with  $t \in [0, 1]$ ), the solution  $x(\cdot) \in W^{1,1}([t, 1], \mathbb{R}^N)$  of  $x'(\cdot) = f(\cdot)(x(\cdot))$  (almost everywhere) with  $x(t) = x$  satisfies  $x(\tau) \in K(\tau)$  for any  $\tau \in [t, 1]$ . Due to  $K(0) = K_0$ , this property implies  $\vartheta_f(t, K_0) \subset K(t)$  for every  $t \in [0, 1]$ .

Indeed, existence and uniqueness of this solution  $x(\cdot)$  result from (generalized) Filippov's theorem (see, e.g., [35, Theorem 2.4.3]) since  $[0, 1] \times \mathbb{R}^N$ ,  $(s, y) \longmapsto f(s)(y)$  is measurable/Lipschitz (in the sense of [7, Definition 9.5.1]). Each  $x \in K(t) = \text{Lim}_{n \rightarrow \infty} K_n(t)$  is the limit of a sequence  $(x_n)_{n \in \mathbb{N}}$  with  $x_n \in K_n(t)$ , and there exist corresponding solutions  $x_n(\cdot) \in W^{1,1}([t, 1], \mathbb{R}^N)$  ( $n \in \mathbb{N}$ ) of  $x'_n(\cdot) = f_{n_j}(\cdot)(x_n(\cdot))$  (almost everywhere) with  $x_n(t) = x_n$ . For the same reasons as before, we obtain a subsequence  $(x_{n_j}(\cdot))_{j \in \mathbb{N}}$  and a limit function  $y(\cdot) \in W^{1,1}([t, 1], \mathbb{R}^N)$  satisfying

$$\begin{cases} x_{n_j}(\cdot) \longrightarrow y(\cdot) & \text{uniformly in } [t, 1], \\ x'_{n_j}(\cdot) \longrightarrow y'(\cdot) & \text{weakly in } L^1([t, 1], \mathbb{R}^N), \\ f_{n_j}(\cdot)(x_{n_j}(\cdot)) \longrightarrow f(\cdot)(y(\cdot)) & \text{weakly in } L^1([t, 1], \mathbb{R}^N). \end{cases}$$

So  $y(\cdot)$  is identical to the uniquely determined solution  $x(\cdot)$  of  $x'(\cdot) = f(\cdot)(x(\cdot))$  (almost everywhere) with  $x(t) = x$ ; i.e., the limit  $y(\cdot)$  does not depend on the selection of the subsequence  $(x_{n_j}(\cdot))_{j \in \mathbb{N}}$ . This implies indirectly that even the whole sequence  $(x_n(\cdot))_{n \in \mathbb{N}}$  converges to  $x(\cdot)$  uniformly and all its derivatives tend weakly to  $x'(\cdot)$ . In particular,  $x(\tau) = \lim_{n \rightarrow \infty} x_n(\tau) \in \text{Lim}_{n \rightarrow \infty} K_n(\tau) = K(\tau)$  for every  $\tau \in [t, 1]$ .

Thus,  $K(t) = \vartheta_f(t, K_0)$  for every  $t \in [0, 1]$ .

$K(t)$  as a reachable set and Scorza-Dragoni ensure solution property at almost every time. That is, describing  $K(t)$  as a reachable set of  $f(\cdot)(\cdot) : [0, 1] \times \mathring{\mathbb{R}}^N \longrightarrow \mathbb{R}^N$  implies that  $f(t) \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  belongs to the shape mutation  $\mathring{K}(t)$  for almost every  $t \in [0, 1]$ :

$$\lim_{h \downarrow 0} \frac{1}{h} \cdot d(\vartheta_{f(t)}(h, K(t)), K(t+h)) = 0.$$

Indeed,  $f(\cdot)(\cdot) : [0, 1] \times \mathbb{R}^N \longrightarrow \mathbb{R}^N$  is measurable/Lipschitz, and thus Proposition 3.9 ensures the following (slightly modified) Scorza-Dragoni property:

For any  $\varepsilon > 0$ , there exists a closed subset  $J_\varepsilon \subset [0, 1 - \varepsilon]$  with  $\mathcal{L}^1([0, 1] \setminus J_\varepsilon) < 2\varepsilon$  such that the restriction of  $f(\cdot)(\cdot)$  to  $J_\varepsilon \times \mathbb{R}^N$  is continuous. Seizing an idea in the proof

of [20, Lemma 2.6], let  $\tilde{J}_\varepsilon$  be the subset of all density points of  $J_\varepsilon$  that are also Lebesgue points of the characteristic function  $\chi_{[0,1] \setminus J_\varepsilon}(\cdot)$ . Then  $\mathcal{L}^1(\tilde{J}_\varepsilon) = \mathcal{L}^1(J_\varepsilon) > 1 - 2\varepsilon$ , because Lebesgue points of each  $\mathcal{L}^1$  function always have full Lebesgue measure [37, Theorem 1.3.8] and so, in particular, density points of any measurable set also have full Lebesgue measure.

For any  $t \in \tilde{J}_\varepsilon$ ,  $x \in K(t)$ , there exist unique solutions  $x(\cdot)$ ,  $y(\cdot) \in \text{Lip}([t, 1], \mathbb{R}^N)$  of

$$x'(\cdot) = f(\cdot)(x(\cdot)), \quad y'(\cdot) = f(t)(y(\cdot)) \quad \text{a.e. in } [t, 1],$$

respectively, with  $x(t) = x = y(t)$ . Then we obtain for every  $\tau \in ]t, 1]$

$$\begin{aligned} |x(\tau) - y(\tau)| &= \left| \int_t^\tau (f(s)(x(s)) - f(t)(y(s))) \, ds \right| \\ &\leq \left| \int_{[t, \tau] \cap J_\varepsilon} (f(s)(x(s)) - f(t)(y(s))) \, ds \right| + 2B \cdot \mathcal{L}^1([t, \tau] \setminus J_\varepsilon) \\ &\leq \int_{[t, \tau] \cap J_\varepsilon} |f(s)(x(s)) - f(t)(x(s))| \, ds + 2B \cdot \mathcal{L}^1([t, \tau] \setminus J_\varepsilon) \\ &\quad + \int_{[t, \tau] \cap J_\varepsilon} A \cdot |x(s) - y(s)| \, ds. \end{aligned}$$

For  $\delta > 0$  arbitrarily small and each  $t \in \tilde{J}_\varepsilon$ , the construction of  $J_\varepsilon$  (in regard to continuity of  $f(\cdot)(\cdot)|_{J_\varepsilon \times \mathbb{R}^N}$ ) and the definition of  $\tilde{J}_\varepsilon$  (in regard to Lebesgue points of  $\chi_{[0,1] \setminus J_\varepsilon}(\cdot)$ ) provide some  $T \in ]t, 1]$  satisfying

$$\begin{cases} \sup_{s \in [t, T] \cap J_\varepsilon} \sup_{z: \text{dist}(z, K_0) \leq B} |f(s)(z) - f(t)(z)| < \delta, \\ \sup_{s \in [t, T]} \frac{1}{|s - t|} \cdot \mathcal{L}^1([t, s] \setminus J_\varepsilon) < \delta; \end{cases}$$

thus,  $|x(\tau) - y(\tau)| \leq A \int_{[t, \tau]} |x(s) - y(s)| \, ds + \delta (1 + 2B) (\tau - t)$  for any  $\tau \in ]t, T]$ .

Gronwall's lemma implies  $|x(\tau) - y(\tau)| \leq \delta (1 + 2B) e^{A \cdot (\tau - t)} (\tau - t)$  for any  $\tau$ .

As  $x \in K(t)$  is chosen arbitrarily and  $T$  does not depend on  $x$  (but only on  $\delta, \varepsilon, t$ ), the reachable sets  $\vartheta_{f(t)}(h, K(t))$  and  $K(t + h) = \vartheta_f(h, K(t))$  satisfy for any  $h \in [0, T - t]$

$$d(\vartheta_{f(t)}(h, K(t)), K(t + h)) \leq \delta (1 + 2B) e^{A h} h,$$

i.e.,

$$\lim_{h \downarrow 0} \frac{1}{h} \cdot d(\vartheta_{f(t)}(h, K(t)), K(t + h)) = 0 \quad \text{for every } t \in \tilde{J}_\varepsilon.$$

Finally,  $f(t) \in \mathcal{F}(K(t))$  for almost every  $t \in [0, 1]$ . Due to Lemma 3.13 (e), (g),  $f_n(\cdot)|_{\tilde{K}_j} \rightarrow f(\cdot)|_{\tilde{K}_j}$  weakly in  $L^1([0, 1], C^0(\tilde{K}_j, \mathbb{R}^N))$  for each compact set  $\tilde{K}_j := \mathbb{B}_{j+B}(K_0)$  ( $j \in \mathbb{N}$ ), and  $f_n(t) \in \mathcal{F}(\mathbb{B}_{1/n}(K_n(t)))$  for every  $n \in \mathbb{N}$ ,  $t \in [0, 1]$ .

Fixing the index  $j \in \mathbb{N}$  of compact sets arbitrarily, Proposition 3.8 provides a sequence  $(h_{j,n}(\cdot))_{n \in \mathbb{N}}$  with  $h_{j,n}(\cdot) \in \text{co}\{f_n(\cdot)|_{\tilde{K}_j}, f_{n+1}(\cdot)|_{\tilde{K}_j} \dots\} \subset L^1([0, 1], C^0(\tilde{K}_j, \mathbb{R}^N))$  such that for  $\mathcal{L}^1$  almost every  $t \in [0, 1]$ ,

$$h_{j,n}(t) \rightarrow f(t)|_{\tilde{K}_j} \quad (n \rightarrow \infty) \quad \text{weakly in } C^0(\tilde{K}_j, \mathbb{R}^N).$$

Proposition 3.10 and assumption 2 of Theorem 3.11, i.e.,

$$\sup_{M \in \mathcal{K}(\mathbb{R}^N)} \sup_{g \in \mathcal{F}(M)} \text{Lip } g \leq A < \infty, \quad \sup_{M \in \mathcal{K}(\mathbb{R}^N)} \sup_{g \in \mathcal{F}(M)} \|g\|_\infty \leq B < \infty,$$

imply  $h_{j,n}(t) \rightarrow f(t)|_{\widetilde{K}_j}$  uniformly in  $\widetilde{K}_j$  for  $n \rightarrow \infty$  and almost every  $t \in [0, 1[$ .

Let  $C_j \subset [0, 1[$  denote the set of full measure for which this uniform convergence holds. Then  $C := \bigcap_{j \in \mathbb{N}} C_j \subset [0, 1[$  is also a set of full measure, i.e.,  $\mathcal{L}^1([0, 1] \setminus C) = 0$ .

Choose  $t \in C$  arbitrarily. Then for each  $j \in \mathbb{N}$ , there exists an index  $n_j > j$  such that  $n_j > n_{j-1}$  and  $\|h_{j,n_j}(\cdot)|_{\widetilde{K}_j} - f(\cdot)|_{\widetilde{K}_j}\|_\infty < \frac{1}{j}$ .

Due to  $h_{j,n}(\cdot) \in co\{f_n(\cdot)|_{\widetilde{K}_j}, f_{n+1}(\cdot)|_{\widetilde{K}_j} \dots\}$ , each  $h_{j,n_j}(t)|_{\widetilde{K}_j}$  has a continuation to  $\mathbb{R}^N$  in  $co\{f_n(t), f_{n+1}(t) \dots\} \subset C^0(\mathbb{R}^N, \mathbb{R}^N)$  (that again is denoted by  $h_{j,n_j}(t)$ ), and  $h_{j,n_j}(t) \rightarrow f(t)$  locally uniformly in  $\mathbb{R}^N$  for  $j \rightarrow \infty$ .

Furthermore,  $co\{f_n(t), f_{n+1}(t) \dots\} \subset \overline{co} \mathcal{F}(\mathbb{B}_{1/n}(\bigcup_{m \geq n} K_m(t)))$ .

So finally,  $d(K_n(t), K(t)) \rightarrow 0$  and assumption 3 of Theorem 3.11 about the closed graph of  $\mathcal{F}$  (with its convex values) imply  $f(t) \in \mathcal{F}(K(t))$ .  $\square$

**4. An application to shape optimization under state constraints.** Let  $J : \mathcal{K}(\mathbb{R}^N) \rightarrow \mathbb{R}$  be a functional that is Lipschitz continuous w.r.t. the Pompeiu–Hausdorff distance  $d$ . Moreover,  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  denotes a nonempty closed set of constraints. Detecting a minimizer  $\widehat{K} \in \mathcal{V}$  of the optimization problem

$$\inf \{J(K) \mid K \in \mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)\}$$

usually proves to be rather complicated ([12, 11]; see [18, 25, 38] supplementarily). Thus, we prefer here to isolate candidates (for a minimizer) constructively by means of a necessary condition (similarly to [24]). The viability theorem, Theorem 3.11, for morphological inclusions then lays the basis for a curve  $K(\cdot) : [0, \infty[ \rightarrow \mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  such that

- (i)  $J \circ K : [0, \infty[ \rightarrow \mathbb{R}$ ,  $t \mapsto J(K(t))$  is nonincreasing, and
- (ii) every compact set  $C = \text{Lim}_{n \rightarrow \infty} K(t_n) \in \mathcal{V}$  (for some sequence  $t_n \nearrow \infty$ ) satisfies a necessary condition on minimizers (in the form of Fermat’s rule).

The first step is to specify a map  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  satisfying the following conditions on its values:

- 1. all values of  $\mathcal{F}$  are convex and closed (w.r.t. locally uniform convergence);
- 2.  $\sup_{M \in \mathcal{K}(\mathbb{R}^N)} \sup_{f \in \mathcal{F}(M)} (\|f\|_\infty + \text{Lip } f) < \infty$ ,

Essentially, the choice of  $\mathcal{F}$  is to guarantee that the composition  $t \mapsto J(K(t))$  is nonincreasing for every compact-valued solution  $K(\cdot) : [0, 1] \rightsquigarrow \mathbb{R}^N$  of the morphological inclusion  $\overset{\circ}{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset$ . For combining this aim with the conditions on its values, we do not use the so-called *shape semiderivative* of  $J$  in direction  $v(\cdot)$ ,

$$\delta J(K)(v) := \lim_{h \downarrow 0} \frac{1}{h} \cdot (J(\vartheta_v(h, K)) - J(K)),$$

for  $K \in \mathcal{K}(\mathbb{R}^N)$  (assuming the limit to exist) as in [12, section 7.2], [11], but we prefer the notion of Clarke’s generalized directional derivative in a Banach space (see, e.g., [10, section 1.2]) and extend it to shape transitions.

**DEFINITION 4.1.** Let  $J : (\mathcal{K}(\mathbb{R}^N), d) \rightarrow \mathbb{R}$  be Lipschitz continuous.

Clarke’s generalized shape derivative of  $J$  at  $K \in \mathcal{K}(\mathbb{R}^N)$  in direction  $v \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  is defined as

$$\delta^C J(K)(v) := \limsup_{\substack{h \downarrow 0, M \rightarrow K \\ (M \in \mathcal{K}(\mathbb{R}^N))}} \frac{1}{h} \cdot (J(\vartheta_v(h, M)) - J(M)).$$

Set  $\iota J(K) := \limsup_{\substack{M \rightarrow K \\ (M \in \mathcal{K}(\mathbb{R}^N))}} \inf \{ \delta^C J(M)(v) \mid v \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N), \|v\|_\infty + \text{Lip} v \leq 1 \}$ .

*Remark.* 1. Let  $\Lambda \geq 0$  denote the Lipschitz constant of  $J : (\mathcal{K}(\mathbb{R}^N), d) \rightarrow \mathbb{R}$ . Then, due to Lemma 2.4,  $|J(\vartheta_v(h, K)) - J(K)| \leq \Lambda \cdot d(\vartheta_v(h, K), K) \leq \Lambda \cdot \|v\|_\infty h$  for every  $v \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ , and thus  $|\delta^C J(K)(v)| \leq \Lambda \|v\|_\infty$ ,  $\iota J(K) \geq -\Lambda$ .

In particular,  $\delta^C J(K)(0) = 0$  for every  $K \in \mathcal{K}(\mathbb{R}^N)$ .

2.  $\iota J(\cdot) : \mathcal{K}(\mathbb{R}^N) \rightarrow \mathbb{R}$  is the upper semicontinuous envelope of the minimal generalized shape derivative  $\delta^C J(\cdot)(v)$  over all  $v$  in the unit ball of  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ . Furthermore,  $\iota J(K) \leq \delta^C J(K)(0) = 0$  for all  $K \in \mathcal{K}(\mathbb{R}^N)$ .

DEFINITION 4.2. Using the notation of Definition 4.1, set  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ ,

$$\mathcal{F}(K) := \left\{ v \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N) \mid \|v\|_\infty + \text{Lip} v \leq 1, \quad \delta^C J(K)(v) \leq \frac{1}{2} \cdot \iota J(K) \right\}.$$

Here both the bound 1 and the factor  $\frac{1}{2}$  are rather arbitrary and can be replaced by any constants in  $[0, \infty[$  and  $]0, 1[$ , respectively. We show in Lemma 4.5 below that all values of the set-valued map  $\mathcal{F}$  are nonempty, convex, and closed w.r.t. locally uniform convergence.

LEMMA 4.3. Let  $J : (\mathcal{K}(\mathbb{R}^N), d) \rightarrow \mathbb{R}$  be Lipschitz continuous and  $K(\cdot) : [0, 1] \rightsquigarrow \mathbb{R}^N$  any compact-valued Lipschitz solution of the morphological inclusion  $\mathring{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset$ , with  $\mathcal{F}(\cdot)$  introduced in Definition 4.2. Then we have the following:

1.  $J \circ K : [0, 1] \rightarrow \mathbb{R}$ ,  $t \mapsto J(K(t))$  is nonincreasing.
2. Suppose  $\inf_{\mathcal{K}(\mathbb{R}^N)} J(\cdot) > -\infty$  in addition, and let  $C$  belong to the  $\omega$ -limit set of  $K(\cdot)$  in  $\mathcal{K}(\mathbb{R}^N)$ , i.e.,  $d(K(t_n), C) \rightarrow 0$  for some  $t_n \nearrow \infty$ . Then  $\iota J(C) = 0$ .

*Proof.* 1. The proof of item 1 results from the Lipschitz continuity of the composition  $[0, 1] \rightarrow \mathbb{R}$ ,  $t \mapsto J(K(t))$  and the definition of  $\mathcal{F}$ . Indeed, at almost every time  $t \in [0, 1]$ , there exists  $v \in \mathcal{F}(K(t)) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  with  $\lim_{h \downarrow 0} \frac{1}{h} \cdot d(K(t+h), \vartheta_v(h, K(t))) = 0$ . Thus,

$$\begin{aligned} & \limsup_{h \downarrow 0} \frac{1}{h} \cdot (J(K(t+h)) - J(K(t))) \\ & \leq \limsup_{h \downarrow 0} \frac{1}{h} \cdot \left( J(\vartheta_v(h, K(t))) - J(K(t)) + \text{Lip} J \cdot d(\vartheta_v(h, K(t)), K(t+h)) \right) \\ & \leq \delta^C J(K(t))(v) + 0 \\ & \leq \frac{1}{2} \cdot \iota J(K(t)) \quad (\text{since } v \in \mathcal{F}(K(t))) \\ & \leq 0 \quad (\text{due to preceding remark (item 2)}). \end{aligned}$$

2. Assume the contrary, i.e.,  $\kappa := \iota J(C) < 0$ . Then there exists some small  $\rho > 0$  such that all sets  $M \in \mathcal{K}(\mathbb{R}^N)$  with  $d(M, C) \leq 2\rho$  satisfy  $\iota J(M) < \frac{\kappa}{2} < 0$ . For all  $n \in \mathbb{N}$  sufficiently large,  $K(t_n)$  has the Pompeiu–Hausdorff distance  $< \rho$  from  $C$ . As all values of  $\mathcal{F}$  contain only functions  $v \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  with  $\|v\|_\infty + \text{Lip} v \leq 1$ , every compact-valued solution  $K(\cdot)$  of the morphological inclusion  $\mathring{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset$  has Lipschitz constant  $\leq 1$  (w.r.t.  $d$ ) similarly to Lemma 2.4.

Thus,  $d(K(s), C) < 2\rho$  for all  $s \in [t_n - \rho, t_n + \rho]$ . Now the same approach of estimating as in Lemma 4.3 (1) implies  $J(K(s_2)) \leq J(K(s_1)) + \frac{\kappa}{4} \cdot (s_2 - s_1)$  for all  $t_n - \rho \leq s_1 \leq s_2 \leq t_n + \rho$  and large  $n \in \mathbb{N}$ —contradicting the hypothesis  $\inf J(\cdot) > -\infty$ .  $\square$

The next lemma will be used for verifying the convexity of all values of  $\mathcal{F}$  in Lemma 4.5.

LEMMA 4.4. For every  $\lambda \in ]0, 1[$ , there exists  $\mu \in L^1([0, 1])$  satisfying

$$\frac{1}{t} \cdot \int_0^t (\mu(s) - \lambda) \, ds \longrightarrow 0 \quad (t \downarrow 0), \quad \mu(\cdot) \in \{0, 1\}$$

piecewise constant in  $]0, 1[$ .

*Proof.*  $\mu(\cdot)$  is defined to be piecewise constant in each interval  $[\frac{1}{\sqrt{n+1}}, \frac{1}{\sqrt{n}}[$  ( $n \in \mathbb{N}$ ). Set

$$\mu(t) := \begin{cases} 0 & \text{for } \frac{1}{\sqrt{n+1}} \leq t < \frac{\lambda}{\sqrt{n+1}} + \frac{1-\lambda}{\sqrt{n}}, \\ 1 & \text{for } \frac{\lambda}{\sqrt{n+1}} + \frac{1-\lambda}{\sqrt{n}} \leq t < \frac{1}{\sqrt{n}} \end{cases}$$

for each  $n \in \mathbb{N}$ . Then

$$\int_{\frac{1}{\sqrt{n+1}}}^{\frac{1}{\sqrt{n}}} (\mu(s) - \lambda) \, ds = 0,$$

and thus

$$\int_0^{\frac{1}{\sqrt{n}}} (\mu(s) - \lambda) \, ds = 0.$$

Moreover,

$$\int_{\frac{1}{\sqrt{n+1}}}^{\frac{1}{\sqrt{n}}} |\mu(s) - \lambda| \, ds = 2\lambda(1-\lambda) \left( \frac{1}{\sqrt{n}} - \frac{1}{\sqrt{n+1}} \right)$$

implies

$$\sup_{\frac{1}{\sqrt{n+1}} \leq t \leq \frac{1}{\sqrt{n}}} \frac{1}{t} \cdot \left| \int_0^t (\mu(s) - \lambda) \, ds \right| \leq \sqrt{n+1} \cdot \int_{\frac{1}{\sqrt{n+1}}}^{\frac{1}{\sqrt{n}}} |\mu(s) - \lambda| \, ds \xrightarrow{n \rightarrow \infty} 0. \quad \square$$

LEMMA 4.5. Consider  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  with the topology of locally uniform convergence. All values of the set-valued map  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  introduced in Definition 4.2 are nonempty, convex, and closed.

*Proof.* For every  $K \in \mathcal{K}(\mathbb{R}^N)$ , the value  $\mathcal{F}(K)$  is a nonempty because either

- $\iota J(K) = 0$ , and then  $0 \in \mathcal{F}(K)$ , or
- $\iota J(K) < 0$ , and then there is  $v \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  with  $\|v\|_\infty + \text{Lip } v \leq 1$ ,  $\delta^C J(K)(v) \leq \frac{3}{4} \cdot \iota J(K) < 0$  (due to the definition of infimum); i.e.,  $v \in \mathcal{F}(K)$  induces a shape transition along which  $J(\cdot)$  is strictly decreasing for short times.

Each value  $\mathcal{F}(K) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  of  $\mathcal{F}$  is convex. Indeed, choose any  $v, w \in \mathcal{F}(K)$  and  $\lambda \in ]0, 1[$ . According to Lemma 4.4, there exists some  $\mu \in L^1([0, 1])$  satisfying

$$\frac{1}{t} \cdot \int_0^t (\mu(s) - \lambda) \, ds \longrightarrow 0 \quad (t \downarrow 0), \mu(\cdot) \in \{0, 1\} \text{ piecewise constant in } ]0, 1[.$$

Now we compare the evolution of an arbitrary set  $K \in \mathcal{K}(\mathbb{R}^N)$  along the autonomous Lipschitz field

$$u : \mathbb{R}^N \longrightarrow \mathbb{R}^N, \quad x \longmapsto \lambda \cdot v(x) + (1 - \lambda) \cdot w(x)$$

and along the nonautonomous vector field

$$g: \mathbb{R}^N \times [0, 1] \longrightarrow \mathbb{R}^N, \quad (x, t) \longmapsto \mu(t) \cdot v(x) + (1 - \mu(t)) \cdot w(x).$$

We verify  $d(\vartheta_u(t, M), \vartheta_g(t, M)) \leq o(t)$  for  $t \downarrow 0$  uniformly in  $M$ .

For any initial point  $x_0 \in \mathbb{R}^N$  given, let  $x(\cdot) \in C^1([0, 1], \mathbb{R}^N)$  denote the (unique) solution to  $x'(\cdot) = u(x(\cdot))$ ,  $x(0) = x_0$ . As each  $g(\cdot, t)$  is Lipschitz continuous (with Lipschitz constant  $\leq 1$ ), Filippov's theorem (applied to differential equations here) guarantees that the Cauchy problem

$$\begin{cases} y'(\cdot) = g(y(\cdot), \cdot) & \text{a.e. in } [0, 1], \\ y(0) = x_0 \in \mathbb{R}^N \end{cases}$$

has a solution  $y(\cdot) \in W^{1,1}([0, t], \mathbb{R}^N)$ . These solutions  $x(\cdot), y(\cdot)$  always satisfy

$$\begin{aligned} & |x(t) - y(t)| \\ &= \left| \int_0^t \left( \lambda v(x(s)) - \mu(s) v(y(s)) + (1 - \lambda) w(x(s)) - (1 - \mu(s)) w(y(s)) \right) ds \right| \\ &\leq \left| \int_0^t \left( (\lambda - \mu(s)) v(x(s)) + (\mu(s) - \lambda) w(x(s)) \right) ds \right| \\ &\quad + \int_0^t \mu(s) \cdot \text{Lip } v \cdot |x(s) - y(s)| ds + \int_0^t (1 - \mu(s)) \cdot \text{Lip } w \cdot |x(s) - y(s)| ds \\ &\leq \left| \int_0^t (\lambda - \mu(s)) \cdot (v(x_0) - w(x_0)) ds \right| \\ &\quad + \int_0^t |\lambda - \mu(s)| (\text{Lip } v + \text{Lip } w) |x(s) - x_0| ds + \int_0^t |x(s) - y(s)| ds \\ &\leq 2 \left| \int_0^t (\lambda - \mu(s)) ds \right| + \int_0^t 1 \cdot 2 \cdot s ds + \int_0^t |x(s) - y(s)| ds \end{aligned}$$

due to  $\|v\|_\infty + \text{Lip } v \leq 1$ ,  $\|w\|_\infty + \text{Lip } w \leq 1$ .

Gronwall's lemma ensures  $|x(t) - y(t)| \leq o(t)$  for  $t \downarrow 0$  uniformly in  $x_0 \in \mathbb{R}^N$ . (In particular, the estimate of Filippov's theorem is difficult to apply here immediately, as the integral mean of  $\mu(\cdot) - \lambda$ , but not of  $|\mu(\cdot) - \lambda|$ , is  $o(t)$  for  $t \downarrow 0$ .)

Thus, for any initial set  $M \in \mathcal{K}(\mathbb{R}^N)$ , the reachable sets satisfy

$$\text{dist}(\vartheta_u(t, M), \vartheta_g(t, M)) \leq o(t) \quad \text{for } t \downarrow 0 \quad \text{uniformly in } M \in \mathcal{K}(\mathbb{R}^N).$$

The same uniform estimates holds for  $\text{dist}(\vartheta_g(t, M), \vartheta_u(t, M))$  since the preceding solutions  $x(\cdot)$  and  $y(\cdot)$  have needed only a joint initial point  $x_0 \in \mathbb{R}^N$ .

According to the proof of Lemma 4.4, we can suppose to have a sequence  $s_n \searrow 0$  in  $]0, 1[$  such that  $\mu(\cdot) \in \{0, 1\}$  is constant in  $[s_{n+1}, s_n[$  for each  $n \in \mathbb{N}$ . So for every set  $M \in \mathcal{K}(\mathbb{R}^N)$  and time  $t \in [s_{n+1}, s_n]$ , the reachable set  $\vartheta_g(t, M)$  is either  $\vartheta_v(t - s_{n+1}, \vartheta_g(s_{n+1}, M))$  or  $\vartheta_w(t - s_{n+1}, \vartheta_g(s_{n+1}, M))$ .

Fix  $\varepsilon > 0$  arbitrarily small. For any  $h \in ]0, s_1]$  sufficiently small, we choose  $m \in \mathbb{N}$  with  $s_m < h \leq s_{m-1}$  and obtain for  $M \in \mathcal{K}(\mathbb{R}^N)$  sufficiently close to  $K$

$$\begin{aligned} & J(\vartheta_u(h, M)) - J(M) \\ & \leq J(\vartheta_g(h, M)) - J(M) + o(h) \\ & = J(\vartheta_g(h, M)) - J(\vartheta_g(s_m, M)) + \sum_{n=m}^{\infty} (J(\vartheta_g(s_n, M)) - J(\vartheta_g(s_{n+1}, M))) + o(h) \\ & \leq (h - s_m) \cdot \left( \frac{\iota J(K)}{2} + \varepsilon \right) + \sum_{n=m}^{\infty} (s_n - s_{n+1}) \cdot \left( \frac{\iota J(K)}{2} + \varepsilon \right) + o(h) \\ & = h \cdot \left( \frac{\iota J(K)}{2} + \varepsilon \right) + o(h). \end{aligned}$$

So,  $\delta^C J(K)(u) \leq \frac{\iota J(K)}{2} + \varepsilon$  with any  $\varepsilon > 0$ , i.e.,  $u \stackrel{\text{Def.}}{=} \lambda v + (1 - \lambda) w \in \mathcal{F}(K)$ .

Each value  $\mathcal{F}(K) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  is closed w.r.t. locally uniform convergence. Let  $(v_n)_{n \in \mathbb{N}}$  be a sequence in  $\mathcal{F}(K) \subset \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  converging to  $v \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  locally uniformly. Obviously, the limit holds  $\|v\|_{\infty} + \text{Lip } v \leq 1$ . Moreover, similarly to Lemma 2.4, Filippov's theorem implies

$$\sup_{\substack{M \in \mathcal{K}(\mathbb{R}^N) \\ d(K, M) \leq 1}} d(\vartheta_{v_n}(h, M), \vartheta_v(h, M)) \leq h e^h \cdot \sup_{\mathbb{B}_2(K)} |v_n(\cdot) - v(\cdot)| \longrightarrow 0$$

for  $n \longrightarrow \infty$  uniformly in  $h \in [0, 1]$  and for every set  $K \in \mathcal{K}(\mathbb{R}^N)$ . So due to the Lipschitz continuity of  $J(\cdot)$ , Clarke's generalized shape derivative satisfies

$$\begin{aligned} \delta^C J(K)(v) & \leq \limsup_{\substack{h \downarrow 0, M \rightarrow K \\ (M \in \mathcal{K}(\mathbb{R}^N))}} \frac{1}{h} \cdot (J(\vartheta_{v_n}(h, M)) - J(M)) + \text{Lip } J \cdot \sup_{\mathbb{B}_2(K)} |v_n(\cdot) - v(\cdot)| \\ & \leq \frac{1}{2} \cdot \iota J(K) + \text{Lip } J \cdot \sup_{\mathbb{B}_2(K)} |v_n(\cdot) - v(\cdot)|. \end{aligned}$$

$n \longrightarrow \infty$  reveals  $v \in \mathcal{F}(K)$ .  $\square$

*Remark.* In regard to the viability theorem, Theorem 3.11, the graph of  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  ought to be closed (still using the topology of locally uniform convergence). This feature is closely related with the lower semicontinuity of  $\delta^C J(\cdot)(v) : \mathcal{K}(\mathbb{R}^N) \longrightarrow \mathbb{R}$  (with  $v \in \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  fixed), and it will be used here as an additional assumption on  $J$ .

So now Lemmas 4.3 and 4.5 have laid the basis for applying the morphological viability theorem, Theorem 3.11. We summarize the main result of this section.

**PROPOSITION 4.6.** *Suppose  $J : \mathcal{K}(\mathbb{R}^N) \longrightarrow \mathbb{R}$  to be Lipschitz continuous w.r.t. the Pompeiu–Hausdorff distance  $d$  and bounded from below.*

*Using Definitions 4.1 and 4.2,  $\mathcal{F} : \mathcal{K}(\mathbb{R}^N) \rightsquigarrow \text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$  is assumed to have a closed graph w.r.t. locally uniform convergence on  $\text{Lip}(\mathbb{R}^N, \mathbb{R}^N)$ .*

*Let  $\mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  be nonempty and closed such that for every  $K \in \mathcal{V}$ , the intersection  $\mathcal{F}(K) \cap T_{\mathcal{V}}(K)$  is nonempty.*

*Then there exists a Lipschitz continuous solution  $K : [0, \infty[ \longrightarrow \mathcal{V} \subset \mathcal{K}(\mathbb{R}^N)$  of the morphological inclusion  $\overset{\circ}{K}(\cdot) \cap \mathcal{F}(K(\cdot)) \neq \emptyset$  such that*

- 1.  $J \circ K : [0, \infty[ \longrightarrow \mathbb{R}$ ,  $t \longmapsto J(K(t))$  is nonincreasing, and*
- 2. every element  $C \in \mathcal{K}(\mathbb{R}^N)$  of its  $\omega$ -limit set in  $\mathcal{K}(\mathbb{R}^N)$  satisfies the following necessary condition on minimizers of  $J(\cdot)$  in  $\mathcal{K}(\mathbb{R}^N)$ :  $\iota J(C) = 0$ .*

**Acknowledgments.** The author would like to thank Irina Surovtsova and Daniel Andrej for fruitful complementary discussions. He is also grateful to the anonymous referees since their very detailed reports contributed a lot to improving this article.

# THE BREZIS–EKELAND PRINCIPLE FOR DOUBLY NONLINEAR EQUATIONS\*

ULISSE STEFANELLI†

**Abstract.** The celebrated Brezis–Ekeland principle [*C. R. Acad. Sci. Paris Ser. A-B*, 282 (1976), pp. Ai, A1197–A1198, Aii, and A971–A974] characterizes trajectories of nonautonomous gradient flows of convex functionals as solutions to suitable minimization problems. This note extends this characterization to doubly nonlinear evolution equations driven by convex potentials. The characterization is exploited in order to establish approximation results for gradient flows, doubly nonlinear equations, and rate-independent evolutions.

**Key words.** Brezis–Ekeland principle, gradient flow, doubly nonlinear equation, rate-independent evolution, Mosco convergence, Young measures, approximation

**AMS subject classification.** 35K55

**DOI.** 10.1137/070684574

**1. Introduction.** Let  $H$  denote a Hilbert space and  $T > 0$  be some final reference time. Moreover, let  $\phi : H \rightarrow (-\infty, \infty]$  be convex, proper, and lower semicontinuous,  $f \in L^2(0, T; H)$ , and  $u^0 \in D(\phi) := \{v \in H : \phi(v) \neq \infty\}$ . The variational principle formulated by Brezis and Ekeland [17, 18] and Nayroles [77, 78] (see also [9, sect. 3.4]) characterizes solutions  $u \in H^1(0, T; H)$  of the gradient flow

$$(1.1) \quad u' + \partial\phi(u) \ni f \quad \text{a.e. in } (0, T), \quad u(0) = u^0$$

(where the prime stands for time differentiation and  $\partial\phi$  is the subdifferential of  $\phi$  in the sense of convex analysis; see below) as a global minimizer of the functional  $J : H^1(0, T; H) \rightarrow [0, \infty]$  defined as

$$(1.2) \quad J(u) := \int_0^T (\phi(u) + \phi^*(f - u') - (f, u)) + \frac{1}{2}|u(T)|^2 - \frac{1}{2}|u(0)|^2 + |u(0) - u^0|^2.$$

Here  $(\cdot, \cdot)$  is the scalar product in  $H$ ,  $|\cdot|$  is the corresponding norm, and we have denoted by  $\phi^*$  the conjugate of  $\phi$ , i.e.,  $\phi^*(w) := \sup\{(w, u) - \phi(u), u \in H\}$  for all  $w \in H$ . Let us stress that  $\phi(u) + \phi^*(w) \geq (w, u)$  for all  $u, w \in H$  and that the equality holds iff  $w \in \partial\phi(u)$ . In particular, one readily checks that  $J(v) \geq 0$  for all  $v \in H^1(0, T; H)$  and that  $J(u) = \min J = 0$  iff  $u$  solves the gradient flow (1.1). Namely, the unique solution to (1.1) and the unique minimizer of  $J$  coincide, and we have the following.

**THEOREM 1.1** (Brezis and Ekeland [17, 18]).  *$u$  solves (1.1) iff  $J(u) = 0$ .*

The aim of this note is to extend the latter characterization result to the more general situation of doubly nonlinear equations. In particular, let a second convex, proper, and lower semicontinuous functional  $\psi : H \rightarrow (-\infty, \infty]$  be given. We are interested in solving for  $u \in W^{1,p}(0, T; H)$ ,  $p \in [1, \infty]$ , the equation

$$(1.3) \quad \partial\psi(u') + \partial\phi(u) \ni f \quad \text{a.e. in } (0, T), \quad u(0) = u^0,$$

where now  $f \in L^q(0, T; H)$ , with  $1/p + 1/q = 1$  (usual convention:  $1/\infty = 0$ ).

†IMATI - CNR, v. Ferrata 1, I-27100 Pavia, Italy (ulisse.stefanelli@imati.cnr.it).

The latter equation arises in a variety of different applicative contexts. In particular, inclusion (1.3) may represent a generalized balance relation in thermomechanics. The reader is referred to Moreau [74, 75] and Germain [30] for some justification and to Colli and Visintin [23] and Colli [22] for existence results for functionals  $\psi$  of  $p$ -growth for  $1 < p < \infty$  (see also Barbu [12], Arai [3], and Senba [95] among others). The linear-growth case  $p = 1$  is strictly related with the modeling of rate-independent evolution and has been considered in connection with elasto-plasticity [25, 26, 58, 59, 60, 61], damage [68], brittle fractures [27], delamination [56], ferroelectricity [73], shape-memory alloys [67, 71, 72], and vortex pinning in superconductors [94]; see Mielke [62] for a comprehensive survey of mathematical results.

We shall make precise problem (1.3) by introducing an auxiliary function. Namely, we consider  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H)$  such that

$$(1.4) \quad v \in \partial\psi(u') \quad \text{a.e. in } (0, T),$$

$$(1.5) \quad v + \partial\phi(u) \ni f \quad \text{a.e. in } (0, T),$$

$$(1.6) \quad u(0) = u^0.$$

The above relations have a clear mechanical interpretation. By letting  $u$  represent the displacement of a body from its reference configuration,  $\phi$  can be interpreted as the corresponding energy, and  $\psi$  stands for the related dissipation potential. In particular, relation (1.5) expresses the balance among the system of conservative forces  $\partial\phi(u)$ , the dissipative (viscous) force  $v$ , and the external load  $f$ . On the other hand, relation (1.4) consists of a multivalued constitutive relation for the dissipative forces.

Let now the functional  $I : W^{1,p}(0, T; H) \times L^q(0, T; H) \rightarrow [0, \infty]$  be defined as

$$(1.7) \quad \begin{aligned} I(u, v) := & \left( \int_0^T (\psi(u') + \psi^*(v) - (f, u')) + \phi(u(T)) - \phi(u^0) \right)^+ \\ & + \int_0^T (\phi(u) + \phi^*(f - v) - (f - v, u)) + |u(0) - u^0|^2. \end{aligned}$$

Note that, exactly as for  $J$ , no derivatives of the potentials appear in the definition of  $I$ , making its formulation suited for nonsmooth situations.

The key point of this note is to check that solutions of (1.4)–(1.6) are precisely the (possibly nonunique) minimizers of the nonnegative functional  $I$ . In particular, we prove the following.

**THEOREM 1.2.**  $(u, v)$  solves (1.4)–(1.6) iff  $I(u, v) = 0$ .

Let us explicitly remark that Theorem 1.2 implies the Brezis–Ekeland characterization of Theorem 1.1; namely, the present analysis extends the former. In order to prove this fact, some care has to be used since in the quadratic case  $\psi(\cdot) = |\cdot|^2/2$  the functionals  $I(u, u')$  and  $J(u)$  do not coincide. Precisely, we shall define  $K : H^1(0, T; H) \rightarrow [0, \infty]$  by

$$(1.8) \quad K(u) := I(u, u') = \left( \int_0^T (|u'|^2 - (f, u')) + \phi(u(T)) - \phi(u^0) \right)^+ + J(u).$$

Theorem 1.1 will follow from Theorem 1.2 once we check that  $K$  and  $J$  have the same minimizer. This is exactly the point of the following.

**LEMMA 1.3.**  $K(u) = 0$  iff  $J(u) = 0$ .

Indeed, by letting  $J(u) = 0$  we shall prove that  $K(u) = 0$  (the converse implication being obvious). Since  $u$  is a solution to (1.1) by Theorem 1.1, the chain rule [16, Lem. 3.3, p. 73] yields

$$\phi(u(T)) - \phi(u^0) = \int_0^T \frac{d}{dt} \phi(u) = \int_0^T (f - u', u').$$

Hence, the positive part in (1.8) is 0, and  $K(u) = J(u) = 0$ .

The functional  $J$  is convex and lower semicontinuous with respect to the weak topology of  $H^1(0, T; H)$ . Hence, one is tempted to exploit the Brezis–Ekeland characterization of Theorem 1.1 in order to obtain solutions to the gradient flow (1.1) by applying the direct method to  $J$ . This strategy is, however, much more involved than the classical maximal-monotone operator techniques (see Brezis [16]). The difficulty arises from the fact that one is not just asked to minimize  $J$  but also to prove that the minimum is 0 (the difficulty of proving the existence of a minimizer for  $J$  without using the equation was already pointed out in [18, Rem. 1]). Incidentally, note that  $J$  may fail to be coercive with respect to the weak topology of  $H^1(0, T; H)$  unless  $\phi^*$  has at least a quadratic growth and hence  $\phi$  is quadratically bounded (take  $\phi^*(\cdot) = |\cdot|$ ,  $f = 0$ ,  $u^0 = 0$ , and  $u_n$  to be any  $W^{1,1}(0, T; H)$ -bounded sequence with  $|u_n| \leq 1$  and  $u'_n$  unbounded in  $L^2(0, T; H)$ ). On the other hand,  $K$  is clearly convex, lower semicontinuous, and coercive with respect to the weak topology of  $H^1(0, T; H)$ .

Conditional existence results for the gradient flow (1.1) by means of the direct method were first obtained by Rios [85, 88] (see also [86, 87]). Later on, Auchmuty [10] proved that in the controlled-growth case the minimum problem can be reformulated as a saddle point problem for which the minimax value 0 is achieved (see also [8]). Again in the controlled-growth case and by assuming  $\phi$  to be continuously differentiable, Roubíček [90] directly checked that the optimality conditions imply (1.1) (see also the recent monograph [91, sect. 8.10]). Finally, the full extent of maximal-monotone methods has been recovered via the Brezis–Ekeland approach by Ghoussoub and Tzou [39]. In the latter paper, the authors eventually overcome the controlled-growth assumption and recast the problem within the far-reaching theory of (anti)self-dual Lagrangians by Ghoussoub [35, 34, 31, 32, 33, 37, 41, 40] (see also the monograph [36]). We mention some further results by Ghoussoub and McCann [38] for quadratic perturbations of convex functionals and the analysis of the long-time dynamics of autonomous gradient flows by Lemaire [51].

Our main focus here is, however, not on existence but rather on the application of the characterization result of Theorem 1.2 to the analysis of general approximation issues. Since solutions and minimizers of the respective functionals coincide, a quite natural idea in order to frame an abstract approach to limiting procedures is that of considering the corresponding approximating minimum problems via  $\Gamma$ -convergence [43, 24]. We shall apply this perspective and generalize some known approximation results for both gradient flows (section 6) and doubly nonlinear equations (section 7). Moreover, we obtain a new proof of a convergence result by Mielke, Roubíček, and Stefanelli [69] for the case of rate-independent problems in section 8.

The key step in the direction of approximations is a suitable  $\Gamma$ -lim inf tool settled in the frame of Young measures with values in separable and reflexive Banach spaces (see subsection 4.2). Let us mention that this perspective has already been considered by Pedregal [81, 82] and Michaille and Valadier [57] in the frame of Sobolev spaces. Here, moving from some recent version in weak topologies of the fundamental result by Balder [11, Thm. 1], we deduce a useful tool in order to pass to lower limits in

sequences of integral functionals whose integrands fulfill a suitable  $\Gamma$ -lim inf inequality. As a by-product, we obtain some generalization of former results by Salvadori [92, Thm. 3.1].

By applying the above-mentioned approximation results, we show in subsection 7.1 the existence of solutions for a class of doubly nonlinear equations by passing to the limit via Theorem 1.2 within a suitable class of regularized problems. In particular, we recover by means of a variational technique a former existence result by Colli and Visintin [23, Thm. 2.1].

Let us mention that some refined version of the functional  $I$  and Theorem 1.2 is discussed in [103] for the specific situation of linearized elastoplasticity with hardening. In particular, the (classical) well-posedness theory and the (more recent) convergence for time and space discretizations [47] is there recovered by means of a variational technique.

Let us close this introduction by observing that, besides the Brezis–Ekeland principle, a variety of global variational principles for dissipative evolutions have already been proposed. We mention Biot’s work on irreversible thermodynamics [15] and Gurtin’s principle for viscoelasticity and elastodynamics [44, 45, 46] among many others (see also the survey in Hlaváček [48]). We shall not attempt to give here a comprehensive report on the literature but rather concentrate on the specific case of doubly nonlinear evolutions. In this concern, the reader is referred to Visintin [105], where generalized solutions are obtained as minimal elements of a certain partial-order relation on the trajectories, and Mielke and Ortiz [63] (see also [70]), where solutions in the rate-independent case are recovered as suitable limits of relaxed global minimization problems.

*Remark 1.4.* The formulation in (1.2) is not the original one but is rather some modification due to Rockafellar (see again [18]) also considered in Ghoussoub and Tzou [39].

**2. Characterization.** The Brezis–Ekeland characterization of Theorem 1.1 makes no essential use of the Hilbert-space structure. Hence, let us move from the very beginning to the reflexive Banach-space framework and start by enlisting our assumptions:

- (A1)  $p \in [1, \infty]$ ,  $1/p + 1/q = 1$ , and  $H$  is a real reflexive Banach space with norm  $|\cdot|$ . We shall use the symbol  $(\cdot, \cdot)$  for the duality pairing between  $H^*$  (dual) and  $H$ .
- (A2)  $\phi, \psi : H \rightarrow (-\infty, \infty]$  are proper, convex, and lower semicontinuous.
- (A3)  $f \in L^q(0, T; H^*)$  and  $u^0 \in D(\phi) := \{v \in H : \phi(v) \neq \infty\}$ .

The subdifferentials occurring in the formulation of the Cauchy problem (1.4)–(1.6) are now acting from  $H$  to  $H^*$  being defined as

$$w \in \partial\phi(z) \quad \text{iff} \quad z \in D(\phi) \quad \text{and} \quad (w, x - z) \leq \phi(x) - \phi(z) \quad \forall x \in H$$

and analogously for  $\partial\psi$ . Notations have been chosen in such a way that the definition of the functional  $I$  in (1.7) still makes sense in the above Banach-space setting. For the sake of clarity, we shall restate here our main result.

**THEOREM 2.1.** *Under assumptions (A1)–(A3), the pair  $(u, v)$  solves (1.4)–(1.6) iff  $I(u, v) = 0$ .*

The proof of Theorem 2.1 relies on a suitable Banach version of the chain rule [16, Lem. 3.3, p. 73]. We state it here for the sake of completeness and provide a direct proof.

PROPOSITION 2.2 (chain rule). *Under assumption (A1), let  $\phi : H \rightarrow (-\infty, \infty]$  be proper, convex, and lower semicontinuous,  $u \in W^{1,p}(0, T; H)$ , and  $w \in L^q(0, T; H^*)$  be such that  $w \in \partial\phi(u)$  almost everywhere in  $(0, T)$ . Then  $t \mapsto \phi(u(t))$  is absolutely continuous and*

$$\phi(u(t)) - \phi(u(s)) = \int_s^t (z, u') \quad \forall 0 \leq s \leq t \leq T,$$

for all  $z \in L^q(0, T; H^*)$ , with  $z \in \partial\phi(u)$  almost everywhere in  $(0, T)$ .

*Proof.* Let us assume from the very beginning that both  $H$  and  $H^*$  are strictly convex ( $H$  can be equivalently renormed in such a way that this holds [5, 6]). We let  $w_\varepsilon := \partial\phi_\varepsilon(u)$  for  $\varepsilon > 0$ , where  $\phi_\varepsilon$  is the Yosida approximation of  $\phi$  (see [13, Prop. 1.1, p. 42] for definition and properties). Since  $\phi_\varepsilon$  is Gâteaux differentiable [13, Thm. 2.2, p. 57] we have

$$(2.1) \quad \phi_\varepsilon(u(t)) - \phi_\varepsilon(u(s)) = \int_s^t (w_\varepsilon, u') \quad \forall 0 \leq s \leq t \leq T.$$

Moreover, one has  $|w_\varepsilon|_* \leq |w^\circ|_* \leq |w|_*$  almost everywhere in  $(0, T)$ , where  $|\cdot|_*$  is the norm of  $H^*$  and  $w^\circ := (\partial\phi(u))^\circ$  is the element of minimal norm in  $\partial\phi(u)$ . Hence, for all  $t \in (0, T)$  such that  $|w_\varepsilon(t)|_* \leq |w^\circ(t)|_* \leq |w(t)|_*$ , one can extract a not relabeled (and a priori depending on  $t$ ) weakly convergent subsequence  $w_\varepsilon(t)$ . On the other hand, by using [13, Prop. 1.1, p. 42] we have  $w_\varepsilon(t) \rightarrow w^\circ(t)$  weakly in  $H^*$ . In particular, the whole sequence  $w_\varepsilon(t)$  converges, and we have  $w_\varepsilon \rightarrow w^\circ$  weakly in  $H^*$  pointwise almost everywhere in  $(0, T)$ . By exploiting the convergence of Yosida approximations and the dominated convergence theorem and by passing to the limit as  $\varepsilon \rightarrow 0$  in (2.1), we prove that  $t \mapsto \phi(u(t))$  is absolutely continuous on  $[0, T]$ .

Let now  $t \in (0, T)$  be a point, where  $t \mapsto \phi(u(t))$  is differentiable and  $u(t) \in D(\partial\phi) := \{v \in H : \partial\phi(v) \neq \emptyset\}$ , and let  $z \in \partial\phi(u(t))$ . Then

$$(z, x - u(t)) \leq \phi(x) - \phi(u(t)) \quad \forall x \in H.$$

By choosing  $x = u(t \pm h)$  for  $h > 0$  and passing to the limit as  $h \rightarrow 0$  we readily check that

$$\frac{d}{dt} \phi(u(t)) = (z, u'(t)),$$

and the assertion follows.  $\square$

*Proof of Theorem 2.1.* Let  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  solve (1.4)–(1.6). In particular, we have

$$\phi(u) + \phi^*(f - v) = (f - v, u), \quad \psi(u') + \psi^*(v) = (v, u') \quad \text{a.e. in } (0, T)$$

so that  $I(u, v) < \infty$ . Moreover, owing to Proposition 2.2, the map  $t \mapsto \phi(u(t))$  is absolutely continuous and

$$(2.2) \quad \phi(u(T)) - \phi(u^0) = \int_0^T \frac{d}{dt} \phi(u) = \int_0^T (f - v, u').$$

Hence, since  $u(0) = u^0$ ,

$$I(u, v) = \left( \int_0^T (\psi(u') + \psi^*(v) - (v, u')) \right)^+ = 0.$$

On the other hand, let  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  be such that  $I(u, v) = 0$ . The functional  $I$  results from the sum of three nonnegative contributions, namely, the positive-part term, the integral term, and the term taking into account the initial datum. As  $I(u, v) = 0$ , one has that all three terms must be 0. In particular,  $u(0) = u^0$ , and relation (1.5) holds. By using Proposition 2.2 and the already established (1.5) we have

$$\begin{aligned} & \int_0^T (\psi(u') + \psi^*(v) - (v, u')) \\ &= \int_0^T (\psi(u') + \psi^*(v) - (f, u')) + \phi(u(T)) - \phi(u^0) \leq 0, \end{aligned}$$

where the last inequality follows from the fact that the positive-part term in  $I(u, v)$  is 0. Finally, as  $\psi(u') + \psi^*(v) \geq (v, u')$  almost everywhere in  $(0, T)$ , relation (1.4) holds as well.  $\square$

Let us remark that the reflexive Banach frame of assumption (A1) includes the original Hilbert-space setting of Theorem 1.1. In particular, the Brezis–Ekeland characterization follows from Theorem 2.1 via Lemma 1.3.

Before going on, we shall comment that the alternative (and somehow more natural) choice  $\tilde{I} : W^{1,p}(0, T; H) \times L^q(0, T; H) \rightarrow [0, \infty]$  given by

$$\begin{aligned} \tilde{I}(u, v) &:= \int_0^T (\psi(u') + \psi^*(v) - (v, u')) \\ &+ \int_0^T (\phi(u) + \phi^*(f - v) - (f - v, u)) + |u(0) - u^0|^2 \end{aligned}$$

would lead to the same characterization of Theorem 2.1. On the other hand, the presence of the term  $(v, u')$  prevents the functional  $\tilde{I}$  from being lower semicontinuous with respect to the natural topologies related to the doubly nonlinear problem (1.3) (see below), making the functional  $\tilde{I}$  not interesting.

In the specific case of a Hilbert space  $H$  and a quadratic potential  $\phi(\cdot) = |\cdot|^2/2$ , relation (1.3) takes the form

$$(2.3) \quad \partial\psi(u') + u \ni f \quad \text{a.e. in } (0, T), \quad u(0) = u^0.$$

By letting the functional  $Q : W^{1,p}(0, T; H) \rightarrow [0, \infty]$  be defined as

$$Q(u) := \int_0^T (\psi(u') + \psi^*(f - u) - (f, u')) + \frac{1}{2}|u(T)|^2 - \frac{1}{2}|u(0)|^2 + |u(0) - u^0|^2,$$

one easily checks via Fenchel's duality that  $u \in W^{1,p}(0, T; H)$  solves (2.3) iff  $Q(u) = \min Q = 0$ . On the other hand, in the same spirit of (1.8), one could consider  $R : W^{1,p}(0, T; H) \rightarrow [0, \infty]$  as  $R(u) := I(u, f - u)$ , and the analogue of Lemma 1.3 holds.

The case of a quadratic potential  $\phi$  bears some relevance with respect to applications (see section 8 and [103]). Hence, we shall explicitly consider the functional  $Q$  in the following.

**3. Some extension.** As already mentioned in the introduction, Theorem 2.1 is valid in some more general frames. In particular, we shall consider the doubly nonlinear relation

$$(3.1) \quad \partial\psi(u'(t)) + \partial\varphi(t, u(t)) \ni 0 \quad \text{for a.e. } t \in (0, T), \quad u(0) = u^0,$$

where the time dependence is now included in  $\varphi$  and the second subdifferential is referred to the variable  $u$  only.

Letting  $X$  be a separable metric space, we denote by  $\mathcal{B}(X)$  its Borel  $\sigma$ -algebra, by  $\mathcal{L}$  the  $\sigma$ -algebra of the Lebesgue measurable subsets of  $(0, T)$ , and by  $\mathcal{L} \otimes \mathcal{B}(X)$  the respective product  $\sigma$ -algebra. A  $\mathcal{L} \otimes \mathcal{B}(X)$ -measurable function  $g : (0, T) \times X \rightarrow (-\infty, \infty]$  is said to be a *normal integrand* if

$$u \mapsto g(t, u) \quad \text{is lower semicontinuous for a.e. } t \in (0, T).$$

The assumptions read as follows:

- (A4)  $\psi : H \rightarrow (-\infty, \infty]$  is convex, proper, and lower semicontinuous,  
 $\varphi : [0, T] \times H \rightarrow (-\infty, \infty]$  is such that:  
 $u \mapsto \varphi(t, u)$  is proper and convex for a.e.  $t \in (0, T)$ ,  
 for all separable subspaces  $X \subset H$ , the restriction of  $\varphi$  to  $[0, T] \times X$  is a normal integrand,  
 there exists  $\pi : W^{1,p}(0, T; H) \rightarrow L^1(0, T)$  such that, for  $u \in W^{1,p}(0, T; H)$  and  $w \in L^q(0, T; H^*)$ , with  $w(t) \in \partial\varphi(t, u(t))$  for a.e.  $t \in (0, T)$ , the mapping  $t \mapsto \varphi(t, u(t))$  is absolutely continuous and satisfies

$$(3.2) \quad \varphi(t, u(t)) - \varphi(s, u(s)) = \int_s^t (w, u') + \int_s^t \pi(u) \quad \forall 0 \leq s \leq t \leq T.$$

- (A5)  $u^0 \in D(\varphi(0, \cdot)) := \{v \in H : \varphi(0, v) \neq \infty\}$ .

Assumption (A4) implies via Pettis' theorem that  $t \mapsto \varphi(t, u(t))$  is measurable for all measurable  $t \mapsto u(t)$ .

As for the generalized chain rule stated in (A4), let us mention that  $\pi$  represents a power of external actions since, at least formally,  $\pi = \partial_t \varphi$  (see also section 8 below). The chain rule (3.2) frequently holds in practice. In particular, it holds in the smooth case and if  $\varphi$  is a smooth perturbation of a convex function. The reader is referred to [64, Prop. 2.6] for a result in the nonperturbative case.

We will consider solutions  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  of the Cauchy problem (see (1.4)–(1.6))

$$(3.3) \quad v \in \partial\psi(u') \quad \text{a.e. in } (0, T),$$

$$(3.4) \quad -v(t) \in \partial\varphi(t, u(t)) \quad \text{for a.e. } t \in (0, T),$$

$$(3.5) \quad u(0) = u^0.$$

Hence, let us define the functional  $\mathcal{I}$  acting on  $W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  as

$$\begin{aligned} \mathcal{I}(u, v) := & \left( \int_0^T (\psi(u') + \psi^*(v) - \pi(u)) + \varphi(T, u(T)) - \varphi(0, u^0) \right)^+ \\ & + \int_0^T (\varphi(\cdot, u) + \varphi^*(\cdot, -v) + (v, u)) + |u(0) - u^0|^2, \end{aligned}$$

where the duality  $\varphi^*$  is taken with respect to the variable  $u$  only. The formulation of Theorem 1.2 in this setting reads as follows.

**THEOREM 3.1.** *Under assumptions (A1) and (A4)–(A5), the pair  $(u, v)$  solves (3.3)–(3.5) iff  $\mathcal{I}(u, v) = 0$ .*

*Sketch of the proof.* This argument follows along the same lines as that of Theorem 1.2. All solutions to (3.3)–(3.5) are easily proved to be minimizers of  $\mathcal{I}$  by means of

the chain rule (3.2). On the other hand, let  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  be such that  $\mathcal{I}(u, v) = 0$ . Then one has  $u(0) = u^0$  and  $-v(t) \in \partial\varphi(t, u(t))$  for almost every  $t \in (0, T)$ . Again by (3.2) one gets

$$\begin{aligned} & \int_0^T (\psi(u') + \psi^*(v) - \langle v, u' \rangle) \\ &= \int_0^T (\psi(u') + \psi^*(v) - \pi(u)) + \varphi(T, u(T)) - \varphi(0, u^0) \leq 0, \end{aligned}$$

and the assertion follows.  $\square$

*Remark 3.2.* Let us stress that the present situation of (3.1) is not directly extending (1.3) as some extra time regularity is here exploited. As a matter of fact, the case  $\varphi(t, u) = \phi(u) - \langle f(t), u \rangle$  is included in the frame of (A4) for the smooth choice  $f \in W^{1,q}(0, T; H^*)$  only.

*Remark 3.3.* We shall mention that the generalized situation of the equation

$$(3.6) \quad \partial\psi(u(t), u'(t)) + \partial\phi(t, u(t)) \ni 0 \quad \text{for a.e. } t \in (0, T), \quad u(0) = u^0,$$

where the functional  $\psi : H \times H \rightarrow (-\infty, \infty]$  is convex in its second occurrence and subdifferentials are taken with respect to second variables, has recently attracted a good deal of attention. In particular (3.6) arises in connection with quasi-variational problems and has been considered in Aso, Frémond, and Kenmochi [4], Mielke [62], and Mielke, Rossi, and Savaré [66, 65]. The formulation of the above characterization result in Theorem 3.1 could be easily tailored to the case of (3.6) as well as to even more general situations (the nonlocal situations of [97, 98, 99, 100, 49], for instance) with no particular intricacy.

Before closing this section, let us explicitly mention that the choice  $H$  Hilbert space,  $p = 2$ , and  $\psi(\cdot) = |\cdot|^2/2$  in relation (3.1) give rise to the generalized gradient flow

$$(3.7) \quad u'(t) + \partial\varphi(t, u(t)) \ni 0 \quad \text{a.e. in } (0, T), \quad u(0) = u^0,$$

whose consideration has to be traced back to Peralba [83, 84]. We shall consider (3.7) from the point of view of approximation in section 6 below. Let us explicitly observe there that the extension of the functional  $K$  to the latter time-dependent situation is  $\mathcal{K} : H^1(0, T; H) \rightarrow [0, \infty]$  defined by

$$\begin{aligned} \mathcal{K}(u) := \mathcal{I}(u, u') &= \left( \int_0^T (|u'|^2 - \pi(u)) + \varphi(T, u(T)) - \varphi(0, u^0) \right)^+ \\ &+ \int_0^T (\varphi(\cdot, u) + \phi^*(\cdot, -u')) + \frac{1}{2}|u(T)|^2 - \frac{1}{2}|u(0)|^2 + |u(0) - u^0|^2. \end{aligned}$$

**4. Applications to approximation.** We now apply the characterization results of Theorems 2.1 and 3.1 to the approximation of solutions of the gradient flows (1.1) and (3.7) and of the doubly nonlinear equations (1.3) and (3.1). As already mentioned in the introduction, we shall make here use of the notion of  $\Gamma$ -convergence. The reader is referred to the monographs by Attouch [7] and Dal Maso [24] for some comprehensive discussion of this topic as well as to subsection 4.1 for a (minimal) selection of results to be used later.

Our aim will be to present suitable assumptions for the corresponding approximating functionals to be  $\Gamma$ -converging (or rather Mosco-converging; see below). More

precisely, since Theorems 2.1 and 3.1 directly quantify the value of the minima to be 0, what is actually needed for passing to limits are  $\Gamma$ -lim inf inequalities only. In subsection 4.2 we shall prepare a tool in order to deal with these kinds of problems in a quite general fashion. In particular, we will provide a  $\Gamma$ -lim inf result by exploiting the theory of Young measures for weak topologies in separable (and reflexive) Banach spaces. The application of the latter to the current convex situation is discussed in subsection 4.3 along with some relation with the former analysis by Salvadori [92]. Then in section 5 we systematically apply the  $\Gamma$ -lim inf tool to the functionals introduced in sections 1 and 3 and obtain the corresponding  $\Gamma$ -lim inf inequalities. Convergence results will then follow by simply checking the uniform coercivity of the approximating functionals with respect to suitable topologies. In the case of the gradient flows (1.1) and (3.7), we will show in section 6 that a natural choice is that of the weak topology in  $H^1(0, T; H)$  (note that  $K$  is lower semicontinuous and coercive with respect to the latter). This leads us to generalize some known convergence results (see [7, sect. 3.9.2, p. 386]).

In the case of the doubly nonlinear equations (1.3) and (3.1) for  $p \in (1, \infty)$ , we will provide in section 7 some conditions implying uniform coercivity with respect to the topology

$$(4.1) \quad \mathcal{T}(p) = (\text{weak-}W^{1,p}(0, T; H) + \text{strong-}L^p(0, T; H)) \times \text{weak-}L^q(0, T; H^*)$$

(recall that  $I$  is lower semicontinuous with respect to  $\mathcal{T}(p)$ ). Hence, under suitable nondegeneracy and growth-type assumptions (see (7.1)–(7.2)), section 7 leads to some generalization of former convergence results by Aizicovici and Yan [1].

The situation  $p = 1$  is much more delicate, and we shall deal with it in the specific yet relevant case of rate-independent problems in section 8. By focusing on the functional frame of the recent well-posedness theory by Mielke and Rossi [64], we shall provide a new proof of a convergence result by Mielke, Roubíček, and Stefanelli [69], although in a simplified setting. Finally, the special case of (2.3) is discussed.

**4.1. Preliminaries on Mosco convergence.** Recall that  $H$  is a real reflexive Banach space. By letting  $\phi_n, \phi : H \rightarrow (-\infty, \infty]$  be convex, proper, and lower semicontinuous, we say that the sequence  $\phi_n$  is *uniformly proper* iff there exists a bounded sequence  $u_n$  such that  $u_n \in D(\phi_n)$ . Moreover, we say that  $\phi_n \rightarrow \phi$  in the *Mosco sense* [7, 76] iff, for all  $u \in H$ ,

$$\begin{aligned} \phi(u) &\leq \liminf_{n \rightarrow \infty} \phi_n(u_n) \quad \forall u_n \rightarrow u \text{ weakly in } H, \\ \exists u_n &\rightarrow u \text{ strongly in } H \text{ such that } \phi(u) = \limsup_{n \rightarrow \infty} \phi_n(u_n). \end{aligned}$$

In particular,  $\phi_n \rightarrow \phi$  in the Mosco sense iff  $\phi_n \rightarrow \phi$  in the sense of  $\Gamma$ -convergence with respect to both the weak and the strong topology in  $H$ . Let us stress that if  $\phi_n \rightarrow \phi$  in the Mosco sense, then the sequence  $\phi_n$  is uniformly proper. One has the following characterization.

LEMMA 4.1. *The following are equivalent:*

- (i)  $\phi_n \rightarrow \phi$  in the Mosco sense in  $H$ ,
- (ii)  $\left\{ \begin{array}{l} \phi(u) \leq \inf \left\{ \liminf_{n \rightarrow \infty} \phi_n(u_n) : u_n \rightarrow u \text{ weakly in } H \right\}, \\ \phi^*(u) \leq \inf \left\{ \liminf_{n \rightarrow \infty} \phi_n^*(u_n) : u_n \rightarrow u \text{ weakly in } H^* \right\}, \\ \text{and the sequence } \phi_n^* \text{ is uniformly proper.} \end{array} \right.$

*Proof.* Assumption (i) is equivalent to  $\phi_n^* \rightarrow \phi^*$  in the Mosco sense [7, Thm. 3.18, p. 295]. Hence (ii) follows by the definition of Mosco convergence.

The converse implication (ii)  $\Rightarrow$  (i) is more involved. Let us set for convenience, for all  $u \in H$  and  $v \in H^*$ ,

$$\begin{aligned}\phi_{\sharp}(u) &:= \min \left\{ \limsup_{n \rightarrow \infty} \phi_n(u_n) : u_n \rightarrow u \text{ strongly in } H \right\}, \\ \phi_{\flat}(v) &:= \inf \left\{ \liminf_{n \rightarrow \infty} \phi_n^*(v_n) : v_n \rightarrow v \text{ weakly in } H^* \right\},\end{aligned}$$

Owing to [7, Thm. 1.13, p. 29], the minimum in the definition of  $\phi_{\sharp}$  is always attained in  $(-\infty, \infty]$ . In particular, for all  $u \in H$ ,

$$(4.2) \quad \exists u_n \rightarrow u \text{ strongly in } H \text{ such that } \phi_{\sharp}(u) = \limsup_{n \rightarrow \infty} \phi_n(u_n).$$

The sequence  $\phi_n^*$  is uniformly proper, and we can apply [7, Thm. 3.7, p. 271] in order to deduce that  $\phi_{\sharp} = (\phi_{\flat})^*$ . Hence, since by the second part of (ii) we have  $\phi^* \leq \phi_{\flat}$ , we obtain by duality that  $\phi_{\sharp} = (\phi_{\flat})^* \leq \phi$ . Finally, the first part of (ii) and (4.2) yield (i).  $\square$

Let us comment that, for the sake of establishing the following approximation results, only the implication (i)  $\Rightarrow$  (ii) is exploited. We stated the above characterization in order to underline the fact that the Mosco convergence is the natural requirement for passing to the  $\liminf$  in the sum of functionals and their respective duals (which is precisely our situation).

**4.2. A general  $\Gamma$ -lim inf result.** We shall now discuss a technical tool which will be at the basis of the forthcoming analysis. In particular, we present here a  $\Gamma$ -lim inf result in the frame of Young measures for weak topologies. The reader is referred to Castaing, Raynaud de Fitte, and Valadier [20] for a comprehensive discussion of Young measures on separable Banach spaces.

Recall that, by letting  $X$  be a separable metric space, a  $\mathcal{L} \otimes \mathcal{B}(X)$ -measurable function  $g : (0, T) \times X \rightarrow (-\infty, \infty]$  is said to be a *normal integrand* if

$$u \mapsto g(t, u) \text{ is lower semicontinuous for a.e. } t \in (0, T).$$

We denote by  $\mathcal{M}(0, T; X)$  the set of all  $\mathcal{L}$ -measurable functions  $w : (0, T) \rightarrow X$ . Following [11], a sequence  $w_n \in \mathcal{M}(0, T; X)$  is said to be *tight* if there exists a nonnegative normal integrand  $g$  such that

$$(4.3) \quad \{w \in X : g(t, w) \leq c\} \text{ is compact for a.e. } t \in (0, T) \text{ and all } c \geq 0,$$

$$(4.4) \quad \text{and } \sup_n \int_0^T g(t, w_n(t)) dt < \infty.$$

In case  $X$  is a Banach space, a  $\mathcal{L} \otimes \mathcal{B}(X)$ -measurable function  $h : (0, T) \times X \rightarrow (-\infty, \infty]$  is called a *weakly normal integrand* if

$$(4.5) \quad u \mapsto h(t, u) \text{ is weakly lower semicontinuous for a.e. } t \in (0, T),$$

and a sequence  $u_n \in \mathcal{M}(0, T; X)$  is said to be *weakly tight* if there exists a nonnegative weakly normal integrand  $h$  such that

$$(4.6) \quad \lim_{|u| \rightarrow \infty} h(t, u) = \infty \text{ for a.e. } t \in (0, T),$$

$$(4.7) \quad \text{and } \sup_n \int_0^T h(t, u_n(t)) dt < \infty.$$

We prepare a result which will turn out to be useful in the proof of Theorem 4.3.

LEMMA 4.2 (weak tightness implies tightness of the norms). *Let  $H$  be a separable and reflexive Banach space and  $u_n$  be weakly tight. Then  $|u_n|$  is tight in  $\mathbb{R}$ .*

*Proof.* Let  $h : (0, T) \times H \rightarrow [0, \infty]$  be a weakly normal integrand fulfilling (4.6)–(4.7), and define  $\tilde{h} : (0, T) \times [0, \infty] \rightarrow [0, \infty]$  as

$$(4.8) \quad \tilde{h}(t, r) := \inf_{|w| \geq r} h(t, w).$$

We shall prove that  $\tilde{h}$  is a normal integrand and that

$$(4.9) \quad \{r \geq 0 : \tilde{h}(t, r) \leq c\} \text{ is compact for a.e. } t \in (0, T) \text{ and all } c \geq 0,$$

$$(4.10) \quad \text{and} \quad \sup_n \int_0^T \tilde{h}(t, |u_n(t)|) dt < \infty.$$

Ad measurability: One directly checks that, given  $\alpha > 0$ , the set  $M = \{(t, u) \in (0, T) \times H : h(t, u) < \alpha\}$  belongs to  $\mathcal{L} \otimes \mathcal{B}(H)$  and hence  $N = \{(t, |u|) : (t, u) \in M\} \in \mathcal{L} \otimes \mathcal{B}([0, \infty))$ . Note that, for all Borel sets  $A \in \mathcal{L} \otimes \mathcal{B}([0, \infty))$ , the set  $\cup_{(t, \rho) \in A} \{t\} \times [0, \rho]$  belongs to  $\mathcal{L} \otimes \mathcal{B}([0, \infty))$  as well. Now we have

$$\tilde{h}^{-1}((-\infty, \alpha)) = \{(t, r) : \exists (t, u) \in M \text{ such that } |u| \geq r\} = \bigcup_{(t, \rho) \in N} \{t\} \times [0, \rho].$$

In particular  $\tilde{h}^{-1}((-\infty, \alpha)) \in \mathcal{L} \otimes \mathcal{B}([0, \infty))$ , and  $\tilde{h}$  is  $\mathcal{L} \otimes \mathcal{B}([0, \infty))$ -measurable.

Ad lower semicontinuity: We start by noting that  $r \mapsto \tilde{h}(t, r)$  is nondecreasing for all  $t \in (0, T)$ . Assume by contradiction that there exists  $t \in (0, T)$  such that  $u \mapsto h(t, u)$  is lower semicontinuous while  $r \mapsto \tilde{h}(t, r)$  is not, namely, that there exist an increasing sequence  $0 \leq r_n \rightarrow r$  and  $\delta > 0$  such that, for all  $n \in \mathbb{N}$ ,

$$(4.11) \quad \tilde{h}(t, r_n) + 2\delta \leq \tilde{h}(t, r).$$

Let now  $w_n \in H$  be such that  $|w_n| \geq r_n$  and  $\tilde{h}(t, r_n) + \delta \geq h(t, w_n)$  (such  $w_n$  exist by (4.8)). Then surely  $|w_n| \leq r$  as, if this was not the case, one would have

$$h(t, w_n) \stackrel{(4.8)}{\geq} \tilde{h}(t, r) \stackrel{(4.11)}{\geq} \tilde{h}(t, r_n) + 2\delta \geq h(t, w_n) + \delta.$$

Hence, we can extract a not relabeled subsequence  $w_n$  weakly converging to some  $w$  in  $H$  and compute

$$h(t, w) \stackrel{(4.5)}{\leq} \liminf_{n \rightarrow \infty} h(t, w_n) \leq \lim_{n \rightarrow \infty} \tilde{h}(t, r_n) + \delta \stackrel{(4.11)}{\leq} \tilde{h}(t, r) - 2\delta + \delta < \tilde{h}(t, r),$$

contradicting the very definition (4.8). Namely,  $r \mapsto \tilde{h}(t, r)$  is lower semicontinuous for almost every  $t \in (0, T)$ .

As a consequence, the sets  $\{(t, r) : \tilde{h}(t, r) \leq c\}$  are closed intervals for almost every  $t \in (0, T)$ . Moreover, they are also bounded for almost every  $t \in (0, T)$  due to (4.7), and we have proved (4.9). Finally, one easily checks that

$$\sup_n \int_0^T \tilde{h}(t, |u_n(t)|) dt \leq \sup_n \int_0^T h(t, u(t)) dt \stackrel{(4.7)}{<} \infty,$$

and (4.10) follows.  $\square$

A parametrized measure on  $X$  is a collection  $\nu = \{\nu_t\}_{t \in (0,T)}$  of Borel probability measures on  $X$  such that

$$t \mapsto \nu_t(B) \quad \text{is } \mathcal{L}\text{-measurable} \quad \forall B \in \mathcal{B}(X),$$

and the set of all parametrized measures is denoted by  $\mathcal{Y}(0, T; X)$ .

**THEOREM 4.3** ( $\Gamma$ -liminf tool). *Let  $H$  be a separable and reflexive Banach space and  $g_n, g_\infty : (0, T) \times H \rightarrow (-\infty, \infty]$  be weakly normal integrands such that*

$$(4.12) \quad g_\infty(t, u) \leq \inf \left\{ \liminf_{n \rightarrow \infty} g_n(t, u_n) : u_n \rightarrow u \text{ weakly in } H \right\} \\ \forall u \in H \quad \text{and for a.e. } t \in (0, T).$$

*Moreover let  $u_n$  be weakly tight. Then there exists a subsequence  $k \mapsto n_k$  and a parametrized measure  $\nu \in \mathcal{Y}(0, T; H)$  such that, for a.e.  $t \in (0, T)$ ,*

$$(4.13) \quad \nu_t \text{ is concentrated on the set } \bigcap_{j=1}^{\infty} \text{cl}_w \left( \{u_{n_k}(t) : k \geq j\} \right),$$

*where  $\text{cl}_w$  denotes the weak closure in  $H$ , and, whenever  $t \mapsto g_{n_k}^-(t, u_{n_k}(t)) = \max \{-g_{n_k}(t, u_{n_k}(t)), 0\}$  are uniformly integrable, namely,*

$$\lim_{|A| \rightarrow 0} \sup_{k \in \mathbb{N}} \int_A g_{n_k}^-(t, u_{n_k}(t)) \, dt = 0$$

*(the limit being restricted to Lebesgue measurable sets  $A \subset (0, T)$ ;  $|A|$  denotes the Lebesgue measure), we have*

$$\int_0^T \left( \int_H g_\infty(t, \xi) \, d\nu_t(\xi) \right) dt \leq \liminf_{k \rightarrow \infty} \int_0^T g_{n_k}(t, u_{n_k}(t)) \, dt.$$

*Proof.* The statement follows directly from the fundamental theorem by Balder [11, Thm. 1] adapted to weak topologies along the same lines of Rossi and Savaré [89, Thm. 3.2] (see also [64, Thm. B.1]). The idea is to rephrase the dependence of the functionals from  $n \in N := \mathbb{N} \cup \{\infty\}$  as an extra variable. As we shall see below, condition (4.12) ensures that the augmented integrand is still normal. The only difficulty arises from the fact that the weak topology of  $H$  is not globally metrizable (apart from finite-dimensional cases). By following closely the proof of [89, Thm. 3.2], we will circumvent this fact by considering the set

$$V := \{(u, r, n) \in H \times \mathbb{R} \times N : |u| \leq r\} \subset H \times \mathbb{R} \times N$$

and endowing it with the metric

$$d(v_1, v_2) := |||u_1 - u_2|||^2 + |r_1 - r_2| + |\arctan(n_1) - \arctan(n_2)| \\ \forall v_i = (u_i, r_i, n_i) \in V, \quad i = 1, 2.$$

In the latter, we have used the convention  $\arctan(\infty) = \pi/2$ , and, given a countable dense subset  $w_n$  of the unit ball in  $H^*$ , we have (classically) defined

$$|||u|||^2 := \sum_{k=0}^{\infty} 2^{-k} |(w_k, u)|^2 \quad \forall u \in H.$$

Hence,  $(V, d)$  is a separable and complete metric space since

$$\begin{aligned} v_k = (u_k, r_k, n_k) \rightarrow v = (u, r, n) \quad \text{in } V \quad \text{iff} \\ u_k \rightarrow u \text{ weakly in } H, \quad r_k \rightarrow r \text{ in } \mathbb{R}, \quad \text{and } n_k \rightarrow n \text{ in } N \end{aligned}$$

(where  $N$  is endowed with the arctan metric). Let us remark that any bounded closed set in  $(V, d)$  is compact with respect to the latter topology. Hence, all intersections of closed balls of  $H \times \mathbb{R} \times N$  with  $V$  are Borel subsets of  $V$ , namely,

$$(4.14) \quad B \in \mathcal{B}(H \times \mathbb{R} \times N) \quad \Rightarrow \quad B \cap V \in \mathcal{B}(V),$$

and any Borel measure on  $V$  can be trivially extended to a Borel measure on  $H \times \mathbb{R} \times N$ .

We apply Balder's theorem [11, Thm. 1] to the family  $v_n = (u_n, |u_n|, n)$  which turns out to be tight by Lemma 4.2 as  $N$  is compact. Hence, we find a subsequence  $k \mapsto n_k$  and a parametrized measure  $\mu = \{\mu_t\}_{t \in (0, T)} \in \mathcal{Y}(0, T; V)$  such that, for almost every  $t \in (0, T)$ ,

$$\mu_t \text{ is concentrated on the set } \Lambda(t) := \bigcap_{j=1}^{\infty} \text{cl}_V \left( \{v_{n_k}(t) : k \geq j\} \right),$$

namely, the set of  $V$ -limit points of  $v_{n_k}(t)$ .

Let now  $f : (0, T) \times V \rightarrow (-\infty, \infty]$  be defined by

$$f(t, v) := g_n(t, u) \quad \forall v = (u, r, n) \in V, \quad t \in (0, T).$$

Given any  $L \in \mathcal{L}, B \in \mathcal{B}(H)$ , and  $n \in N$ , by using (4.14) one checks that

$$(L \times B \times \mathbb{R} \times \{n\}) \cap ((0, T) \times V) \in \mathcal{L} \otimes \mathcal{B}(V).$$

Hence, we have

$$(\mathcal{L} \otimes \mathcal{B}(H) \times \mathbb{R} \times \{n\}) \cap ((0, T) \times V) \subset \mathcal{L} \otimes \mathcal{B}(V).$$

On the other hand, for all  $a \in \mathbb{R}$ ,

$$\begin{aligned} & \{(t, v) : f(t, v) \leq a\} \\ &= \bigcup_{n=1}^{\infty} \left( (\{(t, u) : g_n(t, u) \leq a\} \times \mathbb{R} \times \{n\}) \cap ((0, T) \times V) \right) \in \mathcal{L} \otimes \mathcal{B}(V), \end{aligned}$$

since all elements under the union sign are in  $\mathcal{L} \otimes \mathcal{B}(V)$ . Hence, the function  $f$  is  $\mathcal{L} \otimes \mathcal{B}(V)$ -measurable. Moreover,  $f$  is a normal integrand. Indeed, let  $v_k \rightarrow v$  in  $V$ . Then either  $n_k = n$  definitely or  $n_k \rightarrow \infty$ . In the first case, lower semicontinuity follows from the weak sequential lower semicontinuity of  $g_n$ , whereas in the second case it can be deduced from (4.12).

Since  $t \mapsto f^-(t, v_{n_k}(t)) = g_{n_k}^-(t, u_{n_k}(t))$  are uniformly integrable, again by [11, Thm. 1] we have

$$\begin{aligned} & \int_0^T \left( \int_V f(t, \zeta) \, d\mu_t(\zeta) \right) dt \leq \liminf_{k \rightarrow \infty} \int_0^T f(t, v_{n_k}(t)) \, dt \\ (4.15) \quad &= \liminf_{k \rightarrow \infty} \int_0^T g_{n_k}(t, u_{n_k}(t)) \, dt. \end{aligned}$$

By recalling that  $\Lambda(t) \subset H \times \mathbb{R} \times \{\infty\}$  for all  $t \in (0, T)$  and letting

$$\nu_t(B) := \mu_t((B \times \mathbb{R} \times N) \cap V) \quad \forall B \in \mathcal{B}(H),$$

we obtain a parametrized measure  $\nu = \{\nu_t\}_{t \in (0, T)} \in \mathcal{Y}(0, T; H)$  which fulfills (4.13) and is such that

$$\int_0^T \left( \int_V f(t, \zeta) d\mu_t(\zeta) \right) dt = \int_0^T \left( \int_H g_\infty(t, \xi) d\nu_t(\xi) \right) dt,$$

which, together with (4.15), entails the result.  $\square$

Let us remark that, under the frame of Theorem 4.3, whenever  $u_n \rightarrow u$  weakly in  $L^p(0, T; H)$  for some  $p \in [1, \infty)$  (weakly star for  $p = \infty$ ), then

$$(4.16) \quad u(t) = \int_H \xi d\nu_t(\xi) \quad \text{for a.e. } t \in (0, T).$$

This fact was already remarked in [89, Thm. 3.2] for  $p \in (1, \infty)$  (and hence, for  $p = \infty$  as well). As for  $p = 1$ , one can readily choose the weakly normal integrands

$$g(t, u) := (w(t), u) \quad \forall u \in H, \text{ a.e. } t \in (0, T), \quad \text{with } w \in L^\infty(0, T; H^*),$$

and exploit Theorem 4.3 with the constant sequence  $g_n = g$  (or [64, Thm. B.1]) in order to conclude.

**4.3. The  $\Gamma$ -lim inf result for normal convex integrands.** Let us now specify the result of Theorem 4.3 in the case of normal convex integrands  $g_n, g_\infty : [0, T] \times H \rightarrow (-\infty, \infty]$ .

**COROLLARY 4.4.** *Let  $p \in [1, \infty]$ ,  $H$  be a separable and reflexive Banach space, and  $g_n, g_\infty : (0, T) \times H \rightarrow (-\infty, \infty]$  be normal convex integrands such that (4.12) holds. Moreover, let  $u_n \rightarrow u$  weakly in  $L^p(0, T; H)$  (weakly star if  $p = \infty$ ). Then, whenever  $t \mapsto g_n^-(t, u_n(t))$  are uniformly integrable, we have*

$$(4.17) \quad \int_0^T g_\infty(t, u(t)) dt \leq \liminf_{n \rightarrow \infty} \int_0^T g_n(t, u_n(t)) dt.$$

*Proof.* Let  $j \mapsto n_j \in \mathbb{N}$  be an increasing sequence. As  $u_n$  are uniformly bounded in  $L^p(0, T; H)$ , the family  $u_{n_j}$  is weakly tight. Hence, by applying Theorem 4.3, we may extract a further subsequence  $k \mapsto n_{j_k}$  such that

$$(4.18) \quad \begin{aligned} \liminf_{k \rightarrow \infty} \int_0^T g_{n_{j_k}}(t, u_{n_{j_k}}(t)) dt &\geq \int_0^T \left( \int_H g_\infty(t, \xi) d\nu_t(\xi) \right) dt \\ &\geq \int_0^T g_\infty(t, u(t)) dt, \end{aligned}$$

where the last inequality follows from (4.16) and Jensen's inequality. Namely, for all subsequences of  $u_n$  there exist further subsequences such that (4.18) holds. An easy argument ensures that indeed (4.18) holds for the whole sequence  $g_n(\cdot, u_n(\cdot))$  as well.  $\square$

Let us now comment on the uniform integrability condition of Corollary 4.4. First of all, it is clear that the latter holds if  $g_n$  are uniformly bounded below. More generally, one can consider the case

$$(4.19) \quad \begin{aligned} g_n(t, u) &\geq -c_0|u| - \gamma(t) \quad \text{for some } c_0 > 0, \gamma \in L^1(0, T), \\ &\forall u \in H, n \in \mathbb{N}, \text{ for a.e. } t \in (0, T). \end{aligned}$$

In fact, whenever  $u_n$  converges weakly in  $L^p(0, T; H)$  (weakly star in  $p = \infty$ ), the functions  $t \mapsto |u_n(t)|$  are uniformly integrable [28, Thm. 4, p. 104], and (4.19) entails the uniform integrability of  $t \mapsto g_n^-(t, u_n(t))$ .

We shall explicitly remark that, in case  $g_n$  are independent of time, the lower bound (4.19) follows directly from the condition (4.12). Indeed, owing to [7, Thm. 3.7, p. 271], by letting  $v \in D(g_\infty^*)$  be fixed, there exist  $v_n$  such that  $v_n \rightarrow v$  strongly in  $H^*$  and  $\limsup_{n \rightarrow \infty} g_n^*(v_n) = g_\infty^*(v)$ . Then (4.19) follows with the choice

$$c_0 = \sup_n |v_n|_*, \quad \gamma(t) = g_\infty^*(v) + 1.$$

In particular, we have the following.

**COROLLARY 4.5** ( $g_n$  independent of time). *Let  $p \in [1, \infty]$ ,  $H$  be a separable and reflexive Banach space, and  $g_n, g_\infty : H \rightarrow (-\infty, \infty]$  be convex, proper, and lower semicontinuous such that (4.12) holds. Moreover, let  $u_n \rightarrow u$  weakly in  $L^p(0, T; H)$  (weakly star if  $p = \infty$ ). Then we have*

$$(4.20) \quad \int_0^T g_\infty(u(t)) \, dt \leq \liminf_{n \rightarrow \infty} \int_0^T g_n(u_n(t)) \, dt.$$

Before moving on, we remark that some result in the direction of Corollary 4.4 was already contained in the convergence analysis by Salvadori [92, Thm. 3.1]. The latter was focused on establishing conditions under which the integral functionals

$$G_n(u) = \begin{cases} \int_0^T g_n(t, u(t)) \, dt & \text{if } t \mapsto g_n^+(t, u(t)) \in L^1(0, T), \\ \infty & \text{otherwise} \end{cases}$$

would Mosco-converge to the limit functional

$$G_\infty(u) = \begin{cases} \int_0^T g_\infty(t, u(t)) \, dt & \text{if } t \mapsto g_\infty^+(t, u(t)) \in L^1(0, T), \\ \infty & \text{otherwise} \end{cases}$$

(and analogously for  $G_n^*$  and  $G_\infty^*$ , which are defined from  $g_n^*$  and  $g_\infty^*$ , respectively). The Mosco-convergence result in [92, Thm. 3.2] was obtained under some uniform quantitative properness of the functionals. In particular, both sequences  $G_n$  and  $G_n^*$  are asked to be uniformly proper on  $L^p(0, T; H)$  and  $L^q(0, T; H^*)$ , respectively. Moreover, by letting  $u_n$  and  $v_n$  be the corresponding bounded sequences, the existence of two functions  $f, f_* \in L^1(0, T)$  such that

$$|g_n(t, u_n(t))| \leq f(t) \quad \text{and} \quad |g_n^*(t, v_n(t))| \leq f_*(t) \quad \text{for a.e. } t \in (0, T)$$

is required.

The frame of Corollary 4.4 is quite weaker, since we are not assuming any control on the domains of the functionals but rather some standard uniform integrability of negative parts of the integrands. Hence, by exploiting the characterization of Lemma 4.1 and restricting to the case where  $p \in (1, \infty)$ , we can obtain a refined version of [92, Thm. 3.1] as follows.

**COROLLARY 4.6.** *Let  $p \in (1, \infty)$ ,  $H$  be a separable and reflexive Banach space, and  $g_n, g_\infty : (0, T) \times H \rightarrow (-\infty, \infty]$  be normal convex integrands such that  $g_n \rightarrow g_\infty$*

in the Mosco sense. Moreover, assume that

$$(4.21) \quad \begin{aligned} & t \rightarrow g_n^-(t, u_n(t)) \quad \text{and} \quad t \rightarrow (g_n^*)^-(t, v_n(t)) \quad \text{are uniformly integrable} \\ & \forall (u_n, v_n) \rightarrow (u, v) \text{ weakly in } L^p(0, T; H) \times L^q(0, T; H^*), \\ & G_n \quad \text{and} \quad G_n^* \quad \text{are proper on } L^p(0, T; H) \quad \text{and} \quad L^q(0, T; H^*), \text{ respectively,} \\ (4.22) \quad & \text{and either } G_n \text{ or } G_n^* \text{ is uniformly proper.} \end{aligned}$$

Then  $G_n \rightarrow G_\infty$  in the Mosco sense in  $L^p(0, T; H)$  and  $G_n^* \rightarrow G_\infty^*$  in the Mosco sense in  $L^q(0, T; H^*)$ . In particular, both sequences  $G_n$  and  $G_n^*$  are uniformly proper.

*Proof.* Owing to (4.21), Corollary 4.4 gives the  $\Gamma$ -liminf inequalities for  $G_n$  and  $G_n^*$ . Owing to the properness of  $G_n$  and  $G_n^*$ , we have that  $(G_n)^* = G_n^*$  and  $(G_n^*)^* = G_n$  [21, Thm. VII.7, p. 200]. Since  $L^p(0, T; H)$  is reflexive, the assertion follows from the uniform properness in (4.22) and Lemma 4.1.  $\square$

In the same spirit of Corollary 4.5, whenever  $g_n$  are independent of time, both the uniform integrability condition (4.21) and the uniform properness condition (4.22) are straightforward.

**5. Lim inf inequalities.** We shall now apply this functional convergence machinery to our problems. Throughout the remainder of the paper, we will assume that

$$(A6) \quad \begin{aligned} & p \in [1, \infty], \quad 1/p + 1/q = 1, \text{ and} \\ & H \text{ is a real, separable, and reflexive Banach space.} \end{aligned}$$

As for the sequences of approximating functionals we will systematically ask that

$$(5.1) \quad \begin{aligned} & t \rightarrow g_n^-(t, u_n(t)) \quad \text{and} \quad t \rightarrow (g_n^*)^-(t, v_n(t)) \quad \text{are uniformly integrable} \\ & \forall (u_n, v_n) \rightarrow (u, v) \text{ weakly (star) in } L^p(0, T; H) \times L^q(0, T; H^*) \end{aligned}$$

for the choices  $g_n = \phi_n, \psi_n, \varphi_n$  and admit the limiting cases  $p = 1, \infty$  as well.

Let us start from the case of the gradient flow (1.1). Assume that we are given data  $\phi_n$ ,  $f_n$ , and  $u_0^n$  as in section 1, and define the corresponding approximating functionals  $J_n, K_n : H^1(0, T; H) \rightarrow [0, \infty]$  for all  $u \in H^1(0, T; H)$  as

$$\begin{aligned} J_n(u) &:= \int_0^T (\phi_n(u) + \phi_n^*(f_n - u')) - (f_n, u) \\ &\quad + \frac{1}{2}|u(T)|^2 - \frac{1}{2}|u(0)|^2 + |u(0) - u_0^n|^2, \\ K_n(u) &:= \left( \int_0^T (|u'|^2 - (f_n, u')) + \phi_n(u(T)) - \phi_n(u_0^n) \right)^+ + J_n(u). \end{aligned}$$

We have the following.

**LEMMA 5.1** (lim inf inequality for  $K_n$ ). *Assume (A6), and let  $H$  be a Hilbert space,  $\phi_n \rightarrow \phi$  in the Mosco sense,  $f_n \rightarrow f$  strongly in  $L^2(0, T; H)$ ,  $u_0^n \rightarrow u^0$  in  $H$ , and  $\phi_n(u_0^n) \rightarrow \phi(u^0)$ . Then, for all  $u \in H^1(0, T; H)$ ,*

$$K(u) \leq \inf_{n \rightarrow \infty} \{ \liminf K_n(u_n) : u_n \rightarrow u \text{ weakly in } H^1(0, T; H) \}.$$

*Proof.* By applying Corollary 4.5 we readily check that

$$\int_0^T (\phi(u) + \phi^*(f - u')) \leq \liminf_{n \rightarrow \infty} \int_0^T (\phi_n(u_n) + \phi_n^*(f_n - u'_n)).$$

On the other hand, owing to the strong convergence of  $f_n$  we have

$$\int_0^T (f_n, u_n) \rightarrow \int_0^T (f, u) \quad \text{and} \quad \int_0^T (f_n, u'_n) \rightarrow \int_0^T (f, u'),$$

and, by the pointwise weak convergences  $u_n(T) \rightarrow u(T)$  and  $u_n(0) \rightarrow u(0)$  in  $H$  and the Mosco convergence of  $\phi_n$ , one obtains

$$\begin{aligned} \phi(u(T)) &\leq \liminf_{n \rightarrow \infty} \phi_n(u_n(T)) \quad \text{and} \\ \frac{1}{2}|u(T)|^2 - \frac{1}{2}|u(0)|^2 + |u(0) - u^0|^2 &= \frac{1}{2}|u(T)|^2 + \frac{1}{2}|u(0)|^2 + |u^0|^2 - 2(u(0), u^0) \\ &\leq \liminf_{n \rightarrow \infty} \left( \frac{1}{2}|u_n(T)|^2 + \frac{1}{2}|u_n(0)|^2 + |u_n^0|^2 - 2(u_n(0), u_n^0) \right) \\ &= \liminf_{n \rightarrow \infty} \left( \frac{1}{2}|u_n(T)|^2 - \frac{1}{2}|u_n(0)|^2 + |u_n(0) - u_n^0|^2 \right). \end{aligned}$$

Finally, the assertion follows by lower semicontinuity.  $\square$

In fact, an analogous result holds for  $J_n$  as well, the convergence of the initial energies  $\phi_n(u_n^0)$  not being needed. We prefer to state the  $\liminf$  inequality for  $K_n$  since, as already remarked, the sublevels of  $K_n$  are uniformly bounded in  $H^1(0, T; H)$  whereas those of  $J_n$  are not, in general.

Let us now move to the doubly nonlinear situation by fixing  $p \in [1, \infty]$  and recalling that  $1/p + 1/q = 1$ . Assume that we are given  $\phi_n, \psi_n, f_n$ , and  $u_n^0$  as in section 2, and define the corresponding approximating functionals  $I_n : W^{1,p}(0, T; H) \times L^q(0, T; H^*) \rightarrow [0, \infty]$  for all  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  as

$$\begin{aligned} I_n(u, v) &:= \left( \int_0^T (\psi_n(u') + \psi_n^*(v) - (f_n, u')) + \phi_n(u(T)) - \phi_n(u_n^0) \right)^+ \\ &\quad + \int_0^T (\phi_n(u) + \phi_n^*(f_n - v) - (f_n - v, u)) + |u(0) - u_n^0|^2. \end{aligned}$$

Hence, by recalling (4.1), we have the following lemma.

**LEMMA 5.2** ( $\liminf$  inequality for  $I_n$ ). *Assume (A6), and let  $\phi_n \rightarrow \phi$  and  $\psi_n \rightarrow \psi$  in the Mosco sense and fulfill (5.1),  $f_n \rightarrow f$  strongly in  $L^q(0, T; H^*)$ ,  $u_n^0 \rightarrow u^0$  in  $H$ , and  $\phi_n(u_n^0) \rightarrow \phi(u^0)$ . Then, for all  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$ ,*

$$I(u, v) \leq \inf \left\{ \liminf_{n \rightarrow \infty} I_n(u_n, v_n) : (u_n, v_n) \rightarrow (u, v) \text{ in } \mathcal{T}(p) \right\}.$$

*Proof.* The proof of the latter lemma follows along the very same lines as that of Lemma 5.1 by systematically considering the  $p - q$  frame and additionally applying once again Corollary 4.5 in order to deduce that

$$\int_0^T (\psi(u) + \psi^*(v)) \leq \liminf_{n \rightarrow \infty} \int_0^T (\psi_n(u_n) + \psi_n^*(v_n)). \quad \square$$

We shall explicitly mention that, in the separable Hilbert-space setting and in the (quadratic) case of (2.3), namely, for  $\phi(\cdot) = |\cdot|^2/2$ , the above  $\liminf$  inequality holds also in some stronger form. By introducing the approximating functionals  $Q_n :$

$W^{1,p}(0, T; H) \rightarrow [0, \infty]$  as

$$Q_n(u) := \int_0^T (\psi_n(u') + \psi_n^*(f_n - u) - (f_n, u')) \\ + \frac{1}{2}|u(T)|^2 - \frac{1}{2}|u(0)|^2 + |u(0) - u_n^0|^2,$$

we have the following.

LEMMA 5.3 (lim inf inequality for  $Q_n$ ). *Assume that  $H$  is a separable Hilbert space,  $\psi_n \rightarrow \psi$  in the Mosco sense and fulfill (5.1),  $f_n \rightarrow f$  strongly in  $L^q(0, T; H)$ , and  $u_n^0 \rightarrow u^0$  in  $H$ . Then, for all  $u \in W^{1,p}(0, T; H)$ ,*

$$(5.2) \quad Q(u) \leq \inf \left\{ \liminf_{n \rightarrow \infty} Q_n(u_n) : u_n \rightarrow u \text{ weakly (star) in } W^{1,p}(0, T; H) \right\}.$$

The assertion follows via the same arguments of the proofs above, this case being indeed simplified since  $\phi$  is quadratic.

Finally, we consider the generalized situation of (3.1) by letting  $\psi_n, \varphi_n, \pi_n$ , and  $u_n^0$  be as in section 3 and defining the functionals  $\mathcal{I}_n : W^{1,p}(0, T; H) \times L^q(0, T; H^*) \rightarrow [0, \infty]$  for all  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  as

$$\mathcal{I}_n(u, v) := \left( \int_0^T (\psi_n(u') + \psi_n^*(v) - \pi_n(u)) + \varphi_n(T, u(T)) - \varphi_n(0, u_n^0) \right)^+ \\ + \int_0^T (\varphi_n(\cdot, u) + \varphi_n^*(\cdot, -v) + (u, v)) + |u(0) - u_n^0|^2.$$

In order to establish a lim inf inequality result for  $\mathcal{I}_n$ , the limiting behavior of  $\pi_n$  has to be prescribed. We shall directly ask that, for all  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$ ,

$$(5.3) \quad \int_0^T \pi(u) \geq \sup \left\{ \limsup_{n \rightarrow \infty} \int_0^T \pi_n(u_n) : (u_n, v) \rightarrow (u, v) \text{ in } \mathcal{T}(p) \right\}.$$

The latter is readily fulfilled if  $\varphi_n(t, u) = \phi_n(u) - (f_n(t), u)$ ,  $\varphi(t, u) = \phi(u) - (f(t), u)$ , and  $f_n \rightarrow f$  strongly in  $W^{1,p}(0, T; H^*)$ ; see Remark 3.2. We have the following.

LEMMA 5.4 (lim inf inequality for  $\mathcal{I}_n$ ). *Assume (A6), and let  $\varphi_n \rightarrow \varphi$  and  $\psi_n \rightarrow \psi$  in the Mosco sense and fulfill (5.1) and (5.3),  $u_n^0 \rightarrow u^0$  in  $H$ , and  $\varphi_n(0, u_n^0) \rightarrow \varphi(0, u^0)$ . Then, for all  $(u, v) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$ ,*

$$\mathcal{I}(u, v) \leq \inf \left\{ \liminf_{n \rightarrow \infty} \mathcal{I}_n(u_n, v_n) : (u_n, v_n) \rightarrow (u, v) \text{ in } \mathcal{T}(p) \right\}.$$

*Sketch of the proof.* This proof differs from that of Lemma 5.2 for the sole use of (5.3) instead of the strong convergence of  $f_n$ .  $\square$

Before closing this section, let us explicitly consider the case of the nonautonomous gradient flow (3.7). To this aim, let the approximating functionals  $\mathcal{K}_n : H^1(0, T; H) \rightarrow [0, \infty]$  be defined as

$$\mathcal{K}_n(u) := \left( \int_0^T (|u'|^2 - \pi_n(u)) + \varphi_n(T, u(T)) - \varphi_n(0, u_n^0) \right)^+ \\ + \int_0^T (\varphi_n(\cdot, u) + \varphi_n^*(\cdot, -u')) + \frac{1}{2}|u(T)|^2 - \frac{1}{2}|u(0)|^2 + |u(0) - u_n^0|^2.$$

In order to possibly obtain some stronger convergence result in this case, we shall need some additional convergence property for  $\pi_n$ . Namely, we ask, for all  $u \in H^1(0, T; H)$ , that

$$(5.4) \quad \int_0^T \pi(u) \geq \sup \left\{ \limsup_{n \rightarrow \infty} \int_0^T \pi_n(u_n) : u_n \rightarrow u \text{ weakly in } H^1(0, T; H) \right\}.$$

Again, in the case where  $\varphi_n(t, u) = \phi_n(u) - (f_n(t), u)$ ,  $\varphi(t, u) = \phi(u) - (f(t), u)$ , the latter is fulfilled if  $f_n \rightarrow f$  strongly in  $H^1(0, T; H^*)$ . Hence, we have the following.

LEMMA 5.5 (lim inf inequality for  $\mathcal{K}_n$ ). *Assume (A6), and let  $\varphi_n \rightarrow \varphi$  in the Mosco sense and fulfill (5.1) and (5.4),  $u_n^0 \rightarrow u^0$  in  $H$ , and  $\varphi_n(0, u_n^0) \rightarrow \varphi(0, u^0)$ . Then, for all  $u \in H^1(0, T; H)$ ,*

$$\mathcal{K}(u) \leq \inf \left\{ \liminf_{n \rightarrow \infty} \mathcal{K}_n(u_n) : u_n \rightarrow u \text{ weakly in } H^1(0, T; H) \right\}.$$

The proof of the latter is obtained by easily adapting the arguments of Lemmas 5.1 and 5.4. Let us stress that, in case the weaker convergence (5.3) holds, a lim inf inequality for  $\mathcal{K}_n$  is still available as a corollary to Lemma 5.4.

**6. Approximation of gradient flows.** We shall exploit Theorems 2.1 and 3.1 and Lemmas 5.1 and 5.5 in order to recover and further generalize some approximation results for gradient flows under the separability assumption in (A6). By assuming the above notations and recalling the uniform coercivity of  $K_n$  with respect to the weak topology in  $H^1(0, T; H)$ , we obtain a first convergence result which we state below by omitting the easy proof.

LEMMA 6.1 (convergence for gradient flows). *Under the assumptions of Lemma 5.1, let  $u_n \in H^1(0, T; H)$  be such that  $K_n(u_n) \rightarrow 0$ . Then  $u_n \rightarrow u$  weakly in  $H^1(0, T; H)$  and  $K(u) = 0$ .*

Note in particular that the whole approximating sequence  $u_n$  converges since  $K$  admits a unique minimizer  $u$ .

By reducing ourselves to the case  $K_n(u_n) = 0$  (i.e., letting  $u_n$  be solutions to the respective differential problems), the above lemma recovers the result by Attouch on the approximation of gradient flows under the Mosco convergence of the functionals [7, Thm. 3.74(2), p. 388] under the separability assumption in (A6) (here no strong  $H^1(0, T; H)$  nor energy convergence is proved, though). Let us, however, remark that our result turns out to be slightly more general than the former since  $u_n$  are a priori not required to be solutions at level  $n$ . In particular, the functions  $u_n$  could be approximated solutions of the corresponding gradient flows as well. Moreover, the functional frame is here extended from (separable) Hilbert to separable reflexive Banach spaces. One has, however, to mention that the specific case of regularization by means of the Yosida approximation (in Hilbert spaces) was already discussed within the existence proof by Ghoussoub and Tzou [39]. In case the convergence of the initial energies  $\phi_n(u_n^0)$  does not hold, one is still in the position of proving a convergence result by arguing on  $J_n$  if  $J_n(u_n) = 0$  (or, more generally, in case of a weakly  $H^1(0, T; H)$ -precompact sequence  $u_n$  such that  $J_n(u_n) \rightarrow 0$ ).

Our second convergence result concerns the generalized situation of (3.7). Again, the following lemma is implied by the fact that, by assuming  $\pi_n$  to be uniformly linearly bounded,  $\mathcal{K}_n$  are uniformly coercive with respect to the weak topology of  $H^1(0, T; H)$ .

LEMMA 6.2 (convergence for generalized gradient flows). *Under the assumptions of Lemma 5.5, let  $\pi_n$  be uniformly linearly bounded and  $u_n \in H^1(0, T; H)$  be such that  $\mathcal{K}_n(u_n) \rightarrow 0$ . Then  $u_n \rightarrow u$  weakly in  $H^1(0, T; H)$  and  $\mathcal{K}(u) = 0$ .*

The latter convergence result for the nonautonomous gradient flow (3.7) is to be compared with the former results by Ortner [79, sect. 3.2] which hold in the general metric and  $\lambda$ -geodesically convex setting but under more restrictive functional convergence assumptions (see also [80]). We shall, however, stress that here the approximating  $u_n$  need not be solutions to the corresponding differential problems at level  $n$ .

Before closing this section, we shall mention the work by Mabrouk [52, 53] where the Brezis–Ekeland principle is exploited within an approximation procedure in order to establish the existence of generalized solutions to some semilinear parabolic equation with measure data (see also the results by the same author [54, 55] for some second order in time equations). Moreover, we mention that some identification result for nonlinear parabolic problems based on (a variational technique related to) the Brezis–Ekeland principle has been obtained by Barbu and Kunisch [14]. Finally, the issue of approximating nonconvex gradient flows has recently attracted some attention (see Ambrosio, Gigli, and Savaré [2] and Sandier and Serfaty [93]).

**7. Approximation of doubly nonlinear equations.** Let us now move to the situation of the doubly nonlinear relation (1.3) and fix from the very beginning and throughout this section

$$p \in (1, \infty).$$

For Lemma 5.2 to serve as the basis for a convergence result, one just needs to provide coercivity for  $I_n$  with respect to the topology  $\mathcal{T}(p)$  (see (4.1)). The latter holds, for instance, in the situation of potentials  $\psi_n$  of  $p$ -growth and functionals  $\phi_n$  with compact sublevels. In particular, we let

$$(7.1) \quad c_1|w|^p - c_2 \leq \psi(w) \leq c_3(|w|^p + 1) \quad \forall w \in H,$$

$$(7.2) \quad \phi(w) \geq c_4\|w\|^p - c_5 \quad \forall w \in V \subset H,$$

where the injection of the reflexive Banach space  $V$  into  $H$  is compact,  $\|\cdot\|$  is the norm in  $V$ , and  $c_1, c_3, c_4 > 0$ ,  $c_2, c_5 \geq 0$  are given. In this case, it may be checked that  $c_6|w|_*^q - c_7 \leq \psi^*(w)$  for all  $w \in H^*$  and with some constants  $c_6, c_7 > 0$  depending on  $c_3$  and  $p$  ( $|\cdot|_*$  is the norm in  $H^*$ ). Hence, all sublevels of  $I$  are relatively compact with respect to the topology  $\mathcal{T}(p)$  by means of well-known compactness results (see, e.g., Simon [96]). Namely, we have the following.

**LEMMA 7.1** (convergence for doubly nonlinear equations). *Under the assumptions of Lemma 5.2, let  $\phi_n$  and  $\psi_n$  fulfill (7.1)–(7.2) uniformly with respect to  $n$ . Moreover, let  $(u_n, v_n) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  be such that  $I_n(u_n, v_n) \rightarrow 0$ . Then there exists a (not relabeled) subsequence such that  $(u_n, v_n) \rightarrow (u, v)$  in  $\mathcal{T}(p)$  and  $I(u, v) = 0$ .*

Here the convergence of the whole sequence  $(u_n, v_n)$  cannot be expected since the limiting minimum problem for  $I$  need not admit a unique minimizer.

By restricting to the case of a sequence  $(u_n, v_n)$  of solutions to the approximating doubly nonlinear problem (i.e., imposing  $I_n(u_n, v_n) = 0$ ), we recover the convergence result of Aizicovici and Yan [1, Thm. 3.1] under the extra separability assumption in (A6). The referred result is in fact slightly stronger, since the subdifferentials  $\partial\psi_n$  are replaced by general maximal monotone operators  $A_n$  and the growth and compactness requirements are weaker (although quite similar). On the other hand, under assumptions (7.1)–(7.2), our result turns out to be more general than the former, since the approximating  $(u_n, v_n)$  need not be solutions to the corresponding equations. This fact allows some possible extra freedom in the choice of the approximating sequence.

Finally, we are in the position of providing a convergence lemma which applies to the generalized situation of (3.1). The following is to our knowledge the first result in this direction.

**THEOREM 7.2** (convergence for generalized doubly nonlinear equations). *Under the assumptions of Lemma 5.4, let  $\varphi_n(t, \cdot)$  and  $\psi_n$  fulfill (7.1)–(7.2) for almost every  $t \in (0, T)$  and uniformly with respect to  $n$ . Moreover, let  $(u_n, v_n) \in W^{1,p}(0, T; H) \times L^q(0, T; H^*)$  be such that  $\mathcal{I}_n(u_n, v_n) \rightarrow 0$ . Then there exists a (not relabeled) subsequence such that  $(u_n, v_n) \rightarrow (u, v)$  in  $\mathcal{T}(p)$  and  $\mathcal{I}(u, v) = 0$ .*

**LEMMA 7.3** (convergence for case  $\phi(\cdot) = \phi_n(\cdot) = |\cdot|^2/2$ ). *Under the assumptions of Lemma 5.3, for  $p \in (1, \infty]$  let  $\psi_n$  fulfill (7.1) uniformly with respect to  $n$ . Moreover, let  $u_n \in W^{1,p}(0, T; H)$  be such that  $Q_n(u_n) \rightarrow 0$ . Then there exists a (not relabeled) subsequence such that  $u_n \rightarrow u$  weakly in  $W^{1,p}(0, T; H)$  and  $Q(u) = 0$ .*

Note that, in the frame of Lemma 7.3, if  $f \in W^{1,1}(0, T; H)$ , then the solution of (2.3) is unique and the whole sequence  $u_n$  of the statement converges.

**7.1. Existence for some doubly nonlinear equation via the Brezis–Ekeland approach.** We shall now apply the above-developed convergence theory in order to possibly (re)obtain the existence of solutions of some specific doubly nonlinear equation (1.3) via the variational characterization of Theorem 3.1. For the sake of simplicity, we reduce our attention to the Hilbert-space framework of Colli and Visintin [23]. More specifically, we shall ask that

(7.3)  $H$  is a real Hilbert space and  $p = 2$ .

**LEMMA 7.4.** *Under assumptions (A2) and (A3) and (7.1)–(7.3), there exists a solution  $(u, v)$  of (1.4)–(1.6).*

Note that the latter stands as a weaker version of [23, Thm. 2.1] where indeed  $\partial\psi$  is replaced by a general maximal monotone operator and some weaker coercivity assumption on  $\phi$  is considered.

*Proof.* For all  $n \in \mathbb{N}$  let

$$\psi_n(u) = \frac{1}{2n}|u|^2 + \psi(u) \quad \text{and} \quad \phi_n(u) = \inf_{v \in H} \left( \frac{n}{2}|v - u|^2 + \phi(v) \right).$$

Namely,  $\phi_n$  is the Yosida approximation of  $\phi$  at level  $1/n$ . The corresponding regularized problem reads now as follows:

$$v \in \frac{1}{n}u' + \partial\psi(u'), \quad v + \partial\phi_n(u) = f \quad \text{a.e. in } (0, T), \quad u(0) = u^0,$$

and clearly admits a unique solution  $(u_n, v_n) \in H^1(0, T; H) \times L^2(0, T; H)$  since  $(1/n + \partial\psi)^{-1} \circ \partial\phi_n$  is Lipschitz continuous. Hence, by Theorem 2.1 we have that  $\mathcal{I}_n(u_n, v_n) = 0$ .

We now aim at applying the  $\liminf$  result of Lemma 5.2. First of all, we have  $\psi_n \rightarrow \psi$  and  $\phi_n \rightarrow \phi$  in the Mosco sense [7, Thm. 3.26, p. 305]. Second, condition (5.1) is trivially satisfied by  $\psi_n$  since we are requiring (7.1). In particular,  $\psi \leq \psi_n$  and  $\psi_n^* \geq -\psi(0)$ . Moreover, owing to the fact that  $(\phi_n)^*(u) = \phi^*(u) + |u|^2/(2n)$  (see, for instance, [42, subsect. 4.1]), we have

$$\phi_n(u) = \sup_{v \in H} \left( (v, u) - \phi^*(v) - \frac{1}{2n}|v|^2 \right) \geq (w, u) - \phi^*(w) - \frac{1}{2}|w|^2$$

for any fixed  $w \in D(\phi^*)$ . Finally, the fact that

$$(\phi_n)^*(u) \geq \phi^*(u) \geq (u, z) - \phi(z) \quad \forall u \in H,$$

for some  $z \in D(\phi)$  fixed, entails that condition (5.1) holds for  $\phi_n$  as well.

It is a standard matter to determine new constants  $c'_1, c'_2$ , and  $c'_3$  in such a way that  $\psi_n$  fulfills the corresponding nondegeneracy and growth assumption (7.1) uniformly with respect to  $n$ . In particular, we have the fact that

$$(7.4) \quad u'_n \text{ and } v_n \text{ are bounded in } L^2(0, T; H) \text{ independently of } n.$$

Since  $D(\phi_n) = H$ , the coercivity (7.2) cannot hold at level  $n$ . In fact one can check that

$$\phi_n(u) = \frac{1}{2n} |\partial \phi_n(u)|^2 + \phi(j_n u) \geq c_4 \|j_n u\|^2 - c_5 \quad \forall u \in H,$$

where  $j_n := (1 + (1/n)\partial\phi)^{-1}$  is the resolvent. By recalling that  $j_n$  is Lipschitz continuous, uniformly with respect to  $n$ , we have the fact that

$$(7.5) \quad j_n u_n \text{ is bounded in } H^1(0, T; H) \cap L^2(0, T; V) \text{ independently of } n.$$

The bounds (7.4)–(7.5) imply that  $(u_n, v_n)$  is precompact in  $\mathcal{T}(2)$ . By extracting a not relabeled subsequence  $(u_n, v_n) \rightarrow (u, v)$  in  $\mathcal{T}(2)$  and applying Lemma 5.2, we get  $I(u, v) = 0$ , and the assertion follows from Theorem 2.1.  $\square$

Let us comment that the Hilbert-space frame of (7.3) is chosen as a possible first illustration of this technique and that the Brezis–Ekeland approach applies to the more general Banach case as well. However, in the latter case, one should consider a time-discretized problem rather than a regularized one (this was exactly the strategy in [22]). The development of a discrete version of the characterization of Theorem 3.1 is presented and applied to the convergence of time discretizations for (1.3) in [101]. As a by-product, the existence of solutions to the doubly nonlinear equation (1.3) in the Banach framework is there recovered by a purely variational technique.

**8. Approximation of rate-independent evolutions.** Let us now focus on a specific class of potentials  $\psi$  of growth  $p = 1$  (see (7.1)). In particular, in addition to (A4) we shall ask that

$$(8.1) \quad \psi \text{ is positively homogeneous of degree 1,}$$

letting the evolution problem be rate-independent (see Mielke [62]). Equivalently,  $\psi$  is required to be the support function of a convex and closed set  $C \subset H^*$  containing 0, namely,

$$(8.2) \quad \psi(w) = \sup\{(v, w) : v \in C\} \quad \forall w \in H.$$

Note in particular that  $D(\psi) = H$ . In the present rate-independent situation we are allowed to weaken the assumptions on  $\psi$  in (7.1) and ask for the upper bound only. Owing to positive homogeneity, we take with no loss of generality

$$(8.3) \quad \psi(w) \leq c_3 |w| \quad \forall w \in H,$$

which in particular says that  $C$  is contained in a ball of center 0 and radius  $c_3$ . As for  $\varphi$ , besides (A4) we require

$$(8.4) \quad t \mapsto \varphi(t, u) \text{ differentiable and } t \mapsto \partial_t \varphi(t, u) \text{ measurable } \forall u \in H.$$

Moreover, we ask for a nonnegative function  $\lambda \in L^1(0, T)$  and a constant  $c_8 > 0$  such that

$$(8.5) \quad |\partial_t \varphi(t, u)| \leq \lambda(t)(\varphi(t, u) + 1) \quad \forall u \in H,$$

$$(8.6) \quad |\partial_t \varphi(t, u) - \partial_t \varphi(t, w)| \leq c_8 |u - w| \quad \forall u, w \in H, \text{ for a.e. } t \in (0, T).$$

The latter and [64, Prop. 2.6] entail that the choice  $\pi(u(t)) := \partial_t \varphi(t, u(t))$  is admissible and fulfills the chain rule (3.2). Finally, we ask for the uniform convexity of  $\varphi$ , namely,

$$\begin{aligned} & \exists \kappa > 0 \text{ such that, } \forall u_0, u_1 \in H, \forall t \in [0, T], \forall \theta \in [0, 1], \\ & \varphi(t, (1 - \theta)u_0 + \theta u_1) \\ (8.7) \quad & \leq (1 - \theta)\varphi(t, u_0) + \theta\varphi(t, u_1) - \frac{\kappa}{2}\theta(1 - \theta)|u_0 - u_1|^2. \end{aligned}$$

In [64, subsect. 4.2] the authors discuss a nontrivial situation inspired by continuum mechanics where the latter conditions (8.2)–(8.7) are met. The crucial point now is that uniform convexity yields the Lipschitz time regularity of the solutions. In particular, under assumptions (8.2)–(8.7), all solutions  $(u, v)$  to the doubly nonlinear equation (3.1) fulfill [64, Thm. 3.2]

$$(8.8) \quad \|u'\|_{L^\infty(0, T; H)} \leq c_8/\kappa.$$

LEMMA 8.1 (convergence for rate-independent problems). *Under the assumptions of Lemma 5.4, let  $\psi_n$  fulfill (8.1) and (8.3) and  $\varphi_n$  fulfill (7.2) and (8.4)–(8.7) uniformly with respect to  $n$ . Moreover, let  $(u_n, v_n) \in W^{1,1}(0, T; H) \times L^\infty(0, T; H^*)$  be such that  $\mathcal{I}_n(u_n, v_n) = 0$ . Then there exists a (not relabeled) subsequence such that  $(u_n, v_n) \rightarrow (u, v)$  weakly star in  $W^{1,\infty}(0, T; H) \times L^\infty(0, T; H^*)$  and  $\mathcal{I}(u, v) = 0$ .*

*Proof.* First of all, one has that  $v_n \in C$  almost everywhere in  $(0, T)$  and hence are uniformly bounded in  $L^\infty(0, T; H^*)$ . Moreover, since  $(u_n, v_n)$  are solutions to (3.1), the Lipschitz continuity estimate (8.8) holds uniformly with respect to  $n$ . Additionally,  $u_n$  are uniformly bounded in  $L^1(0, T; V)$  due to (7.2). Hence, Lemma 5.4 yields the result.  $\square$

We shall mention that, differently from Lemmas 6.1 and 7.2, the latter result holds for sequences of solutions only since the estimate (8.8) is crucially used in order to obtain strong compactness in  $L^1(0, T; H)$  for  $u_n$ . In particular, we are not entitled to approximate a rate-independent situation by means of rate-dependent approximations. The reader is referred instead to Efendiev and Mielke [29] and Mielke, Rossi, and Savaré [66, 65] for some results in this direction.

The above convergence result could be alternatively obtained by applying the abstract analysis by Mielke, Roubíček, and Stefanelli [69, Thm. 3.1]. In the latter, besides the convergences of the functionals  $\psi_n \rightarrow \psi$  and  $\varphi_n \rightarrow \varphi$ , some extra closure condition, indeed fulfilled in the present situation, is crucially required [69, equation (2.11)]. Let us mention that [69] is devoted to a quite more general situation where the state space is just a Hausdorff topological space (in particular, no convexity is assumed on  $\varphi_n$ ).

We specialize further the results on rate-independent evolutions by explicitly discussing the fundamental case of (2.3), i.e., the so-called *play operator* in a Hilbert space  $H$ . The latter stands as the basic element for the construction of a relevant class of hysteresis operators, namely, the so-called Prandtl–Ishlinskii operators. The reader is referred to the classic monographs by Brokate and Sprekels [19], Krejčí [50], and Visintin [104] for a comprehensive collection of results on these operators. In particular, let us mention the convergence result [50, Thm. 3.12, p. 34] where the approximation of play operators under the Hausdorff convergence of the related characteristic convex sets  $C_n$  (see (8.2)) is discussed. Here we exploit instead the quite weaker situation of  $C_n \rightarrow C$  in the Mosco sense [7] (namely, the corresponding indicator functions Mosco-converge).

Comparing the case of the play operator with the above general result for rate-independent problems, we stress that, owing to the  $\liminf$  inequality (5.2), no strong compactness is here needed, and (7.2) can be omitted. We have the following convergence result.

LEMMA 8.2 (convergence for the play operator). *Let  $H$  be a separable Hilbert space and  $\psi_n \rightarrow \psi$  in the Mosco sense and fulfill (5.1), (8.1), and (8.3) uniformly with respect to  $n$ . Moreover, let  $f_n \rightarrow f$  strongly in  $C([0, T]; H^*)$ ,  $f_n$  be uniformly Lipschitz continuous, and  $u_n^0 \rightarrow u^0$  in  $H$ . Finally, let  $u_n \in W^{1,1}(0, T; H)$  be such that  $Q_n(u_n) = 0$ . Then  $u_n \rightarrow u$  weakly star in  $W^{1,\infty}(0, T; H)$  and  $Q(u) = 0$ .*

*Proof.* The Lipschitz regularity of  $f_n$  entails (8.5)–(8.6). Hence, the uniform control of (8.3) yields via (8.8) the uniform bound of  $u_n$  in  $W^{1,\infty}(0, T; H)$ . The assertion follows by extracting weakly star convergent subsequences and exploiting Lemma 5.3. In particular, the convergence of the whole sequence is ensured by the uniqueness of the solution of the limit problem [50, Thm. 3.1, p. 27 and Prop. 3.9, p. 33].  $\square$

The latter convergence result extends the former analysis by this author [102, Lemma 4.4] to the more natural setting  $W^{1,1}$ . One has, however, to mention that the former result was including the possibility of approximating the play operator with non-rate-independent evolutions (such as those stemming from penalizations or singular perturbations, for instance) while Lemma 8.2 is restricted to approximating plays only. On the other hand, the present convergence result is slightly more precise than the former since no strong convergence on the derivatives  $f'_n$  is required. The reader is referred to [103] for further results in this direction.

## NONLINEAR OPTIMAL CONTROL VIA OCCUPATION MEASURES AND LMI-RELAXATIONS\*

JEAN B. LASSERRE<sup>†</sup>, DIDIER HENRION<sup>‡</sup>, CHRISTOPHE PRIEUR<sup>§</sup>, AND  
EMMANUEL TRÉLAT<sup>¶</sup>

**Abstract.** We consider the class of nonlinear optimal control problems (OCPs) with polynomial data, i.e., the differential equation, state and control constraints, and cost are all described by polynomials, and more generally for OCPs with smooth data. In addition, state constraints as well as state and/or action constraints are allowed. We provide a simple hierarchy of LMI- (linear matrix inequality)-relaxations whose optimal values form a nondecreasing sequence of lower bounds on the optimal value. Under some convexity assumptions, the sequence converges to the optimal value of the OCP. Preliminary results show that good approximations are obtained with few moments.

**Key words.** nonlinear control, optimal control, semidefinite programming, measures, moments

**AMS subject classifications.** 90C22, 93C10, 28A99

**DOI.** 10.1137/070685051

**1. Introduction.** Solving a general nonlinear optimal control problem (OCP) is a difficult challenge, despite the powerful theoretical tools available, e.g., the maximum principle and Hamilton–Jacobi–Bellman (HJB) optimality equation. The problem is even more difficult in the presence of state and/or control constraints. State constraints are particularly difficult to handle, and the interested reader is referred to Capuzzo-Dolcetta and Lions [8] and Soner [41] for a detailed account of HJB theory in the case of state constraints. There exist many numerical methods to compute the solution of a given OCP [37, 43]; for instance, *multiple shooting* techniques which solve two-point boundary value problems as described, e.g., in [42, 36], or *direct methods*, as, e.g., in [46, 13, 15], which use, among other things, descent or gradient-like algorithms. To deal with OCPs with state constraints, some adapted versions of the maximum principle have been developed (see [27, 34], and see [16] for a survey of this theory) but are very hard to implement in general.

On the other hand, the OCP can be written as an infinite-dimensional linear program (LP) over two spaces of measures. This is called the *weak* formulation of the OCP in Vinter [45] (stated in the more general context of differential inclusions). The two unknown measures are the state-action *occupation measure* (o.m.) *up to* the final time  $T$ , and the state o.m. *at* time  $T$ . The optimal value of the resulting LP always provides a lower bound on the optimal value of the OCP, and under some convexity

---

assumptions, both values coincide; see Vinter [45] and Hernandez-Hernandez et al. [20] as well. See Gaitsgory and Rossomakhine [14] for a more recent related work where, in addition, a numerical scheme is also defined for approximating an optimal control.

The dual of the original infinite-dimensional LP has an interpretation in terms of “subsolutions” of related HJB-like optimality conditions, as for the unconstrained case. The only difference with the unconstrained case is the underlying function space involved, which directly incorporates the state constraints. Namely, the functions are only defined on the state constraint set.

An interesting feature of this LP approach with o.m.’s is that state constraints, as well as state and/or action constraints, are all easy to handle; indeed they simply translate into constraints on the supports of the unknown o.m.’s. It thus provides an alternative to the use of maximum principles with state constraints. Although this LP approach is valid for any OCP, solving the corresponding (infinite-dimensional) LP is difficult in general; however, general LP approximation schemes based on grids have been proposed in, e.g., Hernández-Lerma and Lasserre [22].

This LP approach has also been used in the context of discrete-time Markov control processes, and is dual to Bellman’s optimality principle. For more details the interested reader is referred to the convex analytic approach described in Borkar [6], Hernández-Lerma and Lasserre [21, 23, 24], and the many references therein. For some continuous-time stochastic control problems (e.g., modeled by diffusions) and optimal stopping problems, the LP approach has also been used with success to prove existence of stationary optimal policies; see, for instance, Bhatt and Borkar [4], Cho and Stockbridge [9], Helmes and Stockbridge [18], Helmes, Röhl, and Stockbridge [17], Kurtz and Stockbridge [29], and also Fleming and Vermes [12]. In some of these works, the moment approach is also used to approximate the resulting infinite-dimensional LP.

**Contribution.** In this paper, we consider the particular class of nonlinear OCPs with state and/or control constraints, for which all data describing the problem (dynamics and state and control constraints) are *polynomials*. The approach also extends to the case of problems with *smooth* data and compact sets, because polynomials are dense in the space of functions considered; this point of view is detailed in section 4. In this restricted polynomial framework, the LP approach has interesting additional features that can be exploited for effective numerical computation. Indeed, for the class of OCPs considered, the following features make this LP approach attractive:

- Only the *moments* of the o.m.’s appear in the LP formulation, so that we already end up with countably many variables—a significant progress.
- Constraints on the support of the o.m.’s translate easily into either LP or SDP (semidefinite programming) *necessary* constraints on their moments. Even more, for (semialgebraic) compact supports, relatively recent powerful results from real algebraic geometry make these constraints also *sufficient*.
- When truncating to finitely many moments, the resulting LPs or SDPs are solvable and their optimal values form a monotone nondecreasing sequence (indexed by the number of moments considered) of lower bounds on the optimal value of the LP (and thus of the OCP). See [19, 30] for applications of this technique to nonconvex polynomial optimization.

Therefore, based on the above observations, we propose an approximation of the optimal value of the OCP via solving a hierarchy of SDPs (or linear matrix inequalities, LMIs) that provides a monotone nondecreasing sequence of lower bounds on the optimal value of the weak LP formulation of the OCP. In addition, under some compactness assumption of the state and control constraint sets, the sequence of lower

bounds is shown to converge to the optimal value of the LP, and thus to the optimal value of the OCP when the former and latter are equal.

As such, it could be seen as a complement to the above shooting or direct methods and, when the sequence of lower bounds converges to the optimal value, as a test of their efficiency. Finally this approach can also be used to provide a *certificate* of infeasibility. Indeed, if, in the hierarchy of LMI-relaxations of the minimum time OCP, one is infeasible, then the OCP itself is infeasible. It turns out that sometimes this certificate is provided at an early stage in the hierarchy, i.e., with very few moments. This is illustrated in two simple examples.

In a pioneering paper, Dawson [11] had suggested the use of *moments* in the LP approach with o.m.'s, but results on the  $\mathbf{K}$ -moment problem by Schmüdgen [40] and Putinar [39] were not available at that time. Later, Helmes and Stockbridge [18] and Helmes, Röhl, and Stockbridge [17] used LP moment conditions for computing some exit time moments in some diffusion model, whereas for the same models, Lasserre and Priéto-Rumeau [31] showed that SDP moment conditions are superior in terms of precision and number of moments to consider; in [32], they extended the moment approach for options pricing problems in some mathematical finance models. More recently, Lasserre, Prieur, and Henrion [33] used the o.m. approach for minimum time OCP without state constraint. Preliminary experimental results on Brockett's integrator example and on the double integrator show fast convergence with few moments.

## 2. Occupation measures and the LP approach.

**2.1. Definition of the OCP.** Let  $n$  and  $m$  be nonzero integers. Consider on  $\mathbb{R}^n$  the control system

$$(2.1) \quad \dot{x}(t) = f(t, x(t), u(t)),$$

where  $f : [0, +\infty) \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^n$  is smooth, and where the controls are bounded measurable functions, defined on intervals  $[0, T(\mathbf{u})]$  of  $\mathbb{R}^+$ , and taking their values in a compact subset  $\mathbf{U}$  of  $\mathbb{R}^m$ . Let  $x_0 \in \mathbb{R}^n$ , and let  $\mathbf{X}$  and  $\mathbf{K}$  be compact subsets of  $\mathbb{R}^n$ . For  $T > 0$ , a control  $u$  is said to be *admissible* on  $[0, T]$  whenever the solution  $x(\cdot)$  of (2.1), such that  $x(0) = x_0$ , is well defined on  $[0, T]$  and satisfies

$$(2.2) \quad (x(t), u(t)) \in \mathbf{X} \times \mathbf{U} \quad \text{a.e. on } [0, T]$$

and

$$(2.3) \quad x(T) \in \mathbf{K}.$$

Denote by  $\mathcal{U}_T$  the set of *admissible controls* on  $[0, T]$ .

For  $\mathbf{u} \in \mathcal{U}_T$ , the *cost* of the associated trajectory  $x(\cdot)$  is defined by

$$(2.4) \quad J(0, T, x_0, \mathbf{u}) = \int_0^T h(t, x(t), u(t)) dt + H(x(T)),$$

where  $h : [0, +\infty) \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}$  and  $H : \mathbb{R}^n \rightarrow \mathbb{R}$  are smooth functions.

Consider the *optimal control problem* (OCP) of determining a trajectory solution of (2.1), starting from  $x(0) = x_0$ , satisfying the state and control constraints (2.2), the terminal constraint (2.3), and minimizing the cost (2.4). The final time  $T$  may or may not be fixed.

If the final time  $T$  is fixed, we set

$$(2.5) \quad J^*(0, T, x_0) := \inf_{\mathbf{u} \in \mathcal{U}_T} J(0, T, x_0, \mathbf{u}),$$

and if  $T$  is free, we set

$$(2.6) \quad J^*(0, x_0) := \inf_{T>0, \mathbf{u} \in \mathcal{U}_T} J(0, T, x_0, \mathbf{u}).$$

Note that a particular OCP is the minimal time problem from  $x_0$  to  $\mathbf{K}$ , by letting  $h \equiv 1$ ,  $H \equiv 0$ . In this particular case, the minimal time is the first *hitting time* of the set  $\mathbf{K}$ .

It is possible to associate a stochastic or deterministic OCP with an abstract infinite-dimensional LP problem  $\mathbf{P}$  together with its dual  $\mathbf{P}^*$  (see, for instance, Hernández-Lerma and Lasserre [21] for discrete-time Markov control problems, and Vinter [45], Hernandez et al. [20] for deterministic optimal control problems, as well as the many references therein). We next describe this LP approach in the present context.

**2.2. Notations and definitions.** For a topological space  $\mathcal{X}$ , let  $\mathcal{M}(\mathcal{X})$  be the Banach space of finite signed Borel measures on  $\mathcal{X}$ , equipped with the norm of total variation, and denote by  $\mathcal{M}(\mathcal{X})_+$  its positive cone, that is, the space of finite measures on  $\mathcal{X}$ . Let  $C(\mathcal{X})$  be the Banach space of bounded continuous functions on  $\mathcal{X}$ , equipped with the sup-norm. Notice that when  $\mathcal{X}$  is compact Hausdorff, then  $\mathcal{M}(\mathcal{X}) \simeq C(\mathcal{X})^*$ ; i.e.,  $\mathcal{M}(\mathcal{X})$  is the topological dual of  $C(\mathcal{X})$ .

Let  $\mathbb{R}[x] = [x_1, \dots, x_n]$  (resp.,  $\mathbb{R}[t, x, u] = \mathbb{R}[t, x_1, \dots, x_n, u_1, \dots, u_m]$ ) denote the set of polynomial functions of the variable  $x$  (resp., of the variables  $t, x, u$ ).

Let  $\Sigma := [0, T] \times \mathbf{X}$ ,  $\mathbf{S} := \Sigma \times \mathbf{U}$ , and let  $C_1(\Sigma)$  be the Banach space of functions  $\varphi \in C(\Sigma)$  that are continuously differentiable. For ease of exposition we use the same notation  $g$  (resp.,  $h$ ) for a polynomial  $g \in \mathbb{R}[t, x]$  (resp.,  $h \in \mathbb{R}[x]$ ) and its restriction to the compact set  $\Sigma$  (resp.,  $\mathbf{K}$ ).

Next, with  $u \in \mathbf{U}$ , let  $A : C_1(\Sigma) \rightarrow C(\mathbf{S})$  be the mapping

$$(2.7) \quad \varphi \mapsto A\varphi(t, x, u) := \frac{\partial \varphi}{\partial t}(t, x) + \langle f(t, x, u), \nabla_x \varphi(t, x) \rangle.$$

Notice that  $\partial \varphi / \partial t + \langle \nabla_x \varphi, f \rangle \in C(\mathbf{S})$  for every  $\varphi \in C_1(\Sigma)$ , because both  $\mathbf{X}$  and  $\mathbf{U}$  are compact, and  $f$  is understood as its restriction to  $\mathbf{S}$ .

Next, let  $\mathcal{L} : C_1(\Sigma) \rightarrow C(\mathbf{S}) \times C(\mathbf{K})$  be the linear mapping

$$(2.8) \quad \varphi \mapsto \mathcal{L}\varphi := (-A\varphi, \varphi_T),$$

where  $\varphi_T(x) := \varphi(T, x)$  for all  $x \in \mathbf{X}$ . Obviously,  $\mathcal{L}$  is continuous with respect to the strong topologies of  $C_1(\Sigma)$  and  $C(\mathbf{S}) \times C(\mathbf{K})$ .

Both  $(C(\mathbf{S}), \mathcal{M}(\mathbf{S}))$  and  $(C(\mathbf{K}), \mathcal{M}(\mathbf{K}))$  form a *dual pair* of vector spaces, with duality brackets

$$\langle h, \mu \rangle = \int h \, d\mu \quad \forall (h, \mu) \in C(\mathbf{S}) \times \mathcal{M}(\mathbf{S})$$

and

$$\langle g, \nu \rangle = \int g \, d\nu \quad \forall (g, \nu) \in C(\mathbf{K}) \times \mathcal{M}(\mathbf{K}).$$

Let  $\mathcal{L}^* : M(\mathbf{S}) \times M(\mathbf{K}) \rightarrow C_1(\Sigma)^*$  be the adjoint mapping of  $\mathcal{L}$ , defined by

$$(2.9) \quad \langle (\mu, \nu), \mathcal{L}\varphi \rangle = \langle \mathcal{L}^*(\mu, \nu), \varphi \rangle$$

for all  $((\mu, \nu), \varphi) \in M(\mathbf{S}) \times M(\mathbf{K}) \times C_1(\Sigma)$ .

*Remark 2.1.*

- (i) The mapping  $\mathcal{L}^*$  is continuous with respect to the weak topologies  $\sigma(\mathcal{M}(\mathbf{S}) \times \mathcal{M}(\mathbf{K}), C(\mathbf{S}) \times C(\mathbf{K}))$  and  $\sigma(C_1(\Sigma)^*, C_1(\Sigma))$ .
- (ii) Since the mapping  $\mathcal{L}$  is continuous in the strong sense, it is also continuous with respect to the weak topologies  $\sigma(C_1(\Sigma), C_1(\Sigma)^*)$  and  $\sigma(C(\mathbf{S}) \times C(\mathbf{K}), \mathcal{M}(\mathbf{S}) \times \mathcal{M}(\mathbf{K}))$ .
- (iii) In the case of a *free* terminal time  $T \leq T_0$ , it suffices to redefine  $\mathcal{L} : C_1(\Sigma) \rightarrow C(\mathbf{S}) \times C([0, T_0] \times \mathbf{K})$  by  $\mathcal{L}\varphi := (-A\varphi, \varphi)$ . The operator  $\mathcal{L}^* : M(\mathbf{S}) \times M([0, T_0] \times \mathbf{K}) \rightarrow C_1(\Sigma)^*$  is still defined by (2.9) for all  $((\mu, \nu), \varphi) \in M(\mathbf{S}) \times M([0, T_0] \times \mathbf{K}) \times C_1(\Sigma)$ .

For time-homogeneous free terminal time problems, one needs functions  $\varphi$  of  $x$  only, and so  $\Sigma = \mathbf{S} = \mathbf{X} \times \mathbf{U}$  and  $\mathcal{L} : C_1(\Sigma) \rightarrow C(\mathbf{S}) \times C(\mathbf{K})$ .

**2.3. Occupation measures and primal LP formulation.** Let  $T > 0$ , and let  $\mathbf{u} = \{u(t), 0 \leq t < T\}$  be a control such that the solution of (2.1), with  $x(0) = x_0$ , is well defined on  $[0, T]$ . Define the probability measure  $\nu^{\mathbf{u}}$  on  $\mathbb{R}^n$ , and the measure  $\mu^{\mathbf{u}}$  on  $[0, T] \times \mathbb{R}^n \times \mathbb{R}^m$ , by

$$(2.10) \quad \nu^{\mathbf{u}}(D) := \mathbf{I}_D[x(T)], \quad D \in \mathcal{B}_n,$$

$$(2.11) \quad \mu^{\mathbf{u}}(A \times B \times C) := \int_{[0, T] \cap A} \mathbf{I}_{B \times C}[(x(t), u(t))] dt$$

for all *rectangles*  $(A \times B \times C)$ , with  $(A, B, C) \in \mathcal{A} \times \mathcal{B}_n \times \mathcal{B}_m$ , and where  $\mathcal{B}_n$  (resp.,  $\mathcal{B}_m$ ) denotes the usual Borel  $\sigma$ -algebra associated with  $\mathbb{R}^n$  (resp.,  $\mathbb{R}^m$ ),  $\mathcal{A}$  the Borel  $\sigma$ -algebra of  $[0, T]$ , and  $\mathbf{I}_B(\bullet)$  the indicator function of the set  $B$ .

The measure  $\mu^{\mathbf{u}}$  is called the *occupation measure* (o.m.) of the state-action (deterministic) process  $(t, x(t), u(t))$  up to time  $T$ , whereas  $\nu^{\mathbf{u}}$  is the o.m. of the state  $x(T)$  at time  $T$ .

*Remark 2.2.* If the control  $\mathbf{u}$  is admissible on  $[0, T]$ , i.e., if the trajectory  $x(\cdot)$  satisfies the constraints (2.2) and (2.3), then  $\nu^{\mathbf{u}}$  is a probability measure supported on  $\mathbf{K}$  (i.e.,  $\nu^{\mathbf{u}} \in \mathcal{M}(\mathbf{K})_+$ ), and  $\mu^{\mathbf{u}}$  is supported on  $[0, T] \times \mathbf{X} \times \mathbf{U}$  (i.e.,  $\mu^{\mathbf{u}} \in \mathcal{M}(\mathbf{S})_+$ ). In particular,  $T = \mu^{\mathbf{u}}(\mathbf{S})$ .

Conversely, if the support of  $\mu^{\mathbf{u}}$  is contained in  $\mathbf{S} = [0, T] \times \mathbf{X} \times \mathbf{U}$  and if  $\mu^{\mathbf{u}}(\mathbf{S}) = T$ , then  $(x(t), u(t)) \in \mathbf{X} \times \mathbf{U}$  for almost every  $t \in [0, T]$ . Indeed, with (2.11),

$$\begin{aligned} T &= \int_0^T \mathbf{I}_{\mathbf{X} \times \mathbf{U}}[(x(s), u(s))] ds \\ &\Rightarrow \mathbf{I}_{\mathbf{X} \times \mathbf{U}}[(x(s), u(s))] = 1 \quad \text{a.e. in } [0, T], \end{aligned}$$

and hence  $(x(t), u(t)) \in \mathbf{X} \times \mathbf{U}$  for almost every  $t \in [0, T]$ . If moreover the support of  $\nu^{\mathbf{u}}$  is contained in  $\mathbf{K}$ , then  $x(T) \in \mathbf{K}$ . Therefore,  $\mathbf{u}$  is an admissible control on  $[0, T]$ .

Then observe that the optimization criterion (2.5) can now be written as

$$J(0, T, x_0, \mathbf{u}) = \int_{\mathbf{K}} H d\nu^{\mathbf{u}} + \int_{\mathbf{S}} h d\mu^{\mathbf{u}} = \langle (\mu^{\mathbf{u}}, \nu^{\mathbf{u}}), (h, H) \rangle,$$

and one infers from (2.1), (2.2), and (2.3) that

$$(2.12) \quad \int_{\mathbf{K}} g_T d\nu^{\mathbf{u}} - g(0, x_0) = \int_{\mathbf{S}} \left( \frac{\partial g}{\partial t} + \langle \nabla_x g, f \rangle \right) d\mu^{\mathbf{u}}$$

for every  $g \in C_1(\Sigma)$  (where  $g_T(x) \equiv g(T, x)$  for every  $x \in \mathbf{K}$ ), or equivalently, in view of (2.8) and (2.9),

$$\langle g, \mathcal{L}^*(\mu^u, \nu^u) \rangle = \langle g, \delta_{(0, x_0)} \rangle \quad \forall g \in C_1(\Sigma).$$

This in turn implies that

$$\mathcal{L}^*(\mu^u, \nu^u) = \delta_{(0, x_0)}.$$

Therefore, consider the infinite-dimensional linear program  $\mathbf{P}$ :

$$(2.13) \quad \mathbf{P} : \quad \inf_{(\mu, \nu) \in \Delta} \{ \langle (\mu, \nu), (h, H) \rangle \mid \mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)} \}$$

(where  $\Delta := \mathcal{M}(\mathbf{S})_+ \times \mathcal{M}(\mathbf{K})_+$ ). Denote by  $\inf \mathbf{P}$  its optimal value and by  $\min \mathbf{P}$  the infimum attained, in which case  $\mathbf{P}$  is said to be *solvable*. The problem  $\mathbf{P}$  is said to be *feasible* if there exists  $(\mu, \nu) \in \Delta$  such that  $\mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)}$ .

Note that  $\mathbf{P}$  is feasible whenever there exists an admissible control.

The linear program  $\mathbf{P}$  is a rephrasing of the OCP (2.1)–(2.5) in terms of the *o.m.*'s of its trajectories  $(t, x(t), u(t))$ . Its dual LP reads

$$(2.14) \quad \mathbf{P}^* : \quad \sup_{\varphi \in C_1(\Sigma)} \{ \langle \delta_{(0, x_0)}, \varphi \rangle \mid \mathcal{L}\varphi \leq (h, H) \},$$

where

$$\mathcal{L}\varphi \leq (h, H) \Leftrightarrow \begin{cases} A\varphi(t, x, u) + h(t, x, u) \geq 0 & \forall (t, x, u) \in \mathbf{S}, \\ \varphi(T, x) \leq H(x) & \forall x \in \mathbf{K}. \end{cases}$$

Denote by  $\sup \mathbf{P}^*$  its optimal value and by  $\max \mathbf{P}^*$  the supremum attained, i.e., if  $\mathbf{P}^*$  is solvable.

Discrete-time stochastic analogues of the LPs  $\mathbf{P}$  and  $\mathbf{P}^*$  are also described in Hernández-Lerma and Lasserre [21, 23] for discrete-time Markov control problems. Similarly, see Cho and Stockbridge [9], Kurtz and Stockbridge [29], and Helmes and Stockbridge [17] for some continuous-time stochastic problems.

**THEOREM 2.3.** *If  $\mathbf{P}$  is feasible, then the following hold:*

- (i)  $\mathbf{P}$  is solvable, i.e.,  $\inf \mathbf{P} = \min \mathbf{P} \leq J(0, T, x_0)$ .
- (ii) There is no duality gap, i.e.,  $\sup \mathbf{P}^* = \min \mathbf{P}$ .
- (iii) If, moreover, for every  $(t, x) \in \Sigma$  the set  $f(t, x, \mathbf{U}) \subset \mathbb{R}^n$  is convex, and the function

$$v \mapsto g_{t,x}(v) := \inf_{u \in \mathbf{U}} \{ h(t, x, u) : v = f(t, x, u) \}$$

is convex, then the OCP (2.1)–(2.5) has an optimal solution and

$$\sup \mathbf{P}^* = \inf \mathbf{P} = \min \mathbf{P} = J^*(0, T, x_0).$$

For a proof see section A.1. Theorem 2.3(iii) is due to Vinter [45].

**3. Semidefinite programming relaxations of  $\mathbf{P}$ .** The LP  $\mathbf{P}$  is infinite-dimensional, and thus not tractable as it stands. Therefore, we next present a relaxation scheme that provides a sequence of SDPs, or linear matrix inequality relaxations (in short, LMI-relaxations)  $\{\mathbf{Q}_r\}$ , each with *finitely many* constraints and variables.

Assume that  $\mathbf{X}$  and  $\mathbf{K}$  (resp.,  $\mathbf{U}$ ) are compact semialgebraic subsets of  $\mathbb{R}^n$  (resp., of  $\mathbb{R}^m$ ) of the form

$$(3.1) \quad \mathbf{X} := \{x \in \mathbb{R}^n \mid v_j(x) \geq 0, \quad j \in J\},$$

$$(3.2) \quad \mathbf{K} := \{x \in \mathbb{R}^n \mid \theta_j(x) \geq 0, \quad j \in J_T\},$$

$$(3.3) \quad \mathbf{U} := \{u \in \mathbb{R}^m \mid w_j(u) \geq 0, \quad j \in W\}$$

for some finite index sets  $J_T$ ,  $J$ , and  $W$ , where  $v_j$ ,  $\theta_j$ , and  $w_j$  are polynomial functions. Define

$$(3.4) \quad d(\mathbf{X}, \mathbf{K}, \mathbf{U}) := \max_{j \in J_1, l \in J, k \in W} (\deg \theta_j, \deg v_l, \deg w_k).$$

To highlight the main ideas, in this section we assume that  $f$ ,  $h$ , and  $H$  are polynomial functions, that is,  $h \in \mathbb{R}[t, x, u]$ ,  $H \in \mathbb{R}[x]$ , and  $f : [0, +\infty) \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$  is polynomial; i.e., every component of  $f$  satisfies  $f_k \in \mathbb{R}[t, x, u]$  for  $k = 1, \dots, n$ .

**3.1. The underlying idea.** Observe the following important facts.

The restriction of  $\mathbb{R}[t, x]$  to  $\Sigma$  belongs to  $C_1(\Sigma)$ . Therefore,

$$\mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)} \quad \Leftrightarrow \quad \langle g, \mathcal{L}^*(\mu, \nu) \rangle = g(0, x_0) \quad \forall g \in \mathbb{R}[t, x],$$

because  $\Sigma$  being compact, polynomial functions are *dense* in  $C_1(\Sigma)$  for the sup-norm. Indeed, on a compact set, one may *simultaneously* approximate a function and its (continuous) partial derivatives by a polynomial and its derivatives uniformly (see [26, pp. 65–66]). Hence, the LP  $\mathbf{P}$  can be written

$$\mathbf{P} : \begin{cases} \inf_{(\mu, \nu) \in \Delta} \langle (\mu, \nu), (h, H) \rangle \\ \text{s.t.} \quad \langle g, \mathcal{L}^*(\mu, \nu) \rangle = g(0, x_0) \quad \forall g \in \mathbb{R}[t, x], \end{cases}$$

or equivalently, by linearity,

$$(3.5) \quad \mathbf{P} : \begin{cases} \inf_{(\mu, \nu) \in \Delta} \langle (\mu, \nu), (h, H) \rangle \\ \text{s.t.} \quad \langle \mathcal{L}g, (\mu, \nu) \rangle = g(0, x_0) \quad \forall g = (t^p x^\alpha); \quad (p, \alpha) \in \mathbb{N} \times \mathbb{N}^n. \end{cases}$$

The constraints of  $\mathbf{P}$ ,

$$(3.6) \quad \langle \mathcal{L}g, (\mu, \nu) \rangle = g(0, x_0) \quad \forall g = (t^p x^\alpha); \quad (p, \alpha) \in \mathbb{N} \times \mathbb{N}^n,$$

define countably many *linear* equality constraints linking the *moments* of  $\mu$  and  $\nu$ , because if  $g$  is polynomial, then so are  $\partial g / \partial t$  and  $\partial g / \partial x_k$ , for every  $k$ , and  $\langle \nabla_x g, f \rangle$ . And so,  $\mathcal{L}g$  is polynomial.

The functions  $h, H$  being also polynomial, the cost  $\langle (\mu, \nu), (h, H) \rangle$  of the OCP (2.1)–(2.5) is also a linear combination of the moments of  $\mu$  and  $\nu$ .

Therefore, the LP  $\mathbf{P}$  in (3.5) can be formulated as an LP with countably many variables (the moments of  $\mu$  and  $\nu$ ) and countably many linear equality constraints. However, it remains to express the fact that the variables should be moments of some measures  $\mu$  and  $\nu$ , with support contained in  $\mathbf{S}$  and  $\mathbf{K}$ , respectively.

At this stage, one will make some (weak) additional assumptions on the polynomials that define the compact semialgebraic sets  $\mathbf{X}, \mathbf{K}$ , and  $\mathbf{U}$ . Under such assumptions, one may then invoke recent results of real algebraic geometry on the representation of

polynomials positive on a compact set, and get necessary and sufficient conditions on the variables of  $\mathbf{P}$  to be indeed moments of two measures  $\mu$  and  $\nu$ , with appropriate support. We will use Putinar's Positivstellensatz [39] described in the next section, which yields SDP constraints on the variables.

One might also use other representation results like, e.g., Krivine [28] and Vasilescu [44] and obtain *linear* constraints on the variables (as opposed to SDP constraints). This is the approach taken by, e.g., Helmes, Röhl, and Stockbridge [17]. However, a comparison of the use of LP constraints versus SDP constraints on a related problem [31] has dictated our choice of the former.

Finally, if  $g$  in (3.6) runs only over all monomials of degree less than  $r$ , one then obtains a corresponding relaxation  $\mathbf{Q}_r$  of  $\mathbf{P}$ , which is now a finite-dimensional SDP that one may solve with public software packages. At last, one lets  $r \rightarrow \infty$ .

**3.2. Notations, definitions, and auxiliary results.** For a multi-index  $\alpha = (\alpha_1, \dots, \alpha_n) \in \mathbb{N}^n$ , and for  $x = (x_1, \dots, x_n) \in \mathbb{R}^n$ , denote  $x^\alpha := x_1^{\alpha_1} \cdots x_n^{\alpha_n}$ . Consider the canonical basis  $\{x^\alpha\}_{\alpha \in \mathbb{N}^n}$  (resp.,  $\{t^p x^\alpha u^\beta\}_{p \in \mathbb{N}, \alpha \in \mathbb{N}^n, \beta \in \mathbb{N}^m}$ ) of  $\mathbb{R}[x]$  (resp., of  $\mathbb{R}[t, x, u]$ ).

Given two sequences  $y = \{y_\alpha\}_{\alpha \in \mathbb{N}^n}$  and  $z = \{z_\gamma\}_{\gamma \in \mathbb{N} \times \mathbb{N}^n \times \mathbb{N}^m}$  of real numbers, define the linear functional  $L_y : \mathbb{R}[x] \rightarrow \mathbb{R}$  by

$$H \left( := \sum_{\alpha \in \mathbb{N}^n} H_\alpha x^\alpha \right) \mapsto L_y(H) := \sum_{\alpha \in \mathbb{N}^n} H_\alpha y_\alpha,$$

and similarly, define the linear functional  $L_z : \mathbb{R}[t, x, u] \rightarrow \mathbb{R}$  by

$$h \mapsto L_z(h) := \sum_{\gamma \in \mathbb{N} \times \mathbb{N}^n \times \mathbb{N}^m} h_\gamma z_\gamma = \sum_{p \in \mathbb{N}, \alpha \in \mathbb{N}^n, \beta \in \mathbb{N}^m} h_{p\alpha\beta} z_{p\alpha\beta},$$

where  $h(t, x, u) = \sum_{p \in \mathbb{N}, \alpha \in \mathbb{N}^n, \beta \in \mathbb{N}^m} h_{p\alpha\beta} t^p x^\alpha u^\beta$ .

Note that for a given measure  $\nu$  (resp.,  $\mu$ ) on  $\mathbb{R}$  (resp., on  $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m$ ), there holds, for every  $H \in \mathbb{R}[x]$  (resp., for every  $h \in \mathbb{R}[t, x, u]$ ),

$$\langle \nu, H \rangle = \int_{\mathbb{R}} H d\nu = \int_{\mathbb{R}} \sum_{\alpha \in \mathbb{N}^n} H_\alpha x^\alpha d\nu = \sum_{\alpha \in \mathbb{N}^n} H_\alpha y_\alpha = L_y(H),$$

where the real numbers  $y_\alpha = \int x^\alpha d\nu$  are the moments of the measure  $\nu$  (resp.,  $\langle \mu, h \rangle = L_z(h)$ , where  $z$  is the sequence of moments of the measure  $\mu$ ).

**DEFINITION 3.1.** For a given sequence  $z = \{z_\gamma\}_{\gamma \in \mathbb{N} \times \mathbb{N}^n \times \mathbb{N}^m}$  of real numbers, the moment matrix  $M_r(z)$  of order  $r$  associated with  $z$  has its rows and columns indexed in the canonical basis  $\{t^p x^\alpha u^\beta\}$  and is defined by

$$(3.7) \quad M_r(z)(\gamma, \beta) = z_{\gamma+\beta}, \quad \gamma, \beta \in \mathbb{N} \times \mathbb{N}^n \times \mathbb{N}^m, \quad |\gamma|, |\beta| \leq r,$$

where  $|\gamma| := \sum_j \gamma_j$ . The moment matrix  $M_r(y)$  of order  $r$  associated with a given sequence  $y = \{y_\alpha\}_{\alpha \in \mathbb{N}^n}$  has its rows and columns indexed in the canonical basis  $\{x^\alpha\}$  and is defined in a similar fashion.

Note that if  $z$  has a representing measure  $\mu$ , i.e., if  $z$  is the sequence of moments of the measure  $\mu$  on  $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m$ , then  $L_z(h) = \int h d\mu$  for every  $h \in \mathbb{R}[t, x, u]$ , and if  $\mathbf{h}$  denotes the vector of coefficients of  $h \in \mathbb{R}[t, x, u]$  of degree less than  $r$ , then

$$\langle \mathbf{h}, M_r(z) \mathbf{h} \rangle = L_z(h^2) = \int h^2 d\mu \geq 0.$$

This implies that  $M_r(z)$  is symmetric nonnegative (denoted  $M_r(z) \succeq 0$ ) for every  $r$ . The same holds for  $M_r(y)$ .

Conversely, not every sequence  $y$  that satisfies  $M_r(y) \succeq 0$  for every  $r$  has a representing measure. However, several sufficient conditions exist, in particular the following one due to Berg [3].

**PROPOSITION 3.2.** *If  $y = \{y_\alpha\}_{\alpha \in \mathbb{N}^n}$  satisfies  $|y_\alpha| \leq 1$  for every  $\alpha \in \mathbb{N}^n$ , and  $M_r(y) \succeq 0$  for every integer  $r$ , then  $y$  has a representing measure on  $\mathbb{R}^n$ , with support contained in the unit ball  $[-1, 1]^n$ .*

We next present another sufficient condition which is crucial in the proof of our main result.

**DEFINITION 3.3.** *For a given polynomial  $\theta \in \mathbb{R}[t, x, u]$ , written*

$$\theta(t, x, u) = \sum_{\delta=(p,\alpha,\beta)} \theta_\delta t^p x^\alpha u^\beta,$$

*define the localizing matrix  $M_r(\theta z)$  associated with  $z, \theta$ , and with rows and columns also indexed in the canonical basis of  $\mathbb{R}[t, x, u]$ , by*

$$(3.8) \quad M_r(\theta z)(\gamma, \beta) = \sum_{\delta} \theta_\delta z_{\delta+\gamma+\beta} \quad \gamma, \beta \in \mathbb{N} \times \mathbb{N}^n \times \mathbb{N}^m, \quad |\gamma|, |\beta| \leq r.$$

*The localizing matrix  $M_r(\theta y)$  associated with a given sequence  $y = \{y_\alpha\}_{\alpha \in \mathbb{N}^n}$  is defined similarly.*

Note that if  $z$  has a representing measure  $\mu$  on  $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m$  with support contained in the level set  $\{(t, x, u) : \theta(t, x, u) \geq 0\}$ , and if  $h \in \mathbb{R}[t, x, u]$  has degree less than  $r$ , then

$$\langle \mathbf{h}, M_r(\theta, z) \mathbf{h} \rangle = L_z(\theta h^2) = \int \theta h^2 d\mu \geq 0.$$

Hence,  $M_r(\theta z) \succeq 0$  for every  $r$ .

Let  $\Sigma^2 \subset \mathbb{R}[x]$  be the convex cone generated in  $\mathbb{R}[x]$  by all squares of polynomials, and let  $\Omega \subset \mathbb{R}^n$  be the compact basic semialgebraic set defined by

$$(3.9) \quad \Omega := \{x \in \mathbb{R}^n \mid g_j(x) \geq 0, \quad j = 1, \dots, m\}$$

for some family  $\{g_j\}_{j=1}^m \subset \mathbb{R}[x]$ .

**DEFINITION 3.4.** *The set  $\Omega \subset \mathbb{R}^n$  defined by (3.9) satisfies Putinar's condition if there exists  $u \in \mathbb{R}[x]$  such that  $u = u_0 + \sum_{j=1}^m u_j g_j$  for some family  $\{u_j\}_{j=0}^m \subset \Sigma^2$ , and the level set  $\{x \in \mathbb{R}^n \mid u(x) \geq 0\}$  is compact.*

Putinar's condition is satisfied if, e.g., the level set  $\{x : g_k(x) \geq 0\}$  is compact for some  $k$ , or if all the  $g_j$ 's are linear, in which case  $\Omega$  is a polytope. In addition, if one knows some  $M$  such that  $\|x\| \leq M$  whenever  $x \in \Omega$ , then it suffices to add the redundant quadratic constraint  $M^2 - \|x\|^2 \geq 0$  in the definition (3.9) of  $\Omega$ , and Putinar's condition is satisfied (take  $u := M^2 - \|x\|^2$ ).

**THEOREM 3.5** (Putinar's Positivstellensatz [39]). *Assume that the set  $\Omega$  defined by (3.9) satisfies Putinar's condition.*

(a) *If  $f \in \mathbb{R}[x]$  and  $f > 0$  on  $\Omega$ , then*

$$(3.10) \quad f = f_0 + \sum_{j=1}^m f_j g_j$$

*for some family  $\{f_j\}_{j=0}^m \subset \Sigma^2$ .*

(b) Let  $y = \{y_\alpha\}_{\alpha \in \mathbb{N}^n}$  be a sequence of real numbers. If

$$(3.11) \quad M_r(y) \succeq 0; \quad M_r(g_j y) \succeq 0, \quad j = 1, \dots, m; \quad \forall r = 0, 1, \dots,$$

then  $y$  has a representing measure with support contained in  $\Omega$ .

**3.3. LMI-relaxations of  $\mathbf{P}$ .** Consider the LP  $\mathbf{P}$  defined by (3.5).

Since the semialgebraic sets  $\mathbf{X}, \mathbf{K}$ , and  $\mathbf{U}$  defined, respectively, by (3.1), (3.2), and (3.3) are compact, with no loss of generality we assume (up to a scaling of the variables  $x, u$ , and  $t$ ) that  $T = 1$ ,  $\mathbf{X}, \mathbf{K} \subseteq [-1, 1]^n$ , and  $\mathbf{U} \subseteq [-1, 1]^m$ .

Next, given a sequence  $z = \{z_\gamma\}$  indexed in the basis of  $\mathbb{R}[t, x, u]$ , denote  $z(t)$ ,  $z(x)$ , and  $z(u)$  its marginals with respect to the variables  $t$ ,  $x$ , and  $u$ , respectively. These sequences are indexed in the canonical basis of  $\mathbb{R}[t]$ ,  $\mathbb{R}[x]$ , and  $\mathbb{R}[u]$ , respectively. For instance, writing  $\gamma = (k, \alpha, \beta) \in \mathbb{N} \times \mathbb{N}^n \times \mathbb{N}^m$ ,

$$\{z(t)\} = \{z_{k,0,0}\}_{k \in \mathbb{N}}; \quad \{z(x)\} = \{z_{0,\alpha,0}\}_{\alpha \in \mathbb{N}^n}; \quad \{z(u)\} = \{z_{0,0,\beta}\}_{\beta \in \mathbb{N}^m}.$$

Let  $r_0$  be an integer such that  $2r_0 \geq \max(\deg f, \deg h, \deg H, 2d(\mathbf{X}, \mathbf{K}, \mathbf{U}))$ , where  $d(\mathbf{X}, \mathbf{K}, \mathbf{U})$  is defined by (3.4). For every  $r \geq r_0$ , consider the LMI-relaxation

$$(3.12) \quad \mathbf{Q}_r : \begin{cases} \inf_{y,z} L_z(h) + L_y(H), \\ M_r(y), M_r(z) \succeq 0, \\ M_{r-\deg \theta_j}(\theta_j y) \succeq 0, \quad j \in J_1, \\ M_{r-\deg v_j}(v_j z(x)) \succeq 0, \quad j \in J, \\ M_{r-\deg w_k}(w_k z(u)) \succeq 0, \quad k \in W, \\ M_{r-1}(t(1-t)z(t)) \succeq 0, \\ L_y(g_1) - L_z(\partial g / \partial t + \langle \nabla_x g, f \rangle) = g(0, x_0) \quad \forall g = (t^p x^\alpha), \\ \text{with } p + |\alpha| - 1 + \deg f \leq 2r, \end{cases}$$

whose optimal value is denoted by  $\inf \mathbf{Q}_r$ .

**OCP with free terminal time.** For the OCP (2.6), i.e., with *free* terminal time  $T \leq T_0$ , we need to adapt the notation because  $T$  is now a variable. As already mentioned in Remark 2.1(iii), the measure  $\nu$  in the infinite-dimensional LP  $\mathbf{P}$  defined in (2.13) is now supported in  $[0, T_0] \times \mathbf{K}$  (and  $[0, 1] \times \mathbf{K}$  after rescaling) instead of  $\mathbf{K}$  previously. Hence, the sequence  $y$  associated with  $\nu$  is now indexed in the basis  $\{t^p x^\alpha\}$  of  $\mathbb{R}[t, x]$  instead of  $\{x^\alpha\}$  previously. Therefore, given  $y = \{y_{k\alpha}\}$  indexed in that basis, let  $y(t)$  and  $y(x)$  be the subsequences of  $y$  defined by

$$y(t) := \{y_{k0}\}_k, \quad k \in \mathbb{N}; \quad y(x) = \{y_{0\alpha}\}, \quad \alpha \in \mathbb{N}^n.$$

Then again (after rescaling), the LMI-relaxation  $\mathbf{Q}_r$  now reads

$$(3.13) \quad \mathbf{Q}_r : \begin{cases} \inf_{y,z} L_z(h) + L_y(H), \\ M_r(y), M_r(z) \succeq 0, \\ M_{r-r(\theta_j)}(\theta_j y) \succeq 0, \quad j \in J_1, \\ M_{r-r(v_j)}(v_j z(x)) \succeq 0, \quad j \in J, \\ M_{r-r(w_k)}(w_k z(u)) \succeq 0, \quad k \in W, \\ M_{r-1}(t(1-t)y(t)) \succeq 0, \\ M_{r-1}(t(1-t)z(t)) \succeq 0, \\ L_y(g) - L_z(\partial g / \partial t + \langle \nabla_x g, f \rangle) = g(0, x_0) \quad \forall g = (t^p x^\alpha), \\ \text{with } p + |\alpha| - 1 + \deg f \leq 2r. \end{cases}$$

The particular case of the minimal time problem is obtained with  $h \equiv 1$ ,  $H \equiv 0$ .

For *time-homogeneous* problems, i.e., when  $h$  and  $f$  do not depend on  $t$ , one may take  $\mu$  (resp.,  $\nu$ ) supported on  $\mathbf{X} \times \mathbf{U}$  (resp.,  $\mathbf{K}$ ), which simplifies the associated LMI-relaxation (3.13).

The following is the main result.

**THEOREM 3.6.** *Let  $\mathbf{X}, \mathbf{K} \subset [-1, 1]^n$  and  $\mathbf{U} \subset [-1, 1]^m$  be compact basic semi-algebraic sets defined, respectively, by (3.1), (3.2), and (3.3). Assume that  $\mathbf{X}, \mathbf{K}$ , and  $\mathbf{U}$  satisfy Putinar's condition (see Definition 3.4), and let  $\mathbf{Q}_r$  be the LMI-relaxation defined in (3.12). Then*

- (i)  $\inf \mathbf{Q}_r \uparrow \min \mathbf{P}$  as  $r \rightarrow \infty$ ;
- (ii) *if, moreover, for every  $(t, x) \in \Sigma$ , the set  $f(t, x, \mathbf{U}) \subset \mathbb{R}^n$  is convex and the function*

$$v \mapsto g_{t,x}(v) := \inf_{u \in \mathbf{U}} \{ h(t, x, u) \mid v = f(t, x, u) \}$$

*is convex, then  $\inf \mathbf{Q}_r \uparrow \min \mathbf{P} = J^*(0, T, x_0)$ , as  $r \rightarrow \infty$ .*

The proof of this result is postponed to section A.2 of the appendix.

**Remark 3.7.** It is known that the HJB optimality equation

$$(3.14) \quad \inf_{u \in \mathbf{U}} \{ A v(s, x, u) + h(s, x, u) \} = 0, \quad (s, x) \in \Sigma,$$

with boundary condition  $v_T(x) (= v(T, x)) = H(x)$  for all  $x \in \mathbf{K}$ , may have no continuously differentiable solution  $v : [0, T] \times \mathbb{R}^n \rightarrow \mathbb{R}$ , because of possible shocks of characteristics. On the other hand, a function  $\varphi \in C_1(\Sigma)$  is said to be a smooth *subsolution* of the HJB equation (3.14) if it is a feasible solution of  $\mathbf{P}^*$ , i.e.,

$$(3.15) \quad A \varphi(t, x, u) + h(t, x, u) \geq 0, \quad (t, x, u) \in \mathbf{S}; \quad \varphi(T, x) \leq H(x), \quad x \in \mathbf{K};$$

see, e.g., Vinter [45]. The dual of the LMI-relaxation  $\mathbf{Q}_r$ , which is also an SDP denoted  $\mathbf{Q}_r^*$ , is a reinforcement of  $\mathbf{P}^*$  in the sense that we consider only polynomial subsolutions, and, in addition, the positivity condition in (3.15) is replaced by the Putinar representation (3.10). Next, as  $\mathbf{Q}_r^*$  is an approximation of  $\mathbf{P}^*$ , a topic of further research, beyond the scope of the present paper, is how to use  $\mathbf{Q}_r^*$  to provide some information on an optimal solution of the OCP (2.1)–(2.5).

**3.4. Certificates of uncontrollability.** For minimum time OCPs, i.e., with free terminal time  $T$  and instantaneous cost  $h \equiv 1$  and  $H \equiv 0$ , the LMI-relaxations  $\mathbf{Q}_r$  defined in (3.13) may provide *certificates* of uncontrollability.

Indeed, if for a given initial state  $x_0 \in \mathbf{X}$  some LMI-relaxation  $\mathbf{Q}_r$  in the hierarchy has *no* feasible solution, then the initial state  $x_0$  *cannot* be steered to the origin in finite time. In other words,  $\inf \mathbf{Q}_r = +\infty$  provides a certificate of uncontrollability of the initial state  $x_0$ . It turns out that sometimes such certificates can be provided at cheap cost, i.e., with LMI-relaxations of low order  $r$ . This is illustrated on the Zermelo problem in section 5.3.

Moreover, one may also consider controllability in given finite time  $T$ ; that is, consider the LMI-relaxations as defined in (3.12) with  $T$  fixed and  $H \equiv 0$ ,  $h \equiv 1$ . Again, if for a given initial state  $x_0 \in \mathbf{X}$  the LMI-relaxation  $\mathbf{Q}_r$  has no feasible solution, then the initial state  $x_0$  cannot be steered to the origin in less than  $T$  units of time. And so  $\inf \mathbf{Q}_r = +\infty$  also provides a certificate of uncontrollability of the initial state  $x_0$ .

**4. Generalization to smooth OCPs.** In the previous section, we assumed, to highlight the main ideas, that  $f$ ,  $h$ , and  $H$  were polynomials. In this section, we generalize Theorem 3.6 and simply assume that  $f$ ,  $h$ , and  $H$  are smooth. Consider the LP  $\mathbf{P}$  defined in the previous section:

$$\mathbf{P} : \begin{cases} \inf_{(\mu, \nu) \in \Delta} \{ \langle (\mu, \nu), (h, H) \rangle \\ \text{s.t.} \quad \langle g, \mathcal{L}^*(\mu, \nu) \rangle = g(0, x_0) \quad \forall g \in \mathbb{R}[t, x]. \end{cases}$$

Since the sets  $\mathbf{X}$ ,  $\mathbf{K}$ , and  $\mathbf{U}$ , defined previously, are compact, it follows from [10] (see also [26, pp. 65–66]) that  $f$  (resp.,  $h$ ,  $H$ ) is the limit in  $C_1(\mathbf{S})$  (resp.,  $C_1(\mathbf{S})$ ,  $C_1(\mathbf{K})$ ) of a sequence of polynomials  $f_p$  (resp.,  $h_p$ ,  $H_p$ ) of degree  $p$  as  $p \rightarrow +\infty$ .

Hence, for every integer  $p$ , consider the LP  $\mathbf{P}_p$ ,

$$\mathbf{P}_p : \begin{cases} \inf_{(\mu, \nu) \in \Delta} \{ \langle (\mu, \nu), (h_p, H_p) \rangle \\ \text{s.t.} \quad \langle g, \mathcal{L}_p^*(\mu, \nu) \rangle = g(0, x_0) \quad \forall g \in \mathbb{R}[t, x], \end{cases}$$

to be the smooth analogue of  $\mathbf{P}$ , where the linear mapping  $\mathcal{L}_p : C_1(\Sigma) \rightarrow C(\mathbf{S}) \times C(\mathbf{K})$  is defined by

$$\mathcal{L}_p \varphi := (-A_p \varphi, \varphi_T),$$

and where  $A_p : C_1(\Sigma) \rightarrow C(\mathbf{S})$  is defined by

$$A_p \varphi(t, x, u) := \frac{\partial \varphi}{\partial t}(t, x) + \langle f_p(t, x, u), \nabla_x \varphi(t, x) \rangle.$$

For every integer  $r \geq \max(p/2, d(\mathbf{X}, \mathbf{K}, \mathbf{U}))$ , let  $\mathbf{Q}_{r,p}$  denote the LMI-relaxation (3.12) associated with the LP  $\mathbf{P}_p$ .

Recall that from Theorem 3.6 if  $\mathbf{K}$ ,  $\mathbf{X}$ , and  $\mathbf{U}$  satisfy Putinar's condition, then  $\inf \mathbf{Q}_{r,p} \uparrow \min \mathbf{P}_p$  as  $r \rightarrow +\infty$ .

The next result, generalizing Theorem 3.6, shows that it is possible to let  $p$  tend to  $+\infty$ . For convenience, set

$$v_{r,p} = \inf \mathbf{Q}_{r,p}, \quad v_p = \min \mathbf{P}_p, \quad v = \min \mathbf{P}.$$

**THEOREM 4.1.** *Let  $\mathbf{X}, \mathbf{K} \subset [-1, 1]^n$  and  $\mathbf{U} \subset [-1, 1]^m$  be compact semialgebraic sets defined, respectively, by (3.1), (3.2), and (3.3). Assume that  $\mathbf{X}, \mathbf{K}$ , and  $\mathbf{U}$  satisfy Putinar's condition (see Definition 3.4). Then*

- (i)  $v = \lim_{p \rightarrow +\infty} \lim_{\substack{r \rightarrow +\infty \\ 2r > p}} v_{r,p} = \lim_{p \rightarrow +\infty} \sup_{r > p/2} v_{r,p} \leq J^*(0, T, x_0);$
- (ii) *moreover, if for every  $(t, x) \in \Sigma$ , the set  $f(t, x, \mathbf{U}) \subset \mathbb{R}^n$  is convex and the function*

$$v \mapsto g_{t,x}(v) := \inf_{u \in \mathbf{U}} \{ h(t, x, u) \mid v = f(t, x, u) \}$$

*is convex, then  $v = J^*(0, T, x_0)$ .*

The proof of this result is in section A.3 of the appendix.

From the numerical point of view, depending on the functions  $f$ ,  $h$ ,  $H$ , the degree of the polynomials of the approximate OCP  $\mathbf{P}_p$  may be required to be large, and hence the hierarchy of LMI-relaxations  $(\mathbf{Q}_r)$  in (3.12) might not be efficiently implementable, at least in view of the performances of public SDP solvers presently available.

*Remark 4.2.* The previous construction extends to smooth OCPs on Riemannian manifolds, as follows. Let  $M$  and  $N$  be smooth Riemannian manifolds. Consider on  $M$  the control system (2.1), where  $f : [0, +\infty) \times M \times N \rightarrow TM$  is smooth, and where the controls are bounded measurable functions, defined on intervals  $[0, T(\mathbf{u})]$  of  $\mathbb{R}^+$ , and taking their values in a compact subset  $\mathbf{U}$  of  $N$ . Let  $x_0 \in M$ , and let  $\mathbf{X}$  and  $\mathbf{K}$  be compact subsets of  $M$ . Admissible controls are defined as previously. For an admissible control  $\mathbf{u}$  on  $[0, T]$ , the cost of the associated trajectory  $x(\cdot)$  is defined by (2.4), where  $h : [0, +\infty) \times M \times N \rightarrow \mathbb{R}$  and  $H : M \rightarrow \mathbb{R}$  are smooth functions.

According to the Nash embedding theorem [35], there exists an integer  $n$  (resp.,  $m$ ) such that  $M$  (resp.,  $N$ ) is smoothly isometrically embedded in  $\mathbb{R}^n$  (resp.,  $\mathbb{R}^m$ ). In this context, all previous results apply.

This remark is important for the applicability of the method described in this article. Indeed, many practical control problems (particularly in mechanics) are expressed on manifolds, and since the OCP investigated here is global, such problems cannot be expressed in general as control systems in  $\mathbb{R}^n$  (in a global chart).

**5. Illustrative examples.** We consider here the minimal time OCP, that is, we aim to approximate the *minimal time* to steer a given initial condition to the origin. We have tested the above methodology on two test OCPs, the double integrator and the Brockett integrator, for which the associated optimal value  $T^*$  can be calculated exactly. The numerical examples in this section were processed with our MATLAB package *GloptiPoly 3*.<sup>1</sup>

**5.1. The double integrator.** Consider the double integrator system in  $\mathbb{R}^2$ ,

$$(5.1) \quad \begin{aligned} \dot{x}_1(t) &= x_2(t), \\ \dot{x}_2(t) &= u(t), \end{aligned}$$

where  $x = (x_1, x_2)$  is the state and the control  $\mathbf{u} = u(t) \in \mathcal{U}$  satisfies the constraint  $|u(t)| \leq 1$  for all  $t \geq 0$ . In addition, the state is constrained to satisfy  $x_2(t) \geq -1$  for all  $t$ . In this time-homogeneous case, and with the notation of section 2, we have  $\mathbf{X} = \{x \in \mathbb{R}^2 : x_2 \geq -1\}$ ,  $\mathbf{K} = \{(0, 0)\}$ , and  $\mathbf{U} = [-1, 1]$ .

Observe that  $\mathbf{X}$  is not compact and so the convergence result of Theorem 3.6 may not hold. In fact, we may impose the additional constraint  $\|x(t)\|_\infty \leq M$  for some large  $M$  (and modify  $\mathbf{X}$  accordingly), because for initial states  $x_0$  with  $\|x_0\|_\infty$  relatively small with respect to  $M$ , the optimal trajectory remains in  $\mathbf{X}$ . However, in the numerical experiments, we have not enforced an additional constraint. We have maintained the original constraint  $x_2 \geq -1$  in the localizing constraint  $M_{r-r(v_j)}(v_j z(x)) \geq 0$ , with  $x \mapsto v_j(x) = x_2 + 1$ .

**5.1.1. Exact computation.** For this very simple system, one is able to compute exactly the optimal minimum time [43]. Denoting  $T(x)$  the minimal time to reach the origin from  $x = (x_1, x_2)$ , we have the following:

If  $x_1 \geq 1 - x_2^2/2$  and  $x_2 \geq -1$ , then  $T(x) = x_2^2/2 + x_1 + x_2 + 1$ . If  $-x_2^2/2 \text{ sign } x_2 \leq x_1 \leq 1 - x_2^2/2$  and  $x_2 \geq -1$ , then  $T(x) = 2\sqrt{x_2^2/2 + x_1 + x_2}$ . If  $x_1 < -x_2^2/2 \text{ sign } x_2$  and  $x_2 \geq -1$ , then  $T(x) = 2\sqrt{x_2^2/2 - x_1 - x_2}$ . Note that the expressions in section III.A.1 of [33] are incorrect.

**5.1.2. Numerical approximation.** Table 1 displays the values of the initial state  $x_0 \in \mathbf{X}$ , and denoting  $\inf \mathbf{Q}_r(x_0)$  the optimal value of the LMI-relaxation (3.13) for the minimum time OCP (5.1) with initial state  $x_0$ , Tables 2, 3, and 4 display

<sup>1</sup> *GloptiPoly 3* can be downloaded from [www.laas.fr/~henrion/software](http://www.laas.fr/~henrion/software).

the numerical values of the ratios  $\inf \mathbf{Q}_r(x_0)/T(x_0)$  for  $r = 2, 3$ , and  $5$ , respectively. Columns and rows in Tables 2, 3, and 4 are, respectively, indexed by values of  $x_{01}$  and  $x_{02}$  indicated in Table 1. A ratio near 1 indicates a good approximation in relative value.

Figures 1, 2, and 3 display the level sets of the ratios  $\inf \mathbf{Q}_r/T(x_0)$  for  $r = 2, 3$ , and  $5$ , respectively. The closer the color is to white, the closer the ratio  $\inf \mathbf{Q}_r/T(x_0)$  is to 1.

Finally, for this double integrator example we have plotted in Figure 4 the level sets of the function  $\Lambda_5(x) - T(x)$ , where  $T(x)$  is the known optimal minimum time to steer the initial state  $x$  to 0; the problem being time-homogeneous, one may take  $\Lambda_r \in \mathbb{R}[x]$  instead of  $\mathbb{R}[t, x]$ . For instance, one may verify that when the initial state is in the region where the approximation is good, then the whole optimal trajectory also lies in that region.

**5.2. The Brockett integrator.** Consider the so-called *Brockett system* in  $\mathbb{R}^3$  (see [7]),

$$\begin{aligned} \dot{x}_1(t) &= u_1(t), \\ \dot{x}_2(t) &= u_2(t), \\ \dot{x}_3(t) &= u_1(t)x_2(t) - u_2(t)x_1(t), \end{aligned} \tag{5.2}$$

where  $x = (x_1, x_2, x_3)$ , and the control  $\mathbf{u} = (u_1(t), u_2(t)) \in \mathcal{U}$  satisfies the constraint

$$u_1(t)^2 + u_2(t)^2 \leq 1 \quad \forall t \geq 0. \tag{5.3}$$

In this case, we have  $\mathbf{X} = \mathbb{R}^3$ ,  $\mathbf{K} = \{(0, 0, 0)\}$ , and  $\mathbf{U}$  is the closed unit ball of  $\mathbb{R}^2$ , centered at the origin.

Note that set  $\mathbf{X}$  is not compact and so the convergence result of Theorem 3.6 may not hold; see the discussion at the beginning of Example 5.1. Nevertheless, in the numerical examples, we have not enforced additional state constraints.

**5.2.1. Exact computation.** Let  $T(x)$  be the minimum time needed to steer an initial condition  $x \in \mathbb{R}^3$  to the origin. We recall the following result of [2] (given in fact for an equivalent (reachability) OCP of steering the origin to a given point  $x$ ).

**PROPOSITION 5.1.** *Consider the minimum time OCP for the system (5.2) with control constraint (5.3). The minimum time  $T(x)$  needed to steer the origin to a point  $x = (x_1, x_2, x_3) \in \mathbb{R}^3$  is given by*

$$(5.4) \quad T(x_1, x_2, x_3) = \frac{\theta \sqrt{x_1^2 + x_2^2 + 2|x_3|}}{\sqrt{\theta + \sin^2 \theta - \sin \theta \cos \theta}},$$

where  $\theta = \theta(x_1, x_2, x_3)$  is the unique solution in  $[0, \pi)$  of

$$(5.5) \quad \frac{\theta - \sin \theta \cos \theta}{\sin^2 \theta} (x_1^2 + x_2^2) = 2|x_3|.$$

Moreover, the function  $T$  is continuous on  $\mathbb{R}^3$  and is analytic outside the line  $x_1 = x_2 = 0$ .

*Remark 5.2.* Along the line  $x_1 = x_2 = 0$ , one has

$$T(0, 0, x_3) = \sqrt{2\pi|x_3|}.$$

The singular set of the function  $T$ , i.e., the set where  $T$  is not  $C^1$ , is the line  $x_1 = x_2 = 0$  in  $\mathbb{R}^3$ . More precisely, the gradients  $\partial T / \partial x_i$ ,  $i = 1, 2$ , are discontinuous at every point  $(0, 0, x_3)$ ,  $x_3 \neq 0$ . For the interested reader, the level sets  $\{(x_1, x_2, x_3) \in \mathbb{R}^3 \mid T(x_1, x_2, x_3) = r\}$ , with  $r > 0$ , are displayed, e.g., in Prieur and Trélat [38].

**5.2.2. Numerical approximation.** Recall that the convergence result of Theorem 3.6 is guaranteed for  $\mathbf{X}$  compact only. However, in the present case  $\mathbf{X} = \mathbb{R}^3$  is not compact. One possibility is to take for  $\mathbf{X}$  a large ball of  $\mathbb{R}^3$  centered at the origin because for initial states  $x_0$  with norm  $\|x_0\|$  relatively small, the optimal trajectory remains in  $\mathbf{X}$ . However, in the numerical experiments presented below, we have chosen to maintain  $\mathbf{X} = \mathbb{R}^3$ , that is, the LMI-relaxation  $\mathbf{Q}_r$  does not include any localizing constraint  $M_{r-r(v_j)}(v_j z(x)) \succeq 0$  on the moment sequence  $z(x)$ .

Recall that  $\inf \mathbf{Q}_r \uparrow \min \mathbf{P}$  as  $r$  increases, i.e., the more moments we consider, the closer to the exact value we get.

In Table 5 we have displayed the optimal values  $\inf \mathbf{Q}_r$  for 16 different values of the initial state  $x(0) = x_0$ , in fact, all 16 combinations of  $x_{01} = 0$ ,  $x_{02} = 0, 1, 2, 3$ , and  $x_{03} = 0, 1, 2, 3$ . So, the entry (2, 3) of Table 5 for the second LMI-relaxation is  $\inf \mathbf{Q}_2$  for the initial condition  $x_0 = (0, 1, 2)$ . At some (few) places in the table, the \* indicates that the SDP solver encountered some numerical problems, which explains why one finds a lower bound  $\inf \mathbf{Q}_{r-1}$  slightly higher than  $\inf \mathbf{Q}_r$ , when practically equal to the exact value  $T^*$ .

Notice that the upper triangular part (i.e., when both first coordinates  $x_{02}, x_{03}$  of the initial condition are away from zero) displays very good approximations with low order moments. In addition, the further the coordinates from zero, the better.

For another set of initial conditions  $x_{01} = 1$  and  $x_{0i} = \{1, 2, 3\}$  Table 6 displays the results obtained at the LMI-relaxation  $\mathbf{Q}_4$ .

The regularity property of the minimal time function seems to be an important topic of further investigation.

**5.3. Certificate of uncontrollability in finite time.** Consider the so-called Zermelo problem in  $\mathbb{R}^2$  studied by Bokanowski et al. [5]:

$$(5.6) \quad \begin{aligned} \dot{x}_1(t) &= 1 - a x_2(t) + v \cos \theta, \\ \dot{x}_2(t) &= v \sin \theta, \end{aligned}$$

with  $a = 0.1$ . The state  $x$  is constrained to remain in the set  $\mathbf{X} := [-6, 2] \times [-2, 2] \subset \mathbb{R}^2$ , and we also have the control constraints  $0 \leq v \leq 0.44$ , as well as  $\theta \in [0, 2\pi]$ . The target  $\mathbf{K}$  to reach from an initial state  $x_0$  is the ball  $B(0, \rho)$ , with  $\rho := 0.44$ .

With the change of variable  $u_1 = v \cos \theta$ ,  $u_2 = v \sin \theta$ , and  $\mathbf{U} := \{u : u_1^2 + u_2^2 \leq \rho^2\}$ , this problem is formulated as a minimum time OCP with associated hierarchy of LMI-

FIG. 5. *Zermelo problem: uncontrollable states with  $\mathbf{Q}_1$ .*FIG. 6. *Zermelo problem: uncontrollable states with  $\mathbf{Q}_2$ .*

relaxations  $(\mathbf{Q}_r)$  defined in (3.13). Therefore, if an LMI-relaxation  $\mathbf{Q}_r$  at some stage  $r$  of the hierarchy is infeasible, then the OCP itself is infeasible; i.e., the initial state  $x_0$  cannot be steered to the target  $\mathbf{K}$  while the trajectory remains in  $\mathbf{X}$ .

Figures 5 and 6 display the uncontrollable initial states  $x_0 \in \mathbf{X}$  found with the infeasibility of the LMI-relaxations  $\mathbf{Q}_1$  and  $\mathbf{Q}_2$ , respectively. With  $\mathbf{Q}_1$ , i.e., by using only second moments, we already have a very good approximation of the controllable set displayed in [5], and  $\mathbf{Q}_2$  brings only a small additional set of uncontrollable states.

## Appendix.

**A.1. Proof of Theorem 2.3.** We first prove item (i). Consider the LP  $\mathbf{P}$  defined in (2.13), and assumed to be feasible. From the constraint  $\mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)}$ ,

one has

$$\int_{\mathbf{K}} g(T, x) d\nu - \int_{\mathbf{S}} \left( \frac{\partial g}{\partial t}(t, x) + \left\langle \frac{\partial g}{\partial x}(t, x), f(t, x, u) \right\rangle \right) d\mu = g(0, x_0) \quad \forall g \in C_1(\Sigma).$$

In particular, taking  $g(t, x) = 1$  and  $g(t, x) = T - t$ , it follows that  $\mu(\mathbf{S}) = T$  and  $\nu(\mathbf{K}) = 1$ . Hence, for every  $(\mu, \nu)$  satisfying  $\mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)}$ , the pair  $(\frac{1}{T}\mu, \nu)$  belongs to the unit ball  $B_1$  of  $(\mathcal{M}(\mathbf{S}) \times \mathcal{M}(\mathbf{K}))$ . From the Banach–Alaoglu theorem,  $B_1$  is compact for the weak\* topology, and even sequentially compact because  $B_1$  is metrizable (see, e.g., Hernández-Lerma and Lasserre [25, Lemma 1.3.2]). Since  $\mathcal{L}^*$  is continuous (see Remark 2.1), it follows that the set of  $(\mu, \nu)$  satisfying  $\mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)}$  is a closed subset of  $B_1 \cap (\mathcal{M}(\mathbf{S})_+ \times \mathcal{M}(\mathbf{K})_+)$ , and thus is compact. Moreover, since the LP  $\mathbf{P}$  is feasible, this set is nonempty. Finally, since the linear functional to be minimized is continuous,  $\mathbf{P}$  is solvable.

We next prove item (ii). Consider the set

$$D := \{(\mathcal{L}^*(\mu, \nu), \langle (h, H), (\mu, \nu) \rangle) \mid (\mu, \nu) \in \mathcal{M}(\mathbf{S})_+ \times \mathcal{M}(\mathbf{K})_+\}.$$

To prove that  $D$  is closed, consider a sequence  $\{(\mu_n, \nu_n)\}_{n \in \mathbb{N}}$  of  $\mathcal{M}(\mathbf{S})_+ \times \mathcal{M}(\mathbf{K})_+$  such that

$$(A.1) \quad (\mathcal{L}^*(\mu_n, \nu_n), \langle (h, H), (\mu_n, \nu_n) \rangle) \rightarrow (a, b)$$

for some  $(a, b) \in C_1(\Sigma)^* \times \mathbb{R}$ . This means that  $\mathcal{L}^*(\mu_n, \nu_n) \rightarrow a$  and  $\langle (h, H), (\mu_n, \nu_n) \rangle \rightarrow b$ . In particular, taking  $\varphi_0 := T - t$  and  $\varphi_1 = 1$ , there must hold

$$\mu_n(\mathbf{S}) = \langle \varphi_0, \mathcal{L}^*(\mu_n, \nu_n) \rangle \rightarrow \langle \varphi_0, a \rangle, \quad \nu_n(\mathbf{K}) = \langle \varphi_1, \mathcal{L}^*(\mu_n, \nu_n) \rangle \rightarrow \langle \varphi_1, a \rangle.$$

Hence, there exist  $n_0 \in \mathbb{N}$  and a ball  $B_r$  of  $\mathcal{M}(\mathbf{S}) \times \mathcal{M}(\mathbf{K})$ , such that  $(\mu_n, \nu_n) \in B_r$  for every  $n \geq n_0$ . Since  $B_r$  is compact, along a subsequence,  $(\mu_n, \nu_n)$  converges weakly to some  $(\mu, \nu) \in \mathcal{M}(\mathbf{S})_+ \times \mathcal{M}(\mathbf{K})_+$ . This fact, combined with (A.1) and the continuity of  $\mathcal{L}^*$ , yields  $a = \mathcal{L}^*(\mu, \nu)$  and  $b = \langle (h, H), (\mu, \nu) \rangle$ . Therefore, the set  $D$  is closed.

From Anderson and Nash [1, Theorems 3.10 and 3.22], it follows that there is no duality gap between  $\mathbf{P}$  and  $\mathbf{P}^*$ , and hence, with (i),  $\sup \mathbf{P}^* = \min \mathbf{P}$ .

Item (iii) follows from Vinter [45, Theorems 2.1 and 2.3] applied to the mappings

$$F(t, x) := f(t, x, U), \quad l(t, x, v) := \inf_{u \in U} \{ h(t, x, u) \mid v = f(t, x, u) \}$$

for  $(t, x) \in \mathbb{R} \times \mathbb{R}^n$ .  $\square$

**A.2. Proof of Theorem 3.6.** First of all, observe that  $\mathbf{Q}_r$  has a feasible solution. Indeed, it suffices to consider the sequences  $y$  and  $z$  consisting of the moments (up to order  $2r$ ) of the o.m.'s  $\nu^{\mathbf{u}}$  and  $\mu^{\mathbf{u}}$  associated with an admissible control  $\mathbf{u} \in \mathcal{U}$  of the OCP (2.1)–(2.5).

Next, observe that for every couple  $(y, z)$  satisfying all constraints of  $\mathbf{Q}_r$ , there must hold  $y_0 = 1$  and  $z_0 = 1$ . Indeed, it suffices to choose  $g(t, x) = 1$  and  $g(t, x) = 1 - t$  (or  $t$ ) in the constraint

$$L_y(g_1) - L_z(\partial g / \partial t + \langle \nabla_x g, f \rangle) = g(0, x_0).$$

We next prove that for  $r$  sufficiently large, one has  $|z(x)_\alpha| \leq 1$ ,  $|z(u)_\beta| \leq 1$ ,  $|z(t)_k| \leq 1$  for every  $k$ , and  $|y_\alpha| \leq 1$ . We provide details only of the proof for  $z(x)$ , the arguments being similar for  $z(u)$ ,  $z(t)$ , and  $y$ .

Let  $\Sigma^2 \subset \mathbb{R}[x]$  be the space of sum of squares polynomials, and let  $Q \subset \mathbb{R}[x]$  be the *quadratic modulus* generated by the polynomials  $v_j \in \mathbb{R}[x]$  that define  $\mathbf{X}$ , i.e.,

$$Q := \left\{ \sigma \in \mathbb{R}[x] \mid \sigma = \sigma_0 + \sum_{j \in J} \sigma_j v_j \quad \text{with } \sigma_j \in \Sigma^2 \quad \forall j \in \{0\} \cup J \right\}.$$

In addition, let  $Q(t) \subset Q$  be the set of elements  $\sigma$  of  $Q$  which have a representation  $\sigma_0 + \sum_{j \in J} \sigma_j v_j$  for some sum of squares family  $\{\sigma_j\} \subset \Sigma^2$  with  $\deg \sigma_0 \leq 2t$  and  $\deg \sigma_j v_j \leq 2t$  for every  $j \in J$ .

Let  $r \in \mathbb{N}$  be fixed. Since  $\mathbf{X} \subset [-1, 1]^n$ , there holds  $1 \pm x^\alpha > 0$  on  $\mathbf{X}$  for every  $\alpha \in \mathbb{N}^n$  with  $|\alpha| \leq 2r$ . Therefore, since  $\mathbf{X}$  satisfies Putinar's condition (see Definition 3.4), the polynomial  $x \mapsto 1 \pm x^\alpha$  belongs to  $Q$  (see Putinar [39]). Moreover, there exists  $l(r)$  such that  $x \mapsto 1 \pm x^\alpha \in Q(l(r))$  for every  $|\alpha| \leq 2r$ . Of course,  $x \mapsto 1 \pm x^\alpha \in Q(l)$  for every  $|\alpha| \leq 2r$  whenever  $l \geq l(r)$ .

For every feasible solution  $z$  of  $\mathbf{Q}_{l(r)}$  one has

$$|z(x)_\alpha| = |L_z(x^\alpha)| \leq z_0 = 1, \quad |\alpha| \leq 2r.$$

This follows from  $z_0 = 1$ ,  $M_{l(r)}(z) \succeq 0$ , and  $M_{l(r)-r(v_j)}(v_j z(x)) \succeq 0$  which implies

$$z_0 \pm z(x)_\alpha = L_z(1 \pm x^\alpha) = L_z(\sigma_0) + \sum_{j=1}^m L_{z(x)}(\sigma_j v_j) \geq 0.$$

With similar arguments, one redefines  $l(r)$  so that, for every couple  $(y, z)$  satisfying the constraints of  $\mathbf{Q}_{l(r)}$ , one has

$$0 \leq z_k(t) \leq 1 \quad \text{and} \quad |z(x)_\alpha|, |z(u)_\beta|, |y_\alpha| \leq 1 \quad \forall k, |\alpha|, |\beta| \leq 2r.$$

From this, and with  $l(r) := 2l(r)$ , we immediately deduce that  $|z_\gamma| \leq 1$  whenever  $|\gamma| \leq 2r$ . In particular,  $L_y(H) + L_z(h) \geq -\sum_\beta |H_\beta| - \sum_\gamma |h_\gamma|$ , which proves that  $\inf \mathbf{Q}_{l(r)} > -\infty$ , and so  $\inf \mathbf{Q}_r > -\infty$  for  $r$  sufficiently large.

Let  $\rho := \inf \mathbf{P} = \min \mathbf{P}$  (by Theorem 2.3), let  $r \geq l(r_0)$ , and let  $(z^r, y^r)$  be a nearly optimal solution of  $\mathbf{Q}_r$  with value

$$(A.2) \quad \inf \mathbf{Q}_r \leq L_{z^r}(h) + L_{y^r}(H) \leq \inf \mathbf{Q}_r + \frac{1}{r} \quad \left( \leq \rho + \frac{1}{r} \right).$$

Complete the finite vectors  $y^r$  and  $z^r$  with zeros to make them infinite sequences. Since for arbitrary  $s \in \mathbb{N}$  one has  $|y_\alpha^r|, |z_\gamma^r| \leq 1$  whenever  $|\alpha|, |\gamma| \leq 2s$ , provided  $r$  is sufficiently large, by a standard diagonal argument, there exists a subsequence  $\{r_k\}$  and two infinite sequences  $y$  and  $z$ , with  $|y_\alpha| \leq 1$  and  $|z_\gamma| \leq 1$  for all  $\alpha, \gamma$ , and such that

$$(A.3) \quad \lim_{k \rightarrow \infty} y_\alpha^{r_k} = y_\alpha \quad \forall \alpha \in \mathbb{N}^n, \quad \lim_{k \rightarrow \infty} z_\gamma^{r_k} = z_\gamma \quad \forall \gamma \in \mathbb{N} \times \mathbb{N}^n \times \mathbb{N}^m.$$

Next, let  $r$  be fixed arbitrarily. Observe that  $M_{r_k}(y^{r_k}) \succeq 0$  implies  $M_r(y^{r_k}) \succeq 0$  whenever  $r_k \geq r$ , and similarly  $M_r(z^{r_k}) \succeq 0$ . Therefore, from (A.3) and  $M_r(y^{r_k}) \succeq 0$ , we deduce that  $M_r(y) \succeq 0$ , and similarly  $M_r(z) \succeq 0$ . Since this holds for arbitrary  $r$ , and  $|y_\alpha|, |z_\gamma| \leq 1$  for all  $\alpha, \gamma$ , one infers from Proposition 3.2 that  $y$  and  $z$  are moment sequences of two measures  $\nu$  and  $\mu$  with support contained in  $[-1, 1]^n$  and  $[0, 1] \times [-1, 1]^n \times [-1, 1]^m$ , respectively. In addition, from the equalities  $y_0^{r_k} = 1$  and

$z_0^{rk} = 1$  for every  $k$ , it follows that  $\nu$  and  $\mu$  are probability measures on  $[-1, 1]^n$  and  $[0, 1] \times [-1, 1]^n \times [-1, 1]^m$ .

Next, let  $(t, \alpha) \in \mathbb{N} \times \mathbb{N}^n$  be fixed arbitrarily. From

$$L_{y^{rk}}(g_1) - g(0, x_0) - L_{z^{rk}}(\partial g / \partial t + \langle \nabla_x g, f \rangle) = 0, \quad \text{with } g = (t^p x^\alpha),$$

and the convergence (A.3), we obtain

$$L_y(g_1) - g(0, x_0) - L_z(\partial g / \partial t + \langle \nabla_x g, f \rangle) = 0, \quad \text{with } g = (t^p x^\alpha),$$

that is,  $\langle \mathcal{L}g, (\mu, \nu) \rangle = \langle g, \delta_{(0, x_0)} \rangle$ . Since  $(t, \alpha) \in \mathbb{N} \times \mathbb{N}^n$  is arbitrary, we have

$$\langle g, \mathcal{L}^*(\mu, \nu) \rangle = \langle \mathcal{L}g, (\mu, \nu) \rangle = \langle g, \delta_{(0, x_0)} \rangle \quad \forall g \in \mathbb{R}[t, x],$$

which implies that  $\mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)}$ .

Let  $z(x)$ ,  $z(u)$ , and  $z(t)$  denote the moment vectors of the marginals of  $\mu$  with respect to the variables  $x \in \mathbb{R}^n$ ,  $u \in \mathbb{R}^m$ , and  $t \in \mathbb{R}$ , respectively, i.e.,

$$z(x)^\alpha = \int x^\alpha \mu(d(t, x, u)) \quad \forall \alpha \in \mathbb{N}^n, \quad z(u)^\beta = \int u^\beta \mu(d(t, x, u)) \quad \forall \beta \in \mathbb{N}^m,$$

and  $z(t)^k = \int t^k \mu(d(t, x, u))$  for every  $k \in \mathbb{N}$ .

With  $r$  fixed arbitrarily, and using again (A.3), we also have  $M_r(\theta_j y) \succeq 0$  for every  $j \in J_T$ , and

$$M_r(v_j z(x)) \succeq 0 \quad \forall j \in J, \quad M_r(w_k z(u)) \succeq 0 \quad \forall k \in W, \quad M_r(t(1-t)z(t)) \succeq 0.$$

Since  $\mathbf{X}$ ,  $\mathbf{K}$ , and  $\mathbf{U}$  satisfy Putinar's condition (see Definition 3.4), from Theorem 3.5 (Putinar's Positivstellensatz),  $y$  is the moment sequence of a probability measure  $\nu$  supported on  $\mathbf{K} \subset [-1, 1]^n$ . Similarly,  $z(x)$  is the moment sequence of a measure  $\mu^x$  supported on  $\mathbf{X} \subset [-1, 1]^n$ ,  $z(u)$  is the moment sequence of a measure  $\mu^u$  supported on  $\mathbf{U} \subset [-1, 1]^m$ , and  $z(t)$  is the moment sequence of a measure  $\mu^t$  supported on  $[0, 1]$ . Since measures on compact sets are moment determinate, it follows that  $\mu^x$ ,  $\mu^u$ , and  $\mu^t$  are the marginals of  $\mu$  with respect to  $x$ ,  $u$ , and  $t$ , respectively. Therefore,  $\mu$  has its support contained in  $\mathbf{S}$ , and from  $\mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)}$  it follows that  $(\mu, \nu)$  satisfies all constraints of the problem  $\mathbf{P}$ .

Moreover, one has

$$\begin{aligned} \lim_{k \rightarrow \infty} \inf \mathbf{Q}_{rk} &= \lim_{k \rightarrow \infty} L_{z^{rk}}(h) + L_{y^{rk}}(H) \quad (\text{by (A.2)}) \\ &= L_z(h) + L_y(H) \quad (\text{by (A.3)}) \\ &= \int h d\mu + \int H d\nu \leq \rho = \min \mathbf{P}. \end{aligned}$$

Hence,  $(\mu, \nu)$  is an optimal solution of  $\mathbf{P}$ , and  $\min \mathbf{Q}_r \uparrow \min \mathbf{P}$  (the sequence is monotone nondecreasing). Item (i) is proved.

Item (ii) follows from Theorem 2.3(iii).  $\square$

**A.3. Proof of Theorem 4.1.** It suffices to prove that  $v_p \rightarrow v$  as  $p \rightarrow +\infty$ . For every integer  $p$ ,  $v_p = \min \mathbf{P}_p$  is attained for a couple of measures  $(\mu_p, \nu_p)$ . As in the proof of Theorem 2.3, the sequence  $\{(\mu_p, \nu_p)\}_{p \in \mathbb{N}}$  is bounded in  $\mathcal{M}(\mathbf{S})_+ \times \mathcal{M}(\mathbf{K})_+$ , and hence, along a subsequence, it converges to an element  $(\mu, \nu)$  of this space for the weak\* topology.

On the one hand, by definition,  $\mathcal{L}_p^*(\mu_p, \nu_p) = \delta_{(0, x_0)}$  for every  $p$ . On the other,  $\mathcal{L}_p^*$  tends strongly to  $\mathcal{L}^*$ , and so  $\mathcal{L}^*(\mu, \nu) = \delta_{(0, x_0)}$ . Moreover, since  $(h_p, H_p)$  tends strongly to  $(h, H)$  in  $C_1(\mathbf{S}) \times C_1(\mathbf{K})$ , one has

$$v_p = \langle (\mu_p, \nu_p), (h_p, H_p) \rangle \longrightarrow \langle (\mu, \nu), (h, H) \rangle,$$

and so  $v \leq \langle (\mu, \nu), (h, H) \rangle$ . We next prove that  $v = \langle (\mu, \nu), (h, H) \rangle$ .

Since  $(\mu_p, \nu_p)$  is an optimal solution of  $\mathbf{P}_p$ ,

$$\langle (\mu_p, \nu_p), (h_p, H_p) \rangle \leq \langle (\bar{\mu}, \bar{\nu}), (h_p, H_p) \rangle \quad \forall (\bar{\mu}, \bar{\nu}) \mid \mathcal{L}_p^*(\bar{\mu}, \bar{\nu}) = \delta_{(0, x_0)}.$$

Hence, passing to the limit,

$$\langle (\mu, \nu), (h, H) \rangle \leq \langle (\bar{\mu}, \bar{\nu}), (h, H) \rangle \quad \forall (\bar{\mu}, \bar{\nu}) \mid \mathcal{L}^*(\bar{\mu}, \bar{\nu}) = \delta_{(0, x_0)},$$

and so  $(\mu, \nu)$  is an optimal solution of  $\mathbf{P}$ , i.e.,  $v = \langle (\mu, \nu), (h, H) \rangle$ .  $\square$

## DUALITY IN LINEAR PROGRAMMING PROBLEMS RELATED TO DETERMINISTIC LONG RUN AVERAGE PROBLEMS OF OPTIMAL CONTROL\*

LUKE FINLAY<sup>†</sup>, VLADIMIR GAITSGORY<sup>†</sup>, AND IVAN LEBEDEV<sup>‡</sup>

**Abstract.** It has been established recently that, under mild conditions, deterministic long run average problems of optimal control are “asymptotically equivalent” to infinite-dimensional linear programming problems (LPPs) and that these LPPs can be approximated by finite-dimensional LPPs. In this paper we introduce the corresponding infinite- and finite-dimensional dual problems and study duality relationships. We also investigate the possibility of using solutions of finite-dimensional LPPs and their duals for numerical construction of the optimal controls in periodic optimization problems. The construction is illustrated with a numerical example.

**Key words.** long run average optimal control, occupational measures, averaging, linear programming, duality

**1. Introduction.** Infinite horizon problems of optimal control have been studied intensively in both deterministic and stochastic settings (see [1], [2], [3], [6], [7], [8], [9], [12], [14], [18], [19], [20], [21], [23], [26], [31], [37], [42], [43], [47], [56], and references therein for a sample of the literature on the subject) with linear programming formulations being one of the main tools of treating stochastic problems (see, e.g., [13], [16], [5], [38], [39], [41], [46], [51], [52], [60]).

A linear programming approach to deterministic long run average problems of optimal control was considered in [32] and [33], where it was established that these problems are “asymptotically equivalent” to infinite-dimensional (I-D) linear programming problems (LPPs) similar to those arising in stochastic control (see [13], [16], [41], [52]), and it has been shown that these I-D LPPs can be approximated by finite-dimensional (F-D) LPPs (F-D approximations of I-D LPPs arising in stochastic control problems and in deterministic problems on finite intervals of time have been studied in [38], [46], and in [48], respectively; F-D approximations of I-D LPPs arising in certain problems of calculus of variations have been considered in [24]).

In this paper we introduce problems dual to the LPPs considered in [32] and [33] (both F-D and I-D), and we study the corresponding duality relationships. We also investigate the possibility of using solutions of F-D LPPs and their duals for numerical construction of optimal controls in periodic optimization problems (thus refining the corresponding results of [32], where the option of using dual solutions was not considered).

Periodic optimization problems (POPs) constitute a special family of long run average problems of optimal control, in which solutions are sought over the class of periodic regimes. POPs arise in various applications, including vibration damping, production planning, flight control, chemical engineering, ecological modeling (see [40], [45], [50], [53], [59], and references therein). A linear programming approach that we continue to develop in the present paper provides a new analytical and numerical tool for dealing with this important family of control problems.

The paper is organized as follows. Sections 2 and 3 contain some preliminaries, the purpose of which is to help the reader put the developments of the subsequent sections into perspective. In section 2, long run average problems of optimal control and their reformulations in terms of occupational measures are considered. In section 3, some results of [32] and [33] that establish connections between the long run average problems of optimal control and the I-D LPPs are restated.

Sections 4, 5, and 6 contain the main duality results. In section 4, the problem dual to the I-D LPP is introduced and duality relationships are established (Theorem 4.1). The dual problem proves to be closely related to the Hamilton–Jacobi–Bellman equation. Its solution is used to state some necessary and sufficient optimality conditions (Proposition 4.3 and Corollaries 4.4 and 4.5). In section 5, duality relationships for an I-D LPP with a finite number of constraints are discussed (Theorem 5.2) and convergence properties (as the number of constraints goes to infinity) are established (Proposition 5.1 and Theorem 5.6). In section 6, an F-D LPPs (defined on grid points) and its dual are considered, with their convergence properties (as the grid size goes to zero) being established (Theorems 6.1 and 6.2). Also, in this section, a construction of an approximate solution of the problem dual to the I-D LPPs introduced in section 4 is discussed (Proposition 6.3).

Sections 7 and 8 are devoted to construction of solutions of periodic optimization problems. In section 7, it is established that, under certain conditions, the control found with the help of an approximate solution of the problem dual to the I-D LPP (constructed in section 6) converges to the optimal control (Theorem 7.1 and Corollary 7.2). In section 8, a numerical example is considered to illustrate the construction.

In sections 9 and 10, the proofs for sections 4, 5, 6, and 7, respectively, are collected.

**2. Preliminaries I: Occupational measures formulations.** Consider the control system

$$(2.1) \quad \dot{y}(\tau) = f(u(\tau), y(\tau)), \quad \tau \in [0, S],$$

where the function  $f(u, y) : U \times \mathbb{R}^m \rightarrow \mathbb{R}^m$  is continuous in  $(u, y)$  and satisfies Lipschitz conditions in  $y$ ; the controls are Lebesgue measurable functions  $u(\tau) : [0, S] \rightarrow U$  and  $U$  is a compact metric space.

A pair  $(u(\tau), y(\tau))$  will be called *admissible* on the interval  $[0, S]$  if (2.1) is satisfied for almost all  $\tau \in [0, S]$  and  $y(\tau) \in Y \quad \forall \tau \in [0, S]$ , where  $Y$  is a given compact subset of  $\mathbb{R}^m$ . The pair will be called admissible on  $[0, \infty)$  if it is admissible on any interval  $[0, S]$ ,  $S > 0$ .

Let  $\mathcal{P}(U)$  be the space of probability measures defined on the Borel subsets of  $U$  and  $\bar{f}(\nu, y) \stackrel{\text{def}}{=} \int_U f(u, y) \nu(du)$ . Along with (2.1), let us consider a relaxed control system

$$(2.2) \quad \dot{y}(\tau) = \bar{f}(\nu(\tau), y(\tau)), \quad \tau \in [0, S],$$

in which controls are measurable functions  $\nu(\tau) \in \mathcal{P}(U)$  (see [58]).

A pair  $(\nu(\tau), y(\tau))$  will be called *relaxed admissible* on the interval  $[0, S]$  if (2.2) is satisfied for almost all  $\tau \in [0, S]$  and  $y(\tau) \in Y \forall \tau \in [0, S]$ . The pair will be called relaxed admissible on  $[0, \infty)$  if it is relaxed admissible on any interval  $[0, S]$ ,  $S > 0$ .

Let  $g(u, y) : U \times \mathbb{R}^m \rightarrow \mathbb{R}^1$  be a continuous function. We will be considering the optimal control problem

$$(2.3) \quad \frac{1}{S} \inf_{(u(\cdot), y(\cdot))} \int_0^S g(u(\tau), y(\tau)) d\tau \stackrel{\text{def}}{=} G(S)$$

and the corresponding relaxed optimal control problem

$$(2.4) \quad \frac{1}{S} \inf_{(\nu(\cdot), y(\cdot))} \int_0^S \bar{g}(\nu(\tau), y(\tau)) d\tau \stackrel{\text{def}}{=} \bar{G}(S),$$

where  $\bar{g}(\nu, u) \stackrel{\text{def}}{=} \int_U g(u, y) \nu(dy)$ , and the first (second) inf is over all admissible (respectively, relaxed admissible) pairs.

Let  $\mathcal{P}(U \times Y)$  stand for the space of probability measures defined on the Borel subsets of  $U \times Y$ . Given an admissible pair  $(u(\cdot), y(\cdot))$ , a probability measure  $\gamma \in \mathcal{P}(U \times Y)$  will be said to be generated by this pair on the interval  $[0, S]$  if

$$(2.5) \quad \int_{U \times Y} q(u, y) \gamma(du, dy) = \frac{1}{S} \int_0^S q(u(\tau), y(\tau)) d\tau$$

for any  $q(\cdot) \in C(U \times Y)$  (the space of continuous functions on  $U \times Y$ ). A probability measure  $\gamma \in \mathcal{P}(U \times Y)$  will be said to be generated by an admissible pair  $(u(\cdot), y(\cdot))$  on  $[0, \infty)$  if

$$(2.6) \quad \int_{U \times Y} q(u, y) \gamma(du, dy) = \lim_{S \rightarrow \infty} \frac{1}{S} \int_0^S q(u(\tau), y(\tau)) d\tau$$

for any  $q(\cdot) \in C(U \times Y)$  (the limit in the right-hand side of (2.6) is assumed to exist). Given a relaxed admissible pair  $(\nu(\tau), y(\tau))$ , a probability measure  $\gamma \in \mathcal{P}(U \times Y)$  will be said to be generated by this pair on the interval  $[0, S]$  if

$$(2.7) \quad \int_{U \times Y} q(u, y) \gamma(du, dy) = \frac{1}{S} \int_0^S \bar{q}(\nu(\tau), y(\tau)) d\tau$$

for any  $q(\cdot) \in C(U \times Y)$ , with

$$(2.8) \quad \bar{q}(\nu, u) \stackrel{\text{def}}{=} \int_U q(u, y) \nu(dy).$$

A probability measure  $\gamma \in \mathcal{P}(U \times Y)$  will be said to be generated by an admissible pair  $(\nu(\cdot), y(\cdot))$  on  $[0, \infty)$  if

$$(2.9) \quad \int_{U \times Y} q(u, y) \gamma(du, dy) = \lim_{S \rightarrow \infty} \frac{1}{S} \int_0^S \bar{q}(\nu(\tau), y(\tau)) d\tau$$

for any  $q(\cdot) \in C(U \times Y)$  and  $\bar{q}(\cdot)$  is as in (2.8) (the limit in the right-hand side of (2.9) is assumed to exist).

Thus defined probability measures are called occupational measures (see, e.g., [7] and [30]). In what follows  $\gamma^{(S,u(\cdot),y(\cdot))}$ ,  $\gamma^{(u(\cdot),y(\cdot))}$  will stand for the occupational measures generated by an admissible pair  $(u(\cdot), y(\cdot))$  on  $[0, S]$  and  $[0, \infty)$ , respectively, and  $\gamma^{(S,\nu(\cdot),y(\cdot))}$ ,  $\gamma^{(\nu(\cdot),y(\cdot))}$  will stand for the occupational measures generated by a relaxed admissible pair  $(\nu(\cdot), y(\cdot))$  on  $[0, S]$  and  $[0, \infty)$ , respectively.

Denote by  $\Gamma(S) \subset \mathcal{P}(U \times Y)$  and  $\bar{\Gamma}(S) \subset \mathcal{P}(U \times Y)$  the set of all occupational measures generated by the admissible (respectively, relaxed admissible) pairs on the interval  $[0, S]$ . That is,

$$(2.10) \quad \Gamma(S) \stackrel{\text{def}}{=} \bigcup_{(u(\cdot), y(\cdot))} \left\{ \gamma^{(S,u(\cdot),y(\cdot))} \right\}, \quad \bar{\Gamma}(S) \stackrel{\text{def}}{=} \bigcup_{(\nu(\cdot), y(\cdot))} \left\{ \gamma^{(S,\nu(\cdot),y(\cdot))} \right\},$$

where the unions are over all admissible and, respectively, relaxed admissible pairs on  $[0, S]$ . Using these notations, one can rewrite the problem (2.3) as

$$(2.11) \quad \inf_{\gamma \in \Gamma(S)} \int_{U \times Y} g(u, y) \gamma(du, dy) = G(S)$$

and the problem (2.4) as

$$(2.12) \quad \inf_{\gamma \in \bar{\Gamma}(S)} \int_{U \times Y} g(u, y) \gamma(du, dy) = \bar{G}(S).$$

Note that  $\Gamma(S) \subset \bar{\Gamma}(S)$  and  $G(S) \geq \bar{G}(S)$ . In a special case when  $Y$  is forward invariant with respect to the solutions of (2.1), from Filippov–Wazewski’s theorem (see, e.g., Theorem 10.4.4 in [11]) it follows that  $\bar{\Gamma}(S)$  is equal to the closure of  $\Gamma(S)$  and  $G(S) = \bar{G}(S)$  for any  $S > 0$ .

Let us introduce a metric  $\rho(\cdot, \cdot)$  on  $\mathcal{P}(U \times Y)$  by the equation

$$(2.13) \quad \rho(\gamma', \gamma'') \stackrel{\text{def}}{=} \sum_{j=1}^{\infty} \frac{1}{2^j} \left| \int_{U \times Y} q_j(u, y) \gamma'(du, dy) - \int_{U \times Y} q_j(u, y) \gamma''(du, dy) \right|,$$

where  $\gamma', \gamma'' \in \mathcal{P}(U \times Y)$ , and  $q_j(\cdot), j = 1, 2, \dots$ , is a sequence of Lipschitz continuous functions that is dense in the unit ball of  $C(U \times Y)$ . Note that this metric is consistent with the topology of weak convergence in  $\mathcal{P}(U \times Y)$ . Namely, a sequence  $\gamma^k \in \mathcal{P}(U \times Y)$  converges to  $\gamma \in \mathcal{P}(U \times Y)$  in this metric if and only if

$$(2.14) \quad \lim_{k \rightarrow \infty} \int_{U \times Y} q(u, y) \gamma^k(du, dy) = \int_{U \times Y} q(u, y) \gamma(du, dy)$$

for any  $q(\cdot) \in C(U \times Y)$ . Note also that the space  $\mathcal{P}(U \times Y)$  is known to be compact in the topology of weak convergence (see, e.g., [15]), and, hence, being equipped with the metric (2.13), it becomes a compact metric space.

Using  $\rho(\cdot, \cdot)$ , one can define the Hausdorff metric on the subsets of  $\mathcal{P}(U \times Y)$  as follows: for any  $\Gamma_1 \subset \mathcal{P}(U \times Y)$  and  $\Gamma_2 \subset \mathcal{P}(U \times Y)$ ,

$$(2.15) \quad \begin{aligned} \rho_H(\Gamma_1, \Gamma_2) &\stackrel{\text{def}}{=} \max \left\{ \sup_{\gamma \in \Gamma_1} \rho(\gamma, \Gamma_2), \sup_{\gamma \in \Gamma_2} \rho(\gamma, \Gamma_1) \right\}, \\ \rho(\gamma, \Gamma_i) &\stackrel{\text{def}}{=} \inf_{\gamma' \in \Gamma_i} \rho(\gamma, \gamma'), \quad i = 1, 2. \end{aligned}$$

Note that, although, by some abuse of terminology, we call  $\rho_H(\cdot, \cdot)$  a metric on the set of subsets of  $\mathcal{P}(U \times Y)$ , it is, in fact, a semimetric on this set (since  $\rho_H(\Gamma_1, \Gamma_2) = 0$  implies that  $\Gamma_1 = \Gamma_2$  if and only if  $\Gamma_1$  and  $\Gamma_2$  are closed).

**3. Preliminaries II: Limit linear programming problem.** Define the set  $W \subset \mathcal{P}(U \times Y)$  by the equation

$$(3.1) \quad W \stackrel{\text{def}}{=} \left\{ \gamma \in \mathcal{P}(U \times Y) : \int_{U \times Y} (\phi'(y))^T f(u, y) \gamma(du, dy) = 0 \quad \forall \phi(\cdot) \in C^1 \right\},$$

where  $C^1$  is the space of continuously differentiable functions  $\phi(y) : \mathbb{R}^m \rightarrow \mathbb{R}^1$  and  $\phi'(y)$  is a vector column of partial derivatives (the gradient) of  $\phi(y)$ .

It is easy to see that  $W$  is closed and compact in weak convergence topology of  $\mathcal{P}(U \times Y)$ . Also, it is easy to see that  $W$  is convex.

Assuming that  $W$  is not empty (see Remark 4.2 below about a necessary and sufficient condition for this to be the case), let us consider the problem

$$(3.2) \quad \min_{\gamma \in W} \int_{U \times Y} g(u, y) \gamma(du, dy) \stackrel{\text{def}}{=} G_*,$$

where  $g(\cdot)$  is the same as in (2.3) and (2.11). Since both the objective function and the constraints defining  $W$  are linear in  $\gamma$ , the problem (3.2) is that of I-D linear programming (see, e.g., [4]). Note that a problem similar to (3.2) was introduced in [41] and [52] in a much more general stochastic setting. The problem (3.2) will in what follows be referred to as the limit linear programming problem (LLPP). In the rest of this section we restate some results of [32] and [33] that are important for our further consideration.

**THEOREM 3.1.** (i) *If the set  $W$  is empty, then there exists  $S_0 > 0$  such that  $\bar{\Gamma}(S)$  (and, hence,  $\Gamma(S)$ ) are empty for  $S \geq S_0$ . If  $W$  is not empty, then  $\bar{\Gamma}(S)$  is not empty for  $S > 0$ . If  $W$  is not empty and, in addition, the set  $f(U, y) \stackrel{\text{def}}{=} \{\eta : \eta = f(u, y), u \in U\}$  is convex for all  $y \in Y$ , then  $\Gamma(S)$  is not empty for  $S > 0$ .*

(ii) *Let  $W$  be not empty. Then*

$$(3.3) \quad \lim_{S \rightarrow \infty} \rho_H(\text{co}\bar{\Gamma}(S), W) = 0$$

and

$$(3.4) \quad \lim_{S \rightarrow \infty} \bar{G}(S) = G_*.$$

(iii) *If  $Y$  is forward invariant, then*

$$(3.5) \quad \lim_{S \rightarrow \infty} \rho_H(\text{co}\Gamma(S), W) = 0$$

and

$$(3.6) \quad \lim_{S \rightarrow \infty} G(S) = G_*.$$

*Proof.* The statements (i) and (ii) have been established in [33], their proofs being similar to the proofs of Theorem 2.1 in [29] and Proposition 5 in [32]. The statement (iii) is implied by Proposition 5 in [32].  $\square$

**Remark 3.2.** In the terminology introduced in [10], the fact that the set  $\Gamma(s)$  (or  $\bar{\Gamma}(s)$ ) is not empty for all  $S > 0$  means that the *viability kernel* of the control system (2.1) (respectively, relaxed control system (2.2)) is not empty in  $Y$ . Hence, from Theorem 3.1(i) it follows that the viability kernel of the relaxed control system (2.2) is not empty in  $Y$  if and only if  $W$  is not empty, and, under the condition that

the set  $f(U, y)$  is convex for all  $y \in Y$ , the viability kernel of the control system (2.1) is not empty in  $Y$  if and only if  $W$  is not empty. Note that an alternative way of establishing this statement was proposed by Quincampoix, and it will be included in a separate publication.

**THEOREM 3.3.** *Assume that  $W$  is not empty. Then, corresponding to any extreme point  $\gamma$  of  $W$ , there exists a relaxed admissible pair  $(\nu(\cdot), y(\cdot))$  such that  $\gamma$  is generated by this pair on  $[0, \infty)$  (that is,  $\gamma = \gamma^{(\nu(\cdot), y(\cdot))}$ ).*

*Proof.* The theorem has been established in [33]. The proof is based on Proposition 4.4 in [17] and on Lemma 5.1 in [29].  $\square$

Consider the problem

$$(3.7) \quad \inf_{(u(\cdot), y(\cdot))} \lim_{S \rightarrow \infty} \frac{1}{S} \int_0^S g(u(\tau), y(\tau)) d\tau \stackrel{\text{def}}{=} G_\infty$$

and the problem

$$(3.8) \quad \inf_{(\nu(\cdot), y(\cdot))} \lim_{S \rightarrow \infty} \frac{1}{S} \int_0^S \bar{g}(\nu(\tau), y(\tau)) d\tau \stackrel{\text{def}}{=} \bar{G}_\infty,$$

where the infs in (3.7) and (3.8) are over all admissible and, respectively, over all relaxed admissible pairs on the interval  $[0, \infty)$  such that the corresponding limits exist.

**COROLLARY 3.4.** *If  $W$  is not empty, then  $\bar{G}_\infty = G_*$  and the problem (3.8) has a solution. That is, there exists  $(\nu(\cdot), y(\cdot))$ , a relaxed admissible pair on  $[0, \infty)$ , such that*

$$(3.9) \quad \lim_{S \rightarrow \infty} \frac{1}{S} \int_0^S \bar{g}(\nu(\tau), y(\tau)) d\tau = G_*.$$

*Proof.* The statement is implied by Theorem 3.3 and by the fact that LLPP (3.2) always has an extreme point solution.  $\square$

For the problem (3.7) to have a solution, one needs to introduce additional assumptions. In particular, one can use Corollary 3.4 and a standard measurable selection argument to show that, if  $(g, f)(U, y) \stackrel{\text{def}}{=} \{(\zeta, \eta) : \zeta = g(u, y), \eta = f(u, y), u \in U\}$  is convex for all  $y \in Y$ , then  $G_\infty = G_*$  and there exists  $(u(\cdot), y(\cdot))$ , an admissible pair on  $[0, \infty)$ , such that

$$(3.10) \quad \lim_{S \rightarrow \infty} \frac{1}{S} \int_0^S g(u(\tau), y(\tau)) d\tau = G_*.$$

Along with the problems considered above, let us also consider the problem

$$(3.11) \quad \inf_{(u(\cdot), y(\cdot))_{\text{per}}} \lim_{S \rightarrow \infty} \frac{1}{S} \int_0^S g(u(\tau), y(\tau)) d\tau \stackrel{\text{def}}{=} G_{\text{per}},$$

where inf is over all periodic admissible pairs, that is, over the admissible pairs such that

$$(3.12) \quad (u(\tau), y(\tau)) = (u(\tau + T), y(\tau + T)) \quad \forall \tau \geq 0,$$

for some  $T > 0$ . Note that the problem (3.11) is equivalent to a so-called periodic optimization problem

$$(3.13) \quad \inf_{(u(\cdot), y(\cdot))} \frac{1}{T} \int_0^T g(u(\tau), y(\tau)) d\tau = G_{\text{per}},$$

where  $\inf$  is over the length of the time interval  $T$  and over the admissible pairs defined on  $[0, T]$  which satisfy the periodicity condition  $y(0) = y(T)$ .

In the general case the optimal values of the problems (2.3), (3.7), and (3.11) satisfy the inequalities

$$(3.14) \quad \overline{\lim}_{S \rightarrow \infty} G(S) \leq G_\infty \leq G_{per} \Rightarrow G_* \leq G_{per},$$

and, under some additional assumptions,

$$(3.15) \quad \lim_{S \rightarrow \infty} G(S) = G_\infty = G_{per} \Rightarrow G_* = G_{per}.$$

Sufficient conditions for the equalities (3.15) to be valid have been considered in [27], [28], [35], and [36].

**LEMMA 3.5.** *If there exists a solution of the LLPP (3.2) that is generated by a periodic admissible pair, then this pair is a solution of the periodic optimization problem (3.13), and the inequalities (3.14) turn into equalities (3.15). Conversely, if equalities (3.15) are valid and if a solution of the periodic optimization problem (3.13) exists, then the occupational measure generated by this pair is a solution of the LLPP (3.2).*

*Proof.* The proof follows from (3.14) and from the definition of the occupational measures.  $\square$

**4. Dual problem and duality relationships.** Define the problem dual to LLPP (D-LLPP) by the equation

$$(4.1) \quad \sup_{(\mu, \psi(\cdot)) \in \mathcal{D}} \mu \stackrel{\text{def}}{=} \mu_*,$$

with the feasible set  $\mathcal{D} \subset \mathbb{R}^1 \times C^1$  defined as

$$(4.2) \quad \mathcal{D} \stackrel{\text{def}}{=} \{(\mu, \psi(\cdot)) : \mu = \min_{(u, y) \in U \times Y} \{g(u, y) + (\psi'(y))^T f(u, y)\}, \psi(\cdot) \in C^1\}.$$

It can be readily seen that, if  $W \neq \emptyset$  and  $\gamma \in W$ , then for any  $(\mu, \psi(\cdot)) \in \mathcal{D}$  (note that  $\mathcal{D}$  is never empty),

$$(4.3) \quad \mu \leq \int_{U \times Y} (g(u, y) + (\psi'(y))^T f(u, y)) \gamma(du, dy) = \int_{U \times Y} g(u, y) \gamma(du, dy)$$

$$(4.4) \quad \Rightarrow \mu_* \leq G_*.$$

The following statements establish more elaborate connections between LLPP (3.2) and D-LLPP (4.1).

**THEOREM 4.1.**

(i) *The optimal value of D-LLPP (4.1) is bounded (that is,  $\mu_* < \infty$ ) if and only if the set  $W$  is not empty.*

(ii) *If the optimal value of D-LLPP (4.1) is bounded, then*

$$(4.5) \quad \mu_* = G_*.$$

(iii) *The optimal value of D-LLPP (4.1) is unbounded (that is,  $\mu_* = \infty$ ) if and only if there exists a function  $\psi(\cdot) \in C^1$  such that*

$$(4.6) \quad \max_{(u, y) \in U \times Y} (\psi'(y))^T f(u, y) < 0.$$

*Proof.* The proof of Theorem 4.1 is given in section 9.  $\square$

Note that, in a stochastic setting, a duality result similar to Theorem 4.1(ii) (with  $Y = \mathbb{R}^m$ ) has been obtained in [16].

*Remark 4.2.* From the statements (i) and (ii) it follows that the set  $W$  and, hence, the set  $\bar{\Gamma}(S)$  (and also the set  $\Gamma(S)$  provided that  $f(U, y)$  is convex for all  $y \in Y$ ) are not empty (see Theorem 3.1(i)) if and only if a function  $\psi(\cdot) \in C^1$  satisfying (4.6) does not exist. Note that, if such a function  $\psi(\cdot)$  exists, then the fact that  $\bar{\Gamma}(S)$  (and, hence,  $\Gamma(S)$ ) are empty for  $S \geq S_0$  (for some  $S_0 > 0$ ) follow from the fact that this  $\psi(\cdot)$  can be used as a Liapunov function decreasing along the trajectories of the system (2.2) (respectively, (2.1)) and “forcing” them to leave  $Y$  in a finite time.

Assume that  $\mu_* < \infty$ . A function  $\psi_*(\cdot) \in C^1$  will be called a solution of D-LLPP (4.1) if

$$(4.7) \quad \mu_* = \min_{(u,y) \in U \times Y} \{g(u, y) + (\psi'_*(y))^T f(u, y)\}.$$

Defining  $H(p, y)$  by the equation

$$(4.8) \quad H(p, y) \stackrel{\text{def}}{=} \min_{u \in U} \{g(u, y) + p^T f(u, y)\}$$

and rewriting (4.7) in the form

$$(4.9) \quad \mu_* = \min_{y \in Y} H(\psi'_*(y), y) \quad \Rightarrow \quad \mu_* \leq H(\psi'_*(y), y) \quad \forall y \in Y,$$

one can come to a conclusion that a solution  $\psi_*(\cdot)$  of D-LLPP (4.1) is a smooth viscosity subsolution of the corresponding Hamilton–Jacobi–Bellman equation (see [12] and [26] for relevant definitions and developments).

Given a solution  $\psi_*(\cdot)$  of D-LLPP (4.1), define the set  $\Omega_* \subset U \times Y$  by the equation

$$(4.10) \quad \Omega_* \stackrel{\text{def}}{=} \{(u, y) \in U \times Y : g(u, y) + (\psi'_*(y))^T f(u, y) = \mu_*\}.$$

**PROPOSITION 4.3.** *Let  $\mu_* < \infty$  and  $\psi_*(\cdot)$  be a solution of D-LLPP (4.1). Then  $\gamma \in W$  will be a solution of the LLPP (3.2) if and only if*

$$(4.11) \quad \gamma(\Omega_*) = 1.$$

*Proof.* By Theorem 4.1(ii), a probability measure  $\gamma$  belonging to  $W$  will be a solution of the LLPP (3.2) if and only if

$$(4.12) \quad \mu_* = \int_{U \times Y} g(u, y) \gamma(du, dy) = \int_{U \times Y} (g(u, y) + (\psi'_*(y))^T f(u, y)) \gamma(du, dy).$$

Since (see (4.7))

$$(4.13) \quad \mu_* \leq g(u, y) + (\psi'_*(y))^T f(u, y) \quad \forall (u, y) \in U \times Y,$$

the equality (4.12) can be valid if and only if (4.11) is true. This proves the proposition.  $\square$

**COROLLARY 4.4.** *For a relaxed admissible pair  $(\nu(\cdot), y(\cdot))$  generating the occupational measure  $\gamma^{(\nu(\cdot), y(\cdot))}$  on  $[0, \infty)$  to be optimal in the problem (3.8) it is necessary and sufficient that  $\gamma^{(\nu(\cdot), y(\cdot))}(\Omega_*) = 1$ .*

*Proof.* By Corollary 3.4, the pair  $(\nu(\cdot), y(\cdot))$  will be optimal in (3.8) (that is, it satisfies (3.9)) if and only if  $\gamma^{(\nu(\cdot), y(\cdot))}$  is a solution of the LLPP (3.2). Hence, the statement is implied by Proposition 4.3.  $\square$

Let

$$(4.14) \quad \mathcal{Y}_* \stackrel{\text{def}}{=} \{y \in Y : H(\psi_*(y), y) = \mu_*\}$$

and

$$(4.15) \quad \mathcal{U}_*(y) \stackrel{\text{def}}{=} \{u \in U : g(u, y) + (\psi'_*(y))^T f(u, y) = H(\psi'_*(y), y)\}.$$

**COROLLARY 4.5.** *Let  $\psi_*(\cdot)$  be a solution of D-LLPP (4.1). A  $T$ -periodic admissible pair  $(u(\tau), y(\tau))$  will be a solution of the periodic optimization problem (3.13) if and, under the condition that the equalities (3.15) are valid, only if*

$$(4.16) \quad y(\tau) \in \mathcal{Y}_* \quad \forall \tau \in [0, T], \quad u(\tau) \in \mathcal{U}_*(y(\tau)) \quad \text{for almost all } \tau \in [0, T].$$

*Proof.* By Lemma 3.5, a  $T$ -periodic admissible pair  $(u(\tau), y(\tau))$  will be a solution of the periodic optimization problem (3.13) if and, under the condition that the equalities (3.15) are valid, only if the occupational measure  $\gamma^{(u(\cdot), y(\cdot))}$  generated by this pair is a solution of LLPP (3.2). According to Proposition 4.3, this is the case if and only if  $\gamma^{(u(\cdot), y(\cdot))}(\Omega_*) = 1$ , which is equivalent to  $(u(\tau), y(\tau)) \in \Omega_*$  for almost all  $\tau \in [0, T]$ . The latter, in turn, is equivalent to the inclusions (4.16) being satisfied for almost all  $\tau \in [0, T]$  since

$$(4.17) \quad \Omega_* = \{(u, y) : u \in \mathcal{U}_*(y), y \in \mathcal{Y}_*\}.$$

The fact that the first inclusion in (4.16) is valid for all  $\tau \in [0, T]$  follows from the fact that the function  $y(\cdot)$  is continuous and that the set  $\mathcal{Y}_*$  is compact.  $\square$

Note that a solution of D-LLPP (4.1) defined as a  $C^1$  function satisfying (4.9) may not exist, and one can consider the possibility of defining the solution as a nondifferentiable function, which satisfies (4.9) in the viscosity sense (see, e.g., [12, p. 399]). We, however, do not follow this path. Instead, in the next sections we discuss a way of constructing  $C^1$  functions that solve D-LLPP (4.1) approximately. First, in section 5, we approximate the LLPP (3.2) with I-D LLPs having a finite number of constraints  $N$  ( $N = 1, 2, \dots$ ), and we study the problem dual to the latter (section 5). Then, in section 6, we approximate the problem with  $N$  constraints and its dual by a family of F-D LPPs defined on grid points of  $U \times Y$  and the corresponding dual, and we show that, by solving these F-D LPPs, one can construct a family of functions  $\psi_{N,\Delta}(\cdot) \in C^1$  ( $\Delta$  being the parameter of the grid) such that, for any  $\delta > 0$ ,

$$(4.18) \quad \mu_* - \delta \leq \min_{(u,y) \in U \times Y} \{g(u, y) + (\psi'_{N,\Delta}(y))^T f(u, y)\} = \min_{y \in Y} H(\psi'_{N,\Delta}(y), y)$$

if  $N$  is large and  $\Delta$  is small enough (see (4.7) and (4.9)). We also show (see section 7) that, under some additional conditions, a feedback control function  $u_{N,\Delta}(\cdot) : Y \rightarrow U$  satisfying the inclusion

$$(4.19) \quad u_{N,\Delta}(y) \in \mathcal{U}_{N,\Delta}(y) \stackrel{\text{def}}{=} \{u \in U : g(u, y) + (\psi'_{N,\Delta}(y))^T f(u, y) = H(\psi'_{N,\Delta}(y), y)\}$$

can serve as an approximation to the optimal feedback control defined on the optimal periodic orbit (provided that the latter exists).

Note also that D-LLPP (4.1) can be rewritten in the form

$$(4.20) \quad \sup_{\psi(\cdot) \in C^1} \min_{y \in Y} H(\psi'(y), y) = \mu_*.$$

Problems similar to (4.20) (but in a different setting and under a different set of conditions) have been considered in the literature, particularly, in relation to finding so-called effective Hamiltonians arising in the homogenization theory (see [34] and references therein). It seems plausible that results that we discuss below could be applicable in this area, but we do not investigate this matter in the present paper.

Finally, to conclude this section, let us also mention that problems dual to I-D LPPs that arise in dealing with deterministic optimal control problems on finite time intervals and the way of how these dual problems can be used for formulating necessary and sufficient optimality conditions have been studied in [57] (see also references therein).

**5.  $N$ -approximating problem and its dual.** Let  $\{\phi_i(\cdot) \in C^1, i = 1, 2, \dots\}$  be a sequence of functions having continuous partial derivatives of second order such that any function  $\psi(\cdot) \in C^1$  and its gradient  $\psi'(\cdot)$  can be simultaneously approximated on  $Y$  by linear combinations of functions from  $\{\phi_i(\cdot), i = 1, 2, \dots\}$  and their corresponding gradients. That is, for any  $\psi(\cdot) \in C^1$  and any  $\delta > 0$ , there exist  $\beta_1, \dots, \beta_k$  (real numbers) such that

$$(5.1) \quad \max_{y \in Y} \left\{ \left| \psi(y) - \sum_1^k \beta_i \phi_i(y) \right| + \left\| \psi'(y) - \sum_1^k \beta_i \phi'_i(y) \right\| \right\} \leq \delta,$$

with  $\|\cdot\|$  being a norm in  $\mathbb{R}^m$ . An example of such an approximating sequence is the sequence of monomials  $y_1^{i_1} \dots y_m^{i_m}$ ,  $i_1, \dots, i_m = 0, 1, \dots$ , where  $y_j$  ( $j = 1, \dots, m$ ) stands for the  $j$ th component of  $y$  (see, e.g., [44]). In what follows it will be assumed that the gradients  $\phi'_i(y)$ ,  $i = 1, 2, \dots, N$ , are linearly independent on  $Y$ . That is,

$$(5.2) \quad \sum_{i=1}^N v_i \phi'_i(y) = 0 \quad \forall y \in Y \quad \Rightarrow \quad v_i = 0, \quad i = 1, 2, \dots, N.$$

Note that this is satisfied automatically if  $\phi_i(y)$  are chosen to be monomials and  $\text{int} Y$  (interior of  $Y$ ) is not empty.

Let us define the set  $W_N$  by the equation

$$(5.3) \quad W_N \stackrel{\text{def}}{=} \left\{ \gamma \mid \gamma \in \mathcal{P}(U \times Y); \int_{U \times Y} (\phi'_i(y))^T f(u, y) \gamma(du, dy) = 0, \quad i = 1, 2, \dots, N \right\}$$

and consider the linear programming problem

$$(5.4) \quad \min_{\gamma \in W_N} \int_{U \times Y} q(u, y) \gamma(du, dy) \stackrel{\text{def}}{=} G_N.$$

This problem will be referred to as  $N$ -approximating LLPP (or just  $N$ -LLPP). Note that  $W_N$  is a convex and compact subset of  $\mathcal{P}(U \times Y)$  and  $W \subset W_N$ , which implies

$$(5.5) \quad G_* \geq G_N.$$

The connection between LLPP (3.2) and  $N$ -LLPP (5.4) is established by the following proposition (see [32]).

PROPOSITION 5.1. *The set  $W$  is not empty if and only if there exists  $N_0 \geq 1$  such that  $W_N$  is not empty for  $N \geq N_0$ . If  $W$  is not empty, then*

$$(5.6) \quad \lim_{N \rightarrow \infty} \rho_H(W_N, W) = 0$$

and

$$(5.7) \quad \lim_{N \rightarrow \infty} G_N = G_*.$$

Also, if  $\gamma^N$  is a solution of the problem (5.4) and  $\lim_{N' \rightarrow \infty} \rho(\gamma^{N'}, \gamma) = 0$  for some subsequence of integers  $N'$  tending to infinity, then  $\gamma$  is a solution of (3.2). If the solution  $\gamma_*$  of the problem (3.2) is unique, then, for any solution  $\gamma^N$  of (5.4),  $\lim_{N \rightarrow \infty} \rho(\gamma^N, \gamma_*) = 0$ .

*Proof.* The proof follows from Proposition 7 in [32].  $\square$

Let us define the problem dual to  $N$ -LLPP (5.4) (referred in what follows to as  $D$ - $N$ -LLPP) by the equation

$$(5.8) \quad \sup_{(\mu, v) \in \mathcal{D}_N} \mu \stackrel{\text{def}}{=} \mu_N,$$

with the feasible set  $\mathcal{D}_N \subset \mathbb{R}^1 \times \mathbb{R}^N$  defined as

$$(5.9) \quad \mathcal{D}_N \stackrel{\text{def}}{=} \left\{ (\mu, v) : \mu = \min_{(u, y) \in U \times Y} \left\{ g(u, y) + \sum_{i=1}^N v_i (\phi'_i(y))^T f(u, y) \right\}, \quad v = (v_i) \in \mathbb{R}^N \right\}.$$

For a fixed  $N$ , the relationships between  $N$ -LLPP (5.4) and  $D$ - $N$ -LLPP (5.8) are similar to those between (3.2) and (4.1). For example, similarly to (4.3), one can obtain that, if  $W_N \neq \emptyset$  and  $\gamma \in W_N$ , then for any  $(\mu, v) \in \mathcal{D}_N$  ( $\mathcal{D}_N$  is never empty),

$$(5.10) \quad \mu \leq \int_{U \times Y} \left( g(u, y) + \sum_{i=1}^N v_i (\phi'_i(y))^T f(u, y) \right) \gamma(du, dy) = \int_{U \times Y} g(u, y) \gamma(du, dy)$$

$$(5.11) \quad \Rightarrow \quad \mu_N \leq G_N.$$

Also, the following result similar to Theorem 4.1 is valid.

THEOREM 5.2. (i) *The optimal value of  $D$ - $N$ -LLPP (5.8) is bounded (that is,  $\mu_N < \infty$ ) if and only if the set  $W_N$  is not empty.*

(ii) *If the optimal value of  $D$ - $N$ -LLPP (5.8) is bounded, then*

$$(5.12) \quad \mu_N = G_N.$$

(iii) *The optimal value of  $D$ - $N$ -LLPP (5.8) is unbounded (that is,  $\mu_N = \infty$ ) if and only if there exists  $v = (v_1, \dots, v_N)$  such that*

$$(5.13) \quad \max_{(u, y) \in U \times Y} (\psi'_v(y))^T f(u, y) < 0, \quad \psi_v(y) \stackrel{\text{def}}{=} \sum_{i=1}^N v_i \phi_i(y).$$

*Proof.* The proof of the theorem follows exactly the same steps as those in the proof of Theorem 4.1. For completeness we briefly outline these steps in section 9.  $\square$

A vector  $v = (v_i), i = 1, \dots, N$ , will be called a solution of D- $N$ -LLPP (5.8) if

$$(5.14) \quad \mu_N = \min_{(u,y) \in U \times Y} \{g(u,y) + (\psi'_v(y))^T f(u,y)\}, \quad \psi_v(y) \stackrel{\text{def}}{=} \sum_{i=1}^N v_i \phi_i(y).$$

Let us introduce the following two assumptions used in the consideration below.

*Assumption 1.* The inequality

$$(5.15) \quad (\psi'_v(y))^T f(u,y) \leq 0 \quad \forall (u,y) \in U \times Y, \quad \psi_v(y) \stackrel{\text{def}}{=} \sum_{i=1}^N v_i \phi_i(y),$$

can be valid only with  $v_i = 0, i = 1, \dots, N$ .

*Assumption 2.* The inequality

$$(5.16) \quad (\psi'(y))^T f(u,y) \leq 0 \quad \forall (u,y) \in U \times Y, \quad \psi(\cdot) \in C^1,$$

can be valid only with  $\psi'(y) = 0 \quad \forall y \in Y$ .

PROPOSITION 5.3. *Assumption 1 is equivalent to the assumption that*

$$(5.17) \quad 0 \in \text{int}(\text{co}K_N),$$

where  $\text{int}(\text{co}K_N)$  stands for the interior of the convex hull of  $K_N$ ,

$$(5.18) \quad K_N \stackrel{\text{def}}{=} \{z \in \mathbb{R}^N : z = (z_i), z_i = (\phi'_i(y))^T f(u,y), i = 1, \dots, N, (u,y) \in U \times Y\}.$$

*Proof.* The proof is in section 9.  $\square$

*Remark 5.4.* (i) It is easy to see that Assumption 2 implies the validity of Assumption 1 with any  $N = 1, 2, \dots$ . In fact, if the former is satisfied, then the inequality  $\sum_{i=1}^N v_i (\phi'_i(y))^T f(u,y) \leq 0 \quad \forall (u,y) \in U \times Y$  implies that  $\sum_{i=1}^N v_i \phi'_i(y) = 0 \quad \forall y \in Y$  and, hence, by (5.2),  $v_i = 0, i = 1, \dots, N$ . Sufficient conditions for Assumption 2 to be satisfied and special cases in which it is satisfied have been considered in [32] (see Proposition 8 and Remark 2 of [32]).

(ii) Assumption 1 implies that the function  $\psi_v(\cdot)$  satisfying (5.13) does not exist, and Assumption 2 implies that the function  $\psi(\cdot)$  satisfying (4.6) does not exist. Thus, from the former it follows that  $\mu_N$  is bounded (by Theorem 5.2(iii)) and from the latter that  $\mu_*$  is bounded (by Theorem 4.1(iii)).

THEOREM 5.5. (i) *If Assumption 1 is satisfied, then the set of solutions of D- $N$ -LLPP (5.8) is nonempty and bounded. That is (see (5.14)),*

$$(5.19) \quad \emptyset \neq V_N \stackrel{\text{def}}{=} \left\{ v = (v_i) : \mu_N = \min_{(u,y) \in U \times Y} \left\{ g(u,y) + \left( \sum_{i=1}^N v_i \phi'_i(y) \right)^T f(u,y) \right\} \right\},$$

$$(5.20) \quad \max_{v \in V_N} \|v\| \leq c_N = \text{const.}$$

(ii) *Conversely, if (5.19) and (5.20) are true, then Assumption 1 is satisfied.*

*Proof.* Proof is in section 9.  $\square$

Let us now establish that the optimal values of the D- $N$ -LLPP (5.8) converge to the optimal value of D-LLPP (4.1) as  $N \rightarrow \infty$ . Note that, as follows directly from the definitions of D- $N$ -LLPP and D-LLPP (see (5.8) and (4.1)),

$$(5.21) \quad \mu_1 \leq \mu_2 \leq \dots \leq \mu_N \leq \dots \leq \mu_*.$$

THEOREM 5.6. *The optimal value of D-N-LLPP (5.8) converges to the optimal value of D-LLPP (4.1). That is,*

$$(5.22) \quad \lim_{N \rightarrow \infty} \mu_N = \mu_*,$$

the statement being valid for both  $\mu_* < \infty$  and  $\mu_* = \infty$ .

*Proof.* If Assumption 2 is satisfied, then  $\mu_* = G_*$  and  $\mu_N = G_N$  for  $N = 1, 2, \dots$ . Hence, (5.22) follows from (5.7). The proof of the general case is in section 9.  $\square$

In conclusion of this section, let us introduce a regularity condition, which will be used in section 7 below. Let Assumption 2 be satisfied and let  $v = (v_i) \in V_N$ ,  $\psi_v(y) \stackrel{\text{def}}{=} \sum_{i=1}^N v_i \phi_i(y)$ . Define the sets  $\Omega_N^v, \mathcal{Y}_N^v$  by the equations

$$(5.23) \quad \Omega_N^v \stackrel{\text{def}}{=} \{(u, y) \in U \times Y : g(u, y) + (\psi'_v(y))^T f(u, y) = \mu_N\},$$

$$(5.24) \quad \mathcal{Y}_N^v \stackrel{\text{def}}{=} \{y : (u, y) \in \Omega_N^v\} = \{y \in Y : H(\psi'_v(y), y) = \mu_N\}$$

and the set  $\mathcal{U}_N^v(y)$  by the equation

$$(5.25) \quad \mathcal{U}_N^v(y) \stackrel{\text{def}}{=} \{u \in U : g(u, y) + (\psi'_v(y))^T f(u, y) = H(\psi'_v(y), y)\},$$

where  $H(p, y)$  is as in (4.8).

*N-regularity condition (N-RC) on Q.* Given  $Q \subset Y$ , we shall say that N-RC is satisfied on  $Q$  if, for any  $v \in V_N$  and any  $y \in \mathcal{Y}_N^v \cap Q$ , a solution of the problem

$$(5.26) \quad \max_{u \in U} \{g(u, y) + (\psi'_v(y))^T f(u, y)\}$$

is unique. That is,  $\mathcal{U}_N^v(y)$  is a singleton for  $v \in V_N$  and  $y \in \mathcal{Y}_N^v \cap Q$ .

Note that N-RC is satisfied on any  $Q \subset Y$  and with any  $N = 1, 2, \dots$  if  $g(u, y)$  is strictly convex and  $f(u, y)$  is linear in  $u$  and if  $U$  is a convex set.

**6. N $\Delta$ -approximating problem and its dual.** Assume first that  $N$  is fixed and that, for any  $\Delta > 0$ , Borel sets  $Q_{l,k}^\Delta \subset U \times Y$  ( $l = 1, \dots, L^\Delta$ ,  $k = 1, \dots, K^\Delta$ ) (called cells) are defined in such a way that two different cells do not intersect, the union of all cells is equal to  $U \times Y$ , and

$$(6.1) \quad \sup_{(u,y) \in Q_{l,k}^\Delta} \|(u, y) - (u_l, y_k)\| \leq c\Delta, \quad c = \text{const},$$

for some point  $(u_l, y_k) \in Q_{l,k}^\Delta$ . For simplicity of notation, it is assumed (from now on) that  $U$  is a compact subset of  $\mathbb{R}^n$  and  $\|\cdot\|$  stands for a norm in  $\mathbb{R}^{n+m}$ . Let us fix the points  $(u_l, y_k)$  ( $l = 1, \dots, L^\Delta$ ,  $k = 1, \dots, K^\Delta$ ) and define a polyhedral set  $W_{N,\Delta} \subset \mathbb{R}^{L^\Delta + K^\Delta}$  by the equation

$$(6.2) \quad W_{N,\Delta} \stackrel{\text{def}}{=} \left\{ \gamma = \{\gamma_{l,k}\} \geq 0 : \sum_{l,k} \gamma_{l,k} = 1, \sum_{l,k} (\phi'_i(y_k))^T f(u_l, y_k) \gamma_{l,k} = 0, i = 1, \dots, N \right\},$$

where  $\sum_{l,k} \stackrel{\text{def}}{=} \sum_{l=1}^{L^\Delta} \sum_{k=1}^{K^\Delta}$ . Consider the problem

$$(6.3) \quad \min_{\gamma \in W_{N,\Delta}} \sum_{l,k} \gamma_{l,k} g(u_l, y_k) \stackrel{\text{def}}{=} G_{N,\Delta}.$$

This is an F-D LLP which will be referred to as  $N\Delta$ -approximating LLPP (or  $N\Delta$ -LLPP).

Note that the polyhedral set  $W_{N,\Delta}$  is the set of probability measures on  $U \times Y$  which assign nonzero probabilities only to the points  $(u_l, y_k)$ , and, as such,

$$(6.4) \quad W_{N,\Delta} \subset W_N \quad \Rightarrow \quad G_{N,\Delta} \geq G_N.$$

**THEOREM 6.1.** *Let Assumption 1 be satisfied. Then the set  $W_N$  is not empty and there exists  $\Delta_0 > 0$  such that  $W_{N,\Delta}$  is not empty for  $\Delta \leq \Delta_0$ . Also*

$$(6.5) \quad \lim_{\Delta \rightarrow 0} \rho_H(W_{N,\Delta}, W_N) = 0$$

and

$$(6.6) \quad \lim_{\Delta \rightarrow 0} G_{N,\Delta} = G_N.$$

If  $\gamma^{N,\Delta}$  is a solution of the problem (6.3) and  $\lim_{\Delta' \rightarrow 0} \rho(\gamma^{N,\Delta'}, \gamma^N) = 0$  for some sequence of  $\Delta'$  tending to zero, then  $\gamma^N$  is a solution of (5.4). If the solution  $\gamma^N$  of the problem (5.4) is unique, then, for any solution  $\gamma^{N,\Delta}$  of (6.3),  $\lim_{\Delta \rightarrow 0} \rho(\gamma^{N,\Delta}, \gamma^N) = 0$ .

*Proof.* The fact that  $W_N$  is not empty if Assumption 1 is satisfied follows from Theorem 5.2(i) and from the fact that  $\mu_N$  is bounded (see Remark 5.4(ii)). The proofs of all other statements of the theorem follow from Proposition 9 in [32].  $\square$

Consider the F-D LPP

$$(6.7) \quad \max_{(\mu, \lambda) \in \mathbb{R}^1 \times \mathbb{R}^N} \left\{ \mu : \mu \leq g(u_l, y_k) + \sum_{i=1}^N \lambda_i (\phi'_i(y_k))^T f(u_l, y_k) \quad \forall (u_l, y_k) \right\} \stackrel{\text{def}}{=} \mu_{N,\Delta},$$

which is dual to  $N\Delta$ -LLPP (6.3) and which will be referred to as D- $N\Delta$ -LLPP. From the duality theory for F-D LPPs (see, e.g., [22]) it follows, in particular, that, if  $W_{N,\Delta}$  is not empty, then the optimal value of  $N\Delta$ -LLPP (6.3) is equal to the optimal value of D- $N\Delta$ -LLPP (6.7)

$$(6.8) \quad G_{N,\Delta} = \mu_{N,\Delta}$$

and the solutions set of D- $N\Delta$ -LLPP (6.7) is not empty:

$$(6.9) \quad \emptyset \neq \Lambda_{N,\Delta} \stackrel{\text{def}}{=} \left\{ \lambda = (\lambda_i) : \mu_{N,\Delta} = \min_{(u_l, y_k)} \left\{ g(u_l, y_k) + \sum_{i=1}^N \lambda_i (\phi'_i(y_k))^T f(u_l, y_k) \right\} \right\}.$$

**THEOREM 6.2.** *Let Assumption 1 be satisfied. Then*

$$(6.10) \quad \lim_{\Delta \rightarrow 0} \max_{\lambda \in \Lambda_{N,\Delta}} \text{dist}(\lambda, V_N) = 0, \quad \text{dist}(\lambda, V_N) \stackrel{\text{def}}{=} \min_{v \in V_N} \|\lambda - v\|,$$

where  $V_N$  is the solutions set of D- $N$ -LLPP (5.8) (explicitly defined in (5.19)).

*Proof.* The proof is in section 10. Let us only note here that, by Theorem 6.1, the set  $W_{N,\Delta}$  is not empty under Assumption 1, and hence, (6.8) and (6.9) are valid for  $\Delta$  small enough.  $\square$

Let us now address the issue of constructing  $\psi_{N,\Delta}(\cdot)$  that approximately solves D-LLPP (4.1) (see the end of section 4).

PROPOSITION 6.3. *Let Assumption 2 be satisfied. Then, for any  $\delta > 0$ , there exist  $N_\delta > 0$  and  $\Delta_N > 0$  such that the function  $\psi_{N,\Delta}(\cdot)$  defined by the equation*

$$(6.11) \quad \psi_{N,\Delta}(y) \stackrel{\text{def}}{=} \sum_{i=1}^N \lambda_i^{N,\Delta} \phi_i(y), \quad \lambda^{N,\Delta} = (\lambda_i^{N,\Delta}) \in \Lambda_{N,\Delta},$$

satisfies (4.18) with  $N \geq N_\delta$  and  $\Delta \leq \Delta_N$ .

*Proof.* As was mentioned above (see Remark 5.4(i)), the validity of Assumption 2 implies the validity of Assumption 1 with all  $N$ . Having this in mind, let us choose  $N_\delta$  in such a way that

$$(6.12) \quad \mu_* - \frac{\delta}{2} \leq \mu_N$$

for any  $N \geq N_\delta$  (this is possible due to Theorem 5.6). By Theorem 5.5(i), the set  $V_N$  is not empty and

$$(6.13) \quad \mu_* - \frac{\delta}{2} \leq \min_{(u,y) \in U \times Y} \left\{ g(u,y) + \left( \sum_{i=1}^N v_i \phi'_i(y) \right)^T f(u,y) \right\} \quad \forall v = (v_i) \in V_N.$$

From (6.10) it follows that, for any  $\Delta \leq \Delta_N$  ( $\Delta_N$  being positive small enough) and any  $\lambda \in \Lambda_{N,\Delta}$ , there exists  $v^{N,\Delta} = (v_i^{N,\Delta}) \in V_N$  such that

$$\begin{aligned} & \min_{(u,y) \in U \times Y} \left\{ g(u,y) + \left( \sum_{i=1}^N v_i^{N,\Delta} \phi'_i(y) \right)^T f(u,y) \right\} - \frac{\delta}{2} \\ & \leq \min_{(u,y) \in U \times Y} \left\{ g(u,y) + \left( \sum_{i=1}^N \lambda_i^{N,\Delta} \phi'_i(y) \right)^T f(u,y) \right\} \\ \Rightarrow \quad & \mu_* - \delta \leq \min_{(u,y) \in U \times Y} \left\{ g(u,y) + \left( \sum_{i=1}^N \lambda_i^{N,\Delta} \phi'_i(y) \right)^T f(u,y) \right\}. \end{aligned}$$

The latter is (4.18) with  $\psi_{N,\Delta}(\cdot)$  as in (6.11).  $\square$

**7. Convergence to the optimal periodic solution.** In this section we will show that, under certain additional conditions, the control satisfying (4.19), that is, defined as a solution of the problem

$$(7.1) \quad \min_{u \in U} \{ g(u,y) + (\psi'_{N,\Delta}(y))^T f(u,y) \},$$

where  $\psi_{N,\Delta}(\cdot)$  is as in (6.11), converges (as  $N \rightarrow \infty$  and  $\Delta \rightarrow 0$ ) to the optimal feedback control defined on the optimal periodic orbit. To ensure the existence of the latter, throughout this section it is assumed that there exists a solution  $\gamma_*$  of LLPP (3.2) that is generated by a  $T$ -periodic admissible pair  $(u_*(\cdot), y_*(\cdot))$  (note that this assumption implies that the pair is a solution of the periodic optimization problem (3.13); see Lemma 3.5).

Define sets  $\Theta_*$  and  $\mathcal{Y}_*$  by the equations

$$(7.2) \quad \Theta_* \stackrel{\text{def}}{=} \{ (u,y) : (u,y) = (u_*(\tau), y_*(\tau)) \text{ for some } \tau \in [0, T] \},$$

$$(7.3) \quad \mathcal{Y}_* \stackrel{\text{def}}{=} \{y : y = y_*(\tau) \text{ for some } \tau \in [0, T]\} = \{y : (u, y) \in \Theta_*\}.$$

The set  $\Theta_*$  can be considered as the graph of the optimal feedback control function, which is defined on the optimal orbit  $\mathcal{Y}_*$  by the equation  $u_*(y) \stackrel{\text{def}}{=} u \forall (u, y) \in \Theta_*$ . For this definition to make sense, it is assumed that from the fact that  $(u', y) \in \Theta_*$  and  $(u'', y) \in \Theta_*$  it follows that  $u' = u''$  (this assumption is satisfied if the closed curve defined by  $y_*(\tau), \tau \in [0, T]$ , does not intersect itself).

Note that the set  $\mathcal{Y}_*$  defined in (7.3) is different from the set defined in (4.14) (despite the fact that the same notation is used in both cases). Underline that in this section it is not assumed that a solution  $\psi_*(\cdot)$  of D-LLPP (4.1) (which is used in (4.14)) exists. If, however, it does exist, then by Corollary 4.5, the set defined in (7.3) is contained in the set defined in (4.14).

Let us introduce the following assumption about the set  $\Theta_*$ .

*Assumption 3.* For any  $(u, y) \in \bar{\Theta}_*$  (the closure of  $\Theta_*$ ) and any  $r > 0$ , the set  $B_r(u, y) \stackrel{\text{def}}{=} ((u, y) + rB) \cap (U \times Y)$  ( $B$  being the open unit ball in  $\mathbb{R}^{n+m}$ ) has a nonzero  $\gamma_*$ -measure:  $\gamma_*(B_r(u, y)) > 0$ .

Note that this assumption is satisfied if the optimal control function  $u_*(\cdot) : [0, T] \rightarrow U$  is piecewise continuous and at every discontinuity point  $\tau$  the value of  $u^*(\tau)$  is equal either to the limit from the left ( $u_*(\tau) = \lim_{\tau' \rightarrow \tau-} u_*(\tau')$ ) or to the limit from the right ( $u_*(\tau) = \lim_{\tau' \rightarrow \tau+} u_*(\tau')$ ).

Under the validity of Assumption 2, from Proposition 5.1 and Theorem 6.1 it follows that there exist solutions  $\gamma^{N, \Delta} = \{\gamma_{l,k}^{N, \Delta}\}$  of the  $N\Delta$ -LLPP (6.3) (considered with  $N \rightarrow \infty$  and  $\Delta \rightarrow 0$ ) such that

$$(7.4) \quad \lim_{N \rightarrow \infty} \lim_{\Delta \rightarrow 0} \rho(\gamma^{N, \Delta}, \gamma_*) = 0,$$

with the latter being valid for any solution of the  $N\Delta$ -LLPP (6.3) if  $\gamma_*$  is a unique solution of LLPP (3.2).

For any Borel subset  $\Theta$  of  $U \times Y$ , let  $\gamma^{N, \Delta}(\Theta)$  stand for the  $\gamma^{N, \Delta}$  measure of  $\Theta$ . That is,  $\gamma^{N, \Delta}(\Theta) \stackrel{\text{def}}{=} \sum_{(u_l, y_k) \in \Theta} \gamma_{l,k}^{N, \Delta}$ .

**THEOREM 7.1.** *Let Assumptions 2 and 3 be satisfied.*

(i) *Let  $Q$  be an open subset of  $Y$  such that the  $N$ -regularity condition (see the end of section 5) is satisfied on  $Q$  for all  $N$  large enough and such that the solution  $u_{N, \Delta}(\cdot)$  of the problem (7.1) is unique on  $Q$ , and it is uniformly equicontinuous on any closed subset  $\bar{Q}'$  of  $Q$  for  $N$  large and  $\Delta$  small enough. That is,*

$$(7.5) \quad \|u_{N, \Delta}(y') - u_{N, \Delta}(y'')\| \leq \omega(\|y' - y''\|) \quad \forall y', y'' \in \bar{Q}',$$

*where  $\omega(\theta)$  tends to zero as  $\theta$  tends to zero and  $N \geq N_0$ ,  $\Delta \leq \Delta_N$  ( $\omega(\cdot)$  and  $N_0$  may be different for different  $\bar{Q}' \subset Q$ ). Then*

$$(7.6) \quad \lim_{N \rightarrow \infty} \overline{\lim}_{\Delta \rightarrow 0} \|u_{N, \Delta}(y) - u_*(y)\| = 0 \quad \forall y \in \mathcal{Y}_* \cap Q,$$

*with the convergence being uniform on any closed subset of  $\mathcal{Y}_* \cap Q$ .*

(ii) *Assume, in addition, that*

$$(7.7) \quad \overline{\lim}_{N \rightarrow \infty} \overline{\lim}_{\Delta \rightarrow 0} \gamma^{N, \Delta}(\bar{Q}) = 1,$$

*where  $\bar{Q}$  is the closure of  $Q$  and that  $\gamma_*(\bar{Q}/Q) = 0$ . Then  $\gamma_*(\mathcal{Y}_* \cap Q) = 1$ . That is,  $u_{N, \Delta}(y)$  converges to  $u_*(y)$  for  $\gamma_*$ -almost all  $y \in Y$ .*

The second statement of the theorem allows an extension, which we state in the form of the following corollary.

**COROLLARY 7.2.** *Let Assumptions 2 and 3 be satisfied, and let  $Q_j, j = 1, \dots, J$ , be nonintersecting open subsets of  $Y$ , such that, for every  $j$ , the  $N$ -regularity condition is satisfied on  $Q_j$ , and (7.5) is valid on any closed  $\bar{Q}' \subset Q_j$ . Assume also that*

$$(7.8) \quad \overline{\lim}_{N \rightarrow \infty} \overline{\lim}_{\Delta \rightarrow 0} \gamma^{N, \Delta}(\overline{\cup_j Q_j}) = 1$$

and that

$$(7.9) \quad \gamma_*(\overline{\cup_j Q_j} / \cup_j Q_j) = 0,$$

where  $\overline{\cup_j Q_j}$  is the closure of  $\cup_j Q_j$ . Then

$$(7.10) \quad \lim_{N \rightarrow \infty} \overline{\lim}_{\Delta \rightarrow 0} \|u_{N, \Delta}(y) - u_*(y)\| = 0$$

for  $\gamma_*$ -almost all  $y \in Y$ .

*Proof.* The proofs of Theorem 7.1 and Corollary 7.2 are given in section 10. They are based on a result of [32] establishing that the sets

$$(7.11) \quad \Theta_{N, \Delta} \stackrel{\text{def}}{=} \{(u_l, y_k) : \gamma_{l, k}^{N, \Delta} > 0\},$$

$$(7.12) \quad \mathcal{Y}_{N, \Delta} \stackrel{\text{def}}{=} \{y : (u, y) \in \Theta_{N, \Delta}\} = \left\{ y_k : \sum_l \gamma_{l, k}^{N, \Delta} > 0 \right\}$$

are “approaching” the sets  $\Theta_*$  and  $\mathcal{Y}_*$  as  $N \rightarrow \infty$  and  $\Delta \rightarrow 0$  (see Theorem 7.3 below).  $\square$

**THEOREM 7.3.** *Let Assumption 2 be satisfied, (7.4) be valid, and  $\gamma_*, \gamma^{N, \Delta}$  be as above. Then the following hold.*

(i) *Corresponding to an arbitrary small  $r > 0$  and arbitrary small  $\delta > 0$ , there exists  $N_0$  such that, for  $N \geq N_0$  and  $\Delta \leq \Delta_N$ ,*

$$(7.13) \quad \gamma^{N, \Delta}(\Theta_{N, \Delta} / (\Theta_* + rB)) < \delta, \quad \gamma^{N, \Delta}(\mathcal{Y}_{N, \Delta} / (\mathcal{Y}_* + rD)) < \delta$$

and

$$(7.14) \quad \Theta_{N, \Delta, \delta} \subset \Theta_* + rB, \quad \mathcal{Y}_{N, \Delta, \delta} \subset \mathcal{Y}_* + rD,$$

where  $B$  and  $D$  are open unit balls in  $\mathbb{R}^{n+m}$  and  $\mathbb{R}^m$ , respectively, and

$$\Theta_{N, \Delta, \delta} \stackrel{\text{def}}{=} \{(u_l, y_k) : \gamma_{l, k}^{N, \Delta} \geq \delta\}, \quad \mathcal{Y}_{N, \Delta, \delta} \stackrel{\text{def}}{=} \left\{ y_k : \sum_l \gamma_{l, k}^{N, \Delta} \geq \delta \right\}.$$

(ii) *If, in addition, Assumption 3 is satisfied, then, corresponding to an arbitrary small  $r > 0$ , there exists  $N_0$  such that, for  $N \geq N_0$  and  $\Delta \leq \Delta_N$ ,*

$$(7.15) \quad \Theta_* \subset \Theta_{N, \Delta} + rB, \quad \mathcal{Y}_* \subset \mathcal{Y}_{N, \Delta} + rB.$$

*Proof.* The validity of (i) and (ii) is implied by Propositions 10 and 11 from [32].  $\square$

Note that from (7.4) it follows that  $\gamma^{N,\Delta} \stackrel{\text{def}}{=} \{\gamma_{l,k}^{N,\Delta}\}$  can be considered as an “approximation” of  $\gamma_*$  for  $N$  large and  $\Delta$  small enough. Due to the fact that  $\gamma_*$  is the occupational measure generated by the optimal periodic pair  $(u^*(\cdot), y^*(\cdot))$ , an element  $\gamma_{l,k}^{N,\Delta}$  of  $\gamma^{N,\Delta}$  can be interpreted as an estimate of “proportion” of time spent by the optimal pair in a “small” vicinity of the point  $(u_l, y_k)$ , while the fact that  $\gamma_{l,k}^{N,\Delta}$  is positive or zero can be interpreted as an indication of whether or not the optimal pair attends this vicinity. Theorem 7.3 can be viewed as a justification of the latter interpretation.

Based on the consideration above, one can propose the following steps to construct an approximate solution to the periodic optimization problem.

(1) Find the optimal value  $G_{N,\Delta}$  and a solution  $\gamma^{N,\Delta}$  of  $N\Delta$ -LLPP (6.3), and also find a solution  $\mu_{N,\Delta}, \lambda^{N,\Delta}$  of problem (6.7) dual to  $N\Delta$ -LLPP (6.3).

(2) Define the sets  $\Theta_{N,\Delta}$  and  $\mathcal{Y}_{N,\Delta}$  according to (7.11) and (7.12).

(3) Construct the function  $\psi_{N,\Delta}(y)$  according to (6.11) and find the control  $u_{N,\Delta}(y)$  by solving the problem (7.1) for every  $y$  in a neighborhood of  $\mathcal{Y}_{N,\Delta}$ .

(4) Integrate the system (2.1) starting from an initial point  $y(0) \in \mathcal{Y}_{N,\Delta}$  and using  $u_{N,\Delta}(y)$  as the feedback control. One can expect that the obtained solution of the system will return to a small vicinity of the starting point  $y(0)$  and it will be possible to identify the end point of the integration period,  $T_{N,\Delta}$ , as the moment of entering this vicinity.

(5) Adjust the initial condition and/or control to obtain a periodic admissible pair  $(u_{N,\Delta}(\tau), y_{N,\Delta}(\tau))$  defined on the interval  $[0, T_{N,\Delta}]$ . Calculate the integral

$$\frac{1}{T_{N,\Delta}} \int_0^{T_{N,\Delta}} g(u_{N,\Delta}(\tau), y_{N,\Delta}(\tau)) d\tau$$

and compare it with  $G_{N,\Delta}$ . If the value of the integral proves to be close to  $G_{N,\Delta}$ , then the constructed admissible pair is a “good” approximation to the solution of the periodic optimization problem.

Note that these steps are similar to the procedure described in [32]. The difference is that the approximation  $u_{N,\Delta}(\cdot)$  to the optimal control is determined as a solution of the problem (7.1). The objective function of the latter is constructed with the help of a solution of the problem (6.7) dual to  $N\Delta$ -LLPP (6.3) (the opportunity of using dual solutions for finding an approximation to the optimal control was not discussed in [32]). In the next section we consider a numerical example to illustrate the above steps.

Let us conclude this section by noting that most of the existing computational methods for periodic optimization problems are either aimed at solving the system of necessary optimality conditions (so-called dynamic optimization schemes; see, e.g., [45], [53], and references therein) or based on approximating the POP with F-D nonlinear mathematical programming problems. The latter are defined either via a discretization of the time interval (as in direct optimization schemes; see, e.g., [45]) or with the help of special parametrization techniques (as in the flatness-based algorithm of [54]). In all instances the time interval (period) is assumed to be finite, with its length being one of the optimization parameters.

In contrast to these methods, the approach of this paper is based on the fact that, if the optimal periodic regime exists, then, under mild conditions, it is a solution of the long run average optimal control problem, and, also, it generates the occupational measure that is a solution of the LLPP (3.2); the latter does not involve the time parameter at all. As has been noticed in section 4, finding a solution of the problem

dual to LLPP (3.2) is equivalent to finding a subsolution of the Hamilton–Jacobi–Bellman equation for the corresponding long run average problem of optimal control. Thus, the approach under consideration can be characterized as one belonging to the class of algorithms that solve Hamilton–Jacobi–Bellman equations for infinite time horizon optimal control problems via a discretization of the state and control spaces (see [25], [26], [43], and references therein). The obvious advantage of the approach is in its simplicity (no software except standard linear programming and ordinary differential equation solvers is needed). Its disadvantage is in computer memory requirements (especially in problems of higher dimensions). A comparison of the linear programming approach with other algorithms of the given class will be a matter of further research.

**8. A numerical example.** Let  $m = 2$ ,  $n = 1$ , and let

$$y(t) = (y_1(t), y_2(t)) \subset Y \stackrel{\text{def}}{=} [-0.25, 0.25] \times [1.3, 1.9], \quad u(t) \in U \stackrel{\text{def}}{=} [-0.4, 0.4].$$

Also, let  $f(\cdot)$  and  $g(\cdot)$  be defined by the equations

$$(8.1) \quad f^T(u, y_1, y_2) \stackrel{\text{def}}{=} (y_2 - 1.6, u),$$

$$(8.2) \quad g(u, y_1, y_2) \stackrel{\text{def}}{=} ((y_2 - 3)(y_2 - 1)^2 + 2.5)(y_2 - 1) + 3 + 1.126y_1^2 + 0.4u^2.$$

The periodic optimization problem (3.13) with this data was considered and numerically solved using the “flatness-based algorithm” in [54]. Below we present a numerical solution of the problem obtained by following the steps outlined in section 7. Define the grid of  $U \times Y$  by the equations

$$u_i^\Delta \stackrel{\text{def}}{=} i\Delta - 0.4, \quad y_{1,j}^\Delta \stackrel{\text{def}}{=} j\Delta - 0.25, \quad y_{2,k}^\Delta \stackrel{\text{def}}{=} k\Delta + 1.3,$$

where  $i = 0, 1, \dots, \frac{0.8}{\Delta}$ ,  $j = 0, 1, \dots, \frac{0.5}{\Delta}$ , and  $k = 0, 1, \dots, \frac{0.6}{\Delta}$  ( $\Delta$  is chosen in such a way that  $\frac{0.8}{\Delta}$ ,  $\frac{0.5}{\Delta}$ , and  $\frac{0.6}{\Delta}$  are integers). In this case, the  $N\Delta$ -approximating LLPP (6.3) can be written in the form

$$(8.3) \quad G_{N,\Delta} \stackrel{\text{def}}{=} \min_{\gamma \in W_{N,\Delta}} \sum_{i,j,k} g(u_i^\Delta, y_{1,j}^\Delta, y_{2,k}^\Delta) \gamma_{i,j,k},$$

with  $W_{N,\Delta}$  being the polyhedral set defined by the equation

$$(8.4) \quad \left. \begin{aligned} W_{N,\Delta} \stackrel{\text{def}}{=} \left\{ \gamma = \{\gamma_{i,j,k}\} \geq 0 : \sum_{i,j,k} \gamma_{i,j,k} = 1, \right. \\ \left. \sum_{i,j,k} (\phi'_{i_1,i_2}(y_{1,j}^\Delta, y_{2,k}^\Delta))^T f(u_i^\Delta, y_{1,j}^\Delta, y_{2,k}^\Delta) \gamma_{i,j,k} = 0, (i_1, i_2) \in I_N \right\}. \end{aligned} \right\}$$

Here,  $\phi_{i_1,i_2}(y_1, y_2) \stackrel{\text{def}}{=} y_1^{i_1} y_2^{i_2}$  and  $I_N$  is the set of multi-indices

$$I_N \stackrel{\text{def}}{=} \{i : i = (i_1, i_2), \quad i_1, i_2 = 0, 1, \dots, N, \quad i_1 + i_2 \geq 1\}.$$

Note that  $g(\cdot)$  in (8.3) and  $f(\cdot)$  in (8.4) are as in (8.2) and (8.1), respectively.

The problem (8.3) was solved using the CPLEX linear programming solver [61] for different values of  $N$  and  $\Delta$ . The obtained optimal values  $G_{N,\Delta}$  are summarized in the following table:

$\Delta$	$N$		
	4	5	6
0.05	4.1959526	4.1959709	4.1959726
0.025	4.1958774	4.1958808	4.1958807
0.0125	4.1958750	4.1958751	4.1958751

On the basis of this data, one may conclude that  $G_6 = \lim_{\Delta \rightarrow 0} G_{6,\Delta} \approx 4.1958751 \approx 4.196$ , the latter coinciding with the optimal value of the given periodic optimization problem obtained in [54]. Thus, if for some  $T$ -periodic admissible pair  $(u(\tau), y(\tau))$ ,

$$(8.5) \quad \frac{1}{T} \int_0^T \left[ ((y_2(\tau) - 3)(y_2(\tau) - 1)^2 + 2.5)(y_2(\tau) - 1) + 3 + 1.126y_1(\tau)^2 + 0.4u(\tau)^2 \right] d\tau \approx 4.196,$$

then this pair is an approximate solution of the periodic optimization problem under consideration.

Let  $\gamma^{N,\Delta} = \{\gamma_{i,j,k}^{N,\Delta}\}$  stand for the solution of (8.3), and let  $\lambda^{N,\Delta} = \{\lambda_{i_1,i_2}^{N,\Delta}\}$  stand for the solution of the problem dual to (8.3)

$$(8.6) \quad \max_{(\mu,\lambda)} \left\{ \mu : \mu \leq g(u_i^\Delta, y_{1,j}^\Delta, y_{2,k}^\Delta) - \sum_{(i_1,i_2) \in I_N} \lambda_{i_1,i_2} (\phi'_{i_1,i_2}(y_{1,j}^\Delta, y_{2,k}^\Delta))^T f(u_i^\Delta, y_{1,j}^\Delta, y_{2,k}^\Delta) \quad \forall (u_i^\Delta, y_{1,j}^\Delta, y_{2,k}^\Delta) \right\}$$

(see (6.7) for comparison). Define the sets  $\Theta_{N,\Delta}$  and  $\mathcal{Y}_{N,\Delta}$  by the equations

$$(8.7) \quad \Theta_{N,\Delta} \stackrel{\text{def}}{=} \left\{ (u_i^\Delta, y_{1,j}^\Delta, y_{2,k}^\Delta) : \gamma_{i,j,k}^{N,\Delta} \neq 0 \right\},$$

$$(8.8) \quad \mathcal{Y}_{N,\Delta} \stackrel{\text{def}}{=} \left\{ (y_{1,j}^\Delta, y_{2,k}^\Delta) : \sum_i \gamma_{i,j,k}^{N,\Delta} \neq 0 \right\}$$

(see (7.11) and (7.12) for comparison). For  $N = 6$  and  $\Delta = 0.0125$ , the graphs of  $\Theta_{N,\Delta}$  and  $\mathcal{Y}_{N,\Delta}$  are depicted in Figures 1 and 2 below (the points belonging to these sets are marked). As follows from Theorem 7.3, these graphs can serve as approximations, respectively, to the graph of the optimal periodic control  $\Theta_*$  and to the optimal periodic orbit  $\mathcal{Y}_*$ .

Define the function  $\psi_{N,\Delta}(y_1, y_2)$  by the equation (see (6.11) for comparison)

$$(8.9) \quad \psi_{N,\Delta}(y_1, y_2) \stackrel{\text{def}}{=} \sum_{(i_1,i_2) \in I_N} \lambda_{i_1,i_2}^{N,\Delta} \phi_{i_1,i_2}(y_1, y_2).$$

The problem (7.1) is in this case of the form

$$(8.10) \quad \min_{u \in [-0.4, 0.4]} \Phi_{N,\Delta}(u, y_1, y_2),$$

 FIG. 1.  $\Theta_{N,\Delta}$ . Approximation to the graph of the optimal periodic control  $\Theta_*$ .

 FIG. 2.  $\mathcal{Y}_{N,\Delta}$ . Approximation to the optimal periodic orbit  $\mathcal{Y}_*$ .

where

$$\begin{aligned}
 \Phi_{N,\Delta}(u, y_1, y_2) = & \left[ ((y_2 - 3)(y_2 - 1)^2 + 2.5)(y_2 - 1) + 3 + 1.126y_1^2 + 0.4u^2 \right. \\
 (8.11) \quad & \left. + \left( \frac{\partial \psi_{N,\Delta}(y_1, y_2)}{\partial y_1} (y_2 - 1.6) + \frac{\partial \psi_{N,\Delta}(y_1, y_2)}{\partial y_2} u \right) \right].
 \end{aligned}$$

Note that the function  $\Phi_{N,\Delta}(u, y_1, y_2)$  is strictly convex in  $u$  and, hence, the  $N$ -regularity condition is satisfied on every subset  $Q$  of  $Y$ . Also, the solution  $u_{N,\Delta}(y_1, y_2)$

of the problem (8.10) is unique and is defined by the equation (8.12)

$$u_{N,\Delta}(y_1, y_2) = \begin{cases} -1.25 \frac{\partial \psi_{N,\Delta}(y_1, y_2)}{\partial y_2}, & -0.4 \leq -1.25 \frac{\partial \psi_{N,\Delta}(y_1, y_2)}{\partial y_2} \leq 0.4, \\ -0.4, & -1.25 \frac{\partial \psi_{N,\Delta}(y_1, y_2)}{\partial y_2} < -0.4, \\ 0.4, & -1.25 \frac{\partial \psi_{N,\Delta}(y_1, y_2)}{\partial y_2} > 0.4. \end{cases}$$

The graph of this function (with  $N$  and  $\Delta$  as in Figures 1 and 2 is depicted in Figure 3, where the points belonging to the set  $\Theta_{N,\Delta}$  are marked, for convenience, as well (the latter being visibly close to the surface defined by  $u_{N,\Delta}(\cdot)$ ).

FIG. 3.  $u_{N,\Delta}(y_1, y_2)$ . Obtained feedback control function.

As can be seen from Figures 2 and 3, the function  $u_{N,\Delta}(y_1, y_2)$ , being defined by the right-hand side of (8.12), is smooth in a neighborhood  $Q$  of  $\mathcal{Y}_{N,\Delta}$ , the latter being close to the optimal periodic orbit  $\mathcal{Y}_*$ . Hence, one can assume (based on Theorem 7.1) that  $u_{N,\Delta}(y_1, y_2)$  can serve as an approximation for the optimal control  $u_*(y_1, y_2)$  on  $\mathcal{Y}_*$ . To verify that this is the case, we used MATLAB to integrate our system with the feedback control  $u_{N,\Delta}(y_1, y_2)$  and with the initial conditions  $y_1(0) = 0$ ,  $y_2(0) = 1.848$  (a point in  $\mathcal{Y}_{N,\Delta}$ ). The result of such integration is the  $T$ -periodic solution  $y(\tau) = (y_1(\tau), y_2(\tau))$  and the corresponding  $T$ -periodic control  $u(\tau) \stackrel{\text{def}}{=} u_{N,\Delta}(y_1(\tau), y_2(\tau))$ , with  $T = 4.8597$ . The graphs of these functions are shown in Figures 4 and 5 below (which look very similar to those obtained in [54]). The value of the objective function obtained on this periodic solution is evaluated to be equal to  $4.195877 \approx 4.196$ . That is, (8.5) is satisfied and, hence, an approximate solution to the periodic optimization problem is found. Note that the closed curve  $\mathcal{Y}$  defined by  $(y_1(\tau), y_2(\tau))$ ,

$$(8.13) \quad \mathcal{Y} \stackrel{\text{def}}{=} \{(y_1, y_2) : (y_1, y_2) = (y_1(\tau), y_2(\tau)) \text{ for some } \tau \in [0, T]\},$$

passes very close to the points of  $\mathcal{Y}_{N,\Delta}$  as illustrated by Figure 6.

**9. Proofs for sections 4 and 5.** Due to the approximating property of the sequence of the functions  $\phi_i(\cdot)$ ,  $i = 1, 2, \dots$ , (see (5.1)), the set  $W$  can be presented in the form

$$(9.1) \quad W = \left\{ \gamma \in \mathcal{P}(U \times Y) : \int_{U \times Y} (\phi'_i(y))^\top f(u, y) \gamma(du, dy) = 0, \quad i = 1, 2, \dots \right\},$$

FIG. 4.  $(y_1(\tau), y_2(\tau))$ . *Obtained periodic solution.*

FIG. 5.  $u(\tau)$ . *Obtained periodic control.*

FIG. 6.  $\mathcal{Y}$ . *Obtained periodic orbit.*

where, without loss of generality, one may assume that the functions  $\phi_i(\cdot)$  satisfy the following normalization conditions:

$$(9.2) \quad \max_{y \in \bar{D}} \{|\phi_i(y)|, \|\phi'_i(y)\|, \|\phi''_i(y)\|\} \leq \frac{1}{2^i}, \quad i = 1, 2, \dots$$

In the above expression,  $\|\phi_i''(y)\|$  is a norm of the Hessian (the matrix of second derivatives of  $\phi_i(y)$ ) in  $\mathbb{R}^m \times \mathbb{R}^m$ ,  $\|\phi_i'(y)\|$  is a norm of  $\phi_i'(y)$  in  $\mathbb{R}^m$ , and  $\hat{D}$  is a closed ball in  $\mathbb{R}^m$  that contains  $Y$  in its interior.

Let  $l_1$  and  $l_\infty$  stand for the Banach spaces of infinite sequences such that, for any  $x = (x_1, x_2, \dots) \in l_1$ ,  $\|x\|_{l_1} \stackrel{\text{def}}{=} \sum_i |x_i| < \infty$  and, for any  $\lambda = (\lambda_1, \lambda_2, \dots) \in l_\infty$ ,  $\|\lambda\|_{l_\infty} \stackrel{\text{def}}{=} \sup_i |\lambda_i| < \infty$ . It is easy to see that, given an element  $\lambda \in l_\infty$ , one can define a linear continuous functional  $\lambda(\cdot) : l_1 \rightarrow \mathbb{R}^1$  by the equation

$$(9.3) \quad \lambda(x) = \sum_i \lambda_i x_i \quad \forall x \in l_1, \quad \|\lambda(\cdot)\| = \|\lambda\|_{l_\infty}.$$

It is also known (see, e.g., [49, p. 86]) that any continuous linear functional  $\lambda(\cdot) : l_1 \rightarrow \mathbb{R}^1$  can be presented in the form (9.3) with some  $\lambda \in l_\infty$ .

By (9.2),  $(\phi_1(y), \phi_2(y), \dots) \in l_1$  and  $(\frac{\partial \phi_1}{\partial y_j}, \frac{\partial \phi_2}{\partial y_j}, \dots) \in l_1$  for any  $y \in Y$ . Hence, the function  $\psi_\lambda(y)$ ,

$$(9.4) \quad \psi_\lambda(y) \stackrel{\text{def}}{=} \sum_i \lambda_i \phi_i(y), \quad \lambda = (\lambda_1, \lambda_2, \dots) \in l_\infty,$$

is continuously differentiable, with  $\psi'_\lambda(y) = \sum_i \lambda_i \phi'_i(y)$ .

*Proof of Theorem 4.1(iii).* If the function  $\psi(\cdot)$  satisfying (4.6) exists, then  $\min_{(u,y) \in U \times Y} (-\psi'(y))^T f(u, y) > 0$  and, hence,

$$(9.5) \quad \lim_{\alpha \rightarrow \infty} \min_{(u,y) \in U \times Y} \{g(u, y) + \alpha(-\psi'(y))^T f(u, y)\} = \infty.$$

This implies that the optimal value of the dual problem is unbounded ( $\mu_* = \infty$ ).

Assume now that the optimal value of the dual problem is unbounded. That is, there exists a sequence  $(\mu_k, \psi_k(\cdot))$  such that

$$(9.6) \quad \mu_k \leq g(u, y) + (\psi'_k(y))^T f(u, y) \quad \forall (u, y) \in U \times Y, \quad \lim_{k \rightarrow \infty} \mu_k = \infty$$

$$(9.7) \quad \Rightarrow 1 \leq \frac{1}{\mu_k} g(u, y) + \frac{1}{\mu_k} (\psi'_k(y))^T f(u, y) \quad \forall (u, y) \in U \times Y.$$

For  $k$  large enough,  $\frac{1}{\mu_k} |g(u, y)| \leq \frac{1}{2} \quad \forall (u, y) \in U \times Y$ . Hence

$$\frac{1}{2} \leq \frac{1}{\mu_k} (\psi'_k(y))^T f(u, y) \quad \forall (u, y) \in U \times Y.$$

That is, the function  $\psi(y) \stackrel{\text{def}}{=} -\frac{1}{\mu_k} \psi_k(y)$  satisfies (4.6).  $\square$

*Proof of Theorem 4.1(i).* From (4.4) it follows that, if  $W$  is not empty, then the optimal value of the dual problem is bounded.

Conversely, let us assume that the optimal value  $\mu_*$  of the dual problem is bounded and let us establish that  $W$  is not empty. Assume that this is not true and  $W$  is empty. Define the set  $\mathcal{Q}$  by the equation

$$(9.8) \quad \mathcal{Q} \stackrel{\text{def}}{=} \left\{ x = (x_1, x_2, \dots) : x_i = \int_{u,y} (\phi'_i(y))^T f(u, y) \gamma(du, dy), \quad \gamma \in \mathcal{P}(U \times Y) \right\}.$$

It is easy to see that the set  $\mathcal{Q}$  is a convex and compact subset of  $l_1$  (the fact that  $\mathcal{Q}$  is relatively compact in  $l_1$  is implied by (9.2); the fact that it is closed follows from that  $\mathcal{P}(U \times Y)$  is compact in weak convergence topology).

By (9.1), the assumption that  $W$  is empty is equivalent to the assumption that the set  $\mathcal{Q}$  does not contain the “zero element” ( $0 \notin \mathcal{Q}$ ). Hence, by a separation theorem (see, e.g., [49, p. 59]), there exists  $\bar{\lambda} = (\bar{\lambda}_1, \bar{\lambda}_2, \dots) \in l_\infty$  such that

$$\begin{aligned} 0 = \bar{\lambda}(0) &> \max_{x \in \mathcal{Q}} \sum_i \bar{\lambda}_i x_i = \max_{\gamma \in \mathcal{P}(U \times Y)} \int_{U \times Y} (\psi'_{\bar{\lambda}}(y))^T f(u, y) \gamma(du, dy) \\ &= \max_{(u, y) \in U \times Y} (\psi'_{\bar{\lambda}}(y))^T f(u, y), \end{aligned}$$

where  $\psi_{\bar{\lambda}}(y) = \sum_i \bar{\lambda}_i \phi_i(y)$  (see (9.4)). This implies that the function  $\psi(y) \stackrel{\text{def}}{=} \psi_{\bar{\lambda}}(y)$  satisfies (4.6), and, by Theorem 4.1(iii),  $\mu_*$  is unbounded. Thus, we have obtained a contradiction that proves that  $W$  is not empty.  $\square$

*Proof of Theorem 4.1(ii).* By Theorem 4.1(i), if the optimal value of the dual problem (4.1) is bounded, then  $W$  is not empty and, hence, a solution of the problem (3.2) exists.

Define the set  $\hat{\mathcal{Q}} \subset \mathbb{R}^1 \times l_1$  by the equation

$$\begin{aligned} \hat{\mathcal{Q}} &\stackrel{\text{def}}{=} \left\{ (\theta, x) : \theta \geq \int_{U \times Y} g(u, y) \gamma(du, dy), \right. \\ (9.9) \quad x &= (x_1, x_2, \dots), \quad x_i = \int_{U \times Y} (\phi'_i(y))^T f(u, y) \gamma(du, dy), \quad \gamma \in \mathcal{P}(U \times Y) \left. \right\}. \end{aligned}$$

The set  $\hat{\mathcal{Q}}$  is convex and closed. Also, for any  $j = 1, 2, \dots$ , the point  $(\theta_j, 0) \notin \hat{\mathcal{Q}}$ , where  $\theta_j \stackrel{\text{def}}{=} G_* - \frac{1}{j}$  and 0 is the zero element of  $l_1$ . On the basis of a separation theorem (see [49, p. 59]), one may conclude that there exists a sequence  $(\kappa^j, \lambda^j) \in \mathbb{R}^1 \times l_\infty$ ,  $j = 1, 2, \dots$  (with  $\lambda^j \stackrel{\text{def}}{=} (\lambda_1^j, \lambda_2^j, \dots)$ ) such that

$$\begin{aligned} \kappa^j \left( G_* - \frac{1}{j} \right) + \delta^j &\leq \inf_{(\theta, x) \in \hat{\mathcal{Q}}} \left\{ \kappa^j \theta + \sum_i \lambda_i^j x_i \right\} = \inf_{\gamma \in \mathcal{P}(U \times Y)} \left\{ \kappa^j \theta \right. \\ (9.10) \quad &+ \left. \int_{U \times Y} (\psi'_{\lambda^j}(y))^T f(u, y) \gamma(du, dy) \text{ s.t. } \theta \geq \int_{U \times Y} g(u, y) \gamma(du, dy) \right\}, \end{aligned}$$

where  $\delta^j > 0$  for all  $j$  and  $\psi_{\lambda^j}(y) = \sum_i \lambda_i^j \phi_i(y)$ . From (9.10) it immediately follows that  $\kappa^j \geq 0$ . Let us show that  $\kappa^j > 0$ . In fact, if this were not the case, one would obtain that

$$\begin{aligned} 0 < \delta^j &\leq \min_{\gamma \in \mathcal{P}(U \times Y)} \int_{U \times Y} (\psi'_{\lambda^j}(y))^T f(u, y) \gamma(du, dy) = \min_{(u, y) \in U \times Y} \{ (\psi'_{\lambda^j}(y))^T f(u, y) \} \\ &\Rightarrow \max_{(u, y) \in U \times Y} \{ (-\psi'_{\lambda^j}(y))^T f(u, y) \} \leq -\delta^j < 0. \end{aligned}$$

The latter would lead to the validity of the inequality (4.6) with  $\psi(y) = -\psi_{\lambda^j}(y)$ , which, by Theorem 4.1(iii), would imply that the optimal value of the dual problem is unbounded. Thus,  $\kappa^j > 0$ .

Dividing (9.10) by  $\kappa^j$  one can obtain that

$$\begin{aligned} G_* - \frac{1}{j} &< \left( G_* - \frac{1}{j} \right) + \frac{\delta^j}{\kappa_j} \\ &\leq \min_{\gamma \in \mathcal{P}(U \times Y)} \left\{ \int_{U \times Y} \left( g(u, y) + \frac{1}{\delta^j} (\psi'_{\lambda^j}(y))^T f(u, y) \right) \gamma(du, dy) \right\} \\ &= \min_{(u, y) \in U \times Y} \left\{ g(u, y) + \frac{1}{\delta^j} (\psi'_{\lambda^j}(y))^T f(u, y) \right\} \leq \mu^* \Rightarrow G_* \leq \mu_*. \end{aligned}$$

The latter and (4.4) prove (4.5).  $\square$

*Proof of Theorem 5.2.* The proof statement (iii) of the theorem follows the argument used in the proof of Theorem 4.1(iii), with the replacement of  $\psi(y)$  in (9.5) by  $\psi_v(y) = \sum_1^N v_i \phi_i(y)$ ,  $v = (v_i) \in \mathbb{R}^N$ , and with the replacement of  $\psi_k(y)$  in (9.6), (9.7) by  $\psi_{v^k}(y) = \sum_1^N v_i^k \phi_i(y)$ ,  $v^k = (v_i^k) \in \mathbb{R}^N$ .

The proofs of statements (i) and (ii) of the theorem are based on a separation theorem in F-D spaces and follow the argument used in the proofs of Theorem 4.1(i) and Theorem 4.1(ii), with the replacement of the set  $\mathcal{Q}$  defined in (9.8) by the set  $\mathcal{Q}' \subset \mathbb{R}^N$ ,  
(9.11)

$$\mathcal{Q}' \stackrel{\text{def}}{=} \left\{ x = (x_1, \dots, x_N) : x_i = \int_{u, y} (\phi'_i(y))^T f(u, y) \gamma(du, dy), \quad \gamma \in \mathcal{P}(U \times Y) \right\},$$

and with the replacement of the set  $\hat{\mathcal{Q}}$  defined in (9.9) by the set  $\hat{\mathcal{Q}}' \subset \mathbb{R}^1 \times \mathbb{R}^N$ ,

$$\hat{\mathcal{Q}}' \stackrel{\text{def}}{=} \left\{ (\theta, x) : \theta \geq \int_{U \times Y} g(u, y) \gamma(du, dy), \right.$$

(9.12)

$$\left. x = (x_1, \dots, x_N), \quad x_i = \int_{U \times Y} (\phi'_i(y))^T f(u, y) \gamma(du, dy), \quad \gamma \in \mathcal{P}(U \times Y) \right\}. \quad \square$$

*Proof of Proposition 5.3.* Let (5.17) be valid. Then, for some positive  $r$ ,

$$r\bar{B} \subset \text{co}K_N,$$

where  $\bar{B}$  is a closed unit ball in  $\mathbb{R}^N$ . By (5.18), the inequality (5.15) is equivalent to

$$(9.13) \quad \max_{z=(z_i) \in K_N} \sum_{i=1}^N v_i z_i \leq 0 \quad \Rightarrow \quad \max_{z=(z_i) \in r\bar{B}} \sum_{i=1}^N v_i z_i \leq 0.$$

Since  $\max_{z=(z_i) \in r\bar{B}} \sum_{i=1}^N v_i z_i = r\|v\|$ , the second inequality in (9.13) implies that  $v = 0$ . That is, Assumption 1 is satisfied.

Assume now that (5.17) is not valid, that is, either 0 is a boundary point of  $\text{co}K_N$  or it does not belong to the closure of  $\text{co}K_N$ . Then, by separation theorem, there exists a vector  $v = (v_i) \neq 0$  such that

$$(9.14) \quad \max_{z=(z_i) \in K_N} \sum_{i=1}^N v_i z_i = \max_{z=(z_i) \in \text{co}K_N} \sum_{i=1}^N v_i z_i \leq 0.$$

This implies that Assumption 1 is not satisfied.  $\square$

*Proof of Theorem 5.5.* The fact that Assumption 1 is satisfied implies, in particular, that the function  $\psi_v(\cdot)$  satisfying (5.13) does not exist. Hence, by Theorem 5.2(iii), the optimal value  $\mu_N$  of the D-N-LLPP (5.8) is bounded. Let  $v^k = (v_i^k) \in \mathbb{R}^N$  be such that

$$(9.15) \quad \mu_N - \frac{1}{k} \leq g(u, y) + \left( \sum_{i=1}^N v_i^k \phi'_i(y) \right)^T f(u, y) \quad \forall (u, y) \in U \times Y, \quad k = 1, 2, \dots$$

Show that the sequence  $v^k$  is bounded. That is,

$$(9.16) \quad \|v^k\| \leq c_N, \quad k = 1, 2, \dots$$

In fact, if  $v^k$ ,  $k = 1, 2, \dots$ , were not bounded, then there would exist a subsequence  $v^{k'}$  such that

$$(9.17) \quad \lim_{k' \rightarrow \infty} \|v^{k'}\| = \infty, \quad \lim_{k' \rightarrow \infty} \frac{v^{k'}}{\|v^{k'}\|} \stackrel{\text{def}}{=} \tilde{v}, \quad \|\tilde{v}\| = 1.$$

Dividing (9.15) by  $\|v^k\|$  and passing to the limit over the subsequence  $\{k'\}$ , one would obtain the following inequality:

$$(9.18) \quad 0 \leq \left( \sum_{i=1}^N \tilde{v}_i \phi'_i(y) \right)^T f(u, y) \quad \forall (u, y) \in U \times Y.$$

By Assumption 1, the fact that (9.18) is valid implies that  $\tilde{v} = (\tilde{v}_i) = 0$ , which is in contradiction to (9.17). Thus, the validity of (9.16) is established.

Due to (9.16), there exists a subsequence  $\{k'\}$  such that there exists a limit

$$(9.19) \quad \lim_{k' \rightarrow \infty} v^{k'} \stackrel{\text{def}}{=} v.$$

Passing over this subsequence to the limit in (9.15), one obtains

$$(9.20) \quad \mu_N \leq g(u, y) + \left( \sum_{i=1}^N v_i \phi'_i(y) \right)^T f(u, y) \quad \forall (u, y) \in U \times Y \quad \Rightarrow \quad v = (v_i) \in V_N.$$

The latter proves that  $V_N$  is not empty. The proof of that  $V_N$  is bounded follows the same argument as that used above to establish (9.16). This completes the proof of statement (i) of the theorem.

To prove statement (ii), let us assume that (5.19) and (5.20) are valid but Assumption 1 is not satisfied, and, hence, there exists a vector  $v = (v_i) \neq 0$  such that

$$(9.21) \quad \left( \sum_{i=1}^N v_i \phi'_i(y) \right)^T f(u, y) \leq 0 \quad \forall (u, y) \in U \times Y.$$

By (9.21), for an arbitrary  $v^0 = (v_i^0) \in V_N$  and for an arbitrary  $\alpha \geq 0$ ,

$$(9.22) \quad \mu_N \leq g(u, y) + \left( \sum_{i=1}^N (v_i^0 - \alpha v_i) \phi'_i(y) \right)^T f(u, y) \quad \forall (u, y) \in U \times Y.$$

The latter implies that  $(v^0 - \alpha v) \in V_N \forall \alpha \geq 0$ , which contradicts the fact that  $V_N$  is bounded (postulated by (5.20)). This proves statement (ii) of the theorem.  $\square$

*Proof of Theorem 5.6.* Consider first the case when  $\mu_* < \infty$ . For arbitrary small  $\delta > 0$ , there exists a function  $\psi(\cdot) \in C^1$  such that

$$\min_{(u,y) \in U \times Y} \{g(u, y) + \psi'(y)f(u, y)\} \geq \mu_* - \delta.$$

By the approximating property (5.1), there exist numbers  $v_1, v_2, \dots, v_{\bar{N}}$  (with  $\bar{N}$  being large enough) such that

$$(9.23) \quad \max_{y \in Y} \left\| \psi'(y) - \sum_{i=1}^{\bar{N}} v_i \phi'_i(y) \right\| \leq \delta$$

$$(9.24) \quad \Rightarrow \left| \min_{(u,y) \in U \times Y} \{g(u, y) + \psi'(y)f(u, y)\} - \min_{(u,y) \in U \times Y} \left\{ g(u, y) + \sum_{i=1}^{\bar{N}} v_i (\phi'_i(y))^T f(u, y) \right\} \right| \leq c\delta,$$

where  $c \stackrel{\text{def}}{=} \max_{(u,y) \in U \times Y} \|f(u, y)\|$ . From the above expressions and from the fact that

$$(9.25) \quad \min_{(u,y) \in U \times Y} \left\{ g(u, y) + \sum_{i=1}^N v_i (\phi'_i(y))^T f(u, y) \right\} \leq \mu_{\bar{N}},$$

it follows that  $\mu_* - \delta \leq \mu_{\bar{N}} + c\delta$ . This and (5.21) imply that  $0 \leq \mu_* - \mu_N \leq c(1 + \delta)$  for  $N \geq \bar{N}$ . Since  $\delta$  is arbitrarily small, the latter proves (5.22) for bounded  $\mu_*$ .

Assume now that  $\mu_* = \infty$ . Then, for an arbitrary large  $A > 0$ , there exists a function  $\psi(\cdot) \in C^1$  such that

$$\min_{(u,y) \in U \times Y} \{g(u, y) + \psi'(y)f(u, y)\} \geq A.$$

By the approximating property (5.1), there exist numbers  $v_1, v_2, \dots, v_{\bar{N}}$  (with  $\bar{N}$  being large enough), such that (9.23) and (9.24) are valid. Also, the inequality (9.25) remains valid due to the definition of  $\mu_N$  (see (5.8)). Consequently,  $\mu_{\bar{N}} \geq A - c\delta$ . Since  $\delta > 0$  can be chosen arbitrarily small, the latter implies that  $\mu_{\bar{N}} \geq A$ . Hence,  $\lim_{N \rightarrow \infty} \mu_N = \infty$ .  $\square$

## 10. Proofs for sections 6 and 7.

*Proof of Theorem 6.2.* First, let us show that the set  $\Lambda_{N,\Delta}$  is bounded for  $\Delta$  small enough. That is, show that

$$(10.1) \quad \sup_{\lambda \in \Lambda_{N,\Delta}} \|\lambda\| \leq c_N = \text{const}$$

for  $\Delta \leq \Delta_N$  ( $\Delta_N > 0$ ). Assume that this is not true and, hence, there exist sequences  $\Delta_s$  and  $\lambda^{N,\Delta_s} \in \Lambda_{N,\Delta_s}$ ,  $s = 1, 2, \dots$ , such that

$$\lim_{s \rightarrow \infty} \Delta_s = 0, \quad \lim_{s \rightarrow \infty} \|\lambda^{N,\Delta_s}\| = \infty.$$

Without loss of generality one may assume that there exists a limit

$$(10.2) \quad \lim_{s \rightarrow \infty} \frac{\lambda^{N, \Delta_s}}{\|\lambda^{N, \Delta_s}\|} \stackrel{\text{def}}{=} v, \quad \|v\| = 1.$$

From the definition of  $\Lambda_{N, \Delta}$  (see (6.9)) it follows that the inequality

$$(10.3) \quad \mu_{N, \Delta} \leq g(u_l, y_k) + \sum_{i=1}^N \lambda_i^{N, \Delta} (\phi'_i(y_k))^T f(u_l, y_k)$$

is valid for any grid point  $(u_l, y_k) \in U \times Y$ . Substituting  $\Delta_s$  for  $\Delta$  in (10.3) and then dividing the latter by  $\|\lambda^{N, \Delta_s}\|$  and passing to the limit as  $s \rightarrow \infty$ , one can prove that

$$(10.4) \quad 0 \leq \sum_{i=1}^N v_i (\phi'_i(y))^T f(u, y) \quad \forall (u, y) \in U \times Y.$$

Note that the proof of the above inequality is based on the fact that (see (5.12), (6.6), and (6.8))

$$(10.5) \quad \lim_{\Delta \rightarrow 0} \mu_{N, \Delta} = \mu_N,$$

which, in particular, implies that  $\mu_{N, \Delta_s}$  remains bounded as  $s \rightarrow \infty$ , and also on the fact that any point  $(u, y)$  in  $U \times Y$  can be presented as a limit of a sequence of grid points. From Assumption 1 it now follows that  $v = (v_i) = 0$ , which contradicts (10.2). This proves (10.1).

Let us now prove (6.10). Assuming that it is not true, one can come to a conclusion that there exist a positive number  $\alpha$  and sequences  $\Delta_s$  and  $\lambda^{N, \Delta_s} \in \Lambda_{N, \Delta_s}$ ,  $s = 1, 2, \dots$ , such that

$$(10.6) \quad \lim_{s \rightarrow \infty} \Delta_s = 0, \quad \text{dist}(\lambda^{N, \Delta_s}, V_N) \geq \alpha, \quad s = 1, 2, \dots$$

Due to (10.1), one may assume without loss of generality that there exists a limit

$$(10.7) \quad \lim_{s \rightarrow \infty} \lambda^{N, \Delta_s} \stackrel{\text{def}}{=} v^N \Rightarrow \text{dist}(v^N, V_N) \geq \alpha.$$

Substituting  $\Delta_s$  for  $\Delta$  in (10.3), taking into account (10.5), and passing to the limit as  $s \rightarrow \infty$ , one can obtain that

$$(10.8) \quad \mu_N \leq g(u, y) + \sum_{i=1}^N v_i^N (\phi'_i(y))^T f(u, y) \quad \forall (u, y) \in U \times Y \Rightarrow v^N = (v_i^N) \in V_N.$$

The latter contradicts (10.7) and, thus, proves (6.10).  $\square$

*Proofs of Theorem 7.1 and Corollary 7.2.* Fix an arbitrary  $\bar{y} \in \mathcal{Y}_* \cap Q$ . From Theorem 7.3(ii) it follows that there exists  $(u_{l, \Delta}, y_{k, \Delta}) \in \Theta_{N, \Delta}$  such that

$$(10.9) \quad \lim_{N \rightarrow \infty} \overline{\lim_{\Delta \rightarrow 0}} \|(u_{l, \Delta}, y_{k, \Delta}) - (u_*(\bar{y}), \bar{y})\| = 0.$$

Note that, since  $Q$  is open, from (10.9) it follows that there exists  $r > 0$  such that, for  $N$  large and  $\Delta$  small enough,

$$(10.10) \quad y_{k, \Delta} \in \bar{y} + r\bar{D} \subset Q, \quad \bar{D} \stackrel{\text{def}}{=} \{y : \|y\| \leq 1\}.$$

Show that the validity of (10.9) also implies the validity of

$$(10.11) \quad \lim_{N \rightarrow \infty} \overline{\lim}_{\Delta \rightarrow 0} \|u_{N,\Delta}(y_{k_{N,\Delta}}) - u_*(\bar{y})\| = 0$$

if  $N$ -RC is satisfied.

Assume that  $N$ -RC is satisfied on  $Q$  but (10.11) is not true. Then, due to (10.9), there exist a number  $\alpha > 0$  and sequences  $N_s$  ( $\lim_{s \rightarrow \infty} N_s = \infty$ ),  $\Delta_{s,j}$  ( $\lim_{j \rightarrow \infty} \Delta_{s,j} = 0$ ) such that

$$(10.12) \quad \|u_{N_s, \Delta_{s,j}}(y_{k_{N_s, \Delta_{s,j}}}) - u_{l_{N_s, \Delta_{s,j}}} \| \geq \alpha.$$

Without loss of generality, one may assume that there exist limits

$$(10.13) \quad \lim_{j \rightarrow \infty} y_{k_{N_s, \Delta_{s,j}}} \stackrel{\text{def}}{=} y_{N_s}, \quad \lim_{j \rightarrow \infty} u_{N_s, \Delta_{s,j}}(y_{k_{N_s, \Delta_{s,j}}}) \stackrel{\text{def}}{=} \tilde{u}_{N_s}, \quad \lim_{j \rightarrow \infty} u_{l_{N_s, \Delta_{s,j}}} \stackrel{\text{def}}{=} \tilde{u}_{N_s},$$

and also that there exists a limit

$$(10.14) \quad \lim_{j \rightarrow \infty} \lambda^{N_s, \Delta_{s,j}} \stackrel{\text{def}}{=} v^{N_s}, \quad v^{N_s} = (v_i^{N_s}) \in V_{N_s},$$

where the validity of the last inclusion is implied by Theorem 6.2 (remember that  $\lambda^{N_s, \Delta_{s,j}} \in \Lambda_{N_s, \Delta_{s,j}}$ ). From the duality relationships between the solutions of  $N\Delta$ -LLPP (6.3) and the solutions of  $D-N\Delta$ -LLPP (6.7) it follows that, for any  $(u_l, y_k) \in \Theta_{N,\Delta}$ ,

$$(10.15) \quad \mu_{N,\Delta} = g(u_l, y_k) + \sum_{i=1}^N \lambda_i^{N,\Delta} (\phi'_i(y_k))^T f(u_l, y_k).$$

From (10.15) and from the fact that  $u_{N,\Delta}(\cdot)$  is defined as a solution of (7.1) it also follows that, for any  $y_k \in \mathcal{Y}_{N,\Delta}$ ,

$$(10.16) \quad \mu_{N,\Delta} \geq g(u_{N,\Delta}(y_k), y_k) + \sum_{i=1}^N \lambda_i^{N,\Delta} (\phi'_i(y_k))^T f(u_{N,\Delta}(y_k), y_k).$$

Via substituting  $N_s, \Delta_{s,j}, u_{l_{N_s, \Delta_{s,j}}}, y_{k_{N_s, \Delta_{s,j}}}$  for, respectively,  $N, \Delta, u_l, y_k$  in (10.15) and then passing to the limit as  $j \rightarrow \infty$ , one can obtain (see (10.13), (10.14) and (5.12), (6.6), (6.8)) that

$$(10.17) \quad \mu_{N_s} = g(\tilde{u}_{N_s}, y_{N_s}) + \sum_{i=1}^N v_i^{N_s} (\phi'_i(y_{N_s}))^T f(\tilde{u}_{N_s}, y_{N_s}).$$

Similarly, via substituting  $N_s, \Delta_{s,j}, u_{N_s, \Delta_{s,j}}(y_{k_{N_s, \Delta_{s,j}}}), y_{k_{N_s, \Delta_{s,j}}}$  for, respectively,  $N, \Delta, u_{N,\Delta}(y_k), y_k$  in (10.16) and passing to the limit as  $j \rightarrow \infty$ , one obtains that

$$(10.18) \quad \mu_{N_s} \geq g(\tilde{u}_{N_s}, y_{N_s}) + \sum_{i=1}^N v_i^{N_s} (\phi'_i(y_{N_s}))^T f(\tilde{u}_{N_s}, y_{N_s})$$

$$(10.19) \quad \Rightarrow \quad \mu_{N_s} = g(\tilde{u}_{N_s}, y_{N_s}) + \sum_{i=1}^N v_i^{N_s} (\phi'_i(y_{N_s}))^T f(\tilde{u}_{N_s}, y_{N_s}).$$

The equality (10.19) is implied by the inequality (10.18) due to the fact that

$$(10.20) \quad \mu_{N_s} = \min_{(u,y) \in U \times Y} \left\{ g(u, y) + \sum_{i=1}^N v_i^{N_s} (\phi'_i(y))^T f(u, y) \right\},$$

which is a consequence of  $v^{N_s} \in V_{N_s}$  (see (5.19)).

From (10.17) and (10.19) it follows (see the notation introduced in (5.23), (5.24), and (5.25)) that

$$(10.21) \quad y_{N_s} \in \mathcal{Y}_{N_s}^{v_{N_s}}, \quad \tilde{u}_{N_s} \in \mathcal{U}_{N_s}^{v_{N_s}}(y_{N_s}), \quad \tilde{u}_{N_s} \in \mathcal{U}_{N_s}^{v_{N_s}}(y_{N_s}).$$

By (10.10),  $y_{N_s} \in Q \cap \mathcal{Y}_{N_s}^{v_{N_s}}$  for  $s$  large enough. Hence, due to the validity of  $N$ -RC on  $Q$  (with  $N = N_s$ ),  $\mathcal{U}_{N_s}^{v_{N_s}}(y_{N_s})$  is a singleton. Consequently, by (10.21),

$$(10.22) \quad \tilde{u}_{N_s} = \tilde{u}_{N_s}.$$

Since, on the other hand, by (10.12) and (10.13),  $\|\tilde{u}_{N_s} - \tilde{u}_{N_s}\| \geq \alpha$ , one obtains a contradiction that establishes the validity of (10.11).

To prove (7.6), let us assume that it is not valid for the given  $\bar{y}$  and, hence, there exist sequences  $N' \rightarrow \infty$  and  $\Delta' \rightarrow 0$  such that

$$(10.23) \quad \lim_{N' \rightarrow \infty} \lim_{\Delta' \rightarrow 0} u_{N', \Delta'}(\bar{y}) = \tilde{u} \neq u_*(\bar{y}).$$

The functions  $u_{N', \Delta'}(\cdot)$  are uniformly equicontinuous on  $\bar{Q}' = \bar{y} + r\bar{D}$ . Consequently, by the Arzela–Ascoli theorem, there exist subsequences  $N'' \rightarrow \infty$  and  $\Delta'' \rightarrow 0$  of  $N'$  and  $\Delta'$ , and there exist a uniformly continuous function  $u_0(\cdot) : \bar{y} + r\bar{D} \rightarrow U$  such that

$$(10.24) \quad \lim_{N'' \rightarrow \infty} \lim_{\Delta'' \rightarrow 0} \max_{x \in \bar{y} + r\bar{D}} \|u_{N'', \Delta''}(x) - u_0(x)\| = 0,$$

where, by (10.23),

$$(10.25) \quad u_0(\bar{y}) = \tilde{u} \neq u_*(\bar{y}).$$

On the other hand, passing to the limit over the subsequences  $N''$  and  $\Delta''$  in the inequality

$$\|u_0(\bar{y}) - u_*(\bar{y})\| \leq \|u_0(\bar{y}) - u_{N, \Delta}(\bar{y})\|$$

$$+ \|u_{N, \Delta}(\bar{y}) - u_{N, \Delta}(y_{k_{N, \Delta}})\| + \|u_{N, \Delta}(y_{k_{N, \Delta}}) - u_*(\bar{y})\|$$

and using (7.5), (10.11), and (10.24), one can obtain that  $\|u_0(\bar{y}) - u_*(\bar{y})\| = 0$ , which contradicts (10.25) and, thus, proves (7.6). The uniform convergence of  $u_{N, \Delta}(\cdot)$  to  $u_*(\cdot)$  on any closed subset of  $\mathcal{Y}_* \cap Q$  follows from (7.6) and the Arzela–Ascoli theorem. Thus, statement (i) of the theorem is proved.

Statement (ii) of theorem is a special case ( $J = 1$ ) of Corollary 7.2, which we now will prove. By Theorem 7.1(i) established above, (7.10) is valid for any

$$y \in \cup_j (\mathcal{Y}_* \cap Q_j) = \mathcal{Y}_* \cap (\cup_j Q_j).$$

Thus, to establish the validity of the required result, one needs to verify that

$$(10.26) \quad \gamma_*(\mathcal{Y}_* \cap (\cup_j Q_j)) = 1.$$

From (7.4) and (7.8) it follows that  $\gamma_*(\overline{\cup_j Q_j}) = 1$ , which implies that

$$y_*(\tau) \in \overline{\cup_j Q_j} \quad \forall \tau \in [0, T].$$

The latter is equivalent to  $\mathcal{Y}_* \subset \overline{\cup_j Q_j}$  and, hence,

$$(10.27) \quad \gamma_*(\mathcal{Y}_* \cap (\cup_j Q_j)) = \gamma_*(\mathcal{Y}_* \cap (\overline{\cup_j Q_j})) - \gamma_*(\mathcal{Y}_* \cap (\overline{\cup_j Q_j} / \cup_j Q_j)).$$

This and (7.9) imply (10.26).  $\square$

# **$L^\infty$ -NULL CONTROLLABILITY FOR THE HEAT EQUATION AND ITS CONSEQUENCES FOR THE TIME OPTIMAL CONTROL PROBLEM\***

GENGSHENG WANG<sup>†</sup>

**Abstract.** In this paper, we establish a certain  $L^\infty$ -null controllability for the internally controlled heat equation in  $\Omega \times [0, T]$ , with the control restricted to a product set of an open nonempty subset in  $\Omega$  and a subset of positive measure in the interval  $[0, T]$ . Based on this, we obtain a bang-bang principle for the time optimal control of the heat equation with controls taken from the set  $\mathcal{U}_{ad} = \{u(\cdot, t) : [0, \infty) \rightarrow L^2(\Omega) \text{ measurable; } u(\cdot, t) \in U, \text{ a.e. in } t\}$ , where  $U$  is a closed and bounded subset of  $L^2(\Omega)$ . Namely, each optimal control  $u^*(\cdot, t)$  of the problem satisfies necessarily the bang-bang property:  $u^*(\cdot, t) \in \partial U$  for almost all  $t \in [0, T^*]$ , where  $\partial U$  denotes the boundary of the set  $U$  and  $T^*$  is the optimal time. We also get the uniqueness of the optimal control when the target set  $S$  is convex and the control set  $U$  is a closed ball.

**Key words.** null controllability, time optimal control, bang-bang principle, heat equation

**1. Introduction.** Let  $T$  be a positive number and let  $\Omega$  be a bounded domain in  $\mathbf{R}^n$ ,  $n \geq 1$ , with a  $C^\infty$ -smooth boundary. Let  $\omega$  stand for an open and nonempty subset of  $\Omega$ . Denote by  $\chi_\omega$  the characteristic function of  $\omega$ . Consider the following controlled heat equation:

$$(1.1) \quad \begin{cases} y_t(x, t) - \Delta y(x, t) = \chi_\omega(x)u(x, t) & \text{in } \Omega \times (0, T), \\ y(x, t) = 0 & \text{on } \partial\Omega \times (0, T), \\ y(x, 0) = y_0(x) & \text{in } \Omega, \end{cases}$$

where  $y_0(\cdot)$  is a function in  $L^2(\Omega)$  and  $u(x, t)$  is a control function taken from the space  $L^\infty(0, T; L^2(\Omega))$ .

In this paper, we establish the following  $L^\infty$ -null controllability for (1.1).

**THEOREM 1.1.** *Let  $T$  be a positive number and let  $E$  be a subset of positive measure in the interval  $[0, T]$ . For each  $\delta \geq 0$ , we write  $E_\delta$  for the set  $\{t \in \mathbf{R}^1; t + \delta \in E\}$  and denote by  $\chi_{E_\delta}$  the characteristic function of the set  $E_\delta$ . Then there exists a number  $\delta_0$  with  $0 < \delta_0 < T$  such that for each  $\delta$  with  $0 \leq \delta \leq \delta_0$  and for each element  $y_0$  in  $L^2(\Omega)$ , there is a control  $u_\delta$  in the space  $L^\infty(0, T - \delta; L^2(\Omega))$  such that the solution  $y^\delta$  to the following controlled heat equation:*

$$(1.2) \quad \begin{cases} y_t^\delta(x, t) - \Delta y^\delta(x, t) = \chi_{E_\delta}(t)\chi_\omega(x)u_\delta(x, t) & \text{in } \Omega \times (0, T - \delta), \\ y^\delta(x, t) = 0 & \text{on } \partial\Omega \times (0, T - \delta), \\ y^\delta(x, 0) = y_0(x) & \text{in } \Omega \end{cases}$$

reaches zero at time  $T - \delta$ , namely,  $y^\delta(x, T - \delta) = 0$  over  $\Omega$ . Moreover, the control  $u_\delta$  satisfies the following estimate:

$$(1.3) \quad \|u_\delta\|_{L^\infty(0, T-\delta; L^2(\Omega))}^2 \leq L \|y_0\|_{L^2(\Omega)}^2,$$

where  $L$  is a positive number independent of  $\delta$  and  $y_0$ .

Notice that we shall give an explicit expression for the constant  $L$  in section 2, from which one can see how the constant  $L$  depends on the set  $E$  and the number  $\delta_0$ .

The main motivation for such an investigation is, besides the novelty of it (to our best knowledge), its applications to the following time optimal control problems for the heat equation:

$$(P) \quad \text{Min } \{\tilde{t}; y(\cdot, \tilde{t}; u, y_0) \in S, u \in \mathcal{U}_{ad}\}.$$

Here  $y(\cdot, t; u, y_0)$  is the solution of the following controlled heat equation:

$$(1.4) \quad \begin{cases} y_t(x, t) - \Delta y(x, t) = \chi_\omega(x)u(x, t) & \text{in } \Omega \times (0, \infty), \\ y(x, t) = 0 & \text{on } \partial\Omega \times (0, \infty), \\ y(x, 0) = y_0(x) & \text{in } \Omega, \end{cases}$$

and

$$\mathcal{U}_{ad} = \{v : [0, \infty) \rightarrow L^2(\Omega) \text{ measurable; } v(\cdot, t) \in U \text{ for almost all } t \geq 0\},$$

with  $U$  being a bounded and closed subset of  $L^2(\Omega)$ , and  $S$  being a subset of  $L^2(\Omega)$ . In the problem (P), we shall call the set  $S$  the target set, the set  $U$  the control set, and the set  $\mathcal{U}_{ad}$  the control function set. For simplicity, we shall call a control function a control. We write  $T^*$  for the number  $\text{Min } \{\tilde{t}; y(\cdot, \tilde{t}; u, y_0) \in S, u \in \mathcal{U}_{ad}\}$  and call it the optimal time for the problem (P). A control  $u^*$  in the set  $\mathcal{U}_{ad}$  having the property

$$y(x, T^*; u^*, y_0) \in S$$

is called an optimal control for problem (P).

The most internally null controllability results for linear parabolic differential equations with control restricted on  $(0, T) \times \omega$  were obtained by making use of the equivalent observability inequality for the dual equations, which were derived by the Carleman inequality for the linear parabolic equation established in [9]. We can prove that Theorem 1.1 is equivalent to the following observability inequality (see the appendix):

(O) There exist positive numbers  $L$  and  $\delta_0$  with  $\delta_0 < T$  such that

$$(1.5) \quad d \int_{\Omega} (p^\delta(x, 0))^2 dx]^{\frac{1}{2}} \leq L \int_0^{T-\delta} \left\{ \int_{\Omega} [\chi_{E_\delta}(t) \chi_\omega(x) p^\delta(x, t)]^2 dx \right\}^{\frac{1}{2}} dt$$

for each number  $\delta$  with  $0 \leq \delta \leq \delta_0$  and each function  $p_T^\delta(x) \in L^2(\Omega)$ , where  $p^\delta(x, t)$  is the solution to the following adjoint equation:

$$(1.6) \quad \begin{cases} p_t^\delta(x, t) + \Delta p^\delta(x, t) = 0 & \text{in } \Omega \times (0, T - \delta), \\ p^\delta(x, t) = 0 & \text{on } \partial\Omega \times (0, T - \delta), \\ p^\delta(x, T - \delta) = p_T^\delta(x) & \text{in } \Omega. \end{cases}$$

However, since the control in this work is restricted in the set  $E \times \omega$ , where  $E$  is an arbitrary measurable set of positive measure in the interval  $(0, T)$ , but not in

the set  $(0, T) \times \omega$  as in most works on the internally null controllability of linear parabolic equations, we do not know how to prove the observability inequality **(O)** either directly or by making use of the Carleman inequality. We establish Theorem 1.1 by applying an iterative argument stimulated by that in [10] (see also [11] and [15]). The iterative argument used here is based on a sharp observability estimate on the eigenfunctions of the Laplacian due to Lebeau and Zuazua in [11] (see also [10]) and also based on a special result in the measure theory given in [14].

With regard to the equivalence of Theorem 1.1 and the observability inequality **(O)**, we cannot find the exact same results in the literature, but similar results, where the control is restricted in  $(0, T) \times \omega$ , were partially given in [8], [4], [2], and [17]; namely, the  $L^1$  observability implies the  $L^\infty$  controllability. For the sake of completeness of the paper, we give the proof in the appendix.

Based on Theorem 1.1, we obtain the following bang-bang principle and the uniqueness for the time optimal control for problem **(P)**.

**THEOREM 1.2.** *Let the target  $S$  be any subset in  $L^2(\Omega)$ . Assume that the problem **(P)** has at least a solution  $u^*$ , with the corresponding optimal time  $T^*$ . Also assume that the control set  $U$  is closed and bounded in  $L^2(\Omega)$ . Then it holds that  $u^*(t) \in \partial U$  for almost all  $t \in [0, T^*]$ . If we further assume that  $\chi_\omega U \subset U$ , then it holds that  $\chi_\omega u^*(t) \in \partial U$  for almost all  $t \in [0, T^*]$ .*

**THEOREM 1.3.** *Suppose that the target set  $S$  is convex and the control set  $U$  is a closed ball. Then the optimal control of problem **(P)** is unique.*

Combining Theorem 1.3 and the existence results for the time optimal control obtained in [17] (see also [20] and [22]), we can have the following unique existence result for problem **(P)**.

**THEOREM 1.4.** *Suppose that the target set  $S$  is a closed and convex subset, which contains the origin of  $L^2(\Omega)$ , and the control set  $U$  is a closed ball in  $L^2(\Omega)$ . Then there exists a unique time optimal control for problem **(P)**.*

To my best knowledge, the observation that the bang-bang principle of time optimal control of the linear parabolic equations is related to a null controllability of the equation with the control restricted to a subset of positive measure in the time interval  $[0, T]$  was first given in [16]. In [16], the authors established such a controllability result for the one-dimensional boundary controlled heat equation. For other works related to the time optimal control problems, we would like to mention [5], [6], [14], [7], [18], [19], [12], [23], [13], [22], [20], [17], and [21].

The rest of the paper is organized as follows. In section 2, we give the proof of Theorem 1.1. In section 3, we prove Theorems 1.2 and 1.3 and also give some consequences of these theorems.

**2. The null controllability (C).** In this section, we shall prove Theorem 1.1. The proof is based on a sharp estimate on the eigenfunctions of the Laplacian due to Lebeau and Zuazua (see [11]) and also based on a fundamental result in the measure theory, which will be given later. Let  $\{\lambda_i\}_{i=1}^\infty$ ,  $0 < \lambda_1 < \lambda_2 \leq \dots$ , be the eigenvalues of  $-\Delta$  with the Dirichlet boundary condition, and let  $\{X_i(x)\}_{i=1}^\infty$  be the corresponding eigenfunctions, which serve as an orthonormal basis of  $L^2(\Omega)$ . Then we have the following result (see [11]).

**THEOREM 2.1.** *Let  $\Omega$  be a bounded domain in  $\mathbf{R}^n$ ,  $n \geq 1$ , with a  $C^\infty$ -smooth boundary. Then there exist two positive constants  $C_1, C_2 > 0$  such that*

$$(2.1) \quad \sum_{\lambda_i \leq r} |a_i|^2 \leq C_1 e^{C_2 \sqrt{r}} \int_\omega \left| \sum_{\lambda_i \leq r} a_i X_i(x) \right|^2 dx$$

for every finite  $r > 0$  and every choice of the coefficients  $\{a_i\}_{\lambda_i \leq r}$  with  $a_i \in \mathbf{R}^1$ .

Notice that the reason we assume the domain  $\Omega$  has a  $C^\infty$ -smooth boundary is because Theorem 2.1 needs the domain  $\Omega$  to have such a property and the proof of Theorem 1.1 is based on Theorem 2.1.

Now, we shall first use Theorem 2.1 to derive a certain controllability result, which will help us in the proof of Theorem 1.1. For each  $r > 0$ , we set  $\mathbf{X}_r = \text{span} \{X_i(x)\}_{\lambda_i \leq r}$  and consider the following dual equation:

$$(2.2) \quad \begin{cases} \varphi_t(x, t) + \Delta \varphi(x, t) = 0 & \text{in } \Omega \times (0, T), \\ \varphi(x, t) = 0 & \text{on } \partial\Omega \times (0, T), \\ \varphi(x, T) \in \mathbf{X}_r. \end{cases}$$

Here, each element  $\varphi(x, T)$  in  $\mathbf{X}_r$  can be written as

$$\varphi(x, T) = \sum_{\lambda_i \leq r} a_i X_i(x)$$

for a certain sequence of real numbers  $\{a_i\}_{\lambda_i \leq r}$ . Then the solution  $\varphi(x, t)$  to (2.2) can be expressed by

$$\varphi(x, t) = \sum_{\lambda_i \leq r} a_i e^{-\lambda_i(T-t)} X_i(x) \quad \text{for all } t \in [0, T].$$

Set  $b_i(t) = a_i e^{-\lambda_i(T-t)}$ ,  $t \in [0, T]$ . Then by (2.1), we have

$$\begin{aligned} \sum_{\lambda_i \leq r} |b_i(t)|^2 &\leq C_1 e^{C_2 \sqrt{r}} \int_{\omega} \left| \sum_{\lambda_i \leq r} b_i(t) X_i(x) \right|^2 dx \\ &= C_1 e^{C_2 \sqrt{r}} \int_{\omega} |\varphi(x, t)|^2 dx \quad \text{for all } t \in [0, T]. \end{aligned}$$

On the other hand,

$$\begin{aligned} \sum_{\lambda_i \leq r} |b_i(t)|^2 &= \sum_{\lambda_i \leq r} a_i^2 e^{-2\lambda_i(T-t)} \geq \sum_{\lambda_i \leq r} a_i^2 e^{-2\lambda_i T} \\ &= \int_{\Omega} \varphi^2(x, 0) dx \quad \text{for all } t \in [0, T]. \end{aligned}$$

Hence,

$$\int_{\Omega} \varphi^2(x, 0) dx \leq C_1 e^{C_2 \sqrt{r}} \int_{\omega} |\varphi(x, t)|^2 dx \quad \text{for all } t \in [0, T],$$

or equivalently,

$$\left[ \int_{\Omega} \varphi^2(x, 0) dx \right]^{\frac{1}{2}} \leq (C_1 e^{C_2 \sqrt{r}})^{\frac{1}{2}} \left[ \int_{\omega} |\varphi(x, t)|^2 dx \right]^{\frac{1}{2}} \quad \text{for all } t \in [0, T],$$

from which it follows that

$$\int_E \left[ \int_{\Omega} \varphi^2(x, 0) dx \right]^{\frac{1}{2}} dt \leq (C_1 e^{C_2 \sqrt{r}})^{\frac{1}{2}} \int_E \left[ \int_{\omega} |\varphi(x, t)|^2 dx \right]^{\frac{1}{2}} dt.$$

Namely, we obtained that for each  $\varphi(\cdot, T) \in \mathbf{X}_r$ ,

$$(2.3) \quad \begin{aligned} \int_{\Omega} \varphi^2(x, 0) dx &\leq \frac{C_1 e^{C_2 \sqrt{r}}}{(m(E))^2} \left\{ \int_0^T \left[ \int_{\Omega} |\chi_E(t) \chi_{\omega}(x) \varphi(x, t)|^2 dx \right]^{\frac{1}{2}} dt \right\}^2 \\ &= \frac{C_1 e^{C_2 \sqrt{r}}}{(m(E))^2} \|\chi_E \chi_{\omega} \varphi\|_{L^1(0, T; L^2(\Omega))}^2. \end{aligned}$$

Write  $P_r$  for the orthogonal projection from  $L^2(\Omega)$  to  $\mathbf{X}_r$ . We next use (2.3) to obtain the following controllability result.

LEMMA 2.2. *For each  $r > 0$ , there exists a control  $u_r$  in the space  $L^\infty(0, T; L^2(\Omega))$  with the estimate*

$$(2.4) \quad \|u_r\|_{L^\infty(0, T; L^2(\Omega))} \leq \frac{C_1 e^{C_2 \sqrt{r}}}{(m(E))^2} \|y_0\|_{L^2(\Omega)}^2$$

such that  $P_r(y(\cdot, T)) = 0$ , where  $y(x, t)$  is the solution of (1.2) with  $\delta = 0$  and  $u = u_r$ , and where  $C_1$  and  $C_2$  are the positive constants given in Theorem 2.1.

*Proof.* Let  $y(x, t)$  be the solution of (2.1) with  $\delta = 0$ , and let  $\varphi(x, t)$  be a solution of (2.2). Then

$$\langle y(\cdot, T), \varphi(\cdot, T) \rangle - \langle y_0(\cdot), \varphi(\cdot, 0) \rangle = \int_0^T \int_{\Omega} \chi_E(t) \chi_{\omega}(x) u(x, t) \varphi(x, t) dx dt.$$

Here and in what follows,  $\langle \cdot, \cdot \rangle$  denotes the inner product in  $L^2(\Omega)$ . If we can show that  $\langle y(\cdot, T), \varphi(\cdot, T) \rangle = 0$  for all  $\varphi(x, T) \in \mathbf{X}_r$ , then  $P_r(y(\cdot, T)) = 0$ . Thus, it suffices to prove that there exists a control  $u_r \in L^\infty(0, T; L^2(\Omega))$  with the estimate (2.4) such that

$$-\langle y_0(\cdot), \varphi(\cdot, 0) \rangle = \int_0^T \int_{\Omega} \chi_E(t) \chi_{\omega}(x) u_r(x, t) \varphi(x, t) dx dt \quad \text{for all } \varphi(\cdot, T) \in \mathbf{X}_r.$$

Now, we set

$$\mathbf{Y}_r = \{\chi_E(t) \chi_{\omega}(x) \varphi(x, t); \varphi(x, t) \text{ is the solution to (2.2)}\}.$$

It is clear that  $\mathbf{Y}_r$  is a linear subspace of  $L^1(0, T; L^2(\Omega))$ . We define a linear functional  $F_r : \mathbf{Y}_r \rightarrow \mathbf{R}^1$  by  $F_r(\chi_E \chi_{\omega} \varphi) = -\langle y_0(\cdot), \varphi(\cdot, 0) \rangle$ . By inequality (2.3), we see that

$$\begin{aligned} |F_r(\chi_E \chi_{\omega} \varphi)|^2 &\leq \|y_0\|_{L^2(\Omega)}^2 \cdot \|\varphi(\cdot, 0)\|_{L^2(\Omega)}^2 \\ &\leq \frac{C_1 e^{C_2 \sqrt{r}}}{(m(E))^2} \|y_0\|_{L^2(\Omega)}^2 \cdot \|\chi_E \chi_{\omega} \varphi\|_{L^1(0, T; L^2(\Omega))}^2. \end{aligned}$$

Namely,

$$\|F_r\|_{L(\mathbf{Y}_r, \mathbf{R}^1)}^2 \leq \frac{C_1 e^{C_2 \sqrt{r}}}{(m(E))^2} \|y_0\|_{L^2(\Omega)}^2,$$

where  $\|F_r\|_{L(\mathbf{Y}_r, \mathbf{R}^1)}^2$  denotes the operator norm of  $F_r$  from the subspace  $\mathbf{Y}_r$ , endowed with the norm of  $L^1(0, T; L^2(\Omega))$ , into the space  $\mathbf{R}^1$ . Thus,  $F_r$  is a bounded linear functional on  $\mathbf{Y}_r$ . By the Hahn–Banach theorem, there is a bounded linear functional

$$G_r : L^1(0, T; L^2(\Omega)) \rightarrow \mathbf{R}^1$$

such that

$$G_r = F_r \text{ on } \mathbf{Y}_r,$$

and such that

$$\|G_r\|_{L(L^1(0,T;L^2(\Omega));\mathbf{R}^1)}^2 = \|F_r\|_{L(\mathbf{Y}_r;R^1)}^2 \leq \frac{C_1 e^{C_2 \sqrt{r}}}{(m(E))^2} \|y_0\|_{L^2(\Omega)}^2.$$

Here  $\|G_r\|_{L(L^1(0,T;L^2(\Omega));\mathbf{R}^1)}$  denotes the operator norm of  $G_r$  from the space  $L^1(0,T;L^2(\Omega))$  to  $\mathbf{R}^1$ .

Then, by making use of the Riesz representation theorem (see, [3, p. 59]), there exists a function  $u_r$  in the space  $L^\infty(0,T;L^2(\Omega))$  such that

$$G_r(f) = \int_0^T \int_\Omega f u_r dx dt \quad \text{for all } f \in L^1(0,T;L^2(\Omega)),$$

and such that

$$\|u_r\|_{L^\infty(0,T;L^2(\Omega))}^2 = \|G_r\|_{L(L^1(0,T;L^2(\Omega));\mathbf{R}^1)}^2 \leq \frac{C_1 e^{C_2 \sqrt{r}}}{(m(E))^2} \|y_0\|_{L^2(\Omega)}^2.$$

In particular,

$$F_r(\chi_E \chi_\omega \varphi) = \int_0^T \int_\Omega \chi_E \chi_\omega \varphi u_r dx dt \quad \text{for all } \chi_E \chi_\omega \varphi \in \mathbf{Y}_r.$$

Namely,

$$-\langle y_0(\cdot), \varphi(\cdot, 0) \rangle = \int_0^T \int_\Omega \chi_E \chi_\omega \varphi u_r dx dt \quad \text{for all } \varphi(\cdot, T) \in \mathbf{X}_r.$$

This completes the proof.  $\square$

The following lemma from the measure theory will be used in our later discussion, whose proof can be found in [14, pp. 256–257].

LEMMA 2.3. *For almost all  $t$  in the set  $E$ , there exists a sequence of numbers  $\{t_i\}_{i=1}^\infty$  in the interval  $[0, T]$  such that*

$$(2.5) \quad t_1 < \cdots < t_i < t_{i+1} < \cdots < \tilde{t}, \quad t_i \rightarrow \tilde{t} \text{ as } i \rightarrow \infty,$$

$$(2.6) \quad m(E \cap [t_i, t_{i+1}]) \geq \rho(t_{i+1} - t_i), \quad i = 1, 2, \dots,$$

and

$$(2.7) \quad \frac{t_{i+1} - t_i}{t_{i+2} - t_{i+1}} \leq C_0, \quad i = 1, 2, \dots,$$

where  $\rho$  and  $C_0$  are two positive constants which depend on the set  $E$ .

Before proceeding with the proof of Theorem 1.1, we introduce briefly our main strategy. By applying Lemma 2.3, there exist a number  $\tilde{t}$  and a sequence  $\{t_N\}_{N=1}^\infty$  in the interval  $(0, T)$  such that (2.5)–(2.7) hold. The main part of the proof is to show that for each  $\tilde{y}_0$  in  $L^2(\Omega)$ , there exists a control  $\tilde{u}$  in the space  $L^\infty(t_1, \tilde{t}; L^2(\Omega))$

with the estimate  $\|\tilde{u}\|_{L^\infty(t_1, \tilde{t}; L^2(\Omega))}^2 \leq L \|\tilde{y}_0\|_{L^2(\Omega)}^2$  for a certain positive constant  $L$  independent of  $\tilde{y}_0$  such that the solution  $\tilde{y}(x, t)$  to the equation

$$(2.8) \quad \begin{cases} \tilde{y}_t(x, t) - \Delta \tilde{y}(x, t) = \chi_E(t) \chi_\omega(x) \tilde{u}(x, t) & \text{in } \Omega \times (t_1, \tilde{t}), \\ \tilde{y}(x, t) = 0 & \text{on } \partial\Omega \times (t_1, \tilde{t}), \\ \tilde{y}(x, t_1) = \tilde{y}_0(x) & \text{in } \Omega \end{cases}$$

has zero value at time  $\tilde{t}$ , namely,  $\tilde{y}(x, \tilde{t}) = 0$  over  $\Omega$ . To this end, we write

$$[t_1, \tilde{t}] = \bigcup_{N=1}^{\infty} (I_N \cup J_N),$$

where  $I_N = [t_{2N-1}, t_{2N}]$  and  $J_N = [t_{2N}, t_{2N+1}]$ ,  $N = 1, 2, \dots$ . Then we choose a suitable sequence of positive numbers  $\{r_N\}_{N=1}^\infty$  having the following properties:

- (a)  $r_1 < r_2 < \dots < r_N < \dots$ ,
- (b)  $r_N \rightarrow \infty$  as  $N \rightarrow \infty$ .

On the subinterval  $I_N$ , we control the heat equation with a control  $u_N$  restricted on the subdomain  $\omega \times (I_N \cap E)$  such that  $P_{r_N}(y_N(\cdot, t_{2N})) = 0$ , where  $P_{r_N}$  denotes the orthogonal projection from  $L^2(\Omega)$  onto  $\text{span} \{X_i(x)\}_{i=1}^{r_N}$ . On the subinterval  $J_N$ , we let the heat equation freely evolve. We start by having the initial data for the equation on  $I_1$  be  $y_0$ . For the initial data on  $I_N$ ,  $N = 2, 3, \dots$ , we define it to be the ending value of the solution for the equation on  $J_{N-1}$ . The initial data of the equation on  $J_N$ ,  $N = 1, 2, \dots$ , is given by the ending value of the solution for the equation on  $I_N$ . Moreover, by making use of Lemmas 2.2 and 2.3, we will show that there is a sequence  $\{r_N\}_{N=1}^\infty$ , having the properties (a) and (b) as above, such that the  $L^\infty(I_N; L^2(\Omega))$ -norm of the control  $u_N$  is bounded by  $L^{\frac{1}{2}} \|\tilde{y}_0\|_{L^2(\Omega)}$  for a certain positive constant  $L$  independent of  $N$  and  $\tilde{y}_0$ . Then, we construct a control  $\tilde{u}$  by setting

$$\tilde{u}(x, t) = \begin{cases} u_N(x, t), & x \in \Omega, t \in I_N, N = 1, 2, \dots, \\ 0, & x \in \Omega, t \in J_N, N = 1, 2, \dots \end{cases}$$

We can show that this control  $\tilde{u}$  makes the corresponding trajectory  $\tilde{y}$  of (2.8) have zero value at time  $\tilde{t}$ .

Now, we set

$$u(x, t) = \begin{cases} \tilde{u}(x, t) & \text{in } \Omega \times (t_1, \tilde{t}), \\ 0 & \text{in } \Omega \times ((0, T) \setminus (t_1, \tilde{t})) \end{cases}$$

and take  $\tilde{y}_0$  to be  $\psi(x, t_1)$ , where  $\psi(x, t)$  is the solution of the heat equation on  $\Omega \times (0, t_1)$  with the initial data  $y_0$ . Then it is clear that this control  $u$  makes the trajectory  $y(x, t)$  of (1.2) with  $\delta = 0$  have zero value at time  $T$ . Moreover,  $\|u\|_{L^\infty(0, T; L^2(\Omega))}^2 \leq L \|y_0\|_{L^2(\Omega)}^2$ .

We next replace the sequence  $\{t_N\}_{N=1}^\infty$  and the number  $\tilde{t}$  by the sequence  $\{t_N - \delta\}_{N=1}^\infty$  and the number  $(\tilde{t} - \delta)$ , respectively, where the number  $\delta$  is such that  $0 \leq \delta \leq t_1$ . Then by making use of the same argument as above, we obtain that for each number  $\delta$  with  $0 \leq \delta \leq t_1$ , there exists a control  $u_\delta$  in the space  $L^\infty(0, T - \delta; L^2(\Omega))$  with the estimate  $\|u_\delta\|_{L^\infty(0, T - \delta; L^2(\Omega))}^2 \leq L_\delta \|y_0\|_{L^2(\Omega)}^2$  for a certain positive number  $L_\delta$ .

independent of  $y_0$ , such that the corresponding solution  $y^\delta$  to (1.2) reaches zero value at time  $T - \delta$ , namely,  $y^\delta(x, T - \delta) = 0$  over  $\Omega$ . We finally prove that  $L_\delta = L$  is independent of  $\delta$ .

Now we prove Theorem 1.1.

*Proof of Theorem 1.1.* Without loss of generality, we can assume that  $C_1 \geq 1$ , where  $C_1$  is the positive constant given in Theorem 2.1. By making use of Lemma 2.3, we can take a number  $\tilde{t}$  in the set  $E$  with  $\tilde{t} < T$  and a sequence  $\{t_N\}_{N=1}^\infty$  in the open interval  $(0, T)$  such that (2.5)–(2.7) hold for certain positive numbers  $\rho$  and  $C_0$  and such that

$$\tilde{t} - t_1 \leq \text{Min}\{\lambda_1, 1\}.$$

We shall first prove that for each  $\tilde{y}_0$  in  $L^2(\Omega)$ , there exists a control  $\tilde{u}$  in the space  $L^\infty(t_1, \tilde{t}; L^2(\Omega))$  with the estimate  $\|\tilde{u}\|_{L^\infty(t_1, \tilde{t}; L^2(\Omega))}^2 \leq L \|\tilde{y}_0\|_{L^2(\Omega)}^2$  for a certain positive constant  $L$  independent of  $\tilde{y}_0$ , such that the solution  $\tilde{y}$  to (2.8) reaches zero value at time  $\tilde{t}$ , namely,  $\tilde{y}(x, \tilde{t}) = 0$  over  $\Omega$ .

To this end, we shall use the strategy presented above. We set  $I_N = [t_{2N-1}, t_{2N}]$ ,  $J_N = [t_{2N}, t_{2N+1}]$  for  $N = 1, 2, \dots$ . Then

$$[t_1, \tilde{t}) = \bigcup_{N=1}^{\infty} (I_N \cup J_N).$$

Notice that for each  $N \geq 1$ , it holds that  $m(E \cap I_N) > 0$ .

Now, on the interval  $I_1 \equiv [t_1, t_2]$ , we consider the following controlled heat equation:

$$\begin{cases} y_1'(x, t) - \Delta y_1(x, t) = \chi_E(t) \chi_\omega(x) u_1(x, t) & \text{in } \Omega \times (t_1, t_2), \\ y_1(x, t) = 0 & \text{on } \partial\Omega \times (t_1, t_2), \\ y_1(x, t_1) = \tilde{y}_0(x) & \text{in } \Omega. \end{cases}$$

By Lemma 2.2, for any  $r_1 > 0$ , there exists a control  $u_1$  in the space  $L^\infty(t_1, t_2; L^2(\Omega))$  with the estimate

$$\|u_1\|_{L^\infty(t_1, t_2; L^2(\Omega))}^2 \leq \frac{C_1 e^{C_2 \sqrt{r_1}}}{(m(E \cap [t_1, t_2]))^2} \|\tilde{y}_0\|_{L^2(\Omega)}^2,$$

such that  $P_{r_1}(y_1(\cdot, t_2)) = 0$ . Then, by (2.6) and (2.7) in Lemma 2.3, we see that

$$\begin{aligned} \|u_1\|_{L^\infty(t_1, t_2; L^2(\Omega))}^2 &\leq \frac{C_1 e^{C_2 \sqrt{r_1}}}{\rho^2(t_2 - t_1)^2} \|\tilde{y}_0\|_{L^2(\Omega)}^2 \\ &\equiv \frac{C_1}{\rho^2(t_2 - t_1)^2} \cdot \alpha_1 \|\tilde{y}_0\|_{L^2(\Omega)}^2, \end{aligned}$$

where  $\alpha_1 = e^{C_2 \sqrt{r_1}}$ . Moreover, we have

$$\begin{aligned} \|y_1(\cdot, t_2)\|_{L^2(\Omega)}^2 &\leq \|y_1(\cdot, t_1)\|_{L^2(\Omega)}^2 + \frac{1}{\lambda_1} \int_{t_1}^{t_2} \|u_1(\cdot, s)\|_{L^2(\Omega)}^2 ds \\ &\leq \|\tilde{y}_0\|_{L^2(\Omega)}^2 + \frac{(t_2 - t_1)}{\lambda_1} \|u_1\|_{L^\infty(t_1, t_2; L^2(\Omega))}^2 \\ &\leq 2 \frac{C_1}{\rho^2(t_2 - t_1)^2} \cdot \alpha_1 \|\tilde{y}_0\|_{L^2(\Omega)}^2. \end{aligned}$$

Here we have used the facts that  $(t_2 - t_1) \leq \text{Min}(\lambda_1, 1)$ ,  $\rho < 1$ , and  $C_1 > 1$ .

On the interval  $J_1 \equiv [t_2, t_3]$ , we consider the following heat equation without control:

$$\begin{cases} z_1'(x, t) - \Delta z_1(x, t) = 0 & \text{in } \Omega \times (t_2, t_3), \\ z_1(x, t) = 0 & \text{on } \partial\Omega \times (t_2, t_3), \\ z_1(x, t_2) = y_1(x, t_2) & \text{in } \Omega. \end{cases}$$

Since  $P_{r_1}(y_1(\cdot, t_2)) = 0$ , we have

$$\begin{aligned} \|z_1(\cdot, t_3)\|_{L^2(\Omega)}^2 &\leq \exp(-2r_1(t_3 - t_2)) \cdot \|y_1(\cdot, t_2)\|_{L^2(\Omega)}^2 \\ &\leq 2 \frac{C_1}{\rho^2(t_2 - t_1)^2} \alpha_1 \cdot \exp(-2r_1(t_3 - t_2)) \cdot \|\tilde{y}_0\|_{L^2(\Omega)}^2. \end{aligned}$$

On the interval  $I_2 \equiv [t_3, t_4]$ , we consider the controlled heat equation as follows:

$$\begin{cases} y_2'(x, t) - \Delta y_2(x, t) = \chi_E(t)\chi_\omega(x)u_2(x, t) & \text{in } \Omega \times (t_3, t_4), \\ y_2(x, t) = 0 & \text{on } \partial\Omega \times (t_3, t_4), \\ y_2(x, t_3) = z_1(x, t_3) & \text{in } \Omega. \end{cases}$$

Then by Lemma 2.2, for any  $r_2 > 0$ , there exists a control  $u_2$  in the space  $L^\infty(t_3, t_4; L^2(\Omega))$  with the estimate

$$\|u_2\|_{L^\infty(t_3, t_4; L^2(\Omega))}^2 \leq \frac{C_1 e^{C_2 \sqrt{r_2}}}{m(E \cap [t_3, t_4])^2} \cdot \|z_1(\cdot, t_3)\|_{L^2(\Omega)}^2,$$

such that  $P_{r_2}(y_2(\cdot, t_4)) = 0$ . By (2.6) and (2.7) in Lemma 2.3, we get

$$\|u_2\|_{L^\infty(t_3, t_4; L^2(\Omega))}^2 \leq 2 \left( \frac{C_1}{\rho^2(t_2 - t_1)^2} \right)^2 C_0^4 \cdot \alpha_1 \cdot \alpha_2 \cdot \|\tilde{y}_0\|_{L^2(\Omega)}^2,$$

where  $\alpha_2 = \exp(C_2 \sqrt{r_2}) \exp(-2r_1(t_3 - t_2))$ . Moreover, it holds that

$$\begin{aligned} \|y_2(\cdot, t_4)\|_{L^2(\Omega)}^2 &\leq \|z_1(\cdot, t_3)\|_{L^2(\Omega)}^2 + \frac{1}{\lambda_1}(t_4 - t_3) \|u_2\|_{L^\infty(t_3, t_4; L^2(\Omega))}^2 \\ &\leq 2^2 \left( \frac{C_1}{\rho^2(t_2 - t_1)^2} \right)^2 C_0^4 \cdot \alpha_1 \cdot \alpha_2 \cdot \|\tilde{y}_0\|_{L^2(\Omega)}^2. \end{aligned}$$

On the interval  $J_2 \equiv [t_4, t_5]$ , we consider the following heat equation without control:

$$\begin{cases} z_2'(x, t) - \Delta z_2(x, t) = 0 & \text{in } \Omega \times (t_4, t_5), \\ z_2(x, t) = 0 & \text{on } \partial\Omega \times (t_4, t_5), \\ z_2(x, t_4) = y_2(x, t_4) & \text{in } \Omega. \end{cases}$$

Since  $P_{r_2}(y_2(\cdot, t_4)) = 0$ , we have

$$\begin{aligned} \|z_2(\cdot, t_5)\|_{L^2(\Omega)}^2 &\leq \exp(-2r_2(t_5 - t_4)) \|y_2(\cdot, t_4)\|_{L^2(\Omega)}^2 \\ &\leq 2^2 \left( \frac{C_1}{\rho^2(t_2 - t_1)^2} \right)^2 C_0^4 \cdot \alpha_1 \cdot \alpha_2 \cdot \|\tilde{y}_0\|_{L^2(\Omega)}^2 \cdot \exp(-2r_2(t_5 - t_4)). \end{aligned}$$

On the interval  $I_3 \equiv [t_5, t_6]$ , we consider the following controlled heat equation:

$$\begin{cases} y'_3(x, t) - \Delta y_3(x, t) = \chi_E(t) \chi_\omega(x) u_3(x, t) & \text{in } \Omega \times (t_5, t_6), \\ y_3(x, t) = 0 & \text{on } \partial\Omega \times (t_5, t_6), \\ y_3(x, t_5) = z_2(x, t_5) & \text{in } \Omega. \end{cases}$$

Then by Lemma 2.2, for any  $r_3 > 0$ , there exists a control  $u_3$  in the space  $L^\infty(t_5, t_6; L^2(\Omega))$  with the estimate

$$\|u_3\|_{L^\infty(t_5, t_6; L^2(\Omega))}^2 \leq \frac{C_1 e^{C_2 \sqrt{r_3}}}{(m(E \cap [t_5, t_6]))^2} \|z_2(\cdot, t_5)\|_{L^2(\Omega)}^2,$$

such that  $P_{r_3}(y_3(\cdot, t_6)) = 0$ . By making use of (2.6) and (2.7) again, we get

$$\|u_3\|_{L^\infty(t_5, t_6; L^2(\Omega))}^2 \leq 2^2 \left( \frac{C_1}{\rho^2(t_2 - t_1)^2} \right)^3 C_0^4 \cdot C_0^{4 \cdot 2} \cdot \alpha_1 \cdot \alpha_2 \cdot \alpha_3 \cdot \|\tilde{y}_0\|_{L^2(\Omega)}^2,$$

where  $\alpha_3 = \exp(C_2 \sqrt{r_3}) \exp(-2r_2(t_3 - t_2)C_0^{-2})$ .

Generally, on the interval  $I_N$ , we consider the controlled heat equation

$$\begin{cases} y'_N(x, t) - \Delta y_N(x, t) = \chi_E(t) \chi_\omega(x) u_N(x, t) & \text{in } \Omega \times (t_{2N-1}, t_{2N}), \\ y_N(x, t) = 0 & \text{on } \partial\Omega \times (t_{2N-1}, t_{2N}), \\ y_N(x, t_{2N-1}) = z_{N-1}(x, t_{2N-1}) & \text{in } \Omega. \end{cases}$$

On the interval  $J_N$ , we consider the following heat equation without control:

$$\begin{cases} z'_N(x, t) - \Delta z_N(x, t) = 0 & \text{in } \Omega \times (t_{2N}, t_{2N+1}), \\ z_N(x, t) = 0 & \text{on } \partial\Omega \times (t_{2N}, t_{2N+1}), \\ z_N(x, t_{2N}) = y_N(x, t_{2N}) & \text{in } \Omega. \end{cases}$$

Then by making use of the induction argument, we can obtain the following: *For each  $r_N > 0$ , there exists a control  $u_N$  in the space  $L^\infty(I_N; L^2(\Omega))$  with the following estimate:*

$$\begin{aligned} & \|u_N\|_{L^\infty(I_N; L^2(\Omega))}^2 \\ & \leq 2^{N-1} \left( \frac{C_1}{\rho^2(t_2 - t_1)^2} \right)^N C_0^4 \cdot C_0^{4 \cdot 2} \cdots C_0^{4(N-1)} \cdot \alpha_1 \cdot \alpha_2 \cdots \alpha_N \cdot \|\tilde{y}_0\|_{L^2(\Omega)}^2, \end{aligned}$$

where

$$(2.9) \quad \alpha_N = \begin{cases} \exp(C_2 \sqrt{r_1}), & N = 1, \\ \exp(C_2 \sqrt{r_N}) \exp(-2r_{N-1}(t_3 - t_2)C_0^{-2(N-2)}), & N \geq 2, \end{cases}$$

such that  $P_{r_N}(y_N(\cdot, t_{2N})) = 0$ . It is easily seen that for each  $N \geq 1$ ,

$$(2.10) \quad \|u_N\|_{L^\infty(I_N; L^2(\Omega))}^2 \leq (\tilde{C})^{N(N-1)} \alpha_1 \cdots \alpha_N \cdot \|\tilde{y}_0\|_{L^2(\Omega)}^2,$$

where

$$(2.11) \quad \tilde{C} = \frac{2C_1}{\rho^2(t_2 - t_1)^2} \cdot C_0^2.$$

Now, we set

$$(2.12) \quad r_N = \left[ \frac{2}{(t_3 - t_2)} \tilde{C}^{N-1} \right]^4 \equiv [A \cdot \tilde{C}^{N-1}]^4, \quad N \geq 1.$$

Because we have  $\tilde{C} > C_0^2 > 1$  and  $t_3 - t_2 < 1$ , it holds that

$$2^4 < r_1 < r_2 < \cdots < r_N < r_{N+1} < \cdots \quad \text{and} \quad r_N \rightarrow \infty \quad \text{as} \quad N \rightarrow \infty.$$

Moreover, we have

$$r_{N-1}^{\frac{1}{4}}(t_3 - t_2)C_0^{-2(N-2)} \geq 2 \quad \text{for each } N \geq 2.$$

Then we get

$$(2.13) \quad \exp \{ -2r_{N-1}(t_3 - t_2)C_0^{-2(N-2)} \} \leq \exp \left( -4r_{N-1}^{\frac{3}{4}} \right) \quad \text{for each } N \geq 2.$$

Since

$$\begin{aligned} \tilde{C}^{N(N-1)} \exp \left( -r_{N-1}^{\frac{3}{4}} \right) &= \frac{\tilde{C}^{N(N-1)}}{(\exp(r_{N-1}^{\frac{1}{4}}))^{r_{N-1}^{\frac{1}{2}}}} \leq \frac{\tilde{C}^{N(N-1)}}{(\exp(2\tilde{C}^{N-1}))^{r_{N-1}^{\frac{1}{2}}}} \\ &\leq \frac{\tilde{C}^{N(N-1)}}{\tilde{C}^{(N-1) \cdot 2 \cdot r_{N-1}^{\frac{1}{2}}}}, \end{aligned}$$

for each  $N \geq 2$ , we derive from (2.12) that there exists a natural number  $N_1$  with  $N_1 \geq 2$  such that for each  $N \geq N_1$ ,

$$(2.14) \quad \tilde{C}^{N(N-1)} \exp \left( -r_{N-1}^{\frac{3}{4}} \right) \leq 1.$$

By making use of (2.12) again, we obtain that for each  $N \geq 2$ ,

$$\exp(C_2 \sqrt{r_N}) \exp \left( -r_{N-1}^{\frac{3}{4}} \right) = \exp(C_2 A^2 \tilde{C}^{2(N-1)}) \exp \left( -A^3 \tilde{C}^{3(N-2)} \right).$$

Thus, there exists a natural number  $N_2$  with  $N_2 \geq 2$  such that for each  $N \geq N_2$ ,

$$(2.15) \quad \exp(C_2 \sqrt{r_N}) \exp \left( -r_{N-1}^{\frac{3}{4}} \right) \leq 1.$$

Now we set

$$(2.16) \quad N_0 = \max \{N_1, N_2\}.$$

Then by (2.13), (2.14), and (2.15), we see that for all  $N \geq N_0$ ,

$$\begin{aligned} (2.17) \quad &\tilde{C}^{N(N-1)} \alpha_N \\ &= \tilde{C}^{N(N-1)} \exp(C_2 \sqrt{r_N}) \exp \left( -2r_{N-1}(t_3 - t_2)C_0^{-2(N-2)} \right) \\ &\leq \tilde{C}^{N(N-1)} \exp(C_2 \sqrt{r_N}) \exp \left( -4r_{N-1}^{\frac{3}{4}} \right) \\ &\leq \exp \left( -2r_{N-1}^{\frac{3}{4}} \right). \end{aligned}$$

Moreover, it is obvious that

$$(2.18) \quad \alpha_N \leq 1 \quad \text{for all } N \geq N_0.$$

Now, we set

$$(2.19) \quad L = \max \{ (\tilde{C})^{N(N-1)} \alpha_1 \cdots \alpha_N, \quad 1 \leq N \leq N_0 \}.$$

It follows from (2.10), (2.17), (2.18), and (2.19) that for all  $N \geq 1$ ,

$$(2.20) \quad \|u_N\|_{L^\infty(I_N; L^2(\Omega))}^2 \leq L \|\tilde{y}_0\|_{L^2(\Omega)}^2.$$

Then we construct a control  $\tilde{u}$  by setting

$$(2.21) \quad \tilde{u}(x, t) = \begin{cases} u_N(x, t), & x \in \Omega, \quad t \in I_N, \quad N \geq 1, \\ 0, & x \in \Omega, \quad t \in J_N, \quad N \geq 1. \end{cases}$$

From (2.20) and (2.21), we easily see that the control  $\tilde{u}$  is in the space  $L^\infty(t_1, \tilde{t}; L^2(\Omega))$  and satisfies the estimate

$$\|\tilde{u}\|_{L^\infty(t_1, \tilde{t}; L^2(\Omega))}^2 \leq L \|\tilde{y}_0\|_{L^2(\Omega)}^2.$$

Let  $\tilde{y}$  be the solution of (2.8) corresponding to the control  $\tilde{u}$  constructed in (2.21). Then on the interval  $I_N$ ,  $\tilde{y}(\cdot, t) = y_N(\cdot, t)$ . Since  $P_{r_N}(y_N(\cdot, t_{2N})) = 0$  for all  $N \geq 1$  and  $r_1 < r_2 < \cdots < r_N < \cdots$ , by making use of (2.21) again, we see that

$$(2.22) \quad P_{r_N}(\tilde{y}(\cdot, t_{2M})) = 0 \quad \text{for all } M \geq N.$$

On the other hand, since  $t_{2M} \rightarrow \tilde{t}$  as  $M \rightarrow \infty$ , we obtain that

$$\tilde{y}(\cdot, t_{2M}) \rightarrow \tilde{y}(\cdot, \tilde{t}) \quad \text{strongly in } L^2(\Omega) \quad \text{as } M \rightarrow \infty.$$

This, together with (2.22), implies that  $P_{r_N}(\tilde{y}(\cdot, \tilde{t})) = 0$  for all  $N \geq 1$ . Since  $r_N \rightarrow \infty$  when  $N \rightarrow \infty$ , it holds that  $\tilde{y}(\cdot, \tilde{t}) = 0$ . Thus, we have proved that for each  $\tilde{y}_0 \in L^2(\Omega)$ , there exists a control  $\tilde{u} \in L^\infty(t_1, \tilde{t}; L^2(\Omega))$  with the estimate  $\|\tilde{u}\|_{L^\infty(t_1, \tilde{t}; L^2(\Omega))}^2 \leq L \|\tilde{y}_0\|_{L^2(\Omega)}^2$ , where the constant  $L$  is given by (2.19), such that the solution  $\tilde{y}$  to (2.8) reaches zero value at time  $\tilde{t}$ , namely,  $\tilde{y}(x, \tilde{t}) = 0$  over  $\Omega$ .

Now, we take  $\tilde{y}_0(x)$  to be  $\psi(x, t_1)$ , where  $\psi(x, t)$  is the solution to the following equation:

$$\begin{cases} \psi_t(x, t) - \Delta \psi(x, t) = 0 & \text{in } \Omega \times (0, t_1), \\ \psi(x, t) = 0 & \text{on } \partial\Omega \times (0, t_1), \\ \psi(x, 0) = y_0(x) & \text{in } \Omega, \end{cases}$$

and we construct a control  $u$  by setting

$$(2.23) \quad u(x, t) = \begin{cases} 0 & \text{in } \Omega \times (0, t_1), \\ \tilde{u}(x, t) & \text{in } \Omega \times (t_1, \tilde{t}), \\ 0 & \text{in } \Omega \times (\tilde{t}, T). \end{cases}$$

It is clear that this control  $u$  is in the space  $L^\infty(0, T; L^2(\Omega))$  and that the corresponding solution  $y$  of (1.2) with  $\delta = 0$  reaches zero value at time  $T$ , namely,  $y(x, T) = 0$  over  $\Omega$ . Moreover, the control  $u$  constructed in (2.23) satisfies the following estimate:

$$\|u\|_{L^\infty(0, T; L^2(\Omega))}^2 \leq L \|y_0\|_{L^2(\Omega)}^2,$$

where  $L$  is given by (2.19).

Next, we take  $\delta_0$  to be the number  $t_1$  given above. For each  $\delta$  with  $0 \leq \delta \leq \delta_0$ , we set

$$\tilde{t}_\delta = \tilde{t} - \delta \quad \text{and} \quad t_{N,\delta} = t_N - \delta \quad \text{for all } N = 1, 2, \dots$$

Then it holds that

$$0 \leq t_{1,\delta} < t_{2,\delta} < \dots < t_{N,\delta} \rightarrow \tilde{t}_\delta < T - \delta.$$

Moreover, we have for each  $N \geq 1$ ,

$$m(E_\delta \cap [t_{N,\delta}, t_{N+1,\delta}]) = m(E \cap [t_N, t_{N+1}]) \geq \rho(t_{N+1} - t_N)$$

and

$$\frac{t_{N+1,\delta} - t_{N,\delta}}{t_{N+2,\delta} - t_{N+1,\delta}} = \frac{t_{N+1} - t_N}{t_{N+2} - t_{N+1}} \leq C_0,$$

where  $C_0$  and  $\rho$  are the positive constants as above.

Now, we can use exactly the same argument as above to get for each  $\delta$  with  $0 \leq \delta \leq \delta_0$  the existence of a control  $u_\delta(t)$  in the space  $L^\infty(0, T - \delta; L^2(\Omega))$  such that the corresponding solution  $y^\delta$  to (1.2) reaches zero value at time  $T - \delta$ , namely,  $y^\delta(x, T - \delta) = 0$  over  $\Omega$ . Moreover, this control  $u_\delta$  satisfies the following estimate (see (2.9)–(2.12) and (2.19)):

$$\|u_\delta\|_{L^\infty(0, T - \delta; L^2(\Omega))}^2 \leq L_\delta \cdot \|y_0\|_{L^2(\Omega)}^2.$$

The constant  $L_\delta$  is given by

$$L_\delta = \max \{ (\tilde{C}_\delta)^{N(N-1)} \alpha_{1,\delta} \cdots \alpha_{N,\delta}, \quad 1 \leq N \leq N_0 \},$$

where

$$\tilde{C}_\delta = \frac{2C_1}{\rho^2(t_{2,\delta} - t_{1,\delta})^2} \cdot C_0^2$$

and

$$\alpha_{N,\delta} = \begin{cases} \exp(C_2 \sqrt{r_{1,\delta}}), & N = 1, \\ \exp(C_2 \sqrt{r_{N,\delta}}) \exp(-2r_{N-1,\delta}(t_{3,\delta} - t_{2,\delta})C_0^{-2(N-2)}), & N \geq 2, \end{cases}$$

with

$$r_{N,\delta} = \left[ \frac{2}{(t_{3,\delta} - t_{2,\delta})} \tilde{C}_\delta^{N-1} \right]^4, \quad N = 1, 2, \dots,$$

and where the natural number  $N_0$  is given by (2.16). Since

$$t_{N+1,\delta} - t_{N,\delta} = t_{N+1} - t_N \quad \text{for all } N = 1, 2, \dots,$$

we see easily that  $\tilde{C}_\delta = \tilde{C}$  and  $\alpha_{N,\delta} = \alpha_N$  for all  $N \geq 1$ . Then it holds that  $L_\delta = L$  for all  $\delta$  with  $0 \leq \delta \leq \delta_0$ . This completes the proof.  $\square$

**3. Applications to the time optimal control problem.** In this section, we shall prove Theorems 1.2 and 1.3. We also will give some consequences of these theorems. Throughout this section, we shall denote by  $y(t; u, y_0)$  the solution of (1.3) corresponding to the control  $u$  and the initial data  $y_0$ .

*Proof of Theorem 1.2.* Seeking a contradiction, we suppose that there exist a subset  $E$  of positive measure in the interval  $[0, T^*]$  and a positive number  $\varepsilon$  such that the following holds:

$$u^*(t) \in U \text{ and } d(u^*(t), \partial U) \geq \varepsilon \text{ for each } t \text{ in the set } E,$$

where  $d(u^*(t), \partial U)$  denotes the distance of the point  $u^*(t)$  to the set  $\partial U$  in  $L^2(\Omega)$ . Then we would get

$$(3.1) \quad B\left(u^*(t), \frac{\varepsilon}{2}\right) \subset U \text{ for each } t \text{ in the set } E.$$

We shall obtain from (3.1) that there exist a positive number  $\delta$  with  $\delta < T^*$  and a control  $v_\delta$  in the set  $\mathcal{U}_{ad}$  such that the following holds:

$$(3.2) \quad y(T^* - \delta; v_\delta, y_0) = y(T^*; u^*, y_0).$$

Thus,  $T^*$  could not be the optimal time for problem (P), which leads to a contradiction.

We write  $\{G(t)\}_{t \geq 0}$  for the semigroup generated by  $\Delta$  with the Dirichlet boundary condition and observe that

$$\begin{aligned} y(T^* - \delta; v_\delta, y_0) &= G(T^* - \delta)y_0 + \int_0^{T^* - \delta} G(T^* - \delta - \sigma)\chi_\omega v_\delta(\sigma)d\sigma, \\ y(T^*; u^*, y_0) &= G(T^*)y_0 + \int_0^{T^*} G(T^* - \sigma)\chi_\omega u^*(\sigma)d\sigma. \end{aligned}$$

Hence, (3.2) is equivalent to the following: There exist a positive number  $\delta$  with  $\delta < T^*$  and a control  $v_\delta$  in the set  $\mathcal{U}_{ad}$  such that the following holds:

$$(3.3) \quad \int_0^{T^* - \delta} G(T^* - \delta - \sigma)\chi_\omega v_\delta(\sigma)d\sigma = [G(T^*) - G(T^* - \delta)]y_0 + \int_0^{T^*} G(T^* - \sigma)\chi_\omega u^*(\sigma)d\sigma.$$

Notice that for any positive number  $\delta$  with  $\delta < T^*$ , we have

$$\begin{aligned} & \int_0^{T^*} G(T^* - \sigma)\chi_\omega u^*(\sigma)d\sigma \\ &= \int_0^\delta G(T^* - \sigma)\chi_\omega u^*(\sigma)d\sigma + \int_\delta^{T^*} G(T^* - \sigma)\chi_\omega u^*(\sigma)d\sigma \\ &= G(T^* - \delta) \int_0^\delta G(\delta - \sigma)\chi_\omega u^*(\sigma)d\sigma + \int_0^{T^* - \delta} G(T^* - \delta - \sigma)\chi_\omega u^*(\delta + \sigma)d\sigma \end{aligned}$$

and

$$[G(T^*) - G(T^* - \delta)]y_0 = G(T^* - \delta)[(G(\delta) - I)y_0].$$

Therefore, (3.3) is equivalent to the following: There exist a positive number  $\delta$  with  $\delta < T^*$  and a control  $v_\delta$  in the set  $\mathcal{U}_{ad}$  such that the following holds:

$$\begin{aligned}
 & \int_0^{T^*-\delta} G(T^*-\delta-\sigma)\chi_\omega v_\delta(\sigma)d\sigma \\
 &= G(T^*-\delta) \left[ \int_0^\delta G(\delta-\sigma)\chi_\omega u^*(\sigma)d\sigma + (G(\delta)-I)y_0 \right] \\
 &+ \int_0^{T^*-\delta} G(T^*-\delta-\sigma)\chi_\omega u^*(\sigma+\delta)d\sigma \\
 &\equiv G(T^*-\delta)h_\delta + \int_0^{T^*-\delta} G(T^*-\delta-\sigma)\chi_\omega u^*(\sigma+\delta)d\sigma,
 \end{aligned}
 \tag{3.4}$$

where

$$h_\delta = \int_0^\delta G(\delta-\sigma)\chi_\omega u^*(\sigma)d\sigma + (G(\delta)-I)y_0.
 \tag{3.5}$$

For each positive number  $\delta$ , we write  $E_\delta$  for the set  $\{t; t+\delta \in E\}$  and denote by  $\chi_{E_\delta}$  the characteristic function of the set  $E_\delta$ . We first claim the following: For each positive number  $\delta$  sufficiently small, there exists a control  $u_\delta$  in the space  $L^\infty(0, \infty; L^2(\Omega))$  such that

$$\|u_\delta(t)\|_{L^2(\Omega)} \leq \frac{\varepsilon}{2} \quad \text{for almost all } t \geq 0,
 \tag{3.6}$$

and such that

$$y(T^*-\delta; \chi_{E_\delta} u_\delta, 0) = G(T^*-\delta)h_\delta.
 \tag{3.7}$$

Recall that  $y(t; \chi_{E_\delta} u_\delta, 0)$  is the solution of the controlled heat equation (1.3) with  $u$  and  $y_0$  being replaced by  $\chi_{E_\delta} u_\delta$  and 0, respectively, and that  $\varphi(t) \equiv G(t)h_\delta$  is the solution of (1.3) with  $u$  and  $y_0$  being replaced by 0 and  $h_\delta$ , respectively. Then, what we claimed above is obviously equivalent to the following: For each positive number  $\delta$  sufficiently small, there exists a control  $u_\delta$  with the estimate

$$\|u_\delta(t)\|_{L^2(\Omega)} \leq \frac{\varepsilon}{2} \quad \text{for almost all } t \geq 0,$$

such that the following holds:

$$z^\delta(T^*-\delta) = 0,$$

where  $z^\delta(t)$  is the solution to the following controlled heat equation:

$$\begin{cases} z_t^\delta(t) - \Delta z^\delta(t) = \chi_\omega \chi_{E_\delta}(t) u_\delta(t) & \text{in } (0, T^*-\delta), \\ z^\delta(0) = -h_\delta. \end{cases}
 \tag{3.8}$$

However, by Theorem 1.1, there exist positive numbers  $\delta_0$  and  $L$  such that for each  $\delta$  with  $0 < \delta \leq \delta_0$ , there is a control  $u_\delta$  in the space  $L^\infty(0, T^*-\delta; L^2(\Omega))$  with the estimate

$$\|u_\delta\|_{L^\infty(0, T^*-\delta; L^2(\Omega))}^2 \leq L \|h_\delta\|_{L^2(\Omega)}^2,
 \tag{3.9}$$

such that the following holds:

$$(3.10) \quad z^\delta(T^* - \delta) = 0.$$

On the other hand, by (3.5), we can get a positive number  $\tilde{\delta}$  such that for each positive number  $\delta$  with  $\delta \leq \tilde{\delta}$ , the following holds:

$$\|h_\delta\|_{L^2(\Omega)}^2 \leq \left(\frac{\varepsilon}{2}\right)^2 / L.$$

This, together with (3.9), implies that for each positive number  $\delta$  with  $\delta \leq \min\{\delta_0, \tilde{\delta}\}$ , there is a control  $u_\delta$  with the estimate

$$(3.11) \quad \|u_\delta\|_{L^\infty(0, T^* - \delta; L^2(\Omega))} \leq \frac{\varepsilon}{2},$$

such that the corresponding solution  $z^\delta$  to (3.8) satisfies (3.10).

Next, we fix a positive number  $\delta$  and the corresponding control  $u_\delta$  such that (3.10) and (3.11) hold. Then we extend the control  $u_\delta(\cdot)$  by setting it to be zero on the interval  $(T^* - \delta, \infty)$  and still denote the extension by  $u_\delta(\cdot)$ . Clearly, this extended control  $u_\delta$  is in the space  $L^\infty(0, \infty; L^2(\Omega))$  and makes (3.6) and (3.7) hold. Thus, we have proved the above mentioned claim.

Now, we take an element  $u_0$  from the control set  $U$  and construct a control  $v_\delta$  by setting

$$(3.12) \quad v_\delta(t) = \begin{cases} u^*(t + \delta) + \chi_{E_\delta}(t)u_\delta(t) & \text{if } t \in [0, T^* - \delta], \\ u_0 & \text{if } t > T^* - \delta. \end{cases}$$

It is clear that  $v_\delta(\cdot) : [0, \infty) \rightarrow L^2(\Omega)$  is measurable. We shall prove  $v_\delta(t) \in U$  for almost all  $t \geq 0$ . Here is the argument: When  $t$  is in the set  $[0, T^* - \delta] \cap E_\delta$ , we have  $t + \delta \in E$ . Then by (3.1), we get  $B(u^*(t + \delta), \frac{\varepsilon}{2}) \in U$ . Since  $\|u_\delta(t)\|_{L^2(\Omega)} \leq \frac{\varepsilon}{2}$  for almost all  $t \geq 0$ , we have

$$\|v_\delta(t) - u^*(t + \delta)\|_{L^2(\Omega)} = \|u_\delta(t)\|_{L^2(\Omega)} \leq \frac{\varepsilon}{2} \quad \text{for almost all } t \text{ in } [0, T^* - \delta] \cap E_\delta,$$

namely,  $v_\delta(t) \in B(u^*(t + \delta), \frac{\varepsilon}{2})$  for almost all  $t$  in the set  $[0, T^* - \delta] \cap E_\delta$ . Hence,  $v_\delta(t) \in U$  for almost all  $t$  in the set  $[0, T^* - \delta] \cap E_\delta$ . On the other hand, for almost all  $t \in [0, T^* - \delta] \cap (E_\delta)^c$ , we have  $v_\delta(t) = u^*(t + \delta) \in U$ . Therefore, we have proved  $v_\delta \in \mathcal{U}_{ad}$ .

Then, by (3.7) and (3.12), we see easily that this control  $v_\delta$  makes the equality (3.4) hold, which leads to a contradiction to the optimality of  $T^*$  for problem **(P)**. Thus we have proved  $u^*(t) \in \partial U$  for almost all  $t \in [0, T^*]$ .

Finally, if the control set  $U$  has the additional property that  $\chi_\omega U \subset U$ , then we have  $\chi_\omega u^* \in \mathcal{U}_{ad}$ . It is clear that  $y(T^*; \chi_\omega u^*, y_0) = y(T^*; u^*, y_0)$ . Thus,  $\chi_\omega u^*$  is also an optimal control for problem **(P)**. Hence, it holds that  $\chi_\omega u^*(t) \in \partial U$  for almost all  $t \in [0, T^*]$ . This completes the proof.  $\square$

By Theorem 1.2, we immediately get the following consequence.

**COROLLARY 3.1.** *Suppose that the control set  $U$  is the ball  $B(0, R)$  with  $R > 0$  and that the target set  $S$  is nonempty in  $L^2(\Omega)$ . Let  $T^*$  be the optimal time and  $u^*$  be an optimal control for problem **(P)**. Then it holds that  $\|\chi_\omega u^*(\cdot, t)\|_{L^2(\Omega)} = R$  for almost all  $t \in [0, T^*]$ .*

*Remark 3.2.* From the proof of Theorem 1.2, we see that if an admissible control  $u(\cdot, t)$  does not take its value on the boundary of the control set  $U$  in a subset of positive measure in the interval  $[0, T]$ , where the number  $T$  is such that  $y(T; u, y_0) \in S$ , then there exists “room” for us to construct another admissible control  $v$  such that the corresponding trajectory  $y(t; v, y_0)$  reaches  $y(T; u, y_0)$  before the time  $T$ . Hence, such an admissible control  $u$  cannot be optimal. This idea has been used in [6], [14], [16], and [19]. The key point is how to use this “room” to construct such an admissible control  $v$ . In this work, the null controllability result established in Theorem 1.1 shows us how. It was already observed in [16] that the null controllability of the boundary controlled one-dimensional heat equation in  $(0, 1) \times (0, T)$ , with controls restricted on an arbitrary subset  $E \subset [0, T]$  of positive measure, leads to a bang-bang principle of time optimal boundary controls for the one-dimensional heat equation.

Next, we shall use Theorem 1.1 to derive the uniqueness of the optimal control for problem **(P)** with certain target sets and control sets.

*Proof of Theorem 1.3.* Let  $U$  be the closed ball  $B(v_0, R)$  in  $L^2(\Omega)$ , centered at  $v_0$  and of positive radius  $R$ . Let  $T^*$  be the optimal time for problem **(P)**. Seeking a contradiction, we suppose that there exist two different optimal controls  $u^*$  and  $v^*$  for problem **(P)**. Then there would exist a subset  $E_1$  of positive measure in the interval  $[0, T^*]$  such that  $u^*(t) \neq v^*(t)$  for every  $t \in E_1$ . We first observe that

$$y(T^*; u^*, y_0), y(T^*; v^*, y_0) \in S.$$

Then we construct a control  $w^*(t)$  by setting

$$w^*(t) = \frac{u^*(t) + v^*(t)}{2} \text{ for almost all } t \in [0, \infty).$$

It is clear that  $w^* \in \mathcal{U}_{ad}$ . Moreover, since  $S$  is convex, we have

$$y(T^*; w^*, y_0) = \frac{y(T^*; u^*, y_0) + y(T^*; v^*, y_0)}{2} \in S.$$

On the other hand, we see that for almost all  $t \in E_1$ ,

$$\begin{aligned} \|w^*(t) - v_0\|_{L^2(\Omega)}^2 &= 2 \left( \left\| \frac{u^*(t) - v_0}{2} \right\|_{L^2(\Omega)}^2 + \left\| \frac{v^*(t) - v_0}{2} \right\|_{L^2(\Omega)}^2 \right) \\ &\quad - \left\| \frac{u^*(t) - v_0}{2} - \frac{v^*(t) - v_0}{2} \right\|_{L^2(\Omega)}^2 \\ &= R^2 - \frac{1}{4} \left\| u^*(t) - v^*(t) \right\|_{L^2(\Omega)}^2 \\ &< R^2. \end{aligned}$$

Thus, there exist a positive number  $\varepsilon$  and a subset  $E$  of positive measure in the set  $E_1$  such that for each  $t \in E$ ,  $d(w^*(t), \partial B(v_0, R)) \geq \varepsilon$ . Then, we can use the same argument as in the proof of Theorem 1.2 to derive a contradiction to the optimality of  $T^*$ . This completes the proof.  $\square$

With regard to the existence of the time optimal controls for problem **(P)**, we recall that if the target set  $S$  is closed and convex in  $L^2(\Omega)$ , which contains the origin in  $L^2(\Omega)$ , and if the control set  $U$  is the ball  $B(0, R)$  with  $R > 0$ , then problem **(P)** with any initial data  $y_0 \in L^2(\Omega)$  has an optimal control (see [17] and [20]). Thus, Theorem

1.4 follows immediately from Corollary 3.1, Theorem 1.3, and the aforementioned existence result.

**Appendix.** In what follows, we shall give the proof of the equivalence of Theorem 1.1 and the observability inequality **(O)**.

We shall first prove that Theorem 1.1 implies inequality **(O)**. To this end, we multiply (1.2) by  $p^\delta$ , where  $p^\delta$  is the solution of (1.6) with  $p_T^\delta(x) \in L^2(\Omega)$  being arbitrarily given, and then integrate it over  $\Omega \times (0, T - \delta)$ . Thus we obtain

$$(A.1) \quad \int_0^{T-\delta} \int_\Omega (\partial_t y^\delta - \Delta y^\delta) p^\delta dx dt = \int_0^{T-\delta} \int_\Omega [\chi_{E_\delta}(t) \chi_\omega(x) p^\delta(x, t) u_\delta(x, t)] dx dt.$$

By using integration by parts, we see that the following equality holds for each  $y_0(\cdot) \in L^2(\Omega)$ :

$$(A.2) \quad \int_0^{T-\delta} \int_\Omega (\partial_t y^\delta - \Delta y^\delta) p^\delta dx dt = \left[ \int_\Omega y^\delta p^\delta dx \right]_0^{T-\delta} = - \int_\Omega y_0 p^\delta(x, 0) dx.$$

Now, we choose  $y_0(x) = p^\delta(x, 0)$  in the above, and then it follows from (1.3), (A.1), and (A.2) that for each  $\varepsilon > 0$ , we have

$$\begin{aligned} \int_\Omega |p^\delta(x, 0)|^2 dx &= - \int_0^{T-\delta} \int_\Omega [\chi_{E_\delta}(t) \chi_\omega(x) p^\delta(x, t) u_\delta(x, t)] dx dt \\ &\leq \int_0^{T-\delta} \|\chi_{E_\delta} \chi_\omega u_\delta\|_{L^2(\Omega)} \|\chi_{E_\delta} \chi_\omega p^\delta\|_{L^2(\Omega)} dt \\ &\leq \|u_\delta\|_{L^\infty(0, T-\delta; L^2(\Omega))} \|\chi_{E_\delta} \chi_\omega p^\delta\|_{L^1(0, T-\delta; L^2(\Omega))} \\ &\leq \frac{1}{2\varepsilon} \|u_\delta\|_{L^\infty(0, T-\delta; L^2(\Omega))}^2 + \frac{\varepsilon}{2} \|\chi_{E_\delta} \chi_\omega p^\delta\|_{L^1(0, T-\delta; L^2(\Omega))}^2 \\ &\leq \frac{1}{2\varepsilon} L \|y_0\|_{L^2(\Omega)}^2 + \frac{\varepsilon}{2} \|\chi_{E_\delta} \chi_\omega p^\delta\|_{L^1(0, T-\delta; L^2(\Omega))}^2. \end{aligned}$$

Since  $y_0 = p^\delta(\cdot, 0)$ , we can get the desired inequality (1.5) by taking  $\varepsilon = L$  in the above inequality.

Next, we prove that inequality **(O)** implies Theorem 1.1.

By (1.2) and (1.6), we have for any  $p_T^\delta \in L^2(\Omega)$  and  $y_0 \in L^2(\Omega)$ ,

$$\begin{aligned} &\langle y^\delta(\cdot, T - \delta), p^\delta(\cdot, T - \delta) \rangle - \langle y_0(\cdot), p^\delta(\cdot), p^\delta(\cdot, 0) \rangle \\ &= \int_0^{T-\delta} \int_\Omega [\chi_{E_\delta}(t) \chi_\omega(x) p^\delta(x, t) u_\delta(x, t)] dx dt. \end{aligned}$$

Here and in what follows, the notation  $\langle \cdot, \cdot \rangle$  stands for the inner product of  $L^2(\Omega)$ . If we can show that there exists a control  $u_\delta \in L^\infty(0, T - \delta; L^2(\Omega))$  with the estimate (1.3) such that

$$\langle y^\delta(\cdot, T - \delta), p^\delta(\cdot, T - \delta) \rangle = 0 \quad \text{for all } p_T^\delta \in L^2(\Omega),$$

then it holds that  $y^\delta(\cdot, T - \delta) = 0$ . Thus, it suffices to prove that there exists a control  $u_\delta \in L^\infty(0, T - \delta; L^2(\Omega))$  with the estimate (1.3) such that

$$-\langle y_0(\cdot), p^\delta(\cdot, 0) \rangle = \int_0^{T-\delta} \int_\Omega [\chi_{E_\delta}(t) \chi_\omega(x) p^\delta(x, t) u_\delta(x, t)] dx dt$$

for any  $p_T^\delta \in L^2(\Omega)$ .

Now, we set

$$X = \{\chi_{E_\delta}(t)\chi_\omega(x)p^\delta(x, t); p^\delta \text{ solves (1.6) with } p_T^\delta \in L^2(\Omega)\}.$$

It is clear that  $X$  is a linear subspace of  $L^1(0, T - \delta; L^2(\Omega))$ . We define a linear functional  $F : X \rightarrow R^1$  by setting

$$F(\chi_{E_\delta}(t)\chi_\omega(x)p^\delta) = -\langle y_0(\cdot), p^\delta(\cdot, 0) \rangle.$$

Then it follows from (1.5) that

$$\begin{aligned} & |F(\chi_{E_\delta}(t)\chi_\omega(x)p^\delta)|^2 \\ & \leq \|y_0\|_{L^2(\Omega)}^2 \|p^\delta(\cdot, 0)\|_{L^2(\Omega)}^2 \\ & \leq L \|y_0\|_{L^2(\Omega)}^2 \|\chi_{E_\delta}\chi_\omega p^\delta\|_{L^1(0, T-\delta; L^2(\Omega))}^2. \end{aligned}$$

Namely,

$$\|F\|_{L(X; R^1)} \leq L^2 \|y_0\|_{L^2(\Omega)}^2.$$

Thus,  $F$  is a bounded linear functional on  $X$ . By the Hahn–Banach theorem, there exists a bounded linear functional  $G : L^1(0, T - \delta; L^2(\Omega)) \rightarrow R^1$  such that  $G = F$  on  $X$  and such that

$$\|G\|_{L^1(0, T-\delta; L^2(\Omega)); R^1}^2 = \|F\|_{L(X, R^1)}^2 \leq L \|y_0\|_{L^2(\Omega)}^2.$$

Then by making use of the Riesz representation theorem, there exists a function  $u_\delta \in L^\infty(0, T - \delta; L^2(\Omega))$  such that for any  $f \in L^1(0, T - \delta; L^2(\Omega))$ ,

$$G(f) = \int_0^{T-\delta} \int_\Omega f u_\delta dx dt,$$

and such that

$$\|u_\delta\|_{L^\infty(0, T-\delta; L^2(\Omega))}^2 = \|G\|_{L^1(0, T-\delta; L^2(\Omega)); R^1}^2 \leq L \|y_0\|_{L^2(\Omega)}^2.$$

Hence,

$$F(\chi_{E_\delta}(t)\chi_\omega(x)p^\delta) = \int_0^{T-\delta} \int_\Omega [\chi_{E_\delta}(t)\chi_\omega(x)p^\delta(x, t)u_\delta(x, t)] dx dt.$$

Namely, for all  $p_T^\delta \in L^2(\Omega)$ , it holds that

$$-\langle y_0(\cdot), p^\delta(\cdot, 0) \rangle = \int_0^{T-\delta} \int_\Omega [\chi_{E_\delta}(t)\chi_\omega(x)p^\delta(x, t)u_\delta(x, t)] dx dt. \quad \square$$

This completes the proof.

**Acknowledgments.** The author would like to express his appreciation to professor Xu Zhang and Dr. K. D. Phung for their valuable suggestions on this work.

## GOAL-ORIENTED ADAPTIVITY IN CONTROL CONSTRAINED OPTIMAL CONTROL OF PARTIAL DIFFERENTIAL EQUATIONS\*

M. HINTERMÜLLER<sup>†</sup> AND R. H. W. HOPPE<sup>‡</sup>

**Abstract.** Dual-weighted goal-oriented error estimates for a class of pointwise control constrained optimal control problems for second order elliptic partial differential equations are derived. It is demonstrated that the constraints give rise to a primal-dual weighted error term representing the mismatch in the complementarity system due to discretization. The paper also contains a posteriori error estimators for the  $L^2$ -norm of the error in the state and in the adjoint state.

**Key words.** adaptive finite element method, a posteriori error estimate, control constraints, goal-oriented adaptivity, PDE-constrained optimization

**1. Introduction.** In many computations involving the discretization of (partial) differential equations or variational inequalities, one is interested in the accurate evaluation of some target quantity. This might be the value of the solution of a partial differential equation (PDE) at some reference point in the domain of interest, a physically relevant quantity such as the drag in airfoil design, or, in optimal control, the value of the objective function at the solution of the underlying minimization problem. Highly accurate numerical evaluations of these targets can be guaranteed by using uniform meshes with a small mesh size  $h$ . This, however, usually represents a significant computational challenge due to the resulting large scale of the discrete problems. Therefore, one seeks to adaptively refine the meshes with the goal of achieving a desired accuracy in the evaluation of the output quantity of interest while keeping the computational cost as small as possible.

For this purpose, recently for (systems of) PDEs an approach based on dual-weighted residual-based error estimates was proposed. Here we point to the pioneering work summarized in [1, 3] and the references therein; see also [7] for related literature. It essentially relies on employing the dual problem of the underlying system with the target on the right-hand side. In fact, let  $A$  denote some possibly nonlinear partial differential operator and let  $f$  be some fixed data. Then, in some abstract form, the primal problem (or PDE) is given by

$$(1.1) \quad A(y) = f.$$

Let  $y_h$  be the result of a Galerkin finite element discretization of the underlying problem. If  $G(\cdot)$  represents some desired target quantity (or goal), then the dual

approach consists of considering

$$(1.2) \quad A'(y_h)^* p_h = G(\cdot)$$

from which an a posteriori error estimate of the type

$$|G(y) - G(y_h)| \leq \sum_{T \in \mathbb{T}_h} \mathbf{p}_T(y_h) \mathfrak{d}_T(p_h)$$

is derived. Above,  $A'(\cdot)^*$  is the dual operator of the Frechét-derivative  $A'(\cdot)$  of  $A(\cdot)$ . Further,  $\mathbb{T}_h = \{T\}$  denotes a computational mesh consisting of elements  $T$ , and  $\mathbf{p}_T$  and  $\mathfrak{d}_T$  stand for the primal residual and the dual weight on each cell  $T$ , respectively.

In [2] this concept was transferred to PDE-constrained optimal control problems of the type

$$(P_0) \quad \text{minimize } J(y, u) \quad \text{subject to } A(y) = f + B(u),$$

where  $(y, u)$  denotes the state-control pair and  $B$  models the control impact. The first order optimality system of  $(P_0)$  can be formally written as

$$(1.3a) \quad A(y) - B(u) = f,$$

$$(1.3b) \quad J_y(y, u) + A'(y)^* p = 0,$$

$$(1.3c) \quad J_u(y, u) - B'(u)^* p = 0.$$

Here,  $J_y$  and  $J_u$  are the partial derivatives of  $J$  with respect to  $y$  and  $u$ . The variable  $p$  is called the adjoint state. Often, (1.3c) results in an algebraic equation, while (1.3a)–(1.3b) form a primal-dual pair of PDEs similar to (1.1)–(1.2). Since (1.3a)–(1.3b) represent a system of PDEs, the dual-weighted approach can be readily carried over to this optimal control setting.

The situation, however, changes significantly if, in addition to the PDE constraint in  $(P_0)$ , one has to account for pointwise almost everywhere (a.e.) constraints on the control variable. In this case, the resulting problem becomes

$$(P_c) \quad \begin{cases} \text{minimize} & J(y, u) \\ \text{subject to} & A(y) = f + B(u), \\ & a \leq u \leq b \quad \text{a.e. on } \Omega_C \subset \Omega, \end{cases}$$

where  $\Omega \subset \mathbb{R}^n$  denotes some suitable domain with  $\Omega_C \neq \emptyset$  a measurable subset, and where  $a < b$  are given bounds. The corresponding first order necessary optimality system now involves a variational inequality as follows:

$$(1.4a) \quad A(y) - B(u) = f,$$

$$(1.4b) \quad J_y(y, u) + A'(y)^* p = 0,$$

$$(1.4c) \quad \langle J_u(y, u) - B'(u)^* p, v - u \rangle \geq 0 \quad \forall v \in U^{\text{ad}}, u \in U^{\text{ad}},$$

where the set

$$U^{\text{ad}} = \{v : a \leq v \leq b\}$$

represents the feasible controls, and  $\langle \cdot, \cdot \rangle$  denotes a suitable duality pairing. The variational inequality induces some nonsmoothness in the first order optimality system. This can be seen best when defining the Lagrange multiplier  $\lambda$  pertinent to the pointwise constraints via

$$(1.5) \quad J_u(y, u) - B'(u)^* p + \lambda = 0$$

and, assuming that  $\lambda$  permits a pointwise interpretation,

$$(1.6) \quad \lambda \geq 0 \quad \text{a.e. on } \{u = b\}, \quad \lambda \leq 0 \quad \text{a.e. on } \{u = a\}, \quad \lambda = 0 \quad \text{else.}$$

The conditions in (1.6) represent the so-called *complementarity system*. It can be written equivalently as

$$(1.7) \quad \lambda = \min\{0, \lambda + \sigma(u - a)\} + \max\{0, \lambda + \sigma(u - b)\},$$

where  $\sigma > 0$  is an arbitrarily fixed real and the max- and min-operations are understood in the pointwise sense. From (1.7) the nonsmoothness involved in the first order necessary optimality conditions becomes apparent. Of course, suitable a posteriori error concepts have to reflect this situation in order to accurately resolve the influence of the constraints on the solution of the optimal control problem.

We note that for pointwisely constrained problems such as variational inequalities of obstacle type, finite element methods based on various concepts in the a posteriori analysis have been considered in the literature. The goal-oriented dual-weighted approach was used in [4], whereas residual-type and hierarchical-type estimators were derived and analyzed in [5, 10, 13, 16]. Although the situation under consideration is different from obstacle-type problems as the pointwise constraints in our case are imposed on the control acting on the right-hand side of the PDE, a common feature in the a posteriori error analysis is the appropriate treatment of the complementarity conditions.

In this paper, our starting point will be a sufficiently general model problem class of the type  $(P_c)$ . Based on the Lagrange function

$$\mathcal{L}(y, u, p, \lambda) = J(y, u) + \langle A(y) - f - B(u), p \rangle + (u - b, \lambda)$$

of  $(P_c)$ , for convenience written here for a unilaterally constrained version of the minimization problem, and with the objective function as the goal, we derive an error representation of the type

$$\begin{aligned} J(y, u) - J(y_h, u_h) &= -\frac{1}{2} \langle \nabla_{xx} \mathcal{L}(x_h, \lambda_h)(x_h - x), x_h - x \rangle + (u_h - b, \lambda) \\ &\quad + \text{osc}_h + r(x_h, x) \end{aligned}$$

with  $x = (p, y, u)$  and its discretized version  $x_h = (p_h, y_h, u_h)$ , respectively, and  $(\cdot, \cdot)$  some inner product. Further,  $\text{osc}_h$  represents data oscillations and  $r$  is the remainder term resulting from a Taylor expansion of  $\mathcal{L}$ . In a second step we then estimate the term due to the inequality constraints and utilize the a posteriori error estimators derived in [8] in order to obtain a computable error representation.

The rest of the paper is organized as follows. In the next section we derive our new dual-weighted residual-based error estimator for a representative control constrained optimal control model problem. Section 3 is devoted to possible extensions. In fact, we study the bilaterally constrained case, a class of nonlinear governing equations, and alternative concepts for obtaining a posteriori estimates pertinent to the complementarity system. In the appendix, for our constrained optimal control problem we derive a new a posteriori error estimate with respect to the  $L^2$ -norm. Finally, in section 4 we report on numerical results due to our new error estimator.

*Notation.* Throughout we use  $\|\cdot\|_{0,\Omega}$  and  $(\cdot, \cdot)_{0,\Omega}$  for the usual  $L^2(\Omega)$ -norm and  $L^2(\Omega)$ -inner product, respectively. For convenience, with respect to the notation we

shall not distinguish between the norm (respectively, inner product) for scalar-valued or vector-valued arguments. We also use  $(\cdot, \cdot)_{0,\mathcal{S}}$ , which is the  $L^2(\mathcal{S})$ -inner product over a (measurable) subset  $\mathcal{S} \subset \Omega$ . By  $|\cdot|_{1,\Omega}$  we denote the  $H^1(\Omega)$ -seminorm  $|y|_{1,\Omega} = \|\nabla y\|_{0,\Omega}$ , which, by the Poincaré–Friedrichs inequality, is a norm on  $H_0^1(\Omega)$ . The norm in  $H^1(\Omega)$  is written as  $\|\cdot\|_{1,\Omega}$ . By  $\mathbb{T}_h = \mathbb{T}_h(\Omega)$  we denote a shape regular finite element triangulation of the domain  $\Omega$ . The subscript  $h = \max\{\text{diam}(T) \mid T \in \mathbb{T}_h\}$  indicates the mesh size of  $\mathbb{T}_h$ .

**2. Residual-based error estimate.** For deriving the structure of the new error estimate due to the inequality constraints, we consider the model problem

$$(P) \quad \begin{cases} \text{minimize} & J(y, u) := \frac{1}{2}\|y - z\|_{0,\Omega}^2 + \frac{\alpha}{2}\|u\|_{0,\Omega}^2 \\ \text{over} & (y, u) \in H_0^1(\Omega) \times L^2(\Omega) \\ \text{subject to} & -\Delta y = u + f, \\ & u \leq b \quad \text{a.e. in } \Omega, \end{cases}$$

which is a particular instance of  $(P_c)$ . The domain  $\Omega \in \mathbb{R}^2$  is assumed to be bounded and polygonal with boundary  $\Gamma := \partial\Omega$ . For the data we assume  $z, b, f \in L^2(\Omega)$  and  $\alpha > 0$ . It is well known that (P) admits a unique solution  $(y^*, u^*) \in H_0^1(\Omega) \times L^2(\Omega)$  (cf., e.g., [12]). Moreover, the optimal solution is characterized by the existence of an adjoint state  $p^* \in H_0^1(\Omega)$  and a Lagrange multiplier  $\lambda^* \in L^2(\Omega)$  which satisfy the first order necessary (and in this case, also sufficient) conditions

$$(2.1a) \quad -\Delta y^* = u^* + f,$$

$$(2.1b) \quad -\Delta p^* + y^* = z,$$

$$(2.1c) \quad \alpha u^* + \lambda^* - p^* = 0,$$

$$(2.1d) \quad u^* \leq b, \quad \lambda^* \geq 0, \quad (u^* - b, \lambda^*)_{0,\Omega} = 0.$$

We define the Lagrange functional  $\mathcal{L} : H_0^1(\Omega) \times L^2(\Omega) \times H_0^1(\Omega) \times L^2(\Omega) \rightarrow \mathbb{R}$  pertinent to (P) as

$$(2.2) \quad \mathcal{L}(y, u, p, \lambda) = J(y, u) + (\nabla y, \nabla p)_{0,\Omega} - (u + f, p)_{0,\Omega} + (u - b, \lambda)_{0,\Omega}.$$

For convenience we use  $x := (p, y, u)$ ,  $x^* = (p^*, y^*, u^*)$ , and  $X = P \times Y \times L = H_0^1(\Omega) \times H_0^1(\Omega) \times L^2(\Omega)$ . Obviously, the weak form of (2.1a)–(2.1b) and (2.1c) of the optimality system (2.1) is equivalent to

$$(2.3) \quad \nabla_x \mathcal{L}(x^*, \lambda^*)(\varphi) = 0 \quad \forall \varphi \in X.$$

Let  $X_h \subset X$ , with  $X_h = P_h \times Y_h \times L_h$ , denote a finite dimensional subspace with the subscript  $h$  indicating the mesh size of the discretization obtained by a standard Galerkin method, let  $\lambda_h \in L_h \subset L^2(\Omega)$  denote the discrete (finite dimensional) counterpart of  $\lambda$  (analogously for  $\lambda^*$ ), and let  $f_h, b_h, z_h \in L_h$  be the  $L^2$ -projections of  $f, b, z$  onto  $L_h$ . The finite dimensional version of (2.1) reads

$$(2.4a) \quad \nabla_x \mathcal{L}_h(x_h^*, \lambda_h^*)(\varphi_h) = 0 \quad \forall \varphi_h \in X_h,$$

$$(2.4b) \quad u_h^* \leq b_h, \quad \lambda_h^* \geq 0, \quad (u_h^* - b_h, \lambda_h^*)_{0,\Omega} = 0,$$

where the discrete Lagrange function is given by

$$(2.5) \quad \begin{aligned} \mathcal{L}_h(x_h, \lambda_h) &= J_h(y_h, u_h) + (\nabla y_h, \nabla p_h)_{0,\Omega} - (u_h + f_h, p_h)_{0,\Omega} \\ &\quad + (u_h - b_h, \lambda_h)_{0,\Omega} \end{aligned}$$

with  $J_h(y_h, u_h) = \frac{1}{2}\|y_h - z_h\|_{0,\Omega}^2 + \frac{\alpha}{2}\|u_h\|_{0,\Omega}^2$ . Observe that the pointwise representation (2.1c) in the discrete setting reads

$$(2.6) \quad \alpha u_h^* + \lambda_h^* - M_h p_h^* = 0,$$

where  $M_h$  represents a projection operator from  $P_h$  onto  $L_h$ .

Further note that for  $x \in X$ ,  $\lambda \in L^2(\Omega)$  and  $x_h \in X_h$ ,  $\lambda_h \in L_h$ ,

$$(2.7) \quad \mathcal{L}(x, \lambda_h) = \mathcal{L}(x, \lambda) + (u - b, \lambda_h - \lambda)_{0,\Omega},$$

$$(2.8) \quad \nabla_x \mathcal{L}(x_h, \lambda_h)(\varphi_h) = \nabla_x \mathcal{L}(x_h, \lambda)(\varphi_h) + (\delta u_h, \lambda_h - \lambda)_{0,\Omega}$$

for all  $(\delta p_h, \delta y_h, \delta u_h) = \varphi_h \in X_h$ . Moreover, for our model problem (P) the second derivative of  $\mathcal{L}$  with respect to  $x$  does not depend on  $x$  and  $\lambda$ . Thus, we can write  $\nabla_{xx} \mathcal{L}(\varphi, \hat{\varphi})$  instead of  $\nabla_{xx} \mathcal{L}(x, \lambda)(\varphi, \hat{\varphi})$ . Similar observations hold true for  $\mathcal{L}_h$ . Due to  $X_h \subset X$ , we have for  $\varphi_h = (\delta p_h, \delta y_h, \delta u_h) \in X_h$ ,

$$(2.9) \quad \begin{aligned} 0 &= \nabla_x \mathcal{L}(x^*, \lambda^*)(\varphi_h) \\ &= \nabla_x \mathcal{L}(x_h^*, \lambda^*)(\varphi_h) + \nabla_{xx} \mathcal{L}(x^* - x_h^*, \varphi_h) \\ &= \nabla_x \mathcal{L}(x_h^*, \lambda_h^*)(\varphi_h) + (\delta u_h, \lambda^* - \lambda_h^*)_{0,\Omega} + \nabla_{xx} \mathcal{L}(x^* - x_h^*, \varphi_h) \\ &= \nabla_x \mathcal{L}_h(x_h^*, \lambda_h^*)(\varphi_h) - (f - f_h, \delta p_h)_{0,\Omega} - (z - z_h, \delta y_h)_{0,\Omega} \\ &\quad + (\delta u_h, \lambda^* - \lambda_h^*)_{0,\Omega} + \nabla_{xx} \mathcal{L}(x^* - x_h^*, \varphi_h) \\ &= (\delta u_h, \lambda^* - \lambda_h^*)_{0,\Omega} + \nabla_{xx} \mathcal{L}(x^* - x_h^*, \varphi_h) - (f - f_h, \delta p_h)_{0,\Omega} \\ &\quad - (z - z_h, \delta y_h)_{0,\Omega}. \end{aligned}$$

From this we further derive the relations

$$(2.10) \quad \begin{aligned} \nabla_{xx} \mathcal{L}(x_h^* - x^*, x_h^* - x^*) \\ = \nabla_{xx} \mathcal{L}(x_h^* - x^*, x_h^* - x^* + \varphi_h) - (\delta u_h, \lambda^* - \lambda_h^*)_{0,\Omega} \\ + (f - f_h, \delta p_h)_{0,\Omega} + (z - z_h, \delta y_h)_{0,\Omega}, \end{aligned}$$

$$(2.11) \quad \nabla_x \mathcal{L}(x_h^*, \lambda^*)(x^* - x_h^* - \varphi_h) = \nabla_{xx} \mathcal{L}(x_h^* - x^*, x^* - x_h^* - \varphi_h)$$

and also

$$(2.12) \quad \begin{aligned} \nabla_x \mathcal{L}(x_h^*, \lambda_h^*)(x^* - x_h^* - \varphi_h) \\ = \nabla_x \mathcal{L}(x^*, \lambda_h^*)(x^* - x_h^* - \varphi_h) + \nabla_{xx} \mathcal{L}(x_h^* - x^*, x^* - x_h^* - \varphi_h) \\ = (\lambda_h^* - \lambda^*, u^* - u_h^* - \delta u_h)_{0,\Omega} + \nabla_{xx} \mathcal{L}(x_h^* - x^*, x^* - x_h^* - \varphi_h). \end{aligned}$$

These preliminary results are now used to prove the following theorem.

**THEOREM 2.1.** *Let  $(x^*, \lambda^*) \in X \times L^2(\Omega)$  and  $(x_h^*, \lambda_h^*) \in X_h \times L_h$  denote the solution of (2.1) and its finite dimensional counterpart (2.4). Then*

$$(2.13) \quad \begin{aligned} J(y^*, u^*) - J_h(y_h^*, u_h^*) &= -\frac{1}{2} \nabla_{xx} \mathcal{L}(x_h^* - x^*, x_h^* - x^*) \\ &\quad + (u_h^* - b, \lambda^*)_{0,\Omega} + \text{osc}_h(x_h^*), \end{aligned}$$

where the oscillations  $\text{osc}_h(x_h^*)$  are given by

$$\text{osc}_h(x_h^*) = (y_h^* - z_h, z_h - z)_{0,\Omega} + \frac{1}{2} \|z - z_h\|_{0,\Omega}^2 + (f_h - f, p_h^*)_{0,\Omega}.$$

*Proof.* Observe that  $J(y^*, u^*) = \mathcal{L}(x^*, \lambda^*)$  and  $J_h(y_h^*, u_h^*) = \mathcal{L}_h(x_h^*, \lambda_h^*)$ . Using Taylor expansions and (2.7)–(2.8), we obtain

$$\begin{aligned}
 J(y^*, u^*) - J_h(y_h^*, u_h^*) &= \mathcal{L}(x^*, \lambda^*) - \mathcal{L}_h(x_h^*, \lambda_h^*) \\
 &= \mathcal{L}(x^*, \lambda^*) - \mathcal{L}_h(x^*, \lambda_h^*) - \nabla_x \mathcal{L}_h(x^*, \lambda_h^*)(x_h^* - x^*) \\
 &\quad - \frac{1}{2} \nabla_{xx} \mathcal{L}_h(x_h^* - x^*, x_h^* - x^*) \\
 &= J(y^*, u^*) - J_h(y^*, u^*) + (f_h - f, p^*)_{0,\Omega} - (u^* - b_h, \lambda_h^*)_{0,\Omega} \\
 &\quad - \nabla_x \mathcal{L}_h(x^*, \lambda_h^*)(x_h^* - x^*) - \frac{1}{2} \nabla_{xx} \mathcal{L}_h(x_h^* - x^*, x_h^* - x^*) \\
 &= \text{osc}_h(x_h^*) - (u^* - b_h, \lambda_h^*)_{0,\Omega} - \nabla_x \mathcal{L}(x^*, \lambda_h^*)(x_h^* - x^*) \\
 &\quad - \frac{1}{2} \nabla_{xx} \mathcal{L}_h(x_h^* - x^*, x_h^* - x^*) \\
 &= \text{osc}_h(x_h^*) - (u^* - u_h^*, \lambda_h^*)_{0,\Omega} + (\lambda^* - \lambda_h^*, u_h^* - u^*)_{0,\Omega} \\
 &\quad - \frac{1}{2} \nabla_{xx} \mathcal{L}_h(x_h^* - x^*, x_h^* - x^*) \\
 &= \text{osc}_h(x_h^*) + (\lambda^*, u_h^* - b)_{0,\Omega} - \frac{1}{2} \nabla_{xx} \mathcal{L}_h(x_h^* - x^*, x_h^* - x^*),
 \end{aligned}$$

where we also used the complementarity relations (2.1d) and (2.4b) as well as (2.3) and (2.4a).  $\square$

Assume, for the moment, that  $\lambda^* = 0$  and  $\lambda_h^* = 0$ ; i.e., the continuous and the discrete control constraints are inactive. Then we infer from (2.10) that for all  $\varphi_h \in X_h$  there holds

$$\begin{aligned}
 \nabla_{xx} \mathcal{L}(x_h^* - x^*, x_h^* - x^*) &= \nabla_{xx} \mathcal{L}(x_h^* - x^*, x_h^* - x^* + \varphi_h) \\
 &\quad + (f - f_h, \delta p_h)_{0,\Omega} + (z - z_h, \delta y_h)_{0,\Omega}
 \end{aligned}$$

as well as

$$\begin{aligned}
 J(y^*, u^*) - J_h(y_h^*, u_h^*) &= \frac{1}{2} \nabla_x \mathcal{L}_h(x_h, \lambda_h)(x^* - x_h^* - \varphi_h) \\
 (2.14) \quad &\quad + \frac{1}{2} (f_h - f, p^* - p_h^*)_{0,\Omega} + \frac{1}{2} (z_h - z, y^* - y_h^*)_{0,\Omega} \\
 &\quad + \text{osc}_h(x_h^*)
 \end{aligned}$$

due to (2.12). This corresponds to the result in [2, Proposition 4.1] for the unconstrained version of (P).

If  $b_h \leq b$  a.e. in  $\Omega$ , then (2.13) implies

$$J(y^*, u^*) \leq J_h(y_h^*, u_h^*) + \text{osc}_h(x_h^*).$$

Next we interpret the new, second term in the right-hand side of (2.13). For this purpose we define the active set  $\mathcal{A}^*$  and the inactive set  $\mathcal{I}^*$  at the optimal solution  $(x^*, \lambda^*)$  of (P) by

$$(2.15) \quad \mathcal{A}^* := \{x \in \Omega : u^*(x) = b(x)\}, \quad \mathcal{I}^* := \Omega \setminus \mathcal{A}^*.$$

Analogously we define the discrete counterparts  $\mathcal{A}_h^*$  and  $\mathcal{I}_h^*$ . Obviously,  $u^* < b$  a.e. in  $\mathcal{I}^*$ . By (2.1d), this implies  $\lambda^* = 0$  a.e. in  $\mathcal{I}^*$ . Therefore, the term  $(u_h^* - b, \lambda^*)_{0,\Omega}$  satisfies

$$(u_h^* - b, \lambda^*)_{0,\Omega} = (u_h^* - b_h, \lambda^*)_{0,\mathcal{A}^* \cap \mathcal{I}_h^*} + (b_h - b, \lambda^*)_{0,\mathcal{A}^*}.$$

The right-hand side above reflects the *error in complementarity*. In fact, the second term represents the data oscillation in the bound in the active set weighted by the continuous Lagrange multiplier. For this term we introduce the notation

$$\text{osc}_h^{A^*}(b; \lambda^*) := (b_h - b, \lambda^*)_{0, A^*}.$$

The first term captures a *primal-dual weighted mismatch in complementarity in  $\mathcal{A}^* \cap \mathcal{I}_h^*$* .

Let  $i_h := (i_h^p, i_h^y, i_h^u)$  be an interpolation operator such that  $i_h x \in X_h$  for  $x \in X$ . Moreover, for  $y, p \in H_0^1(\Omega)$  there exist  $i_h^p$  and  $i_h^y$  such that  $\max\{\|i_h^p p - p\|_{H^1}, \|i_h^y y - y\|_{H^1}\} \rightarrow 0$  for  $h \rightarrow 0$ . In connection with Theorem 2.1 we have the following result.

**THEOREM 2.2.** *Let the assumptions of Theorem 2.1 be satisfied. Then*

$$\begin{aligned} J(y^*, u^*) - J_h(y_h^*, u_h^*) &= -\frac{1}{2} \left( (y_h^* - z_h, i_h^y y^* - y^*)_{0, \Omega} + (\nabla(i_h^y y^* - y^*), \nabla p_h^*)_{0, \Omega} \right. \\ &\quad + (\nabla(i_h^p p^* - p^*), \nabla y_h^*)_{0, \Omega} - (u_h^* + f_h, i_h^p p^* - p^*)_{0, \Omega} \\ &\quad \left. + (M_h p_h^* - p_h^*, i_h^u u^* - u^*)_{0, \Omega} \right) \\ (2.16) \quad &+ \frac{1}{2} [(u_h^* - b, \lambda^*)_{0, \Omega} + (b_h - u^*, \lambda_h^*)_{0, \Omega}] + \frac{1}{2} (f - f_h, p_h^* - p^*)_{0, \Omega} \\ &+ \frac{1}{2} (z - z_h, y_h^* - y^*)_{0, \Omega} + \text{osc}_h(x_h^*). \end{aligned}$$

*Proof.* Utilizing (2.10)–(2.11) and considering  $\varphi_h = (\delta p_h, \delta y_h, \delta u_h) \in X_h$ , we obtain

$$\begin{aligned} J(y^*, u^*) - J_h(y_h^*, u_h^*) &= \frac{1}{2} \nabla_{xx} \mathcal{L}(x, \lambda_h^*)(x^* - x_h^*, x_h^* - x^* + \varphi_h) \\ &\quad + \frac{1}{2} (\delta u_h, \lambda^* - \lambda_h^*)_{0, \Omega} + \frac{1}{2} (f_h - f, \delta p_h)_{0, \Omega} + \frac{1}{2} (z_h - z, \delta y_h)_{0, \Omega} \\ &\quad + (u_h^* - b, \lambda^*)_{0, \Omega} + \text{osc}_h(x_h^*) \\ &= -\frac{1}{2} \nabla_x \mathcal{L}(x_h^*, \lambda_h^*)(x_h^* - x^* + \varphi_h) + \frac{1}{2} (\lambda_h^* + \lambda^*, u_h^* - u^*)_{0, \Omega} \\ &\quad + \frac{1}{2} (f_h - f, \delta p_h)_{0, \Omega} + \frac{1}{2} (z_h - z, \delta y_h)_{0, \Omega} + \text{osc}_h(x_h^*) \\ &= -\frac{1}{2} \nabla_x \mathcal{L}_h(x_h^*, \lambda_h^*)(x_h^* - x^* + \varphi_h) + \frac{1}{2} (\lambda_h^* + \lambda^*, u_h^* - u^*)_{0, \Omega} \\ &\quad + \frac{1}{2} (f - f_h, p_h^* - p^*)_{0, \Omega} + \frac{1}{2} (z - z_h, y_h^* - y^*)_{0, \Omega} + \text{osc}_h(x_h^*). \end{aligned}$$

Choosing  $\varphi_h = (i_h^p p^* - p_h^*, i_h^y y^* - y_h^*, i_h^u u^* - u_h^*) \in X_h$  and using complementary slackness, we continue with

$$\begin{aligned} J(y^*, u^*) - J_h(y_h^*, u_h^*) &= -\frac{1}{2} \nabla_x \mathcal{L}_h(x_h^*, \lambda_h^*)(i_h x^* - x^*) \\ &\quad + \frac{1}{2} [(\lambda_h^*, b_h - u^*)_{0, \Omega} + (\lambda^*, u_h^* - b)_{0, \Omega}] \\ &\quad + \frac{1}{2} (f - f_h, p_h^* - p^*)_{0, \Omega} + \frac{1}{2} (z - z_h, y_h^* - y^*)_{0, \Omega} \\ &\quad + \text{osc}_h(x_h^*). \end{aligned}$$

The assertion now follows from (2.2) and  $\alpha u_h^* - M_h p_h^* + \lambda_h^* = 0$  a.e. in  $\Omega$ .  $\square$

This result is interesting in several ways as follows:

- (i) For  $\|M_h p_h - p_h\|_{0,\Omega} \rightarrow 0$  as  $h \rightarrow 0$  sufficiently fast, only the convergence properties implied by  $i_h^p$  and  $i_h^y$  are required for obtaining an a posteriori error estimate based on (2.16). Since  $y^*$  and  $p^*$  solve elliptic PDEs, they usually enjoy more regularity than  $u^*$  and  $\lambda^*$ .
- (ii) The term in brackets on the right-hand side in (2.16) is again related to errors coming from complementary slackness. The first term of the sum can be interpreted as before, while the second term of the sum reflects the symmetric case, i.e.,

$$(b_h - u^*, \lambda_h^*)_{0,\Omega} = (b - u^*, \lambda_h^*)_{0,\mathcal{A}_h^* \cap \mathcal{I}^*} + (b_h - b, \lambda_h^*)_{0,\mathcal{A}_h^*}.$$

Hence, the first term of the right-hand side above represents the *primal-dual weighted mismatch in complementarity in  $\mathcal{I}^* \cap \mathcal{A}_h^*$* , while the second term denotes the data oscillation on  $\mathcal{A}_h^*$  weighted by the discrete multiplier, i.e.,

$$\text{osc}_h^{\mathcal{A}_h^*}(b; \lambda_h^*) := (b_h - b, \lambda_h^*)_{0,\mathcal{A}_h^*}.$$

Of course, (2.16) is not immediately amenable to numerical realization since  $u^*$  and  $\lambda^*$  are involved. Before we tackle this point, let us first state a posteriori error bounds for the control and the adjoint state which were derived in [8]. A coarser estimate was established in [14]. Recall that  $U^{ad}$  denotes the set of admissible controls, and let  $U_h^{ad}$  be its discretization. Then the following a posteriori error estimates hold true:

$$(2.17a) \quad \max(\|\lambda^* - \lambda_h^*\|_{0,\Omega}^2, \|u^* - u_h^*\|_{0,\Omega}^2) \leq C_1^2 \eta_1^2 + C_2^2 \eta_2^2 + C_b^2 \mu_h^2(b),$$

$$(2.17b) \quad \|p^* - p_h^*\|_{1,\Omega}^2 \leq C_2^2 \eta_2^2 + C_z^2 \text{osc}_h^2(z).$$

In what follows we also use

$$C_3^2 \eta_3^2 := C_1^2 \eta_1^2 + C_2^2 \eta_2^2 + C_b^2 \mu_h^2(b) \quad \text{and} \quad C_4^2 \eta_4^2 := C_2^2 \eta_2^2 + C_z^2 \text{osc}_h^2(z).$$

Here and below,  $C_i > 0$ ,  $i = 1, 2, 3, 4$ , denote constants which depend on  $\alpha$ ,  $\Omega$ , and the shape regularity of  $\mathbb{T}_h$ . The error bounds  $\eta_1$  and  $\eta_2$  are defined as

$$(2.18) \quad \eta_1^2 = \sum_T \int_T h_T^2 (p_h^* - M_h p_h^*)^2,$$

$$(2.19) \quad \eta_2^2 = \sum_T \int_T h_T^2 (f + u_h^* + \Delta y_h^*)^2 + \sum_F \int_F h_F [\nabla y_h^* \cdot n]^2 \\ + \sum_T \int_T h_T^2 (z - y_h^* + \Delta p_h^*)^2 + \sum_F \int_F h_F [\nabla p_h^* \cdot n]^2.$$

Further, the data oscillations

$$(2.20) \quad \mu_h^2(b) = \sum_{T \in \mathbb{T}_h} \|b - b_h\|_{0,T}^2,$$

$$(2.21) \quad \text{osc}_h^2(z) = \sum_{T \in \mathbb{T}_h} h_T^2 \|z - z_h\|_{0,T}^2$$

are involved.

Above,  $T$  denotes an element of the triangulation  $\mathbb{T}_h$  of  $\Omega$ . Further,  $F$  denotes a face of  $T$ , and  $h_F$  is the maximal diameter of the face  $F$ . Moreover,  $[\nabla y_h^* \cdot n]$  is the normal derivative jump over an interior face  $F$ . As noted before, the operator  $M_h$  represents the projection of a mesh function in  $P_h$  ( $= Y_h$ , typically in our context) onto  $L_h$ . If  $L_h$  is given by

$$L_h = \{u_h \in L^2(\Omega) : u_h|_T \in P_0(T), T \in \mathbb{T}_h\},$$

i.e., the function  $u_h$  is piecewise constant on  $\mathbb{T}_h$ , then the action of  $M_h$  in  $T$  is given by

$$(M_h p_h)|_T = \frac{1}{|T|} \int_T p_h(x) dx, \quad T \in \mathbb{T}_h.$$

A final observation concerns the unconstrained case, which is  $U^{ad} = L^2(\Omega)$ . In this situation we have  $\lambda^* = 0$  a.e. in  $\Omega$ . From (2.18)–(2.19) we see that the error estimator remains unaffected.

Our investigations concentrate now on the term

$$(2.22) \quad \frac{1}{2} [(u_h^* - b, \lambda^*)_{0,\Omega} + (b_h - u^*, \lambda_h^*)_{0,\Omega}] =: \Psi^*(\Omega),$$

which contains  $u^*$  and  $\lambda^*$ . A simple manipulation yields

$$\Psi^*(\Omega) = \frac{1}{2} [(\lambda_h^* - \lambda^*, b_h - u^*)_{0,\Omega} + (\lambda^* - \lambda_h^*, u_h^* - b)_{0,\Omega} + (\lambda^* + \lambda_h^*, b_h - b)_{0,\Omega}].$$

From first order optimality we recall

$$(2.23) \quad u^* \leq b, \quad \lambda^* \geq 0, \quad (u^* - b, \lambda^*)_{0,\Omega} = 0, \quad \alpha u^* - p^* + \lambda^* = 0,$$

$$(2.24) \quad u_h^* \leq b_h, \quad \lambda_h^* \geq 0, \quad (u_h^* - b_h, \lambda_h^*)_{0,\Omega} = 0, \quad \alpha u_h^* - M_h p_h^* + \lambda_h^* = 0.$$

Obviously, we have

$$(2.25a) \quad \Psi^*(\mathcal{I}^* \cap \mathcal{I}_h^*) = 0,$$

$$(2.25b) \quad \Psi^*(\mathcal{A}^* \cap \mathcal{A}_h^*) = \frac{1}{2} (\lambda^* - \lambda_h^*, b_h - b)_{0,\mathcal{A}^* \cap \mathcal{A}_h^*} + (\lambda_h^*, b_h - b)_{0,\mathcal{A}^* \cap \mathcal{A}_h^*},$$

where  $\Psi^*(\mathcal{S}) = \frac{1}{2} [(u_h^* - b, \lambda^*)_{0,\mathcal{S}} + (b_h - u^*, \lambda_h^*)_{0,\mathcal{S}}]$ . In the right-hand side of (2.25b), typically the latter term dominates. It is nonpositive if  $b_h \leq b$  a.e. in  $\mathcal{A}_h^*$ . Note that if  $b_h = b$  a.e. in  $\Omega$ , then  $\Psi^*(\mathcal{A}^* \cap \mathcal{A}_h^*) = 0$ . From the structure of  $\Psi^*(\mathcal{A}^* \cap \mathcal{A}_h^*)$  we can see that it represents a dual-weighted data oscillation on  $\mathcal{A}^* \cap \mathcal{A}_h^*$ . Subsequently we use

$$(2.26) \quad \text{osc}_h^{\mathcal{S}}(b; \lambda^* + \lambda_h^*) := (b_h - b, \lambda_h^* + \lambda^*)_{0,\mathcal{S}}.$$

Note that  $\text{osc}_h^{\mathcal{I}^* \cap \mathcal{I}_h^*}(b; \lambda^* + \lambda_h^*) = 0$ .

Utilizing (2.23)–(2.26), for  $\mathcal{C}_1^* = \mathcal{A}^* \cap \mathcal{I}_h^*$  and  $\mathcal{C}_2^* = \mathcal{I}^* \cap \mathcal{A}_h^*$  we obtain

$$(2.27a) \quad \Psi^*(\mathcal{C}_1^*) = \frac{\alpha}{2} \|u_h^* - u^*\|_{0,\mathcal{C}_1^*}^2 + \frac{1}{2} (p^* - M_h p_h^*, u_h^* - u^*)_{0,\mathcal{C}_1^*},$$

$$(2.27b) \quad \Psi^*(\mathcal{C}_2^*) = \frac{1}{2} (b_h - \alpha^{-1} p^*, \lambda_h^*)_{0,\mathcal{C}_2^*}.$$

On the respective sets we get the following estimates:

(i) In  $\mathcal{C}_1^*$  we have  $u_{|\mathcal{C}_1^*}^* = b_{|\mathcal{C}_1^*}$ . Thus,

$$|\Psi^*(\mathcal{C}_1^*)| \leq \frac{1}{2} (\|M_h p_h^* - p_h^*\|_{0,\mathcal{C}_1^*} + \|p_h^* - p^*\|_{0,\mathcal{C}_1^*} + \alpha \|u_h^* - b\|_{0,\mathcal{C}_1^*}) \|u_h^* - b\|_{0,\mathcal{C}_1^*}.$$

Given  $\mathcal{C}_1^*$  and the discrete control  $u_h^*$  and adjoint state  $p_h^*$ , the first and third terms in parentheses above are computable a posteriori. We therefore study  $\|p_h^* - p^*\|_{0,\mathcal{C}_1^*}$  next. Since  $p_h^*, p^* \in H_0^1(\Omega)$  and, for  $n \geq 2$ ,  $H_0^1(\Omega) \subset L^s(\Omega)$  for some  $s \in (2, +\infty)$ , from Hölder's inequality we obtain

$$(2.28) \quad \|p_h^* - p^*\|_{0,\mathcal{C}_1^*} \leq \text{meas}(\mathcal{C}_1^*)^{r(s)} \|p^* - p_h^*\|_{1,\mathcal{C}_1^*} \leq C_4 \text{meas}(\mathcal{C}_1^*)^{r(s)} \eta_4$$

with  $r(s) := \frac{1}{2} - \frac{1}{s} > 0$ . Hence, we get

$$(2.29) \quad \|p_h^* - p^*\|_{0,\mathcal{C}_1^*} \leq \min \left( C_0^p \eta_{0,p}, C_4 \text{meas}(\mathcal{C}_1^*)^{r(s)} \eta_4 \right) =: C^p(\mathcal{C}_1^*),$$

where  $\eta_{0,p}$  denotes the a posteriori estimator for  $\|p^* - p_h^*\|_{0,\Omega}$  (see Appendix A for its derivation) and  $C_0^p > 0$  is a constant. This yields

$$(2.30) \quad |\Psi^*(\mathcal{C}_1^*)| \leq \frac{1}{2} (\|M_h p_h^* - p_h^*\|_{0,\mathcal{C}_1^*} + C^p(\mathcal{C}_1^*) + \alpha \|u_h^* - b\|_{0,\mathcal{C}_1^*}) \cdot \|u_h^* - b\|_{0,\mathcal{C}_1^*} =: \mu_1(\mathcal{C}_1^*).$$

(ii) In  $\mathcal{C}_2^*$  we use the identities  $\lambda_h^* = M_h p_h^* - \alpha u_h^*$  and  $p^* = \alpha u^*$ . From this, and assuming  $b_h \in L^t(\Omega)$ ,  $2 \leq t \leq s$ , we infer

$$\begin{aligned} 2|\Psi^*(\mathcal{C}_2^*)| &= |(u_h^* - u^*, \lambda_h^*)_{\mathcal{C}_2^*}| \\ &\leq \text{meas}(\mathcal{C}_2^*)^{r(t)} \|b_h - \alpha^{-1} p^*\|_{t,\mathcal{C}_2^*} \|\lambda_h^*\|_{0,\mathcal{C}_2^*} \\ &\leq \text{meas}(\mathcal{C}_2^*)^{r(t)} (\|b_h - \alpha^{-1} p_h^*\|_{t,\mathcal{C}_2^*} + \alpha^{-1} \|p_h^* - p^*\|_{1,\Omega}) \|\lambda_h^*\|_{0,\mathcal{C}_2^*} \\ &\leq \text{meas}(\mathcal{C}_2^*)^{r(t)} (\|b_h - \alpha^{-1} p_h^*\|_{t,\mathcal{C}_2^*} + \alpha^{-1} C_4 \eta_4) \|\lambda_h^*\|_{0,\mathcal{C}_2^*} \end{aligned}$$

with  $r(t) \geq 0$ . Alternatively, we may use (2.17a) for estimating  $\|u_h^* - u^*\|_{0,\mathcal{M}_2^*}$ . Hence, setting

$$C^u(\mathcal{C}_2^*) := \min \left( \text{meas}(\mathcal{C}_2^*)^{r(t)} (\|b_h - \alpha^{-1} p_h^*\|_{t,\mathcal{C}_2^*} + \alpha^{-1} C_4 \eta_4), C_3 \eta_3 \right),$$

we obtain

$$(2.31) \quad |\Psi^*(\mathcal{C}_2^*)| \leq \frac{1}{2} C^u(\mathcal{C}_2^*) \|\lambda_h^*\|_{0,\mathcal{C}_2^*} =: \mu_2(\mathcal{C}_2^*).$$

Since  $\lambda_h^* = 0$  in  $\mathcal{I}_h^*$ , we obviously have  $\mu_2(\mathcal{I}_h^*) = 0$ .

In both cases above we assume  $\mu_1(\emptyset) = 0$  and  $\mu_2(\emptyset) = 0$ . Summarizing, we obtain

$$\begin{aligned} |\Psi^*(\Omega)| &= |\Psi^*(\mathcal{A}^* \cap \mathcal{A}_h^*) + \Psi^*(\mathcal{C}_1^*) + \Psi^*(\mathcal{C}_2^*)| \\ &\leq \frac{1}{2} |\text{osc}_h^{\mathcal{A}^* \cap \mathcal{A}_h^*}(b; \lambda^* + \lambda_h^*)| + \mu_1(\mathcal{C}_1^*) + \mu_2(\mathcal{C}_2^*). \end{aligned}$$

An alternative (and possibly coarse) estimate of  $\Psi^*(\Omega)$  uses only the error estimate  $\eta_3$  and  $\|\lambda_h^*\|_{0,\mathcal{A}_h^*}$  as follows:

$$|\Psi^*(\Omega)| = \frac{1}{2} |(\lambda_h^* + \lambda^*, u^* - u_h^*)| \leq \frac{1}{2} C_3 \eta_3 (C_3 \eta_3 + 2 \|\lambda_h^*\|_{0,\mathcal{A}_h^*}) =: \mu_3(\Omega).$$

If the original problem is unconstrained with respect to  $u$ , then  $\lambda^* = 0$ . As a consequence, the first order conditions yield  $\alpha u^* = p^*$ , i.e.,  $u^*$  inherits the regularity of  $p^* \in H_0^1(\Omega)$ . Then we may choose the same ansatz when discretizing  $p$  and  $u$ . Thus, we obtain  $\eta_1 = 0$ , since  $M_h$  becomes the identity operator, and—up to data oscillations— $\eta_2 = \eta_3$ , and further,  $\|M_h p_h^* - p_h^*\|_{0,C_1^*} = 0$  in  $\mu_1$ .

Finally, we express  $\mu_1$  and  $\mu_2$  such that we obtain cell-oriented error estimates. Let us first consider  $\mu_1(\mathcal{C}_1^*)$ . We have

$$\begin{aligned}\mu_1(\mathcal{C}_1^*) &= \frac{1}{2} (C^p(\mathcal{C}_1^*) + \|M_h p_h^* - p_h^*\|_{0,C_1^*} + \alpha \|u_h^* - b\|_{0,C_1^*}) \|u_h^* - b\|_{0,C_1^*} \\ &= \frac{1}{2} \left( \hat{C}^p(\mathcal{C}_1^*) + \hat{C}_5(\mathcal{C}_1^*) \|M_h p_h^* - p_h^*\|_{0,C_1^*}^2 + \alpha \|u_h^* - b\|_{0,C_1^*}^2 \right).\end{aligned}$$

Above, we use

$$\hat{C}_0^p := \begin{cases} C_0^p \frac{\|u_h^* - b\|_{0,C_1^*}}{\eta_{0,p}} & \text{if } \text{meas}(\mathcal{C}_1^*) \neq 0 \text{ and } \eta_{0,p} > 0, \\ 0 & \text{if } \text{meas}(\mathcal{C}_1^*) = 0, \end{cases}$$

as well as

$$\hat{C}_4(\mathcal{C}_1^*) := \begin{cases} C_4 \frac{\|u_h^* - b\|_{0,C_1^*}}{\eta_4} & \text{if } \text{meas}(\mathcal{C}_1^*) \neq 0 \text{ and } \eta_4 > 0, \\ 0 & \text{if } \text{meas}(\mathcal{C}_1^*) = 0, \end{cases}$$

and further,

$$\hat{C}_5(\mathcal{C}_1^*) := \begin{cases} \frac{\|u_h^* - b\|_{0,C_1^*}}{\|M_h p_h^* - p_h^*\|_{0,C_1^*}} & \text{if } \text{meas}(\mathcal{C}_1^*) \neq 0 \text{ and } \|M_h p_h^* - p_h^*\|_{0,C_1^*} > 0, \\ 0 & \text{if } \text{meas}(\mathcal{C}_1^*) = 0. \end{cases}$$

We therefore have

$$\hat{C}^p(\mathcal{C}_1^*) = \min \left( \hat{C}_0^p \eta_{0,p}^2, \hat{C}_4(\mathcal{C}_1^*) \text{meas}(\mathcal{C}_1^*)^{r(s)} \eta_4^2 \right).$$

Finally, we turn to  $\mu_2(\mathcal{C}_2^*)$ . We obtain

$$\mu_2(\mathcal{C}_2^*) = \frac{1}{2} \hat{C}^u(\mathcal{C}_2^*),$$

with

$$\hat{C}_i(\mathcal{C}_2^*) := \begin{cases} C_i \frac{\|\lambda_h^*\|_{0,C_2^*}}{\eta_i} & \text{if } \text{meas}(\mathcal{C}_2^*) \neq 0 \text{ and } \eta_i > 0, \\ 0 & \text{if } \text{meas}(\mathcal{C}_2^*) = 0, \end{cases}$$

for  $i = 3, 4$ , and

$$\begin{aligned}\hat{C}^u(\mathcal{C}_2^*) &:= \min \left( \text{meas}(\mathcal{C}_2^*)^{r(t)} (\|b_h - \alpha^{-1} p_h^*\|_{t,C_2^*} \|\lambda_h^*\|_{0,C_2^*} \right. \\ &\quad \left. + \alpha^{-1} \hat{C}_4(\mathcal{C}_2^*) \eta_4^2), \hat{C}_3(\mathcal{C}_2^*) \eta_3^2 \right).\end{aligned}$$

We summarize our above findings in the following proposition.

**PROPOSITION 2.1.** *Let the assumptions of Theorem 2.1 be satisfied. Then*

$$(2.32) \quad |\Psi^*(\Omega)| \leq \min \left( \frac{1}{2} |\text{osc}_h^{\mathcal{A}^* \cap \mathcal{A}_h^*}(b; \lambda^* + \lambda_h^*)| + \mu_1(\mathcal{C}_1^*) + \mu_2(\mathcal{C}_2^*), \mu_3(\Omega) \right).$$

We denote the right-hand side in (2.32) by  $\hat{\nu}$ . In the case where the solution of (P) satisfies  $u^* < b$  a.e. on  $\Omega$ , we expect that  $\hat{\nu} \approx 0$ . Indeed, for sufficiently small  $h$  we have  $\lambda_h^* \approx 0$  (or even  $\lambda_h^* = 0$ ). Thus,  $\mu_2(\mathcal{C}_2^*) \approx 0$  (or  $\mu_2(\mathcal{C}_2^*) = 0$ ) holds true. Further,  $\mu_1(\mathcal{C}_1^*) = 0$  since  $\mathcal{A}^* = \emptyset$ . Then (2.32) yields  $\hat{\nu} \approx 0$  (or  $\hat{\nu} = 0$ ). If (P) involves no inequality constraints on  $u$ , which means that we can set  $b \equiv +\infty$  on  $\Omega$ , then we naturally obtain  $\hat{\nu} = 0$ . Hence, we recover the error estimator for unconstrained optimal control problems; compare [2, 14].

For deriving the full error estimate, it remains to consider the first term in parentheses on the right-hand side of (2.16) in Theorem 2.2. This term is independent of the control constraints and corresponds to the usual expression obtained for (unconstrained) optimal control problems; see [2, 14]. A standard argument yields

$$\begin{aligned}
 & |(\nabla y_h^*, \nabla(i_h^p p^* - p^*))_{0,\Omega} - (u_h^* + f_h, i_h^p p^* - p^*)_{0,\Omega}| \\
 (2.33) \quad & \leq \sum_T \|-\Delta y_h^* - u_h^* - f_h\|_{0,T} \|p^* - i_h^p p^*\|_{0,T} \\
 & \quad + \sum_F \left\| \left[ \frac{\partial y_h^*}{\partial n} \right] \right\|_{0,F} \|p^* - i_h^p p^*\|_{0,F} =: \eta_2^p
 \end{aligned}$$

for the primal equation,

$$\begin{aligned}
 & |(y_h^* - z_h, i_h^y y^* - y^*)_{0,\Omega} + (\nabla(i_h^y y^* - y^*), \nabla p_h^*)_{0,\Omega}| \\
 (2.34) \quad & \leq \sum_T \|-\Delta p_h^* + y_h^* - z_h\|_{0,T} \|y^* - i_h^y y^*\|_{0,T} \\
 & \quad + \sum_F \left\| \left[ \frac{\partial p_h^*}{\partial n} \right] \right\|_{0,F} \|y^* - i_h^y y^*\|_{0,F} =: \eta_2^d
 \end{aligned}$$

for the dual equation, and

$$(2.35) \quad |(M_h p_h^* - p_h^*, i_h^u u^* - u^*)_{0,\Omega}| =: \eta_2^u.$$

The overall residual- and complementarity-based error estimate is given in the following theorem.

**THEOREM 2.3.** *Let the assumptions of Theorem 2.1 be satisfied. Then we have the following error estimate:*

$$\begin{aligned}
 (2.36) \quad & |J(y^*, u^*) - J(y_h^*, u_h^*)| \leq \frac{1}{2}(\eta_2^p + \eta_2^d + \eta_2^u) + \hat{\nu} \\
 & + \frac{1}{2}[C_0^p \eta_{0,p} \|f - f_h\|_{0,\Omega} + C_0^y \eta_{0,y} \|z - z_h\|_{0,\Omega}] \\
 & + |\text{osc}_h(x_h^*)|
 \end{aligned}$$

with  $\eta_2^p$ ,  $\eta_2^d$ ,  $\eta_2^u$ , and  $\hat{\nu}$  defined by (2.33), (2.34), (2.35), and (2.32), respectively. Further,  $C_0^y > 0$  is a constant and  $\eta_{0,y}$  denotes an error estimate for  $\|y_h^* - y^*\|_{0,\Omega}$ . For the definition of  $\eta_{0,p}$  and  $\eta_{0,y}$  see (A.10) and (A.11) in Appendix A.

The numerical evaluation of (2.36) depends on estimates of  $\|i_h^y y^* - y^*\|_{0,T}$ ,  $\|i_h^y y^* - y^*\|_{0,F}$ , and analogously, for  $i_h^p p^* - p^*$ . When discretizing the state and the adjoint state in two dimensions by continuous piecewise linear finite elements, the following

averaging technique, replacing  $\eta_2^p$  and  $\eta_2^d$  in (2.33) and (2.34), respectively, is appropriate:

$$(2.37) \quad \eta_{2,h}^p := \frac{1}{3} \sum_T \left( h_T \| -\Delta y_h^* - u_h^* - f_h \|_{0,T} \sum_{F(T)} h_F^{1/2} \left\| \left[ \frac{\partial p_h^*}{\partial n} \right] \right\|_{0,F} \right) \\ + \sum_F h_F \left\| \left[ \frac{\partial y_h^*}{\partial n} \right] \right\|_{0,F} \left\| \left[ \frac{\partial p_h^*}{\partial n} \right] \right\|_{0,F}$$

for the primal equation, and

$$(2.38) \quad \eta_{2,h}^d := \frac{1}{3} \sum_T \left( h_T \| -\Delta p_h^* + y_h^* - z_h \|_{0,T} \sum_{F(T)} h_F^{1/2} \left\| \left[ \frac{\partial y_h^*}{\partial n} \right] \right\|_{0,F} \right) \\ + \sum_F h_F \left\| \left[ \frac{\partial p_h^*}{\partial n} \right] \right\|_{0,F} \left\| \left[ \frac{\partial y_h^*}{\partial n} \right] \right\|_{0,F}$$

for the dual equation, where  $F(T)$  denotes the edges pertinent to triangle  $T$ . Notice that (2.37) and (2.38) yield typically sharper estimates than residual-based estimators for our model problem; compare (2.17) and [8]. Further observe that we can only expect boundedness of  $\|i_h^u u^* - u^*\|_{0,\Omega}$  in general. However, typically  $\|M_h p_h^* - p_h^*\|_{0,\Omega}$  is small, or, when using the same ansatz for discretizing  $u^*$  as well as  $p^*$ , it is even zero.

For the numerical evaluation of  $\hat{\nu}$  observe that  $\mathcal{I}_h^* \setminus \mathcal{A}^* \subset \mathcal{I}^*$ , and hence  $\lambda_h^* = 0$  and  $\lambda^* = 0$  on this set. Consequently, we obtain

$$\Psi^*(\mathcal{I}_h^* \setminus \mathcal{A}^*) = 0.$$

Next observe that  $\mathcal{I}_h^* = \mathcal{C}_1^* \dot{\cup} (\mathcal{I}_h^* \setminus \mathcal{A}^*)$ . Therefore, we have

$$(2.39) \quad \Psi^*(\mathcal{C}_1^*) = \Psi^*(\mathcal{I}_h^*) - \Psi^*(\mathcal{I}_h^* \setminus \mathcal{A}^*) = \Psi^*(\mathcal{I}_h^*).$$

If  $b_h = b$ , then we obtain  $\Psi^*(\mathcal{A}_h^* \setminus \mathcal{I}^*) = 0$ , and further,

$$(2.40) \quad \Psi^*(\mathcal{C}_2^*) = \Psi^*(\mathcal{A}_h^*) - \Psi^*(\mathcal{A}_h^* \setminus \mathcal{I}^*) = \Psi^*(\mathcal{A}_h^*).$$

The estimates  $\mu_1(\mathcal{C}_1^*)$  and  $\mu_1(\mathcal{C}_2^*)$ , however, do not satisfy relations analogous to (2.39)–(2.40) even when  $b_h = b$ . Hence,  $\hat{\nu}$  is not a posteriori. In order to have a fully a posteriori estimate, we replace  $\hat{\nu}$  in (2.36) by

$$(2.41) \quad \hat{\nu}^a = \min(\mu_1(\mathcal{I}_h^*), \mu_3(\Omega)) + \min(\mu_2(\mathcal{A}_h^*), \mu_3(\Omega)).$$

An alternative technique based on set estimation is the subject of section 3.2.

**3. Extensions.** Now we consider possible extensions of the concept derived in the previous section. We focus on two aspects as follows: (i) effects due to nonlinear PDEs and/or bilateral constraints; and (ii) alternative ways of making  $\hat{\nu}$  fully a posteriori.

**3.1. Semilinear PDEs and bilateral constraints.** Next we assume that the underlying PDE is semilinear as follows:

$$(3.1) \quad A(y) = Bu + f,$$

where the operators  $A$  and  $B$  induce a semilinear form  $\mathfrak{a}(\cdot)(\cdot)$  and a bilinear form  $\mathfrak{b}(\cdot, \cdot)$ , respectively. Hence, the weak form of (3.1) becomes

$$\mathfrak{a}(y)(v) = (f, v)_{0,\Omega} + \mathfrak{b}(u, v) \quad \forall v \in Y.$$

For our arguments to follow, we assume that  $A$  (respectively,  $\mathfrak{a}$ ) is sufficiently often differentiable. Further, we suppose that the control is subject to bilateral constraints, i.e.,

$$a \leq u \leq b \text{ a.e. in } \Omega.$$

The Lagrange function corresponding to the associated minimization problem has the structure

$$\mathcal{L}(x, \lambda_a, \lambda_b) = J(y, u) + \mathfrak{a}(y)(p) - (f, p)_{0,\Omega} - \mathfrak{b}(u, p) + (a - u, \lambda_a)_{0,\Omega} + (u - b, \lambda_b)_{0,\Omega},$$

where  $\lambda_a, \lambda_b \in L^2(\Omega)$  represent the Lagrange multipliers pertinent to the bilateral pointwise constraints. The first order necessary optimality conditions are given by

$$(3.2a) \quad A(y^*) - Bu^* = f,$$

$$(3.2b) \quad A'(y^*)^* p^* + J_y(y^*, u^*) = 0,$$

$$(3.2c) \quad J_u(y^*, u^*) + \lambda_b^* - \lambda_a^* - B^* p^* = 0,$$

$$(3.2d) \quad u^* \geq a, \quad \lambda_a^* \geq 0, \quad (u^* - a, \lambda_a^*)_{0,\Omega} = 0,$$

$$(3.2e) \quad u^* \leq b, \quad \lambda_b^* \geq 0, \quad (u^* - b, \lambda_b^*)_{0,\Omega} = 0.$$

As the pointwise control constraints are affine, the error estimator for the nonlinear case is similar to the linear case. This parallels the situation in [2], where the unconstrained case was considered. Due to essentially the same proof arguments as in [2, Proposition 6.1], the following result holds true. In what follows, we use

$$\mathcal{L}_0(x) = J(y, u) + \mathfrak{a}(y)(p) - (f, p)_{0,\Omega} - \mathfrak{b}(u, p),$$

and use  $\mathcal{L}_{0,h}(x)$  for its discrete counterpart.

**THEOREM 3.1.** *For a Galerkin finite element discretization of the first order necessary optimality conditions (3.2), the following relation holds true:*

$$\begin{aligned} J(y^*, u^*) - J_h(y_h^*, u_h^*) &= \frac{1}{2} \nabla_x \mathcal{L}_{0,h}(x_h^*)(x^* - i_h x^*) \\ &+ \frac{1}{2} [(u_h^* - b, \lambda_b^*)_{0,\Omega} + (b_h - u^*, \lambda_{b,h}^*)_{0,\Omega}] \\ &+ \frac{1}{2} [(a - u_h^*, \lambda_a^*)_{0,\Omega} + (u^* - a_h, \lambda_{a,h}^*)_{0,\Omega}] \\ &+ \frac{1}{2} ((f - f_h, p_h^* - p^*)_{0,\Omega} + (z - z_h, y_h^* - y^*)_{0,\Omega}) + \text{osc}_h(x_h^*) \\ &+ r(x^*, x_h^*), \end{aligned}$$

where  $r(x^*, x_h^*)$  denotes the remainder term of a Taylor expansion of  $\mathcal{L}_0$  about  $x_h^*$ . It is bounded by

$$|r(x^*, x_h^*)| \leq \sup_{\bar{x} \in [x_h^*, x^*]} |\nabla_x^3 \mathcal{L}_0(\bar{x})[x^* - x_h^*]^3|.$$

**3.2. Alternative a posteriori estimate for  $\hat{\nu}$ .** At the end of section 2 we derived an a posteriori estimate for  $\hat{\nu}$ ; recall  $\hat{\nu}^a$  in (2.41), where we replaced  $\mathcal{C}_1^*$  by  $\mathcal{I}_h^*$  and  $\mathcal{C}_2^*$  by  $\mathcal{A}_h^*$ , respectively. This may give rise to an overestimation of the error term pertinent to the complementarity system. In the following we provide an alternative approach based on set estimation.

Assuming, without loss of generality,  $b_h = b$ , we focus on the unilaterally constrained case and start by considering  $\hat{\mu}_1(\mathcal{C}_1^*)$ . For this purpose recall that  $\mathcal{C}_1^* = \mathcal{I}_h^* \cap \mathcal{A}^*$ . Similarly to [11, section 3.3] we estimate the continuous active set  $\mathcal{A}^*$  by

$$\chi_h^{\mathcal{A}^*} = 1 - \frac{b - u_h^*}{\gamma h^r + b - u_h^*},$$

where  $\gamma$  denotes some (possibly small) positive constant, and  $r > 0$  is fixed. Note that  $\chi_h^{\mathcal{A}^*} = 1$  in  $\mathcal{A}_h^*$ . Further, let  $\chi(\mathcal{S})$  denote the characteristic function of a set  $\mathcal{S} \subset \Omega$ . We briefly argue that our approximation is useful. In fact, assume that  $T \subset \mathcal{A}^*$ . Then

$$\|\chi(\mathcal{A}^*) - \chi_h^{\mathcal{A}^*}\|_{0,T} = \left\| \frac{b - u_h^*}{\gamma h^r + b - u_h^*} \right\|_{0,T} \leq \min\{1, \gamma^{-1} h^{-r} \|u^* - u_h^*\|_{0,T}\},$$

which tends to zero whenever  $\|u^* - u_h^*\|_{0,T} = \mathcal{O}(h^q)$  with  $q > r$ . If  $T \in \mathcal{I}^*$ , then we distinguish two cases as follows:

- (i)  $T \subset \{b - u_h^* > \gamma h^{\epsilon r}\}$  for some  $0 \leq \epsilon < 1$ . Then

$$\|\chi(\mathcal{A}^*) - \chi_h^{\mathcal{A}^*}\|_{0,T} = \left\| \frac{\gamma h^r}{\gamma h^r + b - u_h^*} \right\|_{0,T} \leq h^{(1-\epsilon)r} \rightarrow 0 \text{ as } h \rightarrow 0.$$

- (ii) Finally, in the case where  $T \in \{b - u_h^* \leq \gamma h^{\epsilon r}\}$ , we use  $T \subset \mathcal{I}^*$  and  $\|u^* - u_h^*\|_{0,\Omega} \rightarrow 0$  to conclude that the measure of this set tends to zero as  $h \rightarrow 0$ . We therefore use the following approximation of  $\chi(\mathcal{C}_1^*)$ :

$$\chi(\mathcal{C}_1^*) \approx \chi(\mathcal{I}_h^*) \chi_h^{\mathcal{A}^*} =: \chi_h^{\mathcal{C}_1^*}.$$

In the definition of  $\mu_1(\mathcal{C}_1^*)$ , we then use

$$\|\chi_h^{\mathcal{C}_1^*}(u_h^* - b)\|_{0,\Omega} \quad \text{instead of} \quad \|u_h^* - b\|_{0,\mathcal{C}_1^*}$$

and analogously for  $\|M_h p_h^* - p_h^*\|_{0,\mathcal{C}_1^*}$ . Further, the measure of  $\mathcal{C}_1^*$  is approximated by

$$\text{meas}(\mathcal{C}_1^*) \approx \int_{\Omega} \chi_h^{\mathcal{C}_1^*} dx.$$

The definition of  $\mu_2$  involves the set  $\mathcal{C}_2^* = \mathcal{A}_h^* \cap \mathcal{I}^*$ . Here we employ the approximation

$$\chi_h^{\mathcal{C}_2^*} := \chi(\mathcal{A}_h^*) \chi_h^{\mathcal{I}^*}$$

with  $\chi_h^{\mathcal{I}^*} = 1 - \chi_h^{\mathcal{A}^*}$ . Then we replace  $\|\lambda_h^*\|_{0,\mathcal{C}_2^*}$  by  $\|\chi_h^{\mathcal{C}_2^*} \lambda_h^*\|_{0,\Omega}$ ,  $\|b - \alpha p_h^*\|_{t,\mathcal{C}_2^*}$  by  $\|\chi_h^{\mathcal{C}_2^*} (b - \alpha^{-1} p_h^*)\|_{t,\Omega}$ , and obtain

$$\text{meas}(\mathcal{C}_2^*) \approx \int_{\Omega} \chi_h^{\mathcal{C}_2^*} dx.$$

The extension of this concept to the bilaterally constrained case is straightforward.

**4. Numerics.** For the practical realization of the goal-oriented dual-weighted approach, we follow the cycle SOLVE, ESTIMATE, MARK, and REFINES known from adaptive finite element methods. Here, SOLVE stands for the numerical solution of the discrete optimal control problem which is taken care of by a primal-dual active set strategy [9]. The following step, ESTIMATE, is devoted to the computation of the edge and element residuals of the error estimator  $\eta_h$ , the local components of the consistency error  $\hat{\nu}_h$ , and the data oscillations. We note that

$$(4.1) \quad \eta_h := \eta_{2,h}^p + \eta_{2,h}^d + \eta_{2,h}^u.$$

Here,  $\eta_{2,h}^p$  and  $\eta_{2,h}^d$  are given by (2.38) and (2.37). Moreover,  $\eta_{2,h}^u$  is given by (2.35) with  $i_h^u u^* - u^*$  replaced by  $u_h^* - \bar{u}_h^*$ , where  $\bar{u}_h^*|_T := |T|^{-1} \int_T u_h^* dx$ ,  $T \in \mathbb{T}_h$ . We refer to  $\eta_{2,T}^p$ ,  $\eta_{2,T}^d$ ,  $\eta_{2,T}^u$ ,  $T \in \mathbb{T}_h$ , as the elementwise contributions to  $\eta_{2,h}^p$ ,  $\eta_{2,h}^d$ , and  $\eta_{2,h}^u$ , respectively, so that

$$\eta_h = \sum_{T \in \mathbb{T}_h} \eta_T, \quad \eta_T := \eta_{2,T}^p + \eta_{2,T}^d + \eta_{2,T}^u.$$

Likewise, we have

$$(4.2) \quad \hat{\nu}_h = \sum_{T \in \mathbb{T}_h} \hat{\nu}_T^a,$$

where  $\hat{\nu}_T^a$ ,  $T \in \mathbb{T}_h$ , are the elementwise contributions to  $\hat{\nu}^a$  that can be easily deduced from (2.32). Finally, we summarize the remaining terms of (2.36) in Theorem 2.3 according to

$$(4.3) \quad \text{osc}_h := \frac{1}{2} [C_0^p \eta_{0,p} \|f - f_h\|_{0,\Omega} + C_0^y \eta_{0,y} \|z - z_h\|_{0,\Omega}] + |\text{osc}_h(x_h^*)|$$

and observe

$$\text{osc}_h = \sum_{T \in \mathbb{T}_h} \text{osc}_T,$$

where again  $\text{osc}_T$ ,  $T \in \mathbb{T}_h$ , refers to the elementwise contribution to  $\text{osc}_h$ . In the step MARK of the adaptive cycle, we specify constants  $\Theta_i \in (0, 1)$  and select subsets  $\mathbb{M}_i \subset \mathbb{T}_h$ ,  $1 \leq i \leq 3$ , by means of the bulk criteria

$$(4.4a) \quad \Theta_1 \sum_{T \in \mathbb{T}_h} \eta_T \leq \sum_{T \in \mathbb{M}_1} \eta_T,$$

$$(4.4b) \quad \Theta_2 \sum_{T \in \mathbb{T}_h} \hat{\nu}_T^a \leq \sum_{T \in \mathbb{M}_2} \hat{\nu}_T^a,$$

$$(4.4c) \quad \Theta_3 \sum_{T \in \mathbb{T}_h} \text{osc}_T \leq \sum_{T \in \mathbb{M}_3} \text{osc}_T$$

known from the convergence analysis of adaptive finite element methods (cf., e.g., [6, 15]). The bulk criteria can be realized by a greedy algorithm (cf., e.g., [8]). The final step REFINES of the adaptive loop is devoted to the creation of a new refined mesh based on longest edge bisection of any element  $T \in \mathbb{T}_h$  that has been marked, i.e.,  $T \in \bigcup_{i=1}^3 \mathbb{M}_i$ .

FIG. 4.1. *Example 1: Optimal state (left) and optimal control (right).*FIG. 4.2. *Example 1: Adaptively refined grid after 6 (left) and 10 (right) refinement steps ( $\Theta_i = 0.6$ ,  $1 \leq i \leq 3$ ).*

Finally, we provide documentation of numerical results illustrating the performance of the goal-oriented dual-weighted approach for two representative distributed optimal control problems that have been considered in [8] in the framework of an error analysis of residual-type a posteriori error estimators for control constrained optimal control problems.

*Example 1* (constant obstacle). This first example features a constant obstacle. The data are as follows:

$$\Omega := (0, 1)^2, \quad z := \begin{cases} 200x_1x_2(x_1 - 0.5)^2(1 - x_2) & \text{if } 0 \leq x_1 \leq 0.5, \\ 200(x_1 - 1)x_2(x_1 - 0.5)^2(1 - x_2) & \text{if } 0.5 < x_1 \leq 1, \end{cases}$$

$$\alpha := 0.01, \quad b := 1, \quad f := 0.$$

Figures 4.1 and 4.2 show a visualization of the optimal state and the optimal control as well as the adaptively refined grids after 6 and 10 refinement steps in the case when  $\Theta_i = 0.6$ ,  $1 \leq i \leq 3$  in the bulk criteria (4.4). The active region is an ellipse (cf. the plateau in Figure 4.1 (right)). The convergence history of the adaptive loop is displayed in Table 4.1, containing the total number of degrees of freedom  $N_{DOF}$ , the error  $\delta_h := |J(y^*, u^*) - J_h(y_h^*, u_h^*)|$  in the objective functional, the error estimator  $\eta_h$ , the consistency error  $\hat{\nu}_h^a$ , and the data oscillations  $\text{osc}_h$ . Finally, Figure 4.3 shows the error  $\delta_h$  as a function of the total number of degrees of freedom in the case of adaptive refinement (solid line) and uniform refinement (dotted line). Since in this example the optimal state and adjoint state are smooth, there is only a slight benefit gained when using the adaptive process.

TABLE 4.1

FIG. 4.3. Example 1: Adaptive refinement (solid line) versus uniform refinement (dotted line).

*Example 2* (variable obstacle). This example is constructed in such a way that there is a lack of strict complementarity. It differs from the general setting insofar as the term containing the control in the objective functional additionally includes a fixed shift control  $w \in L^2(\Omega)$  as follows:

$$J(y, u) := \frac{1}{2} \|y - z\|_{0,\Omega}^2 + \frac{\alpha}{2} \|u - w\|_{0,\Omega}^2.$$

The data are as follows:

$$\begin{aligned} \Omega &:= (0, 1)^2, \quad z := 0, \quad w := \hat{u} + \alpha^{-1} (\hat{\sigma} + \Delta^{-2} \hat{u}), \\ b &:= \begin{cases} (x_1 - 0.5)^8 & \text{if } (x_1, x_2) \in \Omega_1, \\ (x_1 - 0.5)^2 & \text{otherwise,} \end{cases} \quad \alpha := 0.1, \quad f := 0. \end{aligned}$$

Here,  $\hat{u}$  and  $\hat{\sigma}$  are given by

$$\hat{u} := \begin{cases} b(x_1, x_2) & \text{if } (x_1, x_2) \in \Omega_1 \cup \Omega_2, \\ -1.01 b(x_1, x_2) & \text{otherwise} \end{cases}$$

FIG. 4.4. *Example 2: Optimal state (left) and optimal control (right).*FIG. 4.5. *Example 2: Adaptively refined grid after 6 (left) and 10 (right) refinement steps ( $\Theta_i = 0.6$ ,  $1 \leq i \leq 3$ ).*

and

$$\hat{\sigma} := \begin{cases} 2.25 (x_1 - 0.75) \cdot 10^{-4} & \text{if } (x_1, x_2) \in \Omega_2, \\ 0 & \text{otherwise} \end{cases}$$

with  $\Omega_1$  and  $\Omega_2$  specified as follows:

$$\begin{aligned} \Omega_1 &:= \{(x_1, x_2) \in \Omega \mid ((x_1 - 0.5)^2 + (x_2 - 0.5)^2)^{1/2} \leq 0.15\}, \\ \Omega_2 &:= \{(x_1, x_2) \in \Omega \mid x_1 \geq 0.75\}. \end{aligned}$$

We note that  $\Omega_2$  corresponds to the strongly active set (where strict complementarity holds true, i.e.,  $\lambda^* > 0$  a.e. in  $\Omega_2$ ), whereas the set  $\Omega_1 \cup \{(x_1, x_2) \in \Omega \mid x_1 = 0.5\}$  represents the weakly active set, where strict complementarity does not hold true, i.e.,  $\lambda^* = 0$  a.e. in this set.

The shift control  $w \in L^2(\Omega)$  is approximated by  $w_h \in L_h$ , giving rise to an additional term in the data oscillations  $\text{osc}_h(x_h^*)$ .

Figure 4.4 displays the computed optimal state and optimal control. Figure 4.5 shows the adaptively refined grids after 6 and 10 refinements steps, where we have chosen  $\Theta_i = 0.6$ ,  $1 \leq i \leq 3$  in the bulk criteria (4.4). Table 4.2 reflects the convergence history of the refinement process in terms of the same data as in the first example, and Figure 4.6 shows the comparison between adaptive and uniform refinement. In this example, the benefits of adaptive refinement are more pronounced than in the previous one.

FIG. 4.6. *Example 2: Adaptive refinement (solid line) versus uniform refinement (dotted line).*

It should be noted that in both examples there is comparably less refinement than in the case of the residual-type a posteriori error estimator from [8]. This does not come as a surprise. As we noted before, the error estimation derived from the goal-oriented dual-weighted approach provides a finer estimate, since the residual-type upper bound can be derived from it by further estimation. On the other hand, the residual-type estimator from [8] has been designed for an estimation of the errors in the state, the adjoint state, the control, and the adjoint control. Therefore, a more pronounced refinement has to be expected.

**Appendix A. A posteriori estimates in the  $L^2$ -norm.** In this section we derive a posteriori error estimates for  $\|p^* - p_h^*\|_{0,\Omega}$  and  $\|y^* - y_h^*\|_{0,\Omega}$ . The subsequent proof technique is based on a combination of the approaches in [8] and [17].

In what follows, we assume that  $\Omega$  is convex and that  $b = b_h$  a.e. in  $\Omega$ , and we use  $a(y, w) = (\nabla y, \nabla w)_{0,\Omega}$ . Given  $u_h^* \in L_h$ , by  $y(u_h^*), p(u_h^*) \in H_0^1(\Omega)$  we denote the solutions to

$$\begin{aligned} a(y(u_h^*), v) &= (f + u_h^*, v)_{0,\Omega}, \\ a(p(u_h^*), v) &= (z - y(u_h^*), v)_{0,\Omega} \end{aligned}$$

for all  $v \in H_0^1(\Omega)$ . The Poincaré–Friedrichs inequality yields

$$(A.1) \quad \|p(u_h^*) - p^*\|_{0,\Omega} \leq c(\Omega) \|y(u_h^*) - y^*\|_{0,\Omega},$$

$$(A.2) \quad \|y(u_h^*) - y^*\|_{0,\Omega} \leq c(\Omega) \|u_h^* - u^*\|_{0,\Omega},$$

where we assume that  $y^* \in H_0^1(\Omega)$  satisfies  $a(y^*, v) = (f + u^*, v)_{0,\Omega}$  for all  $v \in H_0^1(\Omega)$ , and  $c(\Omega)$  is a constant depending only on the domain  $\Omega$ . Hence, for  $p^* \in H_0^1(\Omega)$  satisfying  $a(p^*, v) = (z - y^*, v)_{0,\Omega}$  for all  $v \in H_0^1(\Omega)$ , we get

$$(A.3) \quad \|p^* - p_h^*\|_{0,\Omega} \leq \|p(u_h^*) - p_h^*\|_{0,\Omega} + c(\Omega)^2 \|u_h^* - u^*\|_{0,\Omega}.$$

Next let us assume that  $u^*$ , respectively,  $u_h^*$ , satisfies the system

$$\alpha u^* - p^* + \lambda^* = 0 \quad \text{and} \quad \alpha u_h^* - M_h p_h^* + \lambda_h^* = 0.$$

Then we obtain

$$(A.4) \quad \begin{aligned} \alpha \|u^* - u_h^*\|_{0,\Omega}^2 &\leq (\lambda_h^* - \lambda^*, u^* - u_h^*)_{0,\Omega} + (p^* - p_h^*, u^* - u_h^*)_{0,\Omega} \\ &\quad + \frac{\alpha}{4} \|u^* - u_h^*\|_{0,\Omega}^2 + \frac{1}{\alpha} \|p_h^* - M_h p_h^*\|_{0,\Omega}^2 \\ &\leq (p^* - p_h^*, u^* - u_h^*)_{0,\Omega} + \frac{\alpha}{4} \|u^* - u_h^*\|_{0,\Omega}^2 \\ &\quad + \frac{1}{\alpha} \|p_h^* - M_h p_h^*\|_{0,\Omega}^2 \end{aligned}$$

since  $(\lambda_h^* - \lambda^*, u^* - u_h^*)_{0,\Omega} \leq 0$ . One also has

$$(p^* - p(u_h^*), u^* - u_h^*)_{0,\Omega} \leq 0.$$

Hence, we have

$$\begin{aligned} (p^* - p_h^*, u^* - u_h^*)_{0,\Omega} &\leq (p(u_h^*) - p_h^*, u^* - u_h^*)_{0,\Omega} \\ &\leq \frac{\alpha}{4} \|u^* - u_h^*\|_{0,\Omega}^2 + \frac{1}{\alpha} \|p_h^* - p(u_h^*)\|_{0,\Omega}^2. \end{aligned}$$

This allows us to continue (A.4) as follows:

$$(A.5) \quad \|u^* - u_h^*\|_{0,\Omega}^2 \leq \frac{2}{\alpha^2} \|p_h^* - p(u_h^*)\|_{0,\Omega}^2 + \frac{2}{\alpha^2} \|p_h^* - M_h p_h^*\|_{0,\Omega}^2.$$

Combining the above estimates results in

$$(A.6) \quad \begin{aligned} \|p^* - p_h^*\|_{0,\Omega} &\leq \left(1 + \frac{\sqrt{2}}{\alpha} c(\Omega)^2\right) \|p_h^* - p(u_h^*)\|_{0,\Omega} \\ &\quad + \frac{\sqrt{2}}{\alpha} c(\Omega)^2 \|p_h^* - M_h p_h^*\|_{0,\Omega}, \end{aligned}$$

$$(A.7) \quad \begin{aligned} \|y^* - y_h^*\|_{0,\Omega} &\leq \|y(u_h^*) - y_h^*\|_{0,\Omega} + \frac{\sqrt{2}}{\alpha} c(\Omega) (\|p_h^* - p(u_h^*)\|_{0,\Omega} \\ &\quad + \|p_h^* - M_h p_h^*\|_{0,\Omega}). \end{aligned}$$

Utilizing standard  $L^2$ -estimates (see, e.g., [17, Proposition 3.8]) we infer

$$(A.8) \quad \|y(u_h^*) - y_h^*\|_{0,\Omega}^2 \leq C \left( \sum_T h_T^2 \eta_{y,T}^2 + \sum_F h_F^2 \eta_{y,F}^2 \right) =: C \tilde{\eta}_{0,y}^2,$$

$$(A.9) \quad \|p(u_h^*) - p_h^*\|_{0,\Omega}^2 \leq C \left( \sum_T h_T^2 \tilde{\eta}_{p,T}^2 + \sum_F h_F^2 \eta_{p,F}^2 \right) =: C \tilde{\eta}_{0,p}^2,$$

where the element and edge residuals are given by

$$\begin{aligned}\eta_{y,T} &:= h_T \|f + u_h^*\|_{0,T}, \\ \eta_{y,F} &:= h_F^{1/2} \|n_F \cdot [\nabla y_h^*]\|_{0,F}, \\ \tilde{\eta}_{p,T} &:= h_T \|z - y(u_h^*)\|_{0,T}, \\ \eta_{p,F} &:= h_F^{1/2} \|n_F \cdot [\nabla p_h^*]\|_{0,F}\end{aligned}$$

with  $n_F$  denoting the exterior unit normal of  $T$ . The triangle inequality yields

$$\sum_T h_T^4 \|z - y(u_h^*)\|_{0,T}^2 \leq C h^2 \tilde{\eta}_{0,y}^2 + 2 \sum_T h_T^2 \eta_{p,T}^2$$

with the element residual

$$\eta_{p,T} := h_T^2 \|z - y_h^*\|_{0,T}.$$

Finally, we derive the estimate

$$\begin{aligned}\|p^* - p_h^*\|_{0,\Omega} &\leq C \left( h^2 \tilde{\eta}_{0,y}^2 + \sum_T h_T^2 \eta_{p,T}^2 + \sum_F h_F^2 \eta_{p,F}^2 \right)^{1/2} \\ (A.10) \quad &+ \frac{\sqrt{2}}{\alpha} c(\Omega)^2 \|p_h^* - M_h p_h^*\|_{0,\Omega} + \text{osc}_{0,h}(z) + \text{osc}_{0,h}(f) \\ &=: C_0^p \eta_{0,p} + \text{osc}_{0,h}(z) + \text{osc}_{0,h}(f),\end{aligned}$$

where the data oscillations are given by

$$\begin{aligned}\text{osc}_{0,h}(z) &= \left( \sum_T h_T^2 \text{osc}_T(z)^2 \right)^{1/2}, \\ \text{osc}_T(z) &= h_T \|z - z_h\|_{0,T}\end{aligned}$$

and analogously for  $\text{osc}_{0,h}(f)$ .

The error in the state is estimated a posteriori by

$$\begin{aligned}\|y^* - y_h^*\|_{0,\Omega} &\leq C \tilde{\eta}_{0,y} + \frac{\sqrt{2}}{\alpha} c(\Omega) (\tilde{\eta}_{0,p} + \|p_h^* - M_h p_h^*\|_{0,\Omega}) \\ (A.11) \quad &+ \text{osc}_{0,h}(f) + \text{osc}_{0,h}(z) \\ &=: C_0^y \eta_{0,y} + \text{osc}_{0,h}(f) + \text{osc}_{0,h}(z).\end{aligned}$$

## PARTIAL INFORMATION LINEAR QUADRATIC CONTROL FOR JUMP DIFFUSIONS\*

YAOZHONG HU<sup>†</sup> AND BERNT ØKSENDAL<sup>‡</sup>

**Abstract.** We study a stochastic control problem in which the state process is described by a stochastic differential equation (SDE) that is driven by a Brownian motion and a Poisson random measure, and is affine in both the state and the control. The performance functional is quadratic in the state and the control. All the coefficients are allowed to be random and non-Markovian. Moreover, we may allow the control to be predictable to a given subfiltration of the filtration of the Brownian motion and the random measure (partial information control).

**Key words.** partial information, linear quadratic control, jump diffusions, backward stochastic Riccati equations

**AMS subject classifications.** Primary, 93E20, 60H05, 60G51; Secondary, 91B28

**DOI.** 10.1137/060667566

**1. Introduction.** The problem of stochastic control is always hard. Only in a few cases is there an explicit solution. There are two important approaches to the general stochastic optimal control problem. One is the Bellman dynamic programming principle, which results in the Hamilton–Jacobi–Bellman equation. This approach is applicable when the controlled system is Markovian. Another important approach is the maximum principle. For detailed accounts of the approaches to systems driven by Brownian motions, see the books [7] and [18] and the references therein.

In this paper we will consider the stochastic optimal control problems in which the controlled system is a jump-diffusion. There have been some recent developments in the case when the controlled system is Markovian. See the book [15] and the references therein. Some explicit control problems arising from finance and their solutions are also presented in this book.

Let  $(W_t, t \geq 0)$  be a Brownian motion and  $(N(ds, dz), s \geq 0, z \in \mathbb{R})$  be a Poisson random measure with the intensity measure given by  $\nu(dz)$ . The compensated Poisson random measure is denoted by  $\tilde{N}(ds, dz)$ . We will consider only the case when the state  $x_t$  at time  $t$  is described by a linear controlled jump-diffusion of the form

$$(1.1) \quad \begin{aligned} dx_t &= [A_t x_t + B_t u_t + \alpha_t] dt + [C_t x_t + D_t u_t + \beta_t] dW_t \\ &\quad + \int_{\mathbb{R}} [E_t(z)x_{t-} + F_t(z)u_t + \gamma_t(z)] \tilde{N}(dt, dz), \quad t \in [0, T], \\ x_0 &= x \in \mathbb{R}. \end{aligned}$$

Here  $u_t$  is our control process and  $A_t, B_t, \alpha_t, C_t, D_t, \beta_t, E_t(z), F_t(z)$ , and  $\gamma_t(z)$  are given  $\mathcal{F}_t$ -predictable processes, where  $\mathcal{F}_t$  is the filtration generated by the Brownian

<sup>†</sup>Department of Mathematics, University of Kansas, 405 Snow Hall, Lawrence, KS 66045-2142 (hu@math.ku.edu), and Center of Mathematics for Applications (CMA), Department of Mathematics, University of Oslo, Box 1053 Blindern, N-0316, Oslo, Norway.

<sup>‡</sup>Center of Mathematics for Applications (CMA), Department of Mathematics, University of Oslo, Box 1053 Blindern, N-0316, Oslo, Norway (oksensdal@math.uio.no), and Norwegian School of Economics and Business Administration, Helleveien 30, N-5045, Bergen, Norway.

motion  $W(s)$ ,  $s \leq t$ , and the Poisson random measures are  $\tilde{N}(ds, dz)$ ,  $s \leq t$ . The control  $u_t$  is required to be  $\mathcal{E}_t$ -predictable, where  $\mathcal{E}_t \subseteq \mathcal{F}_t$  is a given filtration representing the information available to the controller at time  $t$ . For example, we could have

$$\mathcal{E}_t = \mathcal{F}_{(t-\delta)^+}, \quad t \in [0, T],$$

where  $\delta > 0$  is a fixed *delay of information*.

The performance functional is assumed to have the form

$$(1.2) \quad J(x, u) = \mathbb{E} \left\{ H_1 x_T^2 + H_2 x_T \right\} + \mathbb{E} \left\{ \int_0^T [Q_{11}(t)x_t^2 + 2Q_{12}(t)x_t u_t + Q_{22}(t)u_t^2 + R_1(t)x_t + 2R_2(t)u_t] dt \right\},$$

where  $Q_{ij}(t)$  and  $R_i(t)$  are given bounded  $\mathcal{F}_t$ -adapted processes and  $H_i$  are given  $\mathcal{F}_T$ -measurable bounded random variables satisfying certain conditions (see section 2). Even in the absence of jumps, namely,

$$E_t(z) = F_t(z) = \gamma_t(z) = 0$$

(the diffusion case), the theory of classical linear quadratic control deals only with the case when

$$\mathcal{E}_t = \mathcal{F}_t \quad (\text{complete information case})$$

and

$$H_2 = 0, \quad \alpha_t = 0, \quad \beta_t = 0, \quad R_1(t) = R_2(t) = 0.$$

Namely, there are no first-order terms in the utility functional and there are no constant terms in the system. If the coefficients are random (but predictable) and/or  $\mathcal{E}_t \subset \mathcal{F}_t$ , then the system is no longer Markovian. The most effective method is the technique of completing squares.

However, even if  $\mathcal{E}_t = \mathcal{F}_t$ , the classical technique of completing squares is not directly applicable to the system we consider because of the appearance of the first-order terms in the utility functional and the constant terms in the controlled system. The appearance of such terms is important when we apply the results to minimum variance portfolio selection, for example.

In this paper we introduce an additional auxiliary backward Riccati equation to handle the extra terms. Thus we will have two (coupled) Riccati equations. Fortunately, they are only weakly coupled in the sense that we can solve one equation first and then substitute the solution into the other. This introduction of an additional equation, which handles the linear and constant terms, was given earlier in [17] for the constant term and in [13] for both linear and constant terms. There is a rich literature on stochastic linear quadratic control and associated Riccati equations; see, e.g., [1], [2], [5], [6], [10], [16], [17].

We will apply our results to minimum variance portfolio selection problems with or without partial information [3], [4], [8]. The results extend those in [9] (which use the Hamilton–Jacobi–Bellman dynamic programming principle) to the case of random coefficients.

It should be pointed out that the approach of the dynamic programming principle or the maximum principle cannot be applied directly here, both because of the general random coefficients in the controlled system and in the utility functional and because of partial information. Moreover, the technique of completing the square also leads us to the solution of the partial information problem.

**2. The complete information case.** Let us first consider the case with complete information, i.e.,  $\mathcal{E}_t = \mathcal{F}_t$ . Let the system be described by a one-dimensional stochastic differential equation, driven both by Brownian white noise and Poissonian random measure, as follows:

$$(2.1) \quad \begin{aligned} dx_t &= dx_t^{(u)} = [A_t x_t + B_t u_t + \alpha_t] dt + [C_t x_t + D_t u_t + \beta_t] dW_t \\ &\quad + \int_{\mathbb{R}} [E_t(z)x_{t-} + F_t(z)u_t + \gamma_t(z)] \tilde{N}(dt, dz), \quad 0 \leq t \leq T, \\ x_0 &= x \in \mathbb{R}. \end{aligned}$$

We assume that  $A_t, C_t, E_t(z), B_t, D_t, F_t(z), \alpha_t, \beta_t$ , and  $\gamma_t(z)$  are bounded  $\mathbb{R}$ -valued  $\mathcal{F}_t$ -predictable processes (they can be random). The goal is to minimize the cost functional

$$(2.2) \quad \begin{aligned} J(x, u) &= \mathbb{E} \{ H_1 x_T^2 + H_2 x_T \} \\ &\quad + \mathbb{E} \left\{ \int_0^T [Q_{11}(t)x_t^2 + 2Q_{12}(t)x_t u_t + Q_{22}(t)u_t^2 + R_1(t)x_t + 2R_2(t)u_t] dt \right\}, \end{aligned}$$

where  $Q_{ij}(t)$  and  $R_i(t)$ ,  $i, j = 1, 2$ , are given bounded  $\mathcal{F}_t$ -adapted (real-valued) stochastic processes and  $H_1$  and  $H_2$  are  $\mathcal{F}_T$ -measurable bounded random variables.

We assume throughout this paper that

$$Q_{22}(t) + \Theta_3(t) \geq 0 \quad \text{for a.a. } t, \omega,$$

where  $\Theta_3(t)$  is defined by (2.14). This is a linear system with a quadratic utility functional. We say that the control  $u_t$  is *admissible* and write  $u_t \in \mathcal{A}_{\mathcal{F}}$  if  $u_t$  is  $\mathcal{F}_t$ -predictable and equation (2.1) has a unique strong solution  $x_t = x_t^{(u)}$  for  $0 \leq t \leq T$  and

$$\mathbb{E} \left[ \int_0^T \left\{ u^2(t) + \left( x_t^{(u)} \right)^2 \right\} dt \right] < \infty.$$

We define

$$\begin{aligned} \rho_1(t) &= \int_{\mathbb{R}} E_t(z)^2 \nu(dz), & \rho_2(t) &= \int_{\mathbb{R}} \mu_t(z) [E_t(z)^2 + 2E_t(z)] \nu(dz), \\ \rho_3(t) &= \int_{\mathbb{R}} E_t(z)F_t(z) \nu(dz), & \rho_4(t) &= \int_{\mathbb{R}} \mu_t(z) [E_t(z)F_t(z) + 2F_t(z)] \nu(dz), \\ \rho_5(t) &= \int_{\mathbb{R}} F_t(z)^2 \nu(dz), & \rho_6(t) &= \int_{\mathbb{R}} \mu_t(z) F_t(z)^2 \nu(dz), \\ \rho_7(t) &= \int_{\mathbb{R}} \gamma_t(z)E_t(z) \nu(dz), & \rho_8(t) &= \int_{\mathbb{R}} \mu_t(z)\gamma_t(z) [1 + E_t(z)] \nu(dz), \\ \rho_9(t) &= \int_{\mathbb{R}} \gamma_t(z)F_t(z) \nu(dz), & \rho_{10}(t) &= \int_{\mathbb{R}} \gamma_t(z)\mu_t(z)F_t(z) \nu(dz), \end{aligned}$$

$$\begin{aligned}\rho_{11}(t) &= \int_{\mathbb{R}} \gamma_t(z)^2 \nu(dz), & \rho_{12}(t) &= \int_{\mathbb{R}} \gamma_t(z)^2 \mu_t(z) \nu(dz), \\ \rho_{13}(t) &= \int_{\mathbb{R}} \tilde{\mu}_t(z) E_t(z) \nu(dz), & \rho_{14}(t) &= \int_{\mathbb{R}} \tilde{\mu}_t(z) F_t(z) \nu(dz), \\ \rho_{15}(t) &= \int_{\mathbb{R}} \tilde{\mu}_t(z) \gamma_t(z) \nu(dz).\end{aligned}$$

We introduce the following system of backward Riccati/backward linear stochastic differential equations in the two unknown processes  $p_t$  and  $\tilde{p}_t$ :

(2.3)

$$\begin{aligned}dp_t &+ [2p_t A_t + p_t C_t^2 + 2\eta_t C_t + \rho_1(t)p_t + \rho_2(t) + Q_{11}(t)] dt \\ &- [Q_{22}(t) + p_t D_t^2 + \rho_5(t)p_t + \rho_6(t)]^{-1} [p_t B_t + p_t C_t D_t + \eta_t D_t \\ &\quad + \rho_3(t)p_t + \rho_4(t) + Q_{12}(t)]^2 dt \\ &- \eta_t dW_t - \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz) = 0,\end{aligned}$$

(2.4)  $p_T = H_1$ ,

(2.5)

$$\begin{aligned}d\tilde{p}_t &+ [2p_t \alpha_t + 2\beta_t p_t C_t + 2\beta_t \eta_t + 2p_t \rho_7(t) + 2\rho_8(t)] dt \\ &+ [\tilde{p}_t A_t + C_t \tilde{\eta}_t + \rho_{13}(t) + R_1(t)] dt \\ &- 2 [Q_{22}(t) + p_t D_t^2 + \rho_5(t)p_t + \rho_6(t)]^{-1} [p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t)p_t + \rho_4(t) \\ &\quad + Q_{12}(t)], \\ &\left[ p_t \beta_t D_t + p_t \rho_9(t) + \rho_{10}(t) + \frac{1}{2} \tilde{p}_t B_t + \frac{1}{2} \tilde{\eta}_t D_t + \frac{1}{2} \rho_{14}(t) + R_2(t) \right] dt \\ &- \tilde{\eta}_t dW_t - \int_{\mathbb{R}} \tilde{\mu}_t(z) \tilde{N}(dt, dz) = 0,\end{aligned}$$

(2.6)  $\tilde{p}_T = H_2$ .

Here the  $\mathcal{F}_t$ -predictable, square integrable processes  $\xi_t$ ,  $\eta_t$ ,  $\mu_t(z)$  and  $\tilde{\xi}_t$ ,  $\tilde{\eta}_t$ ,  $\tilde{\mu}_t(z)$  are (implicitly) determined from  $p_t$  and  $\tilde{p}_t$ , respectively, through the semimartingale representations

$$(2.7) \quad dp_t = \xi_t dt + \eta_t dW_t + \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz)$$

and

$$(2.8) \quad d\tilde{p}_t = \tilde{\xi}_t dt + \tilde{\eta}_t dW_t + \int_{\mathbb{R}} \tilde{\mu}_t(z) \tilde{N}(dt, dz).$$

We now state the first main theorem of this paper.

**THEOREM 2.1.** *Suppose the system of backward Riccati equations (2.3)–(2.6) has a solution  $p_t$  and  $\tilde{p}_t$ . Define*

$$\begin{aligned}(2.9) \quad u_t &= - [Q_{22}(t) + p_t D_t^2 + \rho_5(t)p_t + \rho_6(t)]^{-1}, \\ &\left\{ [p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t)p_t + \rho_4(t) + Q_{12}(t)] x_{t-} \right. \\ &\quad \left. + p_t \beta_t D_t + p_t \rho_9(t) + \rho_{10}(t) + \frac{1}{2} (\tilde{p}_t + \tilde{\eta}_t D_t + \rho_{14}(t)) + R_2(t) \right\}.\end{aligned}$$

Suppose  $u_t \in \mathcal{A}_{\mathcal{F}}$  and

$$(2.10) \quad \mathbb{E} \left[ \int_0^T \left\{ x_t^4 \eta_t^2 + (x_t^4 + u_t^4)(p_t^2 + \int_{\mathbb{R}} \mu_t^2(z) \nu(dz) \right\} dt \right] < \infty.$$

Then  $u_t$  is the unique solution of the complete information linear quadratic control problem (2.1)–(2.2). The corresponding value function is also quadratic and given by

$$(2.11) \quad \mathbb{E} (p_0) x^2 + \mathbb{E} (\tilde{p}_0) x \\ + \mathbb{E} \int_0^T \left\{ \Theta_6(t) + \Theta_9(t) - [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_5(t) + \Theta_8(t) + R_2(t)]^2 \right\} dt,$$

where  $p_t$  and  $\tilde{p}_t$  are found from solving the above backward equation and  $\Theta_i(t)$ ,  $i = 3, 5, 6, 8, 9$ , are defined by (2.12)–(2.20).

*Remark 2.2.* The existence of a solution to (2.3) has been proved recently by Hu and Song. See [11].

If all the parameters are deterministic, then we can take  $\eta_t$ ,  $\tilde{\eta}_t$ ,  $\mu_t(z)$ , and  $\tilde{\mu}_t(z)$  to be 0. In this case the stochastic Riccati equation reduces to the usual (deterministic) Riccati equation.

If at least one of the parameters is stochastic and all of them depend only on Brownian white noise  $W$ , then we may choose  $\mu_t(z)$  and  $\tilde{\mu}_t(z)$  to be 0, but  $\eta_t$  and  $\tilde{\eta}_t$  cannot both be 0. If at least one of them is stochastic and all of them depend only on Poisson noise  $N(\cdot, dz)$ , then we may choose  $\eta_t$  and  $\tilde{\eta}_t$  to be 0. But  $\mu_t(z)$  and  $\tilde{\mu}_t(z)$  cannot both be 0.

*Proof of Theorem 2.1.* We shall use the technique of completing squares.

Applying (2.7) and the integration by parts formula, we have

$$\begin{aligned} dx_t^2 &= 2x_{t-} dx_t + [C_t x_t + D_t u_t + \beta_t]^2 dt + \int_{\mathbb{R}} [E_t(z) x_{t-} + F_t(z) u_t + \gamma_t(z)]^2 N(dt, dz) \\ &= 2x_{t-} \left\{ [A_t x_t + B_t u_t + \alpha_t] dt + [C_t x_t + D_t u_t + \beta_t] dW_t \right. \\ &\quad \left. + \int_{\mathbb{R}} [E_t(z) x_{t-} + F_t(z) u_t + \gamma_t(z)] \tilde{N}(dt, dz) \right\} + [C_t x_t + D_t u_t + \beta_t]^2 dt \\ &\quad + \int_{\mathbb{R}} [E_t(z) x_{t-} + F_t(z) u_t + \gamma_t(z)]^2 \tilde{N}(dt, dz) \\ &\quad + \int_{\mathbb{R}} [E_t(z) x_t + F_t(z) u_t + \gamma_t(z)]^2 \nu(dz) dt. \end{aligned}$$

Another integration by parts yields

$$\begin{aligned} d(p_t x_t^2) &= 2p_{t-} x_{t-} \left\{ [A_t x_t + B_t u_t + \alpha_t] dt + [C_t x_t + D_t u_t + \beta_t] dW_t \right. \\ &\quad \left. + \int_{\mathbb{R}} [E_t(z) x_{t-} + F_t(z) u_t + \gamma_t(z)] \tilde{N}(dt, dz) \right\} \\ &\quad + p_t [C_t x_t + D_t u_t + \beta_t]^2 dt + \int_{\mathbb{R}} p_{t-} [E_t(z) x_{t-} + F_t(z) u_t + \gamma_t(z)]^2 N(dt, dz) \\ &\quad + x_{t-}^2 \left[ \xi_t dt + \eta_t dW_t + \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz) \right] \end{aligned}$$

$$\begin{aligned}
& + 2\eta_t x_t [C_t x_t + D_t u_t + \beta_t] dt + \int_{\mathbb{R}} \mu_t(z) [E_t(z)x_{t-} + F_t(z)u_t + \gamma_t(z)]^2 N(dt, dz) \\
& + 2 \int_{\mathbb{R}} \mu_t(z)x_{t-} [E_t(z)x_{t-} + F_t(z)u_t + \gamma_t(z)] N(dt, dz).
\end{aligned}$$

Denote

$$\begin{aligned}
d\eta_1(t) &= x_{t-}^2 \left[ \eta_t dW_t + \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz) \right] + 2p_t x_t [C_t x_t + D_t u_t + \beta_t] dW_t \\
&+ \int_{\mathbb{R}} \left\{ \mu_t(z)x_{t-}^2 + 2p_{t-}x_{t-} [E_t(z)x_{t-} + F_t(z)u_t + \gamma_t(z)] \right. \\
&\quad \left. + (p_{t-} + \mu_t(z)) [E_t(z)x_{t-} + F_t(z)u_t + \gamma_t(z)]^2 \right\} \tilde{N}(dt, dz) \\
&+ 2 \int_{\mathbb{R}} \mu_t(z)x_{t-} [E_t(z)x_{t-} + F_t(z)u_t + \gamma_t(z)] \tilde{N}(dt, dz)
\end{aligned}$$

and  $\eta_1(0) = 0$ . Then we see from (2.10) that  $\mathbb{E} \eta_1(t) = 0$  for all  $t \geq 0$ . We can rewrite

$$\begin{aligned}
d(p_t x_t^2) &= x_t^2 \xi_t dt + 2p_t x_t [A_t x_t + B_t u_t + \alpha_t] dt \\
&+ p_t [C_t x_t + D_t u_t + \beta_t]^2 dt + 2x_t \eta_t [C_t x_t + D_t u_t + \beta_t] dt \\
&+ \int_{\mathbb{R}} \left\{ [p_t + \mu_t(z)] [E_t(z)x_t + F_t(z)u_t + \gamma_t(z)]^2 \right\} \nu(dz) dt \\
&+ 2 \int_{\mathbb{R}} \mu_t(z)x_t [E_t(z)x_t + F_t(z)u_t + \gamma_t(z)] \nu(dz) dt + d\eta_1(t).
\end{aligned}$$

Introduce the notation

$$\begin{aligned}
\Theta_1(t) &= \xi_t + 2p_t A_t + p_t C_t^2 + 2\eta_t C_t \\
(2.12) \quad &+ \int_{\mathbb{R}} [p_t E_t(z)^2 + \mu_t(z) E_t(z)^2 + 2\mu_t(z) E_t(z)] \nu(dz);
\end{aligned}$$

$$\begin{aligned}
\Theta_2(t) &= p_t B_t + p_t C_t D_t + \eta_t D_t \\
(2.13) \quad &+ \int_{\mathbb{R}} \{p_t E_t(z) F_t(z) + \mu_t(z) E_t(z) F_t(z) + \mu_t(z) F_t(z)\} \nu(dz);
\end{aligned}$$

$$(2.14) \quad \Theta_3(t) = p_t D_t^2 + \int_{\mathbb{R}} \{p_t F_t(z)^2 + \mu_t(z) F_t(z)^2\} \nu(dz);$$

$$\begin{aligned}
\Theta_4(t) &= 2p_t \alpha_t + 2\beta_t p_t C_t + 2\beta_t \eta_t \\
(2.15) \quad &+ 2 \int_{\mathbb{R}} [(p_t + \mu_t(z)) \gamma_t(z) E_t(z) + \mu_t(z) \gamma_t(z)] \nu(dz);
\end{aligned}$$

$$(2.16) \quad \Theta_5(t) = p_t \beta_t D_t + \int_{\mathbb{R}} (p_t + \mu_t(z)) \gamma_t(z) F_t(z) \nu(dz);$$

and

$$(2.17) \quad \Theta_6(t) = p_t \beta_t^2 + \int_{\mathbb{R}} (p_t + \mu_t(z)) \gamma_t^2(z) \nu(dz).$$

Then we have

$$(2.18) \quad \mathbb{E} \{p_T x_T^2\} = \mathbb{E} \{p_0 x^2\} + \mathbb{E} \int_0^T \left\{ \Theta_1(t) x_t^2 + 2\Theta_2(t) x_t u_t + \Theta_3(t) u_t^2 + \Theta_4(t) x_t + 2\Theta_5(t) u_t + \Theta_6(t) \right\} dt.$$

To deal with the first-order terms which appeared above (2.18), we combine (2.8) with the integration by parts formula to get

$$\begin{aligned} d(\tilde{p}_t x_t) &= x_{t-} \left[ \tilde{\xi}_t dt + \tilde{\eta}_t dW_t + \int_{\mathbb{R}} \tilde{\mu}_t(z) \tilde{N}(dt, dz) \right] \\ &\quad + \tilde{p}_{t-} \left\{ [A_t x_t + B_t u_t + \alpha_t] dt + [C_t x_t + D_t u_t + \beta_t] dW_t \right. \\ &\quad \left. + \int_{\mathbb{R}} [E_t(z) x_{t-} + F_t(z) u_t + \gamma_t(z)] \tilde{N}(dt, dz) \right\} \\ &\quad + \tilde{\eta}_t [C_t x_t + D_t u_t + \beta_t] dt \\ &\quad + \int_{\mathbb{R}} \tilde{\mu}_t(z) [E_t(z) x_t + F_t(z) u_t + \gamma_t(z)] \nu(dz) dt \\ &\quad + \int_{\mathbb{R}} \tilde{\mu}_t(z) [E_t(z) x_{t-} + F_t(z) u_t + \gamma_t(z)] \tilde{N}(dt, dz). \end{aligned}$$

Hence

$$\begin{aligned} \mathbb{E} [\tilde{p}_T x_T] &= \mathbb{E} \left[ \tilde{p}_0 x + \int_0^T \left\{ x_t \tilde{\xi}_t + \tilde{p}_t [A_t x_t + B_t u_t + \alpha_t] \right. \right. \\ &\quad \left. \left. + \tilde{\eta}_t [C_t x_t + D_t u_t + \beta_t] + \int_{\mathbb{R}} \tilde{\mu}_t(z) [E_t(z) x_t + F_t(z) u_t + \gamma_t(z)] \nu(dz) \right\} dt \right] \\ (2.19) \quad &= \mathbb{E} \left[ \tilde{p}_0 x + \int_0^T \{ \Theta_7(t) x_t + 2\Theta_8(t) u_t + \Theta_9(t) \} dt \right], \end{aligned}$$

where

$$(2.20) \quad \Theta_7(t) = \tilde{\xi}_t + \tilde{p}_t A_t + C_t \tilde{\eta}_t + \int_{\mathbb{R}} \tilde{\mu}_t(z) E_t(z) \nu(dz),$$

$$(2.21) \quad \Theta_8(t) = \frac{1}{2} \left\{ \tilde{p}_t B_t + \tilde{\eta}_t D_t + \int_{\mathbb{R}} \tilde{\mu}_t(z) F_t(z) \nu(dz) \right\},$$

$$(2.22) \quad \Theta_9(t) = \tilde{p}_t \alpha_t + \tilde{\eta}_t \beta_t + \int_{\mathbb{R}} \tilde{\mu}_t(z) \gamma_t(z) \nu(dz).$$

Let

$$p_T = H_1 \quad \text{and} \quad \tilde{p}_T = H_2.$$

Therefore

$$\begin{aligned}
 & J(x, u) \\
 &= \left\{ \int_0^T \left[ Q_{11}(t)x_t^2 + 2Q_{12}(t)x_t u_t + Q_{22}(t)u_t^2 + R_1(t)x_t + 2R_2(t)u_t \right] dt + p_T x_T^2 + \tilde{p}_T x_T \right\} \\
 &= \mathbb{E} (p_0 x^2) + \mathbb{E} (\tilde{p}_0 x) + \mathbb{E} \int_0^T \left\{ [\Theta_1(t) + Q_{11}(t)] x_t^2 + 2 [\Theta_2(t) + Q_{12}(t)] x_t u_t \right. \\
 &\quad \left. + [Q_{22}(t) + \Theta_3(t)] u_t^2 + [\Theta_4(t) + \Theta_7(t) + R_1(t)] x_t \right. \\
 &\quad \left. + 2 [\Theta_5(t) + \Theta_8(t) + R_2(t)] u_t + \Theta_6(t) + \Theta_9(t) \right\} dt \\
 &= \mathbb{E} (p_0 x^2) + \mathbb{E} (\tilde{p}_0 x) \\
 &\quad + \mathbb{E} \int_0^T \left\{ \left[ \Theta_1(t) + Q_{11}(t) - [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_2(t) + Q_{12}(t)]^2 \right] x_t^2 \right. \\
 &\quad \left. + \left[ \Theta_4(t) + \Theta_7(t) + R_1(t) - 2 [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_2(t) + Q_{12}(t)] \right. \right. \\
 &\quad \left. \left. \times [\Theta_5(t) + \Theta_8(t) + R_2(t)] \right] x_t \right. \\
 &\quad \left. + [Q_{22}(t) + \Theta_3(t)] \left\{ u_t + [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_2(t) + Q_{12}(t)] x_t \right. \right. \\
 &\quad \left. \left. + [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_5(t) + \Theta_8(t) + R_2(t)] \right\}^2 \right. \\
 &\quad \left. \Theta_6(t) + \Theta_9(t) - [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_5(t) + \Theta_8(t) + R_2(t)]^2 \right\} dt.
 \end{aligned}$$

If

$$\begin{aligned}
 & (2.23) \\
 & \left\{ \begin{aligned} & \Theta_1(t) + Q_{11}(t) - [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_2(t) + Q_{12}(t)]^2 = 0, \\ & \Theta_4(t) + \Theta_7(t) + R_1(t) - 2 [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_2(t) + Q_{12}(t)] [\Theta_5(t) + \Theta_8(t) + R_2(t)] \\ & = 0, \end{aligned} \right.
 \end{aligned}$$

then

$$\begin{aligned}
 & J(x, u) = \mathbb{E} (p_0 x^2) + \mathbb{E} (\tilde{p}_0 x) + \mathbb{E} \int_0^T J_0(t) dt \\
 & \quad + \mathbb{E} \int_0^T [Q_{22}(t) + \Theta_3(t)] \left\{ u_t + [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_2(t) + Q_{12}(t)] x_t - \right. \\
 & \quad \left. + [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_5(t) + \Theta_8(t) + R_2(t)] \right\}^2 dt, \tag{2.24}
 \end{aligned}$$

where

$$J_0(t) = \Theta_6(t) + \Theta_9(t) - [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_5(t) + \Theta_8(t) + R_2(t)]^2$$

is independent of  $u_t$  and  $x_t$ . This utility functional will achieve its minimum

$$\mathbb{E} (p_0 x^2) + \mathbb{E} (\tilde{p}_0 x) + \mathbb{E} \int_0^T J_0(t) dt$$

when

$$(2.25) \quad u_t = -[Q_{22}(t) + \Theta_3(t)]^{-1} \{[\Theta_2(t) + Q_{12}(t)]x_{t-} + \Theta_5(t) + \Theta_8(t) + R_2(t)\}.$$

Thus the optimal control is also a feedback one which is linear and depends only on the state  $x_t$ .

Using the notation of  $\rho_i(t)$ , we may rewrite (2.12)–(2.17) and (2.20)–(2.22) as

$$(2.26) \quad \Theta_1(t) = \xi_t + 2p_t A_t + p_t C_t^2 + 2\eta_t C_t + \rho_1(t)p_t + \rho_2(t),$$

$$(2.27) \quad \Theta_2(t) = p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t)p_t + \rho_4(t),$$

$$(2.28) \quad \Theta_3(t) = p_t D_t^2 + \rho_5(t)p_t + \rho_6(t),$$

$$(2.29) \quad \Theta_4(t) = 2p_t \alpha_t + 2\beta_t p_t C_t + 2\beta_t \eta_t + 2p_t \rho_7(t) + 2\rho_8(t),$$

$$(2.30) \quad \Theta_5(t) = p_t \beta_t D_t + p_t \rho_9(t) + \rho_{10}(t),$$

$$(2.31) \quad \Theta_6(t) = p_t \beta_t^2 + p_t \rho_{11}(t) + \rho_{12}(t),$$

$$(2.32) \quad \Theta_7(t) = \tilde{\xi}_t + \tilde{p}_t A_t + C_t \tilde{\eta}_t + \rho_{13}(t),$$

$$(2.33) \quad \Theta_8(t) = \frac{1}{2} \{ \tilde{p}_t B_t + \tilde{\eta}_t D_t + \rho_{14}(t) \},$$

$$(2.34) \quad \Theta_9(t) = \tilde{p}_t \alpha_t + \tilde{\eta}_t \beta_t + \rho_{15}(t).$$

The first equation of (2.23) becomes

$$\begin{aligned} & \xi_t + 2p_t A_t + p_t C_t^2 + 2\eta_t C_t + \rho_1(t)p_t + \rho_2(t) + Q_{11}(t) \\ & + [Q_{22}(t) + p_t D_t^2 + \rho_5(t)p_t + \rho_6(t)]^{-1} \\ & \times [p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t)p_t + \rho_4(t) + Q_{12}(t)]^2 = 0. \end{aligned}$$

Multiplying by  $dt$ , we get

$$\begin{aligned} & \xi_t dt + [2p_t A_t + p_t C_t^2 + 2\eta_t C_t + \rho_1(t)p_t + \rho_2(t) + Q_{11}(t)] dt \\ & - [Q_{22}(t) + p_t D_t^2 + \rho_5(t)p_t + \rho_6(t)]^{-1} \\ & \times [p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t)p_t + \rho_4(t) + Q_{12}(t)]^2 dt = 0. \end{aligned}$$

Substituting

$$\xi_t dt = dp_t - \eta_t dW_t - \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz)$$

into the equation, we have the following backward Riccati equation for  $p_t$ :

$$\begin{aligned} & dp_t + [2p_t A_t + p_t C_t^2 + 2\eta_t C_t + \rho_1(t)p_t + \rho_2(t) + Q_{11}(t)] dt \\ & - [Q_{22}(t) + p_t D_t^2 + \rho_5(t)p_t + \rho_6(t)]^{-1} [p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t)p_t + \rho_4(t) \\ & \quad + Q_{12}(t)]^2 dt \\ & - \eta_t dW_t - \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz) = 0. \end{aligned}$$

In a similar way, we can reduce the second equation of (2.23) to

$$\begin{aligned} & d\tilde{p}_t + [2p_t \alpha_t + 2\beta_t p_t C_t + 2\beta_t \eta_t + 2p_t \rho_7(t) + 2\rho_8(t)] dt \\ & + [\tilde{p}_t A_t + C_t \tilde{\eta}_t + \rho_{13}(t) + R_1(t)] dt \end{aligned}$$

$$\begin{aligned}
& -2 \left[ Q_{22}(t) + p_t D_t^2 + \rho_5(t) p_t + \rho_6(t) \right]^{-1} \left[ p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t) p_t + \rho_4(t) + Q_{12}(t) \right], \\
& \left[ p_t \beta_t D_t + p_t \rho_9(t) + \rho_{10}(t) + \frac{1}{2} \tilde{p}_t B_t + \frac{1}{2} \tilde{\eta}_t D_t + \frac{1}{2} \rho_{14}(t) + R_2(t) \right] dt \\
& - \tilde{\eta}_t dW_t - \int_{\mathbb{R}} \tilde{\mu}_t(z) \tilde{N}(dt, dz) = 0.
\end{aligned}$$

**3. The partial information case.** We now study the case when our control  $u_t$  is required to be  $\mathcal{E}_t$ -predictable, where

$$\mathcal{E}_t \subseteq \mathcal{F}_t \quad \text{for all } t \in [0, T]$$

is a given subfiltration representing the information available to the controller at time  $t$ . The corresponding family of admissible controls is denoted by  $\mathcal{A}_{\mathcal{E}}$ .

**THEOREM 3.1** (partial information linear quadratic control). *Suppose the system of Riccati equations (2.3)–(2.6) has a solution  $p_t$  and  $\tilde{p}_t$ . Define*

$$\begin{aligned}
(3.1) \quad u_t^* &= - \left( \mathbb{E} \left[ \{Q_{22}(t) + \Theta_3(t)\} \middle| \mathcal{E}_t \right] \right)^{-1}, \\
& \mathbb{E} \left[ \{(\Theta_2(t) + Q_{12}(t))x_{t-} + \Theta_5(t) + \Theta_8(t) + R_2(t)\} \middle| \mathcal{E}_t \right],
\end{aligned}$$

where  $\Theta_i(t)$  are given by (2.26)–(2.34).

Suppose  $u_t^* \in \mathcal{A}_{\mathcal{E}}$  and that (2.10) holds. Then  $u_t^*$  is the unique solution of the partial information linear quadratic control problem. The value function  $J_{\mathcal{E}}(x)$  in the partial observation case is given by

$$(3.2) \quad J_{\mathcal{E}}(x) = J_{\mathcal{F}}(x) + \mathbb{E} \left[ \int_0^T \left\{ L_t M_t^2 - \mathbb{E} [L_t | \mathcal{E}_t]^{-1} (\mathbb{E} [L_t M_t | \mathcal{E}_t])^2 \right\} dt \right],$$

where  $J_{\mathcal{F}}$  is the value function in the complete information case and

$$(3.3) \quad L_t = Q_{22}(t) + \Theta_3(t)$$

and

$$(3.4) \quad M_t = L_t^{-1} [(\Theta_2(t) + Q_{12}(t))x_t + \Theta_5(t) + \Theta_8(t) + R_2(t)].$$

*Proof.* We use the computation in the proof of Theorem 2.1. By (2.24), we have

$$(3.5) \quad J(x, u) = J_{\mathcal{F}}(x) + \mathbb{E} \left[ \int_0^T L_t (u_t + M_t)^2 dt \right].$$

Note that  $L_t$  does not depend on  $X_t$  (or  $u_t$ ). For each  $t$ , define the measure  $Q_t$  by

$$(3.6) \quad dQ_t = L_t dP_t \quad \text{on } \mathcal{F}_t.$$

Then

$$\mathbb{E} \left[ \int_0^T L_t (u_t + M_t)^2 dt \right] = \int_0^T \mathbb{E}_{Q_t} [(u_t + M_t)^2] dt.$$

We can minimize this for each  $t$ . By the well-known Kallianpur–Striebel formula [12] we know that the minimum of  $\mathbb{E}_{Q_t} [(u_t + M_t)^2]$  over all  $\mathcal{E}_t$ -measurable  $u_t$  is attained at

$$\begin{aligned} u_t = u_t^* &= -\mathbb{E}_{Q_t} [M_t | \mathcal{E}_t] \\ &= -\frac{\mathbb{E} [L_t M_t | \mathcal{E}_t]}{\mathbb{E} [L_t | \mathcal{E}_t]} \\ (3.7) \quad &= -\frac{\mathbb{E} [\{(\Theta_2(t) + Q_{12}(t))x_{t-} + \Theta_5(t) + \Theta_8(t) + R_2(t)\} | \mathcal{E}_t]}{\mathbb{E} [\{Q_{22}(t) + \Theta_3(t)\} | \mathcal{E}_t]}. \end{aligned}$$

This proves (3.1). Substituting (3.7) into (3.6), we get

$$\begin{aligned} J_{\mathcal{E}}(x) &= J_{\mathcal{F}}(x) + \mathbb{E} \left[ \int_0^T L_t (u_t^* + M_t)^2 dt \right] \\ &= J_{\mathcal{F}}(x) + \mathbb{E} \left[ \int_0^T \left\{ L_t M_t^2 - (\mathbb{E} [L_t | \mathcal{E}_t])^{-1} (\mathbb{E} [L_t M_t | \mathcal{E}_t])^2 \right\} dt \right], \end{aligned}$$

which proves (3.2).  $\square$

*Remark 3.2.* We may regard the term

$$J_{\mathcal{E}}(x) - J_{\mathcal{F}}(x) = \mathbb{E} \left[ \int_0^T \left\{ L_t M_t^2 - (\mathbb{E} [L_t | \mathcal{E}_t])^{-1} (\mathbb{E} [L_t M_t | \mathcal{E}_t])^2 \right\} dt \right]$$

as the reduction of performance (or cost increase) due to the reduced information flow  $\mathcal{E}_t$ .

#### 4. Some particular cases.

**4.1. Absence of Poissonian noise.** Let us first consider the case when the system is under the influence of Brownian white noise. In the controlled system (2.1), we let

$$E_t(z) = F_t(z) = \gamma_t = 0,$$

let all the coefficients be adapted with respect to the filtration  $\mathcal{F}_t^W = \sigma(W_s, s \leq t)$ , and let  $H_1, H_2$  be  $\mathcal{F}_T^W$  measurable. Then

$$\rho_i(t) = 0 \quad \text{for all } 1 \leq i \leq 15.$$

We may assume  $\mu_t = \tilde{\mu}_t = 0$  and write (2.3)–(2.6) as

(4.1)

$$\begin{aligned} dp_t &+ [2p_t A_t + p_t C_t^2 + 2\eta_t C_t + Q_{11}(t)] dt \\ &- [Q_{22}(t) + p_t D_t^2]^{-1} [p_t B_t + p_t C_t D_t + \eta_t D_t + Q_{12}(t)]^2 dt - \eta_t dW_t = 0, \end{aligned}$$

(4.2)  $p_T = H_1,$

(4.3)

$$\begin{aligned} d\tilde{p}_t &+ [2\tilde{p}_t \alpha_t + 2\beta_t p_t C_t + 2\beta_t \eta_t] dt + [\tilde{p}_t A_t + C_t \tilde{\eta}_t + R_1(t)] dt \\ &- 2 [Q_{22}(t) + p_t D_t^2]^{-1} [p_t B_t + p_t C_t D_t + \eta_t D_t + Q_{12}(t)], \\ &\left[ p_t \beta_t D_t + \frac{1}{2} \tilde{p}_t B_t + \frac{1}{2} \tilde{\eta}_t D_t + R_2(t) \right] dt - \tilde{\eta}_t dW_t = 0, \end{aligned}$$

(4.4)  $\tilde{p}_T = H_2.$

THEOREM 4.1. Suppose the system of backward Riccati equations (4.1)–(4.4) has a solution  $p_t$  and  $\tilde{p}_t$ . Define

$$(4.5) \quad u_t = -[Q_{22}(t) + p_t D_t^2]^{-1} \left\{ [p_t B_t + p_t C_t D_t + \eta_t D_t + Q_{12}(t)] x_{t-} - p_t \beta_t D_t + \frac{1}{2} (\tilde{p}_t + \tilde{\eta}_t D_t - R_2(t)) \right\}.$$

Suppose  $u_t \in \mathcal{A}_{\mathcal{F}}$  and that (2.10) holds. Then  $u_t$  is the unique solution of the complete information linear quadratic control problem (2.1)–(2.2). The corresponding value function is also quadratic and is given by

$$\mathbb{E} (p_0) x^2 + \mathbb{E} (\tilde{p}_0) x + \mathbb{E} \int_0^T \left\{ \Theta_6(t) + \Theta_9(t) - [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_5(t) + \Theta_8(t) + R_2(t)]^2 \right\} dt,$$

where  $p_t$  and  $\tilde{p}_t$  are found from solving the above backward equations and

$$\begin{aligned} \Theta_3(t) &= p_t D_t^2, & \Theta_5(t) &= p_t \beta_t D_t, & \Theta_6(t) &= p_t \beta_t^2, \\ \Theta_8(t) &= \frac{1}{2} (\tilde{p}_t + \tilde{\eta}_t D_t), & \Theta_9(t) &= \tilde{p}_t \alpha_t + \tilde{\eta}_t \beta_t. \end{aligned}$$

**4.2. Absence of Brownian white noise.** If, in the controlled system (2.1),  $C_t = D_t = \beta_t = 0$  and all the coefficients are adapted to the filtration  $\mathcal{F}_t^P = \sigma(N(ds, dz), s \leq t)$ , and  $H_1, H_2$  are  $\mathcal{F}_T^P$  measurable, then we may consider the system

$$(4.6) \quad \begin{aligned} dp_t &+ [2p_t A_t + \rho_1(t) p_t + \rho_2(t) + Q_{11}(t)] dt \\ &- [Q_{22}(t) + \rho_5(t) p_t + \rho_6(t)]^{-1} [p_t B_t + \rho_3(t) p_t + \rho_4(t)]^2 dt - \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz) = 0, \end{aligned}$$

$$(4.7) \quad p_T = H_1,$$

$$(4.8) \quad \begin{aligned} d\tilde{p}_t &+ [2\tilde{p}_t \alpha_t + 2\beta_t \eta_t + 2p_t \rho_7(t) + 2\rho_8(t)] dt + [\tilde{p}_t A_t + \rho_{13}(t) + R_1(t)] dt \\ &- 2[Q_{22}(t) + \rho_5(t) p_t + \rho_6(t)]^{-1} [p_t B_t + \rho_3(t) p_t + \rho_4(t) + Q_{12}(t)], \\ &\left[ p_t \rho_9(t) + \rho_{10}(t) + \frac{1}{2} \tilde{p}_t B_t + \frac{1}{2} \rho_{14}(t) + R_2(t) \right] dt - \int_{\mathbb{R}} \tilde{\mu}_t(z) \tilde{N}(dt, dz) = 0, \end{aligned}$$

$$(4.9) \quad \tilde{p}_T = H_2.$$

THEOREM 4.2. Suppose the system of backward Riccati equations (2.3)–(2.6) has a solution  $p_t$  and  $\tilde{p}_t$ . Define

$$(4.10) \quad u_t = -[Q_{22}(t) + \rho_5 p_t + \rho_6(t)]^{-1} \left\{ [p_t B_t + \rho_3(t) p_t + \rho_4(t) + Q_{12}(t)] x_{t-} - p_t \rho_9(t) + \rho_{10}(t) + \frac{1}{2} (\tilde{p}_t + \rho_{14}(t)) - R_2(t) \right\}.$$

Suppose  $u_t \in \mathcal{A}_{\mathcal{F}}$  and that (2.10) holds. Then  $u_t$  is the unique solution of the complete information linear quadratic control problem (2.1)–(2.2). The corresponding value function is also quadratic and is given by

$$\mathbb{E} (p_0)x^2 + \mathbb{E} (\tilde{p}_0)x + \mathbb{E} \int_0^T \left\{ \Theta_6(t) + \Theta_9(t) - [Q_{22}(t) + \Theta_3(t)]^{-1} [\Theta_5(t) + \Theta_8(t) + R_2(t)]^2 \right\} dt,$$

where  $p_t$  and  $\tilde{p}_t$  are found from solving the above backward equations and  $\Theta_i$  are given by corresponding formulas of (2.26)–(2.34).

**4.3. Classical Riccati equations.** To obtain the classical Riccati equation, we may assume that in the controlled system (2.1),

$$\alpha_t = 0, \quad \beta_t = 0, \quad \gamma_t = 0, \quad H_2 = 0, \quad Q_{12}(t) = R_1(t) = R_2(t) = 0.$$

In this case, we have

$$\rho_7(t) = \rho_9(t) = \rho_{10}(t) = \rho_{11}(t) = \rho_{12}(t) = 0.$$

The backward stochastic Riccati equation for  $\tilde{p}_t$  becomes

$$\begin{aligned} & d\tilde{p}_t + [\tilde{p}_t A_t + C_t \tilde{\eta}_t + \rho_{13}(t)] dt - 2 [Q_{22}(t) + p_t D_t^2 + \rho_5(t) p_t + \rho_6(t)]^{-1}, \\ & [p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t) p_t + \rho_4(t)], \\ & \left[ \frac{1}{2} \tilde{p}_t B_t + \frac{1}{2} \tilde{\eta}_t D_t + \frac{1}{2} \rho_{14}(t) \right] dt - \tilde{\eta}_t dW_t - \int_{\mathbb{R}} \tilde{\mu}_t(z) \tilde{N}(dt, dz) = 0, \\ & \tilde{p}_T = 0. \end{aligned}$$

Apparently, this equation has a solution 0. Moreover, (2.3) becomes

$$\begin{aligned} (4.11) \quad & dp_t + [2p_t A_t + p_t C_t^2 + 2\eta_t C_t + \rho_1(t) p_t + \rho_2(t) + Q_{11}(t)] dt \\ & - [Q_{22}(t) + p_t D_t^2 + \rho_5(t) p_t + \rho_6(t)]^{-1} [p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t) p_t + \rho_4(t) \\ & \quad + Q_{12}(t)]^2 dt \\ & - \eta_t dW_t - \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz) = 0, \end{aligned}$$

$$(4.12) \quad p_T = H_1.$$

**THEOREM 4.3.** Suppose the system of backward Riccati equations (4.11)–(4.12) has a solution  $p_t$ . Define

$$\begin{aligned} (4.13) \quad u_t = & - [Q_{22}(t) + p_t D_t^2 + \rho_5 p_t + \rho_6(t)]^{-1}, \\ & \left\{ [p_t B_t + p_t C_t D_t + \eta_t D_t + \rho_3(t) p_t + \rho_4(t) + Q_{12}(t)] x_t - \right. \\ & \left. - p_t \beta_t D_t + p_t \rho_9(t) + \rho_{10}(t) - R_2(t) \right\}. \end{aligned}$$

Suppose that  $u_t \in \mathcal{A}_{\mathcal{F}}$  and that (2.10) holds. Then  $u_t$  is the unique solution of the complete information linear quadratic control problem (2.1)–(2.2). The corresponding value function is also quadratic and is given as before.

If in Theorem 4.3 we further assume

$$E_t(z) = F_t(z) = \gamma_t = 0, \quad Q_{12}(t) = R_1(t) = R_2(t) = 0,$$

then we have the following.

**COROLLARY 4.1.** *Suppose the backward Riccati equation*

$$\begin{aligned} dp_t + [2p_t A_t + p_t C_t^2 + 2\eta_t C_t + Q_{11}(t)] dt \\ - [Q_{22}(t) + p_t D_t^2]^{-1} [p_t B_t + p_t C_t D_t + \eta_t D_t]^2 dt - \eta_t dW_t = 0, \\ p_T = H_1 \end{aligned}$$

has a solution  $p_t$ . Define

$$u_t = -[Q_{22}(t) + p_t D_t^2]^{-1} \{ [p_t B_t + p_t C_t D_t + \eta_t D_t] x_{t-} - p_t \beta_t D_t + p_t \rho_9(t) + \rho_{10}(t) - R_2(t) \}.$$

Suppose  $u_t \in \mathcal{A}_{\mathcal{F}}$  and that (2.10) holds. Then  $u_t$  is the unique solution of the complete information linear quadratic control problem (2.1)–(2.2). The corresponding value function is also quadratic and is given as before.

**Remark 4.4.** This equation coincides with the equation in [13], for example.

**4.4. Deterministic linear quadratic problem.** If all the data are deterministic, then we may assume  $p_t$  and  $\tilde{p}_t$  to be deterministic, too. Hence

$$\eta_t = \mu_t(z) = \tilde{\eta}_t = \tilde{\mu}_t(z) = 0$$

and we have the following.

**THEOREM 4.5.** *Consider the following system of backward Riccati/backward linear stochastic differential equations:*

$$\begin{aligned} (4.14) \\ dp_t + [2p_t A_t + p_t C_t^2 + \rho_1(t)p_t + \rho_2(t) + Q_{11}(t)] dt \\ - [Q_{22}(t) + p_t D_t^2 + \rho_5(t)p_t + \rho_6(t)]^{-1} [p_t B_t + p_t C_t D_t + \rho_3(t)p_t + \rho_4(t) + Q_{12}(t)]^2 dt = 0, \end{aligned}$$

$$\begin{aligned} (4.15) \\ d\tilde{p}_t + [2p_t \alpha_t + 2\beta_t p_t C_t + 2p_t \rho_7(t) + \rho_8(t)] dt + [\tilde{p}_t A_t + \rho_{13}(t) + R_1(t)] dt \\ - 2 [Q_{22}(t) + p_t D_t^2 + \rho_5(t)p_t + \rho_6(t)]^{-1} [p_t B_t + p_t C_t D_t + \rho_3(t)p_t + \rho_4(t) + Q_{12}(t)], \\ \left[ p_t \beta_t D_t + p_t \rho_9(t) + \rho_{10}(t) + \frac{1}{2} \tilde{p}_t B_t + \frac{1}{2} \rho_{14}(t) + R_2(t) \right] dt = 0. \end{aligned}$$

The terminal conditions are

$$p_T = H_1 \quad \text{and} \quad \tilde{p}_T = H_2.$$

If the Riccati system (4.14)–(4.16) has solutions  $p_t$  and  $\tilde{p}_t$ , then the linear quadratic control problem (2.1)–(2.2) has a solution with the optimal control given by

(4.16)

$$u_t = - \left[ Q_{22}(t) + p_t D_t^2 + \rho_5 p_t + \rho_6(t) \right]^{-1},$$

$$\left\{ \begin{aligned} & [p_t B_t + p_t C_t D_t + \rho_3(t) p_t + \rho_4(t) + Q_{12}(t)] x_{t-} \\ & - \left[ p_t \beta_t D_t + p_t \rho_9(t) + \rho_{10}(t) + \frac{1}{2} (\tilde{p}_t + \tilde{\eta}_t D_t + \rho_{14}(t)) \right] - R_2(t) \end{aligned} \right\},$$

provided that  $u_t \in \mathcal{A}_{\mathcal{F}}$  and that (2.10) holds. The corresponding value function is given by (2.11) with

$$\begin{aligned} Q_6(t) &= p_t \beta_t^2 \int_{\mathbb{R}} p_t \gamma_t^2(z) \nu(dz), \\ Q_9(t) &= \tilde{p}_t \alpha_t, \\ Q_3(t) &= p_t D_t^2 + p_t^2 \int_{\mathbb{R}} F_t^2(z) \nu(dz), \\ Q_5(t) &= p_t \beta_t D_t + \int_{\mathbb{R}} p_t \gamma_t(z) F_t(z) \nu(dz), \\ Q_8(t) &= \frac{1}{2} \tilde{p}_t B_t. \end{aligned}$$

**5. Partial information mean-variance portfolio problem.** We now apply our results to a partial information mean-variance portfolio problem in finance.

Suppose we have a market with the following two investment possibilities:

(i) a risk free asset, whose unit price  $S_0(t)$  at time  $t$  is given by

$$(5.1) \quad dS_0(t) = \rho_t S_0(t) dt, \quad S_0(0) = 1, \quad 0 \leq t \leq T;$$

(ii) a risky asset, whose unit price  $S_1(t)$  at time  $t$  is given by

$$(5.2) \quad dS_1(t) = S_1(t-) \left[ a_t dt + b_t dW_t + \int_{\mathbb{R}} c_t(z) \tilde{N}(dt, dz) \right], \quad 0 \leq t \leq T,$$

$$S_1(0) > 0.$$

Here  $\rho_t$ ,  $a_t$ ,  $b_t$ , and  $c_t(z)$  are given  $\mathcal{F}_t$ -predictable processes. We assume that

$$(5.3) \quad \mathbb{E} \left[ \int_0^T \left\{ |\rho_t| + |a_t| + b_t^2 + \int_{\mathbb{R}} c_t(z)^2 \nu(dz) \right\} dt \right] < \infty;$$

$$(5.4) \quad \text{there exists } \varepsilon > 0 \text{ such that } c_t(z) > -1 + \varepsilon \quad \text{a.s. for a.a. } t, z;$$

$$(5.5) \quad p_t b_t^2 + \int_{\mathbb{R}} (p_t + \mu_t(z)) c_t(z)^2 \nu(dz) > 0 \quad \text{for a.a. } t, \omega,$$

where  $p_t$  is the solution of (5.14)–(5.15) following.

Conditions (5.3)–(5.4) ensure that the solution to (5.2) is given by

$$(5.6) \quad S_1(t) = S_1(0) \exp \left\{ \int_0^t \left( a_s - \frac{1}{2} b_s^2 \right) ds + \int_0^t b_s dW_s \right. \\ \left. + \int_0^t \int_{\mathbb{R}} \{ \log(1 + c_s(z)) - c_s(z) \} \nu(dz) ds + \int_0^t \int_{\mathbb{R}} \log(1 + c_s(z)) \tilde{N}(ds, dz) \right\}.$$

A portfolio in this market is a predictable process  $\phi(t) = (\phi_0(t), \phi_1(t)) \in \mathbb{R}^2$  giving the number of units of the risk-free and the risky asset, respectively, held at time  $t$ . The corresponding *wealth process*  $x(t) = x^\phi(t)$  is defined by

$$(5.7) \quad x^\phi(t) = \phi_0(t)S_0(t) + \phi_1(t)S_1(t).$$

We say that  $\phi(t)$  is *self-financing* if

$$(5.8) \quad dx^\phi(t) = \phi_0(t)dS_0(t) + \phi_1(t)dS_1(t).$$

Suppose we are given a subfiltration

$$\mathcal{E}_t \subseteq \mathcal{F}_t, \quad t \in [0, T].$$

Let

$$u_t = \phi_1(t)S_1(t)$$

be the *amount* (instead of number of shares) invested in the risky asset at time  $t$ . We say that  $u_t$  is *admissible* and write  $u_t \in \mathcal{A}_{\mathcal{E}}$  if  $u_t$  is  $\mathcal{E}_t$ -predictable,  $\phi_1(t) = \frac{u_t}{S_1(t)}$  is self-financing, and  $x^{(u)}(t) := x^{(\phi)}(t)$  is *lower bounded*. Combining the above, we see that if  $\phi \in \mathcal{A}_{\mathcal{E}}$ , then

$$(5.9) \quad dx^{(u)}(t) = \left\{ \rho_t x^{(u)}(t) + (a_t - \rho_t)u_t \right\} dt + b_t u_t dW(t) + u_t \int_{\mathbb{R}} c_t(z) \tilde{N}(dt, dz),$$

$$x^{(u)}(0) = x > 0.$$

We now consider the *partial information mean-variance portfolio problem*, which is to find the portfolio  $\hat{u} \in \mathcal{A}_{\mathcal{E}}$  which minimizes the variance

$$(5.10) \quad \mathbb{E} \left[ x^\phi(T) - \mathbb{E} x^\phi(T) \right]^2$$

under the constraint

$$(5.11) \quad \mathbb{E} \left[ x^\phi(T) \right] = K,$$

where  $K$  is a given constant.

Using the Lagrange multiplier method, we see that the problem is equivalent to minimizing

$$(5.12) \quad \mathbb{E} \left[ x^\phi(T) - \lambda \right]^2$$

for a given constant  $\lambda \in \mathbb{R}$ , without constraints. We refer the reader to [18], [14], and [8] for more information about the mean-variance portfolio problem.

For the case when  $\mathcal{E}_t = \mathcal{F}_t$  and the coefficients are all deterministic, this problem was solved in [8] by using the maximum principle for jump-diffusions.

Subsequently this was extended to the partial information case  $\mathcal{E}_t \subseteq \mathcal{F}_t$  (but still with deterministic coefficients) by Bagheri and Øksendal [3].

We now show how Theorem 3.1 gives us a solution also in the case of stochastic coefficients.

Here

$$A_t = \rho_t, \quad B_t = a_t - \rho_t, \quad \alpha_t = 0, \quad C_t = 0, \quad D_t = b_t, \quad \beta_t = 0,$$

$$E_t(z) = 0, \quad F_t(z) = c_t(z), \quad \gamma_t(z) = 0, \quad Q_{ij}(t) = R_i(t) = 0$$

and

$$H_1 = 1, \quad H_2 = -2\lambda.$$

Then (3.1) gives the following candidate for the optimal partial information portfolio:

$$(5.13) \quad u_t^* = - \left( \mathbb{E} \left[ \Theta_3(t) | \mathcal{E}_t \right] \right)^{-1} \mathbb{E} \left[ \left\{ \Theta_2(t) x^{(u)}(t-) + \Theta_5(t) + \Theta_8(t) \right\} | \mathcal{E}_t \right],$$

where  $\Theta_i(t)$ ,  $i = 2, 3, 5, 8$  are defined by (2.26)–(2.34). Hence

$$u_t^* = - \left( \mathbb{E} \left[ \left\{ p_t b_t^2 + \int_{\mathbb{R}} (p_t + \mu_t(z)) c_t(z)^2 \nu(dz) \right\} | \mathcal{E}_t \right] \right)^{-1} \\ \times \mathbb{E} \left[ \left\{ (p_t(a_t - \rho_t) + \eta_t b_t) x^{(u)}(t-) + \frac{1}{2} (\tilde{p}_t + \tilde{\eta}_t b_t) + \int_{\mathbb{R}} \tilde{\mu}_t(z) c_t(z) \nu(dz) \right\} | \mathcal{E}_t \right].$$

Here  $p_t$ ,  $\eta_t$ ,  $\mu_t(z)$  and  $\tilde{p}_t$ ,  $\tilde{\eta}_t$ ,  $\tilde{\mu}_t(z)$  are the solutions of the backward Riccati equations (2.3)–(2.6), i.e.,

$$(5.14) \quad dp_t = - \left\{ 2\rho_t p_t + \left[ p_t b_t^2 + \int_{\mathbb{R}} (p_t + \mu_t(z)) c_t^2(z) \nu(dz) \right]^{-1} \left[ p_t(a_t - \rho_t) + \eta_t b_t \right. \right. \\ \left. \left. + \int_{\mathbb{R}} \mu_t(z) c_t(z) \nu(dz) \right]^2 \right\} dt + \eta_t dW_t + \int_{\mathbb{R}} \mu_t(z) \tilde{N}(dt, dz), \quad t < T,$$

$$(5.15) \quad p_T = 1,$$

and

$$(5.16) \quad d\tilde{p}_t = - \left\{ \rho_t \tilde{p}_t + \frac{1}{2} \left[ p_t b_t^2 + \int_{\mathbb{R}} (p_t + \mu_t(z)) c_t^2(z) \nu(dz) \right]^{-1} \left[ p_t(a_t - \rho_t) + \tilde{\eta}_t b_t \right. \right. \\ \left. \left. + \int_{\mathbb{R}} \mu_t(z) c_t(z) \nu(dz) \right] \right\} dt + \tilde{\eta}_t dW_t + \int_{\mathbb{R}} \tilde{\mu}_t(z) \tilde{N}(dt, dz), \quad t < T,$$

$$(5.17) \quad \tilde{p}_T = -2\lambda.$$

Summarizing the above, we get the following.

**THEOREM 5.1.** *Suppose the system of backward Riccati equations (5.14)–(5.17) has a unique solution  $p_t$  and  $\tilde{p}_t$ . Define*

$$(5.18) \quad u_t^* = - \left( \mathbb{E} \left[ \left\{ p_t b_t^2 + \int_{\mathbb{R}} (p_t + \mu_t(z)) c_t(z)^2 \nu(dz) \right\} | \mathcal{E}_t \right] \right)^{-1} \mathbb{E} \left[ \left\{ (p_t(a_t - \rho_t) + \eta_t b_t) x^{(u)}(t-) \right. \right. \\ \left. \left. + \frac{1}{2} (\tilde{p}_t + \tilde{\eta}_t b_t) + \int_{\mathbb{R}} \tilde{\mu}_t(z) c_t(z) \nu(dz) \right\} | \mathcal{E}_t \right].$$

*Suppose  $u_t^* \in \mathcal{A}_{\mathcal{E}}$  and that (2.10) holds. Then  $u_t^*$  is the unique solution to the minimum variance problem (5.12).*

**Remark 5.2.** Suppose the conditions of Theorem 5.1 hold for each choice of  $\lambda \in \mathbb{R}$ . Let  $x_{\lambda}^*(T)$  be the optimal terminal wealth determined by the optimal control  $u_t^* = u_{\lambda,t}^*$  corresponding to  $\lambda$ . Then, in order to solve the original mean-variance portfolio problem (5.10), it remains to determine  $\lambda$  such that

$$\mathbb{E} [x_{\lambda}^*(T)] = K.$$

We omit the discussion of this equation.

## ABSTRACT SECOND ORDER HYPERBOLIC SYSTEM AND APPLICATIONS TO CONTROLLED NETWORK OF STRINGS\*

GEN QI XU<sup>†</sup>, DONG YI LIU<sup>†</sup>, AND YAN QING LIU<sup>†</sup>

**Abstract.** In this paper we study an abstract second order hyperbolic system valued in  $\mathbb{C}^N$  with appropriate boundary conditions. We prove that the system is well-posed and associates with a  $C_0$  semigroup in a Hilbert state space. Under certain conditions, we show that the spectra of the system operator are located in the vertical strip, and that there is a sequence of eigenvectors and generalized eigenvectors that forms a Riesz basis with parentheses for the Hilbert state space, and hence that the system satisfies the spectrum determined growth assumption. As applications, we investigate the exponential stability of a controlled tree-shaped network of 7-strings and a network of  $N$ -connected strings.

**Key words.** hyperbolic system, spectral distribution, Riesz basis, exponential stability, tree-shaped network

**1. Introduction.** Many mechanical systems (such as cables, spacecraft with flexible attachments, robots with flexible links, etc.) contain certain parts whose dynamic behavior can be rigorously described by the partial differential equations

$$(1.1) \quad M \frac{\partial^2 Y(x, t)}{\partial t^2} = T \frac{\partial^2 Y(x, t)}{\partial x^2} + P \frac{\partial Y(x, t)}{\partial x} + QY(x, t), \quad x \in (0, 1), \quad t > 0,$$

with appropriate boundary conditions, where  $Y(x, t)$  is a function valued in  $\mathbb{C}^N$ ;  $M$ ,  $T$ ,  $P$ , and  $Q$  are  $N \times N$  matrices; and  $M$  and  $T$  are positive definite matrices. For such systems, we study not only their dynamic behavior but also the control problem. To achieve their control goals, scientists have designed many passive and active controllers.

In the past decade, boundary control of systems governed by partial differential equations has become an important research field. For concrete systems many boundary feedback controllers are used to stabilize the system. For example, in [1], [2], [3], [4], and [19] the authors used boundary and pointwise feedback controllers to stabilize one-dimensional wave systems, and in [9], [10], [11], and the references therein, the boundary feedback controllers have been used in string networks; these are the simplest cases of (1.1) when  $P = Q = 0$ .

For the Timoshenko system whose motion is governed by

$$\begin{cases} \rho w_{tt}(x, t) = K(w_{xx}(x, t) - \varphi_x(x, t)), & 0 < x < \ell, \quad t > 0, \\ I_\rho \varphi_{tt}(x, t) = EI\varphi_{xx}(x, t) + K(w_x(x, t) - \varphi(x, t)), & 0 < x < \ell, \quad t > 0, \end{cases}$$

which is exactly of the form in (1.1), the authors in [12], [13], [14], and [20] used the boundary feedback controllers to exponentially stabilize the systems.

The one-dimensional selling porous solid system, whose dynamic behavior is governed by

$$\begin{cases} \rho_0 u_{tt}(x, t) = \mu u_{xx}(x, t) + \beta \varphi_x(x, t), & 0 < x < \ell, \quad t > 0, \\ \rho_0 K \varphi_{tt}(x, t) = \alpha \varphi_{xx}(x, t) - \beta u_x(x, t) - \xi \varphi(x, t) - \gamma \varphi_t(x, t), & 0 < x < \ell, \quad t > 0, \end{cases}$$

is a case of (1.1) with damping. Within this system, [15] and [16] discussed the slow decay, and [17] used the boundary feedback controllers to achieve the uniform stabilization.

We observe that in all the works mentioned above, the stability analysis of the corresponding closed loop system is the most difficult part; it becomes much more difficult when one uses the method of spectral analysis. This is because one asserts the stability of a system from its spectral distribution only when the system satisfies the spectrum determined growth assumption, which means that the decay rate of the system is determined via the spectrum of the system operator. For a distributed parameter system, to prove that the system itself satisfies the spectrum determined growth assumption is a tough problem. Note that if the system is a Riesz one, that is, the multiplicities of eigenvalues are uniformly bounded and there is a sequence of eigenvectors and generalized eigenvectors that forms a Riesz basis for the Hilbert state space, then the spectrum determined growth assumption holds. So verification of the Riesz basis property in the literature becomes an important component (see [4], [14], [20]). Recently, we found a method for verifying the Riesz basis property (see [24], [25]). This method depends only on the distribution of eigenvalues and not on their expression and eigenvectors, which makes it possible to obtain the Riesz basis of the system by determining the asymptotic distribution of the spectrum.

A practice calculation (see, e.g., [14], [20]) shows that the asymptotic spectra of the system (1.1) are entirely determined by its principal part, i.e.,  $P = Q = 0$ . Based on this fact, in this paper we shall discuss a special case of the system (1.1) with  $P = Q = 0$  under appropriate boundary conditions. More precisely, we shall study the following system valued in  $\mathbb{C}^N$ :

$$(1.2) \quad \begin{cases} M \frac{\partial^2 Y(x, t)}{\partial t^2} = T \frac{\partial^2 Y(x, t)}{\partial x^2}, & x \in (0, 1), \quad t > 0, \\ Y(0, t) = CY(1, t), & t > 0, \\ T \frac{\partial Y(1, t)}{\partial x} - C^T T \frac{\partial Y(0, t)}{\partial x} = -\Gamma \frac{\partial Y(1, t)}{\partial t}, & t > 0, \\ Y(x, 0) = Y_0(x), \quad \frac{\partial Y(x, 0)}{\partial t} = Y_1(x), & x \in (0, 1), \end{cases}$$

where  $M$ ,  $T$ , and  $\Gamma$  are positive definite  $N \times N$  matrices;  $C$  is a real  $N \times N$  matrix satisfying  $\det(I - C) \neq 0$ ; and  $C^T$  denotes the transpose of matrix  $C$ . We shall prove that the system is well-posed and that under certain conditions, the eigenvectors and generalized eigenvectors of the system generate a Riesz basis for the Hilbert state space. Under certain conditions, the system decays exponentially.

It is worth mentioning that system (1.2) is different from those systems mentioned before because it has coupled equations and nonseparable boundary conditions. These properties cause some difficulty in practice. However, such a system has many important applications.

The contents of this paper are organized as follows. In section 2, we shall formulate the problem (1.2) into a Hilbert state space and then prove that the system associates

with a  $C_0$  semigroup and is asymptotically stable. In section 3, we shall study the spectral distribution of the system operator and prove the Riesz basis property of eigenvectors and generalized eigenvectors, which deduces that the system satisfies the spectrum determined growth assumption. Finally, in section 4, we give two examples: a tree-shaped network of 7-strings and a network of N-connected strings. We shall show that both systems are exponentially stable.

**2. Well-posedness of abstract differential equations.** In this section, we shall formulate system (1.2) into a Hilbert space and then discuss whether the system is well-posed.

Let an abstract hyperbolic system valued in  $\mathbb{C}^N$  be given by

$$(2.1) \quad \begin{cases} M \frac{\partial^2 Y(x, t)}{\partial t^2} = T \frac{\partial^2 Y(x, t)}{\partial x^2}, & x \in (0, 1), \quad t > 0, \\ Y(0, t) = CY(1, t), & t > 0, \\ T \frac{\partial Y(1, t)}{\partial x} - C^\tau T \frac{\partial Y(0, t)}{\partial x} = -\Gamma \frac{\partial Y(1, t)}{\partial t}, & t > 0, \\ Y(x, 0) = Y_0(x), \quad \frac{\partial Y(x, 0)}{\partial t} = Y_1(x), & x \in (0, 1), \end{cases}$$

where  $M$ ,  $T$ , and  $\Gamma$  are positive definite matrices, and  $C$  is a real matrix satisfying  $\det(I - C) \neq 0$ .

Set

$$V_E^k(0, 1) = \{f \in H^k([0, 1], \mathbb{C}^N) \mid f(0) = Cf(1)\},$$

where  $H^k((0, 1), \mathbb{C}^N)$  is the Sobolev space of order  $k$ .

Let

$$\mathcal{H} = V_E^1(0, 1) \times L^2([0, 1], \mathbb{C}^N)$$

be equipped with the inner product

$$\langle (f_1, f_2), (g_1, g_2) \rangle_{\mathcal{H}} = \int_0^1 (Tf_1'(x), g_1'(x))dx + \int_0^1 (Mf_2(x), g_2(x))dx,$$

and hereafter we always denote by  $(\cdot, \cdot)$  the inner product in  $\mathbb{C}^N$  and by  $\langle \cdot, \cdot \rangle_{\mathcal{H}}$  the inner product in  $\mathcal{H}$ .

It is easy to see that for  $(f_1, f_2) \in \mathcal{H}$ ,

$$\|(f_1, f_2)\|_{\mathcal{H}} = \left( \int_0^1 (Tf_1'(x), f_1'(x))dx + \int_0^1 (Mf_2(x), f_2(x))dx \right)^{1/2}$$

is a norm on  $\mathcal{H}$ , and that  $\mathcal{H}$  is a Hilbert space.

Define an operator  $\mathcal{A}$  in  $\mathcal{H}$  by

$$(2.2) \quad \mathcal{D}(\mathcal{A}) = \{(f, g) \in V_E^2(0, 1) \times V_E^1(0, 1) \mid Tf'(1) - C^\tau Tf'(0) = -\Gamma g(1)\},$$

$$(2.3) \quad \mathcal{A}(f, g) = (g(x), M^{-1}Tf''(x)) \quad \forall (f, g) \in \mathcal{D}(\mathcal{A}).$$

With the help of the above notation we can rewrite (2.1) as an evolutionary equation in  $\mathcal{H}$  as follows:

$$(2.4) \quad \begin{cases} \frac{d}{dt}Z(t) = \mathcal{A}Z(t), & t > 0, \\ Z(t) = (Y(x, t), Y_t(x, t)), \\ Z(0) = (Y_0(x), Y_1(x)). \end{cases}$$

THEOREM 2.1. *Let  $\mathcal{H}$  and  $\mathcal{A}$  be defined as before; then  $\mathcal{A}$  is a dissipative operator,  $\mathcal{A}^{-1}$  exists and is compact on  $\mathcal{H}$ , and hence  $\mathcal{A}$  generates a  $C_0$  semigroup of contraction on  $\mathcal{H}$ .*

*Proof.* Let  $\mathcal{H}$  and  $\mathcal{A}$  be defined as before. It is easy to verify that  $\mathcal{A}$  is a closed and densely defined linear operator in  $\mathcal{H}$ . For any  $(f, g) \in \mathcal{D}(\mathcal{A})$ , we have

$$\begin{aligned} \langle \mathcal{A}(f, g), (f, g) \rangle_{\mathcal{H}} &= \int_0^1 (Tg'(x), f'(x))dx + \int_0^1 (M(M^{-1}T)f''(x), g(x))dx \\ &= (Tg(x), f'(x)) \Big|_0^1 - \int_0^1 (Tg(x), f''(x))dx + \int_0^1 (Tf''(x), g(x))dx, \\ \langle (f, g), \mathcal{A}(f, g) \rangle_{\mathcal{H}} &= \int_0^1 (Tf'(x), g'(x))dx + \int_0^1 (Mg(x), (M^{-1}Tf''(x)))dx \\ &= (Tf'(x), g(x)) \Big|_0^1 - \int_0^1 (Tf''(x), g(x))dx + \int_0^1 (Tg(x), f''(x))dx, \end{aligned}$$

and hence

$$\begin{aligned} \Re \langle \mathcal{A}(f, g), (f, g) \rangle_{\mathcal{H}} &= \Re (Tg(x), f'(x)) \Big|_0^1 \\ &= \Re (Tf'(1), g(1)) - \Re (Tf'(0), g(0)) \\ &= \Re (Tf'(1), g(1)) - \Re (Tf'(0), Cg(1)) \\ &= \Re (Tf'(1) - C^{\tau}Tf'(0), g(1)) \\ (2.5) \quad &= -(\Gamma g(1), g(1)) \leq 0, \end{aligned}$$

where we have used the conditions  $g(0) = Cg(1)$  and  $Tf'(1) - C^{\tau}Tf'(0) = -\Gamma g(1)$  and  $\Gamma$  is a positive definite matrix. So  $\mathcal{A}$  is a dissipative operator.

Now we show that  $0 \in \rho(\mathcal{A})$ . For any given  $(u, v) \in \mathcal{H}$ , we consider the solvability of equation

$$\mathcal{A}(f, g) = (u, v), \quad (f, g) \in \mathcal{D}(\mathcal{A}),$$

i.e.,

$$(2.6) \quad \begin{cases} g(x) = u(x), & x \in [0, 1], \\ M^{-1}Tf''(x) = v(x), & x \in (0, 1). \end{cases}$$

For the second equation in (2.6), integrating from  $x$  to 1 leads to

$$(2.7) \quad Tf'(1) - Tf'(x) = \int_x^1 Mv(s)ds, \quad x \in (0, 1),$$

and

$$(2.8) \quad (1-x)Tf'(1) - Tf(1) + Tf(x) = \int_x^1 dr \int_r^1 Mv(s)ds, \quad x \in (0, 1).$$

From (2.7) and (2.8) we get

$$(2.9) \quad Tf'(1) - Tf'(0) = \int_0^1 Mv(s)ds,$$

$$(2.10) \quad Tf'(1) - Tf(1) + Tf(0) = \int_0^1 dr \int_r^1 Mv(s)ds.$$

Multiplying (2.9) by  $C^\tau$  and recalling the boundary condition  $Tf'(1) - C^\tau Tf'(0) = -\Gamma g(1) = -\Gamma u(1)$  yield

$$(2.11) \quad (I - C^\tau)Tf'(1) = -\Gamma u(1) - \int_0^1 C^\tau Mv(s)ds.$$

Since  $\det(I - C^\tau) \neq 0$ , we have

$$(2.12) \quad Tf'(1) = -[I - C^\tau]^{-1} \left[ \Gamma u(1) + \int_0^1 C^\tau Mv(s)ds \right].$$

Substituting  $f(0) = Cf(1)$  into (2.10) yields

$$(2.13) \quad Tf'(1) - Tf(1) + TCf(1) = \int_0^1 dr \int_r^1 Mv(s)ds.$$

Thus we get from (2.12) and (2.13) that

$$(2.14) \quad \begin{aligned} f(1) &= -[I - C]^{-1}T^{-1}[I - C^\tau]^{-1} \left[ \Gamma u(1) + \int_0^1 C^\tau Mv(s)ds \right] \\ &\quad - [I - C]^{-1}T^{-1} \int_0^1 dr \int_r^1 Mv(s)ds. \end{aligned}$$

Therefore,

$$(2.15) \quad \begin{aligned} f(x) &= f(1) - (1-x)f'(1) + T^{-1} \int_x^1 dr \int_r^1 Mv(s)ds \\ &= -[xI + (I - C)^{-1}C]T^{-1}(I - C^\tau)^{-1} \left[ \Gamma u(1) + \int_0^1 C^\tau Mv(s)ds \right] \\ &\quad - (I - C)^{-1}CT^{-1} \int_0^1 dr \int_r^1 Mv(s)ds - T^{-1} \int_0^x dr \int_r^1 Mv(s)ds. \end{aligned}$$

Let  $f$  be given by (2.15) and  $g(x) = u(x)$ . Then  $(f, g) \in \mathcal{D}(\mathcal{A})$  and  $\mathcal{A}(f, g) = (u, v)$ . Thus the inverse operator theorem implies that  $0 \in \rho(\mathcal{A})$ . Note that  $u \in V_E^1(0, 1)$  and  $f$  has an integral representation. The Sobolev embedding theorem asserts that  $\mathcal{A}^{-1}$  is compact on  $\mathcal{H}$ . Therefore by the Lumer–Philips theorem (cf. [18]),  $\mathcal{A}$  generates a  $C_0$  semigroup of contraction on  $\mathcal{H}$ .  $\square$

**COROLLARY 2.2.** *Let  $\mathcal{A}$  be defined by (2.2) and (2.3) and  $S(t)$  be the semigroup generated by  $\mathcal{A}$ . Then  $\sigma(\mathcal{A})$  consists of all isolated eigenvalues of finite multiplicity, and  $\sigma(\mathcal{A}) \subset \{\lambda \in \mathbb{C} \mid \Re \lambda < 0\}$ . Therefore,  $S(t)$  is asymptotically stable.*

*Proof.* The first assertion follows from  $\mathcal{A}^{-1}$  being a compact operator on  $\mathcal{H}$ . For any  $\lambda \in \sigma(\mathcal{A})$ , we shall prove that  $\Re \lambda < 0$ . If it is not true, then there is at least one  $\lambda \in \sigma(\mathcal{A})$  with  $\Re \lambda = 0$ . Clearly,  $\lambda \neq 0$ . Let  $(f, g) \in \mathcal{D}(\mathcal{A})$  be a corresponding eigenvector. Then we have  $g(x) = \lambda f(x)$  and

$$0 = \Re \lambda \| (f, g) \|_{\mathcal{H}}^2 = \Re \lambda \langle (f, g), (f, g) \rangle_{\mathcal{H}} = \Re \langle \mathcal{A}(f, g), (f, g) \rangle_{\mathcal{H}} = -(\Gamma g(1), g(1)) \leq 0.$$

Since  $\Gamma$  is a positive definite matrix, we must have  $g(1) = 0$ , and hence  $f(1) = 0$ . So the vector-valued function  $f(x)$  satisfies the following differential equation:

$$(2.16) \quad \begin{cases} \lambda^2 Mf(x) = Tf''(x), & x \in (0, 1), \\ f(0) = 0 = f(1), & Tf'(1) - C^\tau Tf'(0) = 0. \end{cases}$$

Since  $M$  and  $T$  are positive definite matrices, so also is matrix  $T^{-1/2}MT^{-1/2}$ . Set  $B^2 = T^{-1/2}MT^{-1/2}$ , where  $B$  also is a positive definite matrix. Then the general solution of (2.16) has the form

$$f(x) = T^{-1/2} \sin(x\lambda B)v, \quad v \in \mathbb{C}^N.$$

Substituting the above into the boundary conditions in (2.16) leads to

$$T^{1/2} \sin(\lambda B)v = 0, \quad \lambda \left( T^{1/2}B \cos(\lambda B) - C^T T^{-1/2}B \right) v = 0.$$

Since  $\lambda \neq 0$ , we get from the above that

$$(I - C^T)T^{1/2}Bv = 0.$$

Notice that  $\det((I - C^T)T^{1/2}B) \neq 0$ . So  $v = 0$ , i.e.,  $f(x) = 0$ , and hence  $(f, g) = (0, 0)$ . This gives the contradiction that  $(f, g)$  is an eigenvector of  $\mathcal{A}$ . Therefore,  $\Re \lambda < 0$  for any  $\lambda \in \sigma(\mathcal{A})$ . The second assertion is proved. The asymptotical stability of  $S(t)$  follows from Lyubich and Phóng's theorem [21].  $\square$

**3. Spectral analysis of  $\mathcal{A}$ .** In order to investigate the properties of the semi-group  $S(t)$  generated by  $\mathcal{A}$ , we need to find some spectral properties of  $\mathcal{A}$ . In this section, we shall study the distribution of  $\sigma(\mathcal{A})$ , the completeness of eigenvectors and the generalized eigenvectors of  $\mathcal{A}$  and their Riesz basis property.

We begin with the eigenvalue problem. Let  $\lambda \in \mathbb{C}$  be an eigenvalue of  $\mathcal{A}$  and  $(f, g)$  be a corresponding eigenvector. Then we have

$$(3.1) \quad \begin{cases} g(x) = \lambda f(x), & x \in [0, 1], \\ \lambda^2 M f(x) = T f''(x), & x \in (0, 1), \\ f(0) = C f(1), \\ T f'(1) - C^T T f'(0) = -\lambda \Gamma f(1). \end{cases}$$

Set

$$\hat{f}(x) = T^{1/2} f(x), \quad \hat{g}(x) = T^{1/2} g(x), \quad B^2 = T^{-1/2} M T^{-1/2},$$

where  $B$  is a positive definite matrix. Then (3.1) is equivalent to the following equation:

$$(3.2) \quad \begin{cases} \hat{g}(x) = \lambda \hat{f}(x), & x \in [0, 1], \\ \lambda^2 B^2 \hat{f}(x) = \hat{f}''(x), & x \in (0, 1), \\ \hat{f}(0) = T^{1/2} C T^{-1/2} \hat{f}(1), \\ \hat{f}'(1) - T^{-1/2} C^T T^{1/2} \hat{f}'(0) = -\lambda T^{-1/2} \Gamma T^{-1/2} \hat{f}(1). \end{cases}$$

Clearly, the general solution of the differential equation in (3.2) is of the form

$$(3.3) \quad \hat{f}(x) = e^{x\lambda B} u + e^{-x\lambda B} v, \quad u, v \in \mathbb{C}^N.$$

Substituting this into the boundary conditions in (3.2) leads to

$$(3.4) \quad \begin{cases} (B + T^{-1/2} \Gamma T^{-1/2}) e^{\lambda B} u + (T^{-1/2} \Gamma T^{-1/2} - B) e^{-\lambda B} v \\ = T^{-1/2} C^T T^{1/2} B(u - v), \\ (u + v) = T^{1/2} C T^{-1/2} (e^{\lambda B} u + e^{-\lambda B} v). \end{cases}$$

The above algebraic equation has a nonzero solution  $(u, v)$  and this implies that the determinant of the coefficient matrix vanishes, i.e.,

$$(3.5) \quad D(\lambda) = \det \begin{bmatrix} I - \widehat{C}e^{\lambda B} & I - \widehat{C}e^{-\lambda B} \\ (B + \widehat{\Gamma})e^{\lambda B} - \widehat{C}^\tau B & (\widehat{\Gamma} - B)e^{-\lambda B} + \widehat{C}^\tau B \end{bmatrix} = 0,$$

where  $\widehat{C} = T^{1/2}CT^{-1/2}$ ,  $\widehat{\Gamma} = T^{-1/2}\Gamma T^{-1/2}$ .

Conversely, if  $\lambda \in \mathbb{C}$  such that  $D(\lambda) = 0$ , then (3.4) has a nonzero solution  $(u, v)$ . We can define function  $\widehat{f}$  as being the same as (3.3). Obviously,  $\widehat{f}$  satisfies the equation

$$\widehat{f}''(x) = \lambda^2 B^2 \widehat{f}(x).$$

Equation (3.4) implies that  $\widehat{f}$  satisfies the boundary conditions in (3.2). Consequently, the functions

$$f(x) = T^{-1/2}\widehat{f}(x), \quad g(x) = \lambda T^{-1/2}\widehat{f}(x)$$

satisfy (3.1). Therefore,  $\lambda$  is an eigenvalue of  $\mathcal{A}$ .

Since

$$\begin{aligned} D(\lambda) &= \det \begin{bmatrix} I - \widehat{C}e^{\lambda B} & I - \widehat{C}e^{-\lambda B} \\ (B + \widehat{\Gamma})e^{\lambda B} - \widehat{C}^\tau B & (\widehat{\Gamma} - B)e^{-\lambda B} + \widehat{C}^\tau B \end{bmatrix} \\ &= \det \begin{bmatrix} e^{-\lambda B} - \widehat{C} & I - \widehat{C}e^{-\lambda B} \\ (B + \widehat{\Gamma}) - \widehat{C}^\tau B e^{-\lambda B} & (\widehat{\Gamma} - B)e^{-\lambda B} + \widehat{C}^\tau B \end{bmatrix} \det \begin{bmatrix} e^{\lambda B} & 0 \\ 0 & I \end{bmatrix} \\ &= \det \begin{bmatrix} I - \widehat{C}e^{\lambda B} & e^{\lambda B} - \widehat{C} \\ (B + \widehat{\Gamma})e^{\lambda B} - \widehat{C}^\tau B & (\widehat{\Gamma} - B) + \widehat{C}^\tau B e^{\lambda B} \end{bmatrix} \det \begin{bmatrix} I & 0 \\ 0 & e^{-\lambda B} \end{bmatrix}, \end{aligned}$$

when  $\Re \lambda \rightarrow \pm\infty$ , we have

$$(3.6) \quad \lim_{\Re \lambda \rightarrow +\infty} \frac{D(\lambda)}{\det(e^{\lambda B})} = \det \begin{bmatrix} -\widehat{C} & I \\ (B + \widehat{\Gamma}) & \widehat{C}^\tau B \end{bmatrix} = (-1)^n \det[\widehat{\Gamma} + B + \widehat{C}^\tau B \widehat{C}]$$

and

$$(3.7) \quad \lim_{\Re \lambda \rightarrow -\infty} \frac{D(\lambda)}{\det(e^{-\lambda B})} = \det \begin{bmatrix} I & -\widehat{C} \\ -\widehat{C}^\tau B & (\widehat{\Gamma} - B) \end{bmatrix} = \det[\widehat{\Gamma} - B - \widehat{C}^\tau B \widehat{C}].$$

Therefore, we have the following result.

**THEOREM 3.1.** *Let  $\mathcal{A}$  be defined as in (2.2) and (2.3) and let*

$$(3.8) \quad B^2 = T^{-1/2}MT^{-1/2}, \quad \widehat{C} = T^{1/2}CT^{-1/2}, \quad \widehat{\Gamma} = T^{-1/2}\Gamma T^{-1/2},$$

*and  $D(\lambda)$  be defined by (3.5). Then*

$$(3.9) \quad \sigma(\mathcal{A}) = \{\lambda \in \mathbb{C} \mid D(\lambda) = 0\}.$$

*When  $\det[\widehat{\Gamma} - B - \widehat{C}^\tau B \widehat{C}] \neq 0$ , there is a positive constant  $h > 0$  such that*

$$(3.10) \quad \sigma(\mathcal{A}) \subset \{\lambda \in \mathbb{C} \mid -h \leq \Re \lambda < 0\}.$$

In this case,  $\sigma(\mathcal{A})$  is a union of finite many separated sets.

*Proof.* Let  $\lambda \in \mathbb{C}$  with  $\lambda \neq 0$ . For any given  $(u, v) \in \mathcal{H}$ , we consider the resolvent equation  $(\lambda I - \mathcal{A})(f, g) = (u, v)$ , i.e.,

$$(3.11) \quad \begin{cases} \lambda f - g = u, \\ \lambda g - M^{-1}Tf'' = v, \\ f(0) = Cf(1), \\ Tf'(1) - C^\tau Tf'(0) = -\Gamma g(1). \end{cases}$$

So,  $g = \lambda f - u$ , and  $f$  satisfies the following differential equation:

$$(3.12) \quad \begin{cases} \lambda^2 f(x) - M^{-1}Tf''(x) = \lambda u(x) + v(x), & x \in (0, 1), \\ f(0) = Cf(1), \\ Tf'(1) - C^\tau Tf'(0) + \lambda \Gamma f(1) = \Gamma u(1). \end{cases}$$

Set

$$\hat{f}(x) = T^{1/2}f(x), \quad \hat{g}(x) = T^{1/2}g(x), \quad \hat{u}(x) = T^{1/2}u(x), \quad \hat{v}(x) = T^{1/2}v(x).$$

Then (3.12) is changed into

$$(3.13) \quad \begin{cases} \lambda^2 B^2 \hat{f}(x) - \hat{f}''(x) = \lambda B^2 \hat{u}(x) + B^2 \hat{v}(x), & x \in (0, 1), \\ \hat{f}(0) = \hat{C}\hat{f}(1), \\ \hat{f}'(1) - \hat{C}^\tau \hat{f}'(0) + \lambda \hat{\Gamma} \hat{f}(1) = \hat{\Gamma} \hat{u}(1), \end{cases}$$

where  $B$ ,  $\hat{C}$ , and  $\hat{\Gamma}$  are defined as in (3.8).

Clearly, the differential equation in (3.13) has the general solution

$$(3.14) \quad \hat{f}(x) = e^{x\lambda B}y + e^{-x\lambda B}z - \int_0^x \sinh(\lambda(x-s)B)[B\hat{u}(s) + \lambda^{-1}B\hat{v}(s)]ds,$$

where  $y, z \in \mathbb{C}^N$ . Substituting (3.14) into the boundary conditions in (3.13) yields

$$(3.15) \quad \begin{cases} (I - \hat{C}e^{\lambda B})y + (I - \hat{C}e^{-\lambda B})z \\ = -\hat{C} \int_0^1 \sinh(\lambda(1-s)B)[B\hat{u}(s) + \lambda^{-1}B\hat{v}(s)]ds, \\ \left[ (\hat{\Gamma} + B)e^{\lambda B} - \hat{C}^\tau B \right] y + \left[ (\hat{\Gamma} - B)e^{-\lambda B} + \hat{C}^\tau B \right] z \\ = \int_0^1 \left[ B \cosh(\lambda(1-s)B) + \hat{\Gamma} \sinh(\lambda(1-s)B) \right] [B\hat{u}(s) + \lambda^{-1}B\hat{v}(s)]ds \\ + \lambda^{-1}\Gamma u(1). \end{cases}$$

Since the coefficient matrix of the above algebraic equations is

$$(3.16) \quad \tilde{G}(\lambda) = \begin{pmatrix} I - \hat{C}e^{\lambda B} & I - \hat{C}e^{-\lambda B} \\ (\hat{\Gamma} + B)e^{\lambda B} - \hat{C}^\tau B & (\hat{\Gamma} - B)e^{-\lambda B} + \hat{C}^\tau B \end{pmatrix},$$

when  $D(\lambda) = \det \tilde{G}(\lambda) \neq 0$ , we have

$$(3.17) \quad \tilde{G}^{-1}(\lambda) = \frac{\text{adj } \tilde{G}(\lambda)}{D(\lambda)} = \frac{1}{D(\lambda)} \begin{pmatrix} \hat{G}_{11}(\lambda) & \hat{G}_{12}(\lambda) \\ \hat{G}_{21}(\lambda) & \hat{G}_{22}(\lambda) \end{pmatrix},$$

where  $\text{adj}(S)$  denotes the adjoint matrix of  $S$ . We define functionals  $F_1, F_2$  on  $\mathcal{H}$  by

$$(3.18) \quad \begin{aligned} F_1(u, v, \lambda) &= -\widehat{G}_{11}(\lambda)\widehat{C} \int_0^1 \sinh(1-s)[B\widehat{u}(s) + \lambda^{-1}B\widehat{v}(s)]ds \\ &+ \widehat{G}_{12}(\lambda) \int_0^1 \left[ \widehat{\Gamma} \sinh(\lambda(1-s)B) + B \cosh(\lambda(1-s)B) \right] [B\widehat{u}(s) + \lambda^{-1}B\widehat{v}(s)]ds \\ &+ \widehat{G}_{12}(\lambda)\lambda^{-1}\widehat{\Gamma}\widehat{u}(1), \end{aligned}$$

$$(3.19) \quad \begin{aligned} F_2(u, v, \lambda) &= -\widehat{G}_{21}(\lambda)\widehat{C} \int_0^1 \sinh(\lambda((1-s)B)[B\widehat{u}(s) + \lambda^{-1}B\widehat{v}(s)]ds \\ &+ \widehat{G}_{22}(\lambda) \int_0^1 \left[ B \cosh(\lambda(1-s)B) + \widehat{\Gamma} \sinh(\lambda(1-s)B) \right] [B\widehat{u}(s) + \lambda^{-1}B\widehat{v}(s)]ds \\ &+ G_{22}(\lambda)\lambda^{-1}\widehat{\Gamma}\widehat{u}(1). \end{aligned}$$

Obviously,  $F_1$  and  $F_2$  as defined by (3.18) and (3.19), respectively, are bounded linear functionals on  $\mathcal{H}$ , and the solution to (3.15) is given by

$$(y, z) = D^{-1}(\lambda)(F_1(u, v, \lambda), F_2(u, v, \lambda)).$$

Therefore, when  $\lambda \in \mathbb{C}$  with  $D(\lambda) \neq 0$ , we have

$$(3.20) \quad \begin{aligned} \widehat{f}(x) &= D^{-1}(\lambda) [e^{x\lambda B}F_1(u, v, \lambda) + e^{-x\lambda B}F_2(u, v, \lambda)] \\ &- \int_0^x \sinh((x-s)\lambda B)[B\widehat{u}(s) + \lambda^{-1}B\widehat{v}(s)]ds. \end{aligned}$$

Set

$$(3.21) \quad f(x) = T^{-1/2}\widehat{f}(x), \quad g(x) = \lambda T^{-1/2}\widehat{f}(x) - u(x).$$

A straightforward calculation shows  $(f, g) \in \mathcal{D}(\mathcal{A})$  and

$$(\lambda I - \mathcal{A})(f, g) = (u, v).$$

So we have that  $\lambda \in \rho(\mathcal{A})$ . The first assertion follows.

Now let  $D(\lambda)$  be defined by (3.5). Then  $D(\lambda)$  is an entire function of finite exponential type on complex plane  $\mathbb{C}$ . From (3.6) and (3.7) we can see that, when  $\det[\widehat{\Gamma} - B - \widehat{C}^\tau B \widehat{C}] \neq 0$ , there are positive constants  $c_1, c_2$ , and  $h$  such that, as  $|\Re \lambda| \geq h$ ,

$$(3.22) \quad c_1 \det(e^{|\lambda|B}) \leq |D(\lambda)| \leq c_2 \det(e^{|\lambda|B}).$$

This means that  $D(\lambda)$  is a sine-type function on  $\mathbb{C}$  (see [23, Definition II.1.27, p. 61]). Levin's theorem (see [23, Proposition II.1.28]) asserts that the set of zeros of  $D(\lambda)$  is a union of finitely many separable sets. So also is  $\sigma(\mathcal{A})$ . The proof is then complete.  $\square$

In what follows we shall discuss the completeness of eigenvectors and generalized eigenvectors of  $\mathcal{A}$ . For this purpose, we begin with the following proposition.

**PROPOSITION 3.2.** *Let  $\mathcal{H}$  be defined as before. Define operator  $\mathcal{A}_0$  in  $\mathcal{H}$  by*

$$\begin{aligned} \mathcal{D}(\mathcal{A}_0) &= \{(f, g) \in V_E^2(0, 1) \times V_E^1(0, 1) \mid T f'(1) - C^\tau T f'(0) = 0\}, \\ \mathcal{A}_0(f, g) &= (g(x), M^{-1}T f''(x)). \end{aligned}$$

Then  $\mathcal{A}_0$  is a skew adjoint operator in  $\mathcal{H}$ , and for any  $(u, v) \in \mathcal{H}$ ,  $\lambda \in \mathbb{R}$ , the solution  $(f_\lambda, g_\lambda)$  of the resolvent equation

$$\lambda(f, g) - \mathcal{A}_0(f, g) = (u, v)$$

satisfies

$$\|g_\lambda(1)\| \leq M\|(u, v)\|_{\mathcal{H}},$$

where  $M > 0$  is a constant.

*Proof.* For any  $(f_i, g_i) \in \mathcal{D}(\mathcal{A}_0)$ ,  $i = 1, 2$ , it holds that

$$\begin{aligned} \langle \mathcal{A}_0(f_1, g_1), (f_2, g_2) \rangle_{\mathcal{H}} &= \int_0^1 (Tg'_1(x), f'_2(x))dx + \int_0^1 (MM^{-1}Tf''_1(x), g_2(x))dx \\ &= (Tg_1(x), f'_2(x)) \Big|_0^1 - \int_0^1 (Tg_1(x), f''_2(x))dx \\ &\quad + (Tf'_1(x), g_2(x)) \Big|_0^1 - \int_0^1 ((Tf'_1(x), g'_2(x))dx \\ &= (Tg_1(x), f'_2(x)) \Big|_0^1 + (Tf'_1(x), g_2(x)) \Big|_0^1 - \langle (f_1, g_1), \mathcal{A}_0(f_2, g_2) \rangle_{\mathcal{H}} \\ &= (g_1(1), Tf'_2(1)) - (g_1(0), Tf'_2(0)) + (Tf'_1(1), g_2(1)) - (Tf'_1(0), g_2(0)) \\ &\quad - \langle (f_1, g_1), \mathcal{A}_0(f_2, g_2) \rangle_{\mathcal{H}} \\ &= (g_1(1), Tf'_2(1) - C^T T f'(0)) + (Tf'_1(1) - C^T Tf'_1(0), g_2(1)) - \langle (f_1, g_1), \mathcal{A}_0(f_2, g_2) \rangle_{\mathcal{H}} \\ &= -\langle (f_1, g_1), \mathcal{A}_0(f_2, g_2) \rangle_{\mathcal{H}}. \end{aligned}$$

So,  $\mathcal{A}_0^* = -\mathcal{A}_0$ .

Now let  $(u, v) \in \mathcal{H}$  be given and  $\lambda \in \mathbb{R}$ . Let  $(f_\lambda, g_\lambda)$  satisfy the resolvent equation

$$(\lambda I - \mathcal{A}_0)(f, g) = (u, v), \quad (f, g) \in \mathcal{D}(\mathcal{A}_0),$$

i.e.,

$$\lambda f_\lambda(x) - g_\lambda(x) = u(x), \quad \lambda g_\lambda(x) - M^{-1}Tf''_\lambda(x) = v(x)$$

and

$$f_\lambda(0) = Cf_\lambda(1), \quad Tf'_\lambda(1) - C^T Tf'_\lambda(0) = 0.$$

Since

$$f_\lambda(1) = \int_0^1 f'_\lambda(x)dx + f_\lambda(0) = \int_0^1 f'_\lambda(x)dx + Cf_\lambda(1),$$

we have

$$f_\lambda(1) = (I - C)^{-1} \int_0^1 f'_\lambda(x)dx.$$

Similarly,

$$u(1) = (I - C)^{-1} \int_0^1 u'(x)dx.$$

Thus,

$$g_\lambda(1) = \lambda f_\lambda(1) - u(1) = (I - C)^{-1}T^{-1/2} \left[ \lambda \int_0^1 T^{1/2} f'(x) dx - \int_0^1 T^{1/2} u'(x) dx \right].$$

Consequently,

$$\begin{aligned} \|g_\lambda(1)\| &\leq \left\| (I - C)^{-1}T^{-1/2} \right\| \left[ |\lambda| \int_0^1 (T f'(x), f'(x)) dx + \int_0^1 (T u'(x), u'(x)) dx \right] \\ &\leq \left\| (I - C)^{-1}T^{-1/2} \right\| [\|\lambda\| R(\lambda, \mathcal{A}_0)(u, v)\|_{\mathcal{H}} + \|(u, v)\|_{\mathcal{H}}]. \end{aligned}$$

Since  $\mathcal{A}_0$  is a skew adjoint operator,  $\|\lambda R(\lambda, \mathcal{A}_0)\| \leq 1$ ,  $\lambda \in \mathbb{R}$ , we have

$$\|g_\lambda(1)\| \leq 2\|(I - C)^{-1}T^{-1/2}\| \|(u, v)\|_{\mathcal{H}} \quad \forall \lambda \in \mathbb{R}.$$

The desired result follows.  $\square$

**THEOREM 3.3.** *Let  $\mathcal{H}$  and  $\mathcal{A}$  be defined as before. If  $\det(\widehat{\Gamma} - B - \widehat{C}^\tau B \widehat{C}) \neq 0$ , then the system of eigenvectors and generalized eigenvectors of  $\mathcal{A}$  is complete in  $\mathcal{H}$ .*

*Proof.* Let  $\mathcal{H}$  and  $\mathcal{A}$  be defined as before, and let  $\mathcal{A}_0$  be as defined in Proposition 3.2. Denote

$$Sp(\mathcal{A}) = \overline{\text{span} \left\{ \sum y_k, y_k \in E(\lambda_k, \mathcal{A})\mathcal{H} \quad \forall \lambda_k \in \sigma(\mathcal{A}) \right\}},$$

where  $E(\lambda_k, \mathcal{A})$  is the Riesz projector corresponding to  $\lambda_k$ . We shall prove  $Sp(\mathcal{A}) = \mathcal{H}$ .

Let  $(u_0, v_0) \in \mathcal{H}$  and  $(u_0, v_0) \perp Sp(\mathcal{A})$ . Then  $R^*(\lambda, \mathcal{A})(u_0, v_0)$  is an entire function on  $\mathbb{C}$  valued in  $\mathcal{H}$ . For any  $(u, v) \in \mathcal{H}$ , we define a function on complex plane  $\mathbb{C}$  by

$$F(\lambda) = \langle (u, v), R^*(\lambda, \mathcal{A})(u_0, v_0) \rangle_{\mathcal{H}}.$$

Clearly,  $F(\lambda)$  is an entire function of finite exponential type, and

$$|F(\lambda)| \leq (\Re \lambda)^{-1} \|(u, v)\|_{\mathcal{H}} \|(u_0, v_0)\|_{\mathcal{H}}, \quad \Re \lambda > 0,$$

and hence  $\lim_{\Re \lambda \rightarrow +\infty} |F(\lambda)| = 0$ .

Now we consider the solution of equations

$$(\lambda I - \mathcal{A})(f_{1\lambda}, g_{1\lambda}) = (u, v), \quad (\lambda I - \mathcal{A}_0)(f_{2\lambda}, g_{2\lambda}) = (u, v), \quad \lambda \in \rho(\mathcal{A}) \cap \rho(\mathcal{A}_0) \cap \mathbb{R}_-.$$

Set

$$\varphi(x) = f_{1\lambda}(x) - f_{2\lambda}(x), \quad \psi(x) = g_{1\lambda}(x) - g_{2\lambda}(x).$$

Then we have

$$R(\lambda, \mathcal{A})(u, v) = (f_{1\lambda}, g_{1\lambda}) = (f_{2\lambda}, g_{2\lambda}) + (\varphi, \psi) = R(\lambda, \mathcal{A}_0)(u, v) + (\varphi, \psi),$$

$\psi(x) = \lambda \varphi(x)$ , and  $\varphi$  satisfies the following equations:

$$\begin{cases} \lambda^2 M \varphi(x) = T \varphi''(x), & x \in (0, 1), \\ \varphi(0) = C \varphi(1), \\ T \varphi'(1) - C^\tau T \varphi'(0) + \lambda \Gamma \varphi(1) = \Gamma g_{2\lambda}(1). \end{cases}$$

Setting  $\widehat{\varphi}(x) = T^{1/2}\varphi(x)$  and using the previous notation, we have

$$\widehat{\varphi}(x) = e^{x\lambda B}y + e^{-x\lambda B}z, \quad y, z \in \mathbb{C}^N,$$

where  $y$  and  $z$  solve the equations

$$\begin{cases} (I - \widehat{C}e^{\lambda B})y + (I - \widehat{C}e^{-\lambda B})z = 0, \\ [(\widehat{\Gamma} + B)e^{\lambda B} - \widehat{C}^\tau B]y + [(\widehat{\Gamma} - B)e^{-\lambda B} + \widehat{C}^\tau B]z = \lambda^{-1}T^{1/2}\Gamma g_{2\lambda}(1). \end{cases}$$

Thus

$$\begin{cases} y = (I - \widehat{C}e^{\lambda B})^{-1}(\widehat{C} - e^{\lambda B})e^{-\lambda B}z = (\widehat{C} - O_1(\lambda))e^{-\lambda B}z, \\ [\widehat{\Gamma} - B - \widehat{C}^\tau B\widehat{C} - O_2(\lambda)]e^{-\lambda B}z = \lambda^{-1}T^{1/2}\Gamma g_{2\lambda}(1), \end{cases}$$

where  $\|O_j(\lambda)\| = o(\lambda^{-1})$ ,  $j = 1, 2$ , as  $\lambda \rightarrow -\infty$ . This means that

$$e^{-\lambda B}z = \lambda^{-1}(\widehat{\Gamma} - B - \widehat{C}^\tau B\widehat{C} + O_2(\lambda))^{-1}T^{1/2}\Gamma g_{2\lambda}(1).$$

Therefore, when  $|\lambda|$  is sufficiently large, we have

$$\begin{aligned} \widehat{\varphi}(1) &= e^{\lambda B}y + e^{-\lambda B}z = e^{\lambda B}(\widehat{C} - O_1(\lambda))e^{-\lambda B}z + e^{-\lambda B}z \\ &= (I + O_3(\lambda))e^{-\lambda B}z \\ &= \lambda^{-1}(I + O_3(\lambda))(\widehat{\Gamma} - B - \widehat{C}^\tau B\widehat{C} + O_2(\lambda))^{-1}T^{1/2}\Gamma g_{2\lambda}(1). \end{aligned}$$

So, there is a constant  $M_1 > 0$  such that

$$\|\widehat{\varphi}(1)\| \leq M_1|\lambda^{-1}|\|g_{2\lambda}(1)\|.$$

Thus,

$$\begin{aligned} \|(\varphi, \psi)\|_{\mathcal{H}}^2 &= \int_0^1 (T\varphi'(x), \varphi'(x))dx + \int_0^1 (M\psi(x), \psi(x))dx \\ &= (T\varphi'(1), \varphi(1)) - (T\varphi'(0), \varphi(0)) \\ &= -\lambda(\Gamma\varphi(1), \varphi(1)) + (\Gamma g_{2\lambda}, \varphi(1)) \\ &= -\lambda(\widehat{\Gamma}\widehat{\varphi}(1), \widehat{\varphi}(1)) + (T^{-1/2}\Gamma g_{2\lambda}(1), \widehat{\varphi}(1)) \\ &\leq -\lambda\|\widehat{\Gamma}\|\|\widehat{\varphi}(1)\|^2 + \|T^{-1/2}\Gamma\|\|g_{2\lambda}\|\|\widehat{\varphi}(1)\| \\ &\leq |\lambda^{-1}|\|\Gamma\|M_1^2\|g_{2\lambda}(1)\|^2 + \|T^{-1/2}\Gamma\|\|g_{2\lambda}(1)\|M_1|\lambda^{-1}|\|g_{2\lambda}\| \\ &\leq M_2|\lambda^{-1}|\|g_{2\lambda}(1)\|^2, \end{aligned}$$

where  $M_2$  is a positive constant. According to Proposition 3.2, we have  $\|g_{2\lambda}(1)\| \leq M\|(u, v)\|_{\mathcal{H}}$ , and hence there is a positive constant  $M_3$  such that

$$\|(\varphi, \psi)\|_{\mathcal{H}} \leq M_3\sqrt{|\lambda^{-1}|}\|(u, v)\|_{\mathcal{H}}.$$

Therefore we get that, for  $\lambda \in \rho(\mathcal{A}) \cap \mathbb{R}_-$  with  $|\lambda|$  large enough,

$$\begin{aligned} |F(\lambda)| &= |\langle R(\lambda, \mathcal{A})(u, v), (u_0, v_0) \rangle_{\mathcal{H}}| = |\langle R(\lambda, \mathcal{A}_0)(u, v), (u_0, v_0) \rangle_{\mathcal{H}} + \langle (\varphi, \psi), (u_0, v_0) \rangle_{\mathcal{H}}| \\ &\leq |\lambda^{-1}|\|(u, v)\|_{\mathcal{H}}\|(u_0, v_0)\|_{\mathcal{H}} + \|(\varphi, \psi)\|_{\mathcal{H}}\|(u_0, v_0)\|_{\mathcal{H}} \\ &\leq |\lambda^{-1}|\|(u, v)\|_{\mathcal{H}}\|(u_0, v_0)\|_{\mathcal{H}} + M_3\sqrt{|\lambda^{-1}|}\|(u, v)\|_{\mathcal{H}}\|(u_0, v_0)\|_{\mathcal{H}}. \end{aligned}$$

Since  $F(\lambda)$  is an entire function of finite exponential type, the above inequality, together with the Phragmén–Lindelöf theorem (cf. [22]), implies  $F(\lambda) \equiv 0$ . So  $R^*(\lambda, \mathcal{A})(u_0, v_0) \equiv 0$ , which implies  $(u_0, v_0) = 0$ . Thus  $Sp(\mathcal{A}) = \mathcal{H}$ . The proof is then complete.  $\square$

In order to obtain the Riesz basis property of eigenvectors and generalized eigenvectors of  $\mathcal{A}$ , we need the following theorem, which comes from [25] and is an extension of the result in [24].

**THEOREM 3.4.** *Let  $\mathcal{A}$  be the generator of a  $C_0$  semigroup  $T(t)$  on a separable Hilbert space  $\mathcal{H}$ . Suppose that the following conditions are satisfied:*

(1) *The spectrum of  $\mathcal{A}$  has a decomposition*

$$(3.23) \quad \sigma(\mathcal{A}) = \sigma_1(\mathcal{A}) \cup \sigma_2(\mathcal{A}),$$

*where  $\sigma_2(\mathcal{A})$  consists of the isolated eigenvalues of  $\mathcal{A}$  of finite multiplicity (repeated many times according to its algebraic multiplicity).*

(2) *There exists a real number  $\alpha \in \mathbb{R}$  such that*

$$(3.24) \quad \sup\{\Re \lambda, \lambda \in \sigma_1(\mathcal{A})\} \leq \alpha \leq \inf\{\Re \lambda, \lambda \in \sigma_2(\mathcal{A})\}.$$

(3) *The set  $\sigma_2(\mathcal{A})$  is a union of finite many separated sets.*

*Then the following statements are true:*

(i) *There exist two  $T(t)$ -invariant closed subspaces  $\mathcal{H}_1$  and  $\mathcal{H}_2$  with the property that  $\sigma(\mathcal{A}|_{\mathcal{H}_1}) = \sigma_1(\mathcal{A})$ ,  $\sigma(\mathcal{A}|_{\mathcal{H}_2}) = \sigma_2(\mathcal{A})$ , and there exists a finite combination  $E(\Omega_k, \mathcal{A})$  of some  $\{E(\lambda_k, \mathcal{A})\}_{k=1}^\infty$ ,*

$$(3.25) \quad E(\Omega_k, \mathcal{A}) = \sum_{\lambda \in \Omega_k \cap \sigma_2(\mathcal{A})} E(\lambda, \mathcal{A}),$$

*such that  $\{E(\Omega_k, \mathcal{A})\mathcal{H}_2\}_{k \in \mathbb{N}}$  forms a Riesz basis of subspaces for  $\mathcal{H}_2$  (see [26, p. 332]). Furthermore,*

$$\mathcal{H} = \overline{\mathcal{H}_1 \oplus \mathcal{H}_2}.$$

(ii) *If  $\sup_{k \geq 1} \|E(\lambda_k, \mathcal{A})\| < \infty$ , then*

$$(3.26) \quad \mathcal{D}(\mathcal{A}) \subset \mathcal{H}_1 \oplus \mathcal{H}_2 \subset \mathcal{H}.$$

(iii)  *$\mathcal{H}$  has a decomposition of the topological direct sum,  $\mathcal{H} = \mathcal{H}_1 \oplus \mathcal{H}_2$ , if and only if*

$$(3.27) \quad \sup_{n \geq 1} \left\| \sum_{k=1}^n E(\Omega_k, \mathcal{A}) \right\| < \infty.$$

Combining Theorems 3.1, 3.3, and 3.4, we can get the following result.

**THEOREM 3.5.** *Let  $\mathcal{A}$  be defined by (2.2) and (2.3); let  $S(t)$  be the  $C_0$  semigroup associated with  $\mathcal{A}$ ; and let  $B$ ,  $\widehat{\Gamma}$ , and  $\widehat{C}$  be defined as in Theorem 3.1. If  $\det(\widehat{\Gamma} - B - \widehat{C}^\tau B \widehat{C}) \neq 0$ , then there is a sequence of eigenvectors and generalized eigenvectors of  $\mathcal{A}$  that forms a Riesz basis with parentheses for  $\mathcal{H}$ . Therefore,  $S(t)$  satisfies the spectrum determined growth assumption. In addition,  $S(t)$  is in fact a  $C_0$  group on  $\mathcal{H}$ .*

*Proof.* Let  $\mathcal{A}$  be defined by (2.2) and (2.3), and let  $S(t)$  be the  $C_0$  semigroup associated with  $\mathcal{A}$ . Set  $\sigma_1(\mathcal{A}) = \{-\infty\}$ ,  $\sigma_2(\mathcal{A}) = \sigma(\mathcal{A})$ . Theorem 3.1 shows that

all the conditions in Theorem 3.4 are fulfilled, so the results of Theorem 3.4 apply. Thus there is a sequence of eigenvectors and generalized eigenvectors of  $\mathcal{A}$  that forms a Riesz basis with parentheses for  $\mathcal{H}_2$ . Theorem 3.3 says that the eigenvectors and generalized eigenvectors sequence is complete in  $\mathcal{H}$ , that is,  $\mathcal{H}_2 = \mathcal{H}$ . Therefore the sequence is also a Riesz basis with parentheses for  $\mathcal{H}$ . The basis property, together with the uniform boundedness of the multiplicities of eigenvalues of  $\mathcal{A}$ , implies that  $S(t)$  satisfies the spectrum determined growth assumption. Also, the basis property of eigenvectors and generalized eigenvectors, together with the spectral distribution of  $\mathcal{A}$ , asserts that  $\mathcal{A}$  generates a  $C_0$  group on  $\mathcal{H}$ . The proof is then complete.  $\square$

As a consequence of the Riesz basis property, we have the following stability result of the system.

**THEOREM 3.6.** *Let  $\mathcal{H}$  and  $\mathcal{A}$  be defined as before, and let  $B$ ,  $\widehat{\Gamma}$ , and  $\widehat{C}$  be defined as in Theorem 3.1. Let  $\det(\widehat{\Gamma} - B - \widehat{C}^\tau B \widehat{C}) \neq 0$  and  $D(\lambda)$  be defined as (3.5). Then the following statements are true:*

- (1) *If  $\inf_{\lambda \in i\mathbb{R}} |D(\lambda)| \neq 0$ , then the system (2.4) is exponentially stable.*
- (2) *If  $\inf_{\lambda \in i\mathbb{R}} |D(\lambda)| = 0$ , then the system (2.4) is asymptotically stable but not exponentially stable.*

*Proof.* Under the above assumptions, Theorem 3.5 shows that the system (2.4) is a Riesz system and satisfies the spectrum determined growth condition. Note that

$$\sigma(\mathcal{A}) = \{\lambda \in \mathbb{C} \mid D(\lambda) = 0\}.$$

If  $\inf_{\lambda \in i\mathbb{R}} |D(\lambda)| \neq 0$ , then the imaginary axis is not an asymptote of  $\sigma(\mathcal{A})$ , which implies the system is exponentially stable. If  $\inf_{\lambda \in i\mathbb{R}} |D(\lambda)| = 0$ , then the imaginary axis is an asymptote of  $\sigma(\mathcal{A})$ , and hence the system is asymptotically stable but not exponentially stable. The proof is then complete.  $\square$

In the discussion above, we assumed that  $\Gamma$  is a positive definite matrix to ensure that there are no eigenvalues on the imaginary axis. This restriction can be relaxed—indeed, if  $\Gamma$  is a nonnegative matrix, then the results in Theorems 3.5 and 3.6 apply.

**4. Applications.** In this section we shall give two examples of this problem in practice. One is the tree-shaped network of 7-strings and the other is a network of  $N$ -connected strings. Both examples are put into the framework of (2.1), and we shall prove that both systems are exponentially stable.

**4.1. Tree-shaped network of 7-strings.** In this subsection we discuss the tree-shaped network of strings whose configuration is a simple, connected graph without closed paths.

In the past decade, the controllability and observability, as well as the stabilization, of networks of strings has been a hot topic. Many authors have obtained some nice results. For example, the authors in [5], [6], [7], and [8] discussed the problem of observability and controllability of a tree-shaped network of  $n$  strings, and the authors in [9] and [10] discussed the stabilization problem of star-shaped networks and generic trees of strings. For a more general discussion on networks of strings, and for a comprehensive list of papers on this subject, we refer the reader to the recently published book [11]. As an example, here we give the Riesz basis property and exponential stability of this system for  $n = 7$  with the shape shown in Figure 1.

First, we formulate the model into a normal form. We denote the strings by  $u_j$ ,  $j = 1, 2, \dots, 7$ . We normalize the strings to length one, and then they satisfy the equation

$$(4.1) \quad m_j u_{j,tt}(x, t) = T_j u_{j,xx}(x, t), \quad x \in (0, 1), \quad j = 1, 2, \dots, 7.$$

FIG. 1.

The root and the connected conditions are given by

$$(4.2) \quad \begin{aligned} u_1(0, t) &= 0, & u_1(1, t) &= u_2(0, t) = u_3(0, t), \\ u_2(1, t) &= u_4(0, t) = u_5(0, t), & u_3(1, t) &= u_6(0, t) = u_7(0, t), \end{aligned}$$

and the forced conditions at the nodes and edges are

$$(4.3) \quad \begin{aligned} T_1 u_{1,x}(1, t) - [T_2 u_{2,x}(0, t) + T_3 u_{3,x}(0, t)] &= -\alpha_1 u_{1,t}(1, t), \\ T_2 u_{2,x}(1, t) - [T_4 u_{4,x}(0, t) + T_5 u_{5,x}(0, t)] &= -\alpha_2 u_{2,t}(1, t), \\ T_3 u_{3,x}(1, t) - [T_6 u_{6,x}(0, t) + T_7 u_{7,x}(0, t)] &= -\alpha_3 u_{3,t}(1, t), \\ T_4 u_{4,x}(1, t) &= -\alpha_4 u_{4,t}(1, t), \\ T_5 u_{5,x}(1, t) &= -\alpha_5 u_{5,t}(1, t), \\ T_6 u_{6,x}(1, t) &= -\alpha_6 u_{6,t}(1, t), \\ T_7 u_{7,x}(1, t) &= -\alpha_7 u_{7,t}(1, t). \end{aligned}$$

Set

$$Y = [u_1(x, t), u_2(x, t), u_3(x, t), u_4(x, t), u_5(x, t), u_6(x, t), u_7(x, t)]^\tau$$

and denote

$$(4.4) \quad \begin{aligned} M &= \text{diag}[m_1, m_2, \dots, m_7], & T &= \text{diag}[T_1, T_2, \dots, T_7], \\ \Gamma &= \text{diag}[\alpha_1, \alpha_2, \dots, \alpha_7], \end{aligned}$$

and

$$(4.5) \quad C = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

Then (4.1)–(4.3) can be rewritten as

$$(4.6) \quad \begin{cases} M \frac{\partial^2 Y(x,t)}{\partial^2 t} = T \frac{\partial Y(x,t)}{\partial^2 x}, & x \in (0,1), \quad t > 0, \\ Y(0,t) = CY(1,t), & t > 0, \\ T \frac{\partial Y(1,t)}{\partial x} - C^\tau T \frac{\partial Y(0,t)}{\partial x} = -\Gamma \frac{\partial Y(1,t)}{\partial t}, & t > 0, \\ Y(x,0) = Y_0(x), \quad \frac{\partial Y(x,0)}{\partial t} = Y_1(x), \end{cases}$$

where  $Y_0(x)$  and  $Y_1(x)$  are given suitable initial value conditions.

According to Theorem 3.5, we have the following result.

THEOREM 4.1. *The system (4.6) is well-posed and asymptotically stable.*

To obtain exponential stability, we discuss the eigenvalue problem of the system.

Let  $\lambda \in \mathbb{C}$ ,  $Y(x,t) = e^{\lambda t} Y(x)$ ; then we have

$$(4.7) \quad \begin{cases} \lambda^2 MY(x) = TY_{xx}(x), & x \in (0,1), \\ Y(0) = CY(1), \\ TY_x(1) - C^\tau TY_x(0) = -\lambda \Gamma Y(1). \end{cases}$$

Let  $B^2 = \text{diag}[\rho_1^2, \rho_2^2, \dots, \rho_7^2]$ , where  $\rho_j^2 = \frac{m_j}{T_j}$ . Then we have

$$(4.8) \quad \begin{cases} \lambda^2 B^2 Y(x) = Y_{xx}(x), & x \in (0,1), \\ Y(0) = CY(1), \\ TY_x(1) - C^\tau TY_x(0) = -\lambda \Gamma Y(1). \end{cases}$$

Thus  $Y(x)$  has the following form:

$$Y(x) = \sinh(x\lambda B)u + \cosh(x\lambda B)v, \quad u, v \in \mathbb{C}^7.$$

Substituting it into the boundary conditions leads to

$$v = C[\sinh \lambda Bu + \cosh \lambda Bv],$$

$$TB[\cosh \lambda Bu + \sinh \lambda Bv] - C^\tau TBu = -\Gamma[\sinh \lambda Bu + \cosh \lambda Bv].$$

So  $\lambda$  is an eigenvalue if and only if

$$(4.9) \quad D(\lambda) = \det \begin{pmatrix} I - C \cosh \lambda B & -C \sinh \lambda B \\ TB \sinh \lambda B + \Gamma \cosh \lambda B & TB \cosh \lambda B + \Gamma \sinh \lambda B - C^\tau TB \end{pmatrix} = 0.$$

When  $\det[\Gamma - TB - C^\tau TBC] \neq 0$ , all eigenvalues are located in a strip. Note that

$$(4.10) \quad TB = \begin{pmatrix} T_1 \rho_1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & T_2 \rho_2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & T_3 \rho_3 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & T_4 \rho_4 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & T_5 \rho_5 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & T_6 \rho_6 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & T_7 \rho_7 \end{pmatrix},$$

$$(4.11) \quad C^\tau TBC = \begin{pmatrix} T_2 \rho_2 + T_3 \rho_3 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & T_4 \rho_4 + T_5 \rho_5 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & T_6 \rho_6 + T_7 \rho_7 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

The condition  $\det[\Gamma - TB - C^T TBC] \neq 0$  means that

$$\begin{aligned} \alpha_1 &\neq T_1\rho_1 + T_2\rho_2 + T_3\rho_3, & \alpha_2 &\neq T_2\rho_2 + T_4\rho_4 + T_5\rho_5, \\ \alpha_3 &\neq T_3\rho_3 + T_6\rho_6 + T_7\rho_7, & \alpha_j &\neq T_j\rho_j, \quad j = 4, 5, 6, 7. \end{aligned}$$

Set

$$(4.12) \quad \begin{cases} w_j(\lambda) = T_j\rho_j \cosh \lambda\rho_j + \alpha_j \sinh \lambda\rho_j, \\ v_j(\lambda) = T_j\rho_j \sinh \lambda\rho_j + \alpha_j \cosh \lambda\rho_j, \end{cases} \quad j = 1, 2, 3, 4, 5, 6, 7,$$

$$(4.13) \quad \begin{cases} F_2(\lambda) = \frac{1}{T_2\rho_2} [(w_5v_4T_4\rho_4 + w_4v_5T_5\rho_5) \sinh \lambda\rho_2 + w_2w_4w_5], \\ G_2(\lambda) = \frac{1}{T_2\rho_2} [(w_5v_4T_4\rho_4 + w_4v_5T_5\rho_5) \cosh \lambda\rho_2 + v_2w_4w_5], \end{cases}$$

and

$$(4.14) \quad \begin{cases} F_3(\lambda) = \frac{1}{T_3\rho_3} [(w_7v_6T_6\rho_6 + w_6v_7T_7\rho_7) \sinh \lambda\rho_3 + w_3w_6w_7], \\ G_3(\lambda) = \frac{1}{T_3\rho_3} [(w_7v_6T_6\rho_6 + w_6v_7T_7\rho_7) \cosh \lambda\rho_3 + v_3w_6w_7]. \end{cases}$$

A complicated calculation shows that

$$(4.15) \quad \begin{aligned} D(\lambda) &= [T_2\rho_2G_2(\lambda)F_3(\lambda) + T_3\rho_3G_3(\lambda)F_2(\lambda)] \sinh \lambda\rho_1 \\ &\quad + w_1(\lambda)F_2(\lambda)F_3(\lambda). \end{aligned}$$

Now we are in a position to calculate  $\inf_{\sigma \in \mathbb{R}} |D(i\sigma)|$ . Note that

$$\inf_{\sigma \in \mathbb{R}} |w_j(i\sigma)| \neq 0, \quad \inf_{\sigma \in \mathbb{R}} |v_j(i\sigma)| \neq 0, \quad j = 1, 2, 3, 4, 5, 6, 7,$$

$$\frac{v_j(i\sigma)}{w_j(i\sigma)} = \frac{v_j(i\sigma)\overline{w_j(i\sigma)}}{|w_j(i\sigma)|^2} = \frac{\alpha_j T_j \rho_j + i \frac{T_j^2 \rho_j^2 - \alpha_j^2}{2} \sin 2\sigma \rho_j}{T_j^2 \rho_j^2 \cos^2 \sigma \rho_j + \alpha_j^2 \sin^2 \sigma \rho_j},$$

and

$$\frac{i \sin \sigma \rho_j}{w_j(i\sigma)} = \frac{i \sin \sigma \rho_j (T_j \rho_j \cos \sigma \rho_j - i \alpha_j \sin \sigma \rho_j)}{|w_j(i\sigma)|^2} = \frac{\alpha_j \sin^2 \sigma \rho_j + i \frac{T_j \rho_j}{2} \sin 2\sigma \rho_j}{T_j^2 \rho_j^2 \cos^2 \sigma \rho_j + \alpha_j^2 \sin^2 \sigma \rho_j},$$

where  $j = 1, 2, 3$ . From (4.13)–(4.14) we can get

$$\inf_{\sigma \in \mathbb{R}} |F_2(i\sigma)| > 0, \quad \inf_{\sigma \in \mathbb{R}} |F_3(i\sigma)| > 0,$$

$$\begin{aligned} \Re(G_2(i\sigma)\overline{F_2(i\sigma)}) &= [|w_5(i\sigma)|^2 \alpha_4 (T_4 \rho_4)^2 + |w_4(i\sigma)|^2 \alpha_5 (T_5 \rho_5)^2] T_2 \rho_2 \\ &\quad + \alpha_2 T_2 \rho_2 |w_4(i\sigma)|^2 |w_5(i\sigma)|^2 > 0, \end{aligned}$$

and

$$\begin{aligned} \Re(G_3(i\sigma)\overline{F_3(i\sigma)}) &= [|w_7(i\sigma)|^2 \alpha_6 (T_6 \rho_6)^2 + |w_6(i\sigma)|^2 \alpha_7 (T_7 \rho_7)^2] T_3 \rho_3 \\ &\quad + \alpha_3 T_3 \rho_3 |w_6(i\sigma)|^2 |w_7(i\sigma)|^2 > 0. \end{aligned}$$

Consequently, we have

$$\begin{aligned} \frac{D(i\sigma)}{w_1(i\sigma)F_2(i\sigma)F_3(i\sigma)} &= \left[ T_2\rho_2 \frac{G_2(i\sigma)\overline{F_2(i\sigma)}}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{G_3(i\sigma)\overline{F_3(i\sigma)}}{|F_3(i\sigma)|^2} \right] \frac{i \sin \sigma \rho_1 \overline{w_1(i\sigma)}}{|w_1(i\sigma)|^2} + 1 \\ &= \left[ T_2\rho_2 \frac{\Re(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Re(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{\alpha_1 \sin^2 \sigma \rho_1}{|w_1(i\sigma)|^2} + 1 \\ &\quad - \left[ T_2\rho_2 \frac{\Im(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Im(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{T_1\rho_1 \sin 2\sigma \rho_1}{2|w_1(i\sigma)|^2} \\ &\quad + i \left[ T_2\rho_2 \frac{\Re(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Re(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{T_1\rho_1 \sin 2\sigma \rho_1}{2|w_1(i\sigma)|^2} \\ &\quad + i \left[ T_2\rho_2 \frac{\Im(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Im(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{\alpha_1 \sin^2 \sigma \rho_1}{|w_1(i\sigma)|^2}. \end{aligned}$$

When  $\sin \sigma \rho_1 \rightarrow 0$ , we have  $D(i\sigma) \not\rightarrow 0$ . Now we assume that  $\sin \sigma \rho_1 \not\rightarrow 0$ , and then

$$\begin{aligned} &\left[ T_2\rho_2 \frac{\Re(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Re(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{T_1\rho_1 \sin 2\sigma \rho_1}{2|w_1(i\sigma)|^2} \\ &+ \left[ T_2\rho_2 \frac{\Im(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Im(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{\alpha_1 \sin^2 \sigma \rho_1}{|w_1(i\sigma)|^2} \rightarrow 0 \end{aligned}$$

if and only if

$$\begin{aligned} &- \left[ T_2\rho_2 \frac{\Im(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Im(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \\ &= \left[ T_2\rho_2 \frac{\Re(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Re(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{T_1\rho_1 \cos \sigma \rho_1}{\alpha_1 \sin \sigma \rho_1} + o(1). \end{aligned}$$

From above we get that

$$\begin{aligned} \frac{D(i\sigma)}{w_1(i\sigma)F_2(i\sigma)F_3(i\sigma)} &= \left[ T_2\rho_2 \frac{\Re(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Re(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{\alpha_1 \sin^2 \sigma \rho_1}{|w_1(i\sigma)|^2} + 1 \\ &\quad + \left[ T_2\rho_2 \frac{\Re(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Re(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{T_1^2 \rho_1^2 \cos^2 \sigma \rho_1}{\alpha_1 |w_1(i\sigma)|^2} \\ &\quad + o(1) + io(1) \\ &= \left[ T_2\rho_2 \frac{\Re(G_2(i\sigma)\overline{F_2(i\sigma)})}{|F_2(i\sigma)|^2} + T_3\rho_3 \frac{\Re(G_3(i\sigma)\overline{F_3(i\sigma)})}{|F_3(i\sigma)|^2} \right] \frac{1}{\alpha_1} + 1 + o(1) + io(1). \end{aligned}$$

Therefore,

$$\inf_{\sigma \in \mathbb{R}} |D(i\sigma)| \neq 0.$$

According to Theorems 3.5 and 3.6, we have the following result.

**THEOREM 4.2.** *Let  $\mathcal{H}$  be defined as in section 3 and let  $\alpha_1 \neq T_1\rho_1 + T_2\rho_2 + T_3\rho_3$ ,  $\alpha_2 \neq T_2\rho_2 + T_4\rho_4 + T_5\rho_5$ ,  $\alpha_3 \neq T_3\rho_3 + T_6\rho_6 + T_7\rho_7$ ,  $\alpha_j \neq T_j\rho_j$ ,  $j = 4, 5, 6, 7$ . Then there is a sequence of eigenvectors and generalized eigenvectors of the system that forms a Riesz basis with parentheses for the state space  $\mathcal{H}$ . The system (4.6) is exponentially stable.*

As shown in Theorem 4.2,  $\Gamma$  being a positive definite matrix is only a sufficient condition for the system (4.1)–(4.3) to decay exponentially. In fact, if we suppose that the network of strings satisfies  $T_j = m_j = 1$ , then we can use three controllers to exponentially stabilize the network. The controllers are set up as follows:

- (1)  $\alpha_1 \neq 0$ ,  $\alpha_5\alpha_7 \neq 0$ ;
- (2)  $\alpha_1 = \alpha_3 = \alpha_5 = 0$ ; one of  $\alpha_j$ ,  $j = 4, 5, 6, 7$ , is 0.

In both cases, it always holds that  $\inf_{\sigma \in \mathbb{R}} |D(i\sigma)| > 0$ . Here we omit the details of calculation.

*Remark.* In this example, we discussed only tree-shaped networks of 7-strings (see Figure 1), the goal being to give an exact expression of the condition  $\det(\Gamma - TB - C^T TBC) \neq 0$ , and to calculate  $\inf_{\sigma \in \mathbb{R}} |D(i\sigma)|$ . Indeed, in the same manner we can discuss any tree-shaped network of strings. The matrix  $C$  is just the connective matrix, and the condition  $f(0) = Cf(1)$  is the condition of the displacement continuity. The difficulty we encounter is that the condition

$$\det[\Gamma - TB - C^T TBC] \neq 0$$

is not obvious, and there is not a general method of calculating the value  $\inf_{\sigma \in \mathbb{R}} |D(i\sigma)|$ .

**4.2.  $N$ -connected strings.** In this subsection we discuss the  $N$ -connected strings with internal nodes and boundary controls. This problem was proposed and discussed for  $N = 2$  in [2]. The exponential stability was investigated in [3]. Here, we give the exponential decay rate of the system and Riesz basis property. Let us recall the model.

Let  $y(x, t)$ , the transverse displacement of  $N$ -connected strings at location  $x$  at time  $t$ , satisfy

$$(4.16) \quad m_i \frac{\partial^2 y(x, t)}{\partial t^2} - T_i \frac{\partial^2 y(x, t)}{\partial x^2} = 0, \quad i-1 < x < i, \quad i = 1, 2, \dots, N, \quad t > 0.$$

We assume the Dirichlet condition at the left-hand  $x = 0$  and Neumann boundary condition at the right-hand  $x = N$ , where a control force  $u_N(t)$  is applied, i.e.,

$$(4.17) \quad y(0, t) = 0, \quad \frac{\partial y(N, t)}{\partial x} = u_N(t), \quad t > 0.$$

At the  $i$ th intermediate node  $x = i$ , we assume the continuity of displacement

$$(4.18) \quad y(i^+, t) = y(i^-, t), \quad i = 1, 2, \dots, N-1, \quad t > 0,$$

and discontinuity of vertical force component

$$(4.19) \quad T_i \frac{\partial y(i^-, t)}{\partial x} - T_{i+1} \frac{\partial y(i^+, t)}{\partial x} = u_i(t), \quad i = 1, 2, \dots, N-1, \quad t > 0,$$

where  $u_j(t)$ ,  $j = 1, 2, \dots, N-1$ , are applied external forces.

An important task in engineering is to design controllers  $U = (u_1(t), u_2(t), \dots, u_N(t))$  such that the system comes back to its equilibrium. The authors in [2] designed the

following feedback controllers at the intermediated point  $x = i$  and the right-hand  $x = N$ :

$$(4.20) \quad u_i(t) = -\alpha_i \frac{\partial y(i, t)}{\partial t}, \quad \alpha_i > 0, \quad i = 1, 2, \dots, N.$$

Then (4.16), together with (4.17)–(4.20), forms a closed loop system. In what follows, we shall prove that this closed loop system is a Riesz system and decays exponentially.

Let  $y_i(x, t) = y(i - 1 + x, t)$ ,  $x \in (0, 1)$ , and

$$Y(x, t) = (y_1(x, t), y_2(x, t), \dots, y_N(x, t)), \quad x \in (0, 1), \quad t > 0.$$

Then (4.16) is equivalent to an equation in  $\mathbb{C}^N$ ,

$$(4.21) \quad M \frac{\partial^2 Y(x, t)}{\partial t^2} = T \frac{\partial^2 Y(x, t)}{\partial x^2}, \quad x \in (0, 1), \quad t > 0,$$

where

$$(4.22) \quad M = \text{diag}(m_1, m_2, \dots, m_N), \quad T = \text{diag}(T_1, T_2, \dots, T_N).$$

The continuity conditions at intermediate nodes, together with the condition at the left-hand endpoint, can be written into

$$(4.23) \quad Y(0, t) = CY(1, t),$$

where

$$(4.24) \quad C = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ \vdots & & \ddots & & & \ddots & & \vdots \\ \vdots & & \ddots & & & \ddots & & \vdots \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \end{pmatrix}.$$

The discontinuity condition of vertical force at the intermediate nodes, together with the condition at the right-hand endpoint, can be written as

$$(4.25) \quad T \frac{\partial Y(1, t)}{\partial x} - C^T T \frac{\partial Y(0, t)}{\partial x} = U(t) = -\Gamma \frac{\partial Y(1, t)}{\partial t},$$

where  $C^T$  denotes the conjugate transpose matrix of  $C$ , and

$$(4.26) \quad \Gamma = \text{diag}(\alpha_1, \alpha_2, \dots, \alpha_N)$$

is an  $N \times N$  positive definite matrix. Thus the closed loop system can be written as

$$(4.27) \quad \begin{cases} M \frac{\partial^2 Y(x, t)}{\partial t^2} = T \frac{\partial^2 Y(x, t)}{\partial x^2}, & x \in (0, 1), \quad t > 0, \\ Y(0, t) = CY(1, t), & t > 0, \\ T \frac{\partial Y(1, t)}{\partial x} - C^T T \frac{\partial Y(0, t)}{\partial x} = -\Gamma \frac{\partial Y(1, t)}{\partial t}, & t > 0, \\ Y(x, 0) = Y_0(x), \quad \frac{\partial Y(x, 0)}{\partial t} = Y_1(x), & x \in (0, 1), \end{cases}$$

where  $Y_0(x)$  and  $Y_1(x)$  are given suitable initial data.

In this case, we can take the matrix

$$B^2 = \text{diag} \left[ \frac{m_1}{T_1}, \frac{m_2}{T_2}, \dots, \frac{m_N}{T_N} \right],$$

and then condition (3.5) is equivalent to

$$D(\lambda) = \det \begin{pmatrix} (I - C)e^{\lambda B} & (I - C)e^{-\lambda B} \\ (\Gamma + TB)e^{\lambda B} - C^T TB & (\Gamma + TB)e^{-\lambda B} + C^T TB \end{pmatrix},$$

and then condition  $\det[\widehat{\Gamma} - B - \widehat{C}^T B \widehat{C}] \neq 0$  is equivalent to  $\det[\Gamma - TB - C^T TBC] \neq 0$ .

Now let us determine  $D(\lambda)$ . Let  $\lambda \in \mathbb{C}$  be an eigenvalue, and let  $Y = (y_1, y_2, \dots, y_N)$  be a corresponding eigenfunction. Then

$$(4.28) \quad \begin{aligned} m_j \lambda^2 y_j(x) &= T_j y_{j,xx}, \\ y_1(0) &= 0, \quad y_j(1) = y_{j+1}(0), \quad j = 1, 2, \dots, N. \end{aligned}$$

$$(4.29) \quad \begin{aligned} T_j y_{j,x}(1) - T_{j+1} y_{j+1,x}(0) &= -\alpha_j \lambda y_j(1), \quad j = 1, 2, \dots, N-1, \\ T_N y_{N,x}(1) &= -\alpha_N \lambda y_N(1). \end{aligned}$$

Set  $\rho_j^2 = \frac{m_j}{T_j}$  and

$$y_1(x) = a_1 \sinh \lambda \rho_1, \quad y_j(x) = a_j \sinh \lambda \rho_j + b_j \cosh \lambda \rho_j, \quad j = 2, 3, \dots, N.$$

From (4.28) and (4.29) we get

$$(4.30) \quad \begin{cases} [T_N \rho_N \cosh \lambda \rho_N + \alpha_N \sinh \lambda \rho_N] a_N + [T_N \rho_N \sinh \lambda \rho_N + \alpha_N \cosh \lambda \rho_N] b_N = 0, \\ [T_j \rho_j \cosh \lambda \rho_j + \alpha_j \sinh \lambda \rho_j] a_j + [T_j \rho_j \sinh \lambda \rho_j + \alpha_j \cosh \lambda \rho_j] b_j = T_{j+1} \rho_{j+1} a_{j+1}, \\ \quad j = 2, \dots, N-1, \\ \sinh \lambda \rho_j a_j + \cosh \lambda \rho_j b_j = b_{j+1}, \quad j = 2, \dots, N-1, \\ [T_1 \rho_1 \cosh \lambda \rho_1 + \alpha_1 \sinh \lambda \rho_1] a_1 = T_2 \rho_2 a_2, \\ [\sinh \lambda \rho_1] a_1 = b_2. \end{cases}$$

Set  $T_{N+1} \rho_{N+1} = 1$  and

$$(4.31) \quad \begin{aligned} w_j(\lambda) &= \frac{1}{T_{j+1} \rho_{j+1}} [T_j \rho_j \cosh \lambda \rho_j + \alpha_j \sinh \lambda \rho_j], \\ v_j(\lambda) &= \frac{1}{T_{j+1} \rho_{j+1}} [T_j \rho_j \sinh \lambda \rho_j + \alpha_j \cosh \lambda \rho_j]. \end{aligned}$$

We can rewrite (4.30) as

$$(4.32) \quad \begin{aligned} (1, 0) \begin{pmatrix} w_N(\lambda) & v_N(\lambda) \\ \sinh \lambda \rho_N & \cosh \lambda \rho_N \end{pmatrix} \begin{pmatrix} a_N \\ b_N \end{pmatrix} &= 0, \\ \begin{pmatrix} w_j(\lambda) & v_j(\lambda) \\ \sinh \lambda \rho_j & \cosh \lambda \rho_j \end{pmatrix} \begin{pmatrix} a_j \\ b_j \end{pmatrix} &= \begin{pmatrix} a_{j+1} \\ b_{j+1} \end{pmatrix}, \\ \begin{pmatrix} a_2 \\ b_2 \end{pmatrix} &= \begin{pmatrix} w_1(\lambda) & v_1(\lambda) \\ \sinh \lambda \rho_1 & \cosh \lambda \rho_1 \end{pmatrix} \begin{pmatrix} a_1 \\ 0 \end{pmatrix}. \end{aligned}$$

Therefore, for  $1 \leq k \leq N-1$ , we have

$$(4.33) \quad \begin{pmatrix} a_{k+1} \\ b_{k+1} \end{pmatrix} = \left[ \prod_{j=0}^{k-1} \begin{pmatrix} w_{k-j}(\lambda) & v_{k-j}(\lambda) \\ \sinh \lambda \rho_{k-j} & \cosh \lambda \rho_{k-j} \end{pmatrix} \right] \begin{pmatrix} a_1 \\ 0 \end{pmatrix}.$$

Note that, for  $j = 1, 2, \dots, N$ , the matrices

$$\begin{pmatrix} w_j(\lambda) & v_j(\lambda) \\ \sinh \lambda \rho_j & \cosh \lambda \rho_j \end{pmatrix} = \begin{pmatrix} \frac{T_j \rho_j}{T_{j+1} \rho_{j+1}} & \frac{\alpha_j}{T_{j+1} \rho_{j+1}} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \cosh \lambda \rho_j & \sinh \lambda \rho_j \\ \sinh \lambda \rho_j & \cosh \lambda \rho_j \end{pmatrix}$$

are invertible. So  $\lambda \in \mathbb{C}$  is an eigenvalue if and only if

$$(4.34) \quad D(\lambda) = (1, 0) \left[ \prod_{j=0}^{N-1} \begin{pmatrix} w_{N-j}(\lambda) & v_{N-j}(\lambda) \\ \sinh \lambda \rho_{N-j} & \cosh \lambda \rho_{N-j} \end{pmatrix} \right] \begin{pmatrix} 1 \\ 0 \end{pmatrix} = 0$$

or

$$(4.35) \quad D(\lambda) = D(\lambda)^\tau = (1, 0) \left[ \prod_{j=1}^N \begin{pmatrix} w_j(\lambda) & \sinh \lambda \rho_j \\ v_j(\lambda) & \cosh \lambda \rho_j \end{pmatrix} \right] \begin{pmatrix} 1 \\ 0 \end{pmatrix} = 0.$$

As before, a complicated calculation shows that

$$\inf_{\sigma \in \mathbb{R}} |D(i\sigma)| > 0.$$

The condition  $\det[\Gamma - TB - C^\tau TBC] \neq 0$  becomes

$$(4.36) \quad \alpha_j \neq T_j \rho_j + T_{j+1} \rho_{j+1}, \quad j = 1, 2, \dots, N-1, \quad \alpha_N \neq T_N \rho_N.$$

Combining this with Theorem 3.5, we have the following result.

**THEOREM 4.3.** *Let (4.36) hold. Then system (4.27) is exponentially stable. There is a sequence of eigenvectors and generalized eigenvectors of the system that forms a Riesz basis with parentheses for the space  $\mathcal{H}$  defined as in section 3.*

## OPTIMAL REFLECTION OF DIFFUSIONS AND BARRIER OPTIONS PRICING UNDER CONSTRAINTS\*

BRUNO BOUCHARD†

**Abstract.** We introduce a new class of control problems in which the gain depends on the solution of a stochastic differential equation (SDE) reflected at the boundary of a bounded domain, along directions which are controlled by a bounded variation process. We provide a PDE characterization of the associated value function. This study is motivated by applications in mathematical finance, where such equations are related to the pricing of barrier options under portfolio constraints.

**Key words.** reflected diffusion, Skorokhod problem, viscosity solutions, barrier option, portfolio constraints

**AMS subject classifications.** 93E20, 60G99, 49L25, 91B28

**DOI.** 10.1137/070697161

**1. Introduction.** This paper is motivated by a previous work [2], where a new class of parabolic PDE with Neumann and Dirichlet conditions is introduced. The starting point of [2] is the problem of hedging a barrier option under portfolio constraints. It shows that the superhedging price is a viscosity solution of an equation of the form

$$(1.1) \quad \begin{cases} \min \left\{ -\mathcal{L}\varphi, \min_{e \in E} \mathcal{H}^e \varphi \right\} = 0 & \text{on } [0, T) \times \mathcal{O}, \\ \min \left\{ \varphi, \min_{e \in E} \mathcal{H}^e \varphi \right\} = 0 & \text{on } [0, T) \times \partial\mathcal{O}, \\ \varphi - \hat{g} = 0 & \text{on } \{T\} \times \bar{\mathcal{O}}. \end{cases}$$

Here,  $\mathcal{O}$  is an open domain of  $\mathbb{R}^d$  outside of which the option is desactivated,  $E$  is a compact subset of  $\mathbb{R}^\ell$  which depends on the constraints imposed on the portfolio,  $\mathcal{L}\varphi = \frac{\partial}{\partial t}\varphi + \frac{1}{2}\text{Tr}\sigma\sigma^*D^2\varphi$  is the Dynkin operator of the diffusion which models the evolution of the risky assets,  $\mathcal{H}^e\varphi := \delta(\cdot, e)\varphi - \langle \gamma(\cdot, e), D\varphi \rangle$  for some (oblique) inward direction  $\gamma(x, e)$ , and  $\hat{g}$  is a “smoothed” version of the payoff of the option which satisfies  $\min_{e \in E} \mathcal{H}^e \hat{g} \geq 0$  (see [2] for details and section 4 below for an example).

When the solution  $\varphi$  of the above equation is positive, the spatial boundary condition reduces to  $\min_{e \in E} \mathcal{H}^e \varphi = 0$  on  $[0, T) \times \partial\mathcal{O}$ , and, in particular cases (see [14] and [15]), the constraint  $\mathcal{H}^e \varphi \geq 0$  on the parabolic boundary of  $[0, T) \times \mathcal{O}$  propagates in the domain, which allows us to simplify the above equation in

$$(1.2) \quad \begin{cases} -\mathcal{L}\varphi = 0 & \text{on } [0, T) \times \mathcal{O}, \\ \min_{e \in E} \mathcal{H}^e \varphi = 0 & \text{on } [0, T) \times \partial\mathcal{O}, \\ \varphi - \hat{g} = 0 & \text{on } \{T\} \times \bar{\mathcal{O}}. \end{cases}$$

When  $E$  is a singleton  $\{e_0\}$ , such equations formally admit a Feynman–Kac representation of the form

$$(1.3) \quad \mathbb{E} \left[ e^{-\int_t^T \delta(X(s), e_0) dL(s)} \hat{g}(X(T)) \right],$$

where  $L$  is a nondecreasing process such that  $(X, L)$  solves on  $[t, T]$

$$(1.4) \quad \begin{aligned} X(s) &= x + \int_t^s \sigma(X(r)) dW(r) + \int_t^s \gamma(X(r), e_0) dL(r), \\ X(s) &\in \bar{\mathcal{O}} \text{ and } L(s) = \int_t^s \mathbb{I}_{\{X(r) \in \partial \mathcal{O}\}} dL(r), \quad t \leq s \leq T, \end{aligned}$$

for a given standard Brownian motion  $W$ . Thus, in this particular case, the price of the barrier option is, at least formally, given by the expectation of a functional depending on the solution of a stochastic differential equation (SDE) which is reflected at the boundary of  $\mathcal{O}$  along the direction  $\gamma(\cdot, e_0)$ . This phenomenon was already observed in [14] in a particular setting and can be easily explained when  $\hat{g} \geq 0$  and  $\hat{g}$  is nondecreasing on  $\mathcal{O}$ ; see Remark 4.4 below.

By analogy, (1.2) should be associated with a control problem of the form

$$(1.5) \quad \sup_{\epsilon \in \mathcal{E}} \mathbb{E} \left[ e^{-\int_t^T \delta(X^\epsilon(s), \epsilon(s)) dL^\epsilon(s)} \hat{g}(X^\epsilon(T)) \right],$$

where  $(X^\epsilon, L^\epsilon)$  is the solution on  $[t, T]$  of

$$(1.6) \quad \begin{aligned} X^\epsilon(s) &= x + \int_t^s \sigma(X^\epsilon(r)) dW(r) + \int_t^s \gamma(X^\epsilon(r), \epsilon(r)) dL^\epsilon(r), \\ X^\epsilon(s) &\in \bar{\mathcal{O}} \text{ and } L^\epsilon(s) = \int_t^s \mathbb{I}_{\{X^\epsilon(r) \in \partial \mathcal{O}\}} dL^\epsilon(r), \quad t \leq s \leq T, \end{aligned}$$

and  $\mathcal{E}$  is a suitable set of adapted processes with values in  $E$ . The difference with (1.3) is that the direction of reflection is now controlled by the process  $\epsilon \in \mathcal{E}$ .

This naturally leads to the introduction of a new class of control problems of the form (1.5), which, to the best of our knowledge, have not been studied so far.

In this paper, we first show that (1.6) admits a strong solution in the case where  $\mathcal{O}$  is bounded,  $|\gamma| = 1$ , and  $(\mathcal{O}, \gamma)$  satisfies the following uniform exterior cone condition:

$$(1.7) \quad \bigcup_{0 \leq \lambda \leq r} B(x - \lambda \gamma(x, e), \lambda r) \subset \mathcal{O}^c \quad \text{for all } (x, e) \in \partial \mathcal{O} \times \mathbb{R}^\ell.$$

There is a huge literature on reflected SDEs and we refer to [7] for an overview of main results. In the case where  $(X, \epsilon)$  is the solution of an SDE with Lipschitz coefficients, the existence of a strong solution under the exterior cone condition (1.7) is easily deduced from [6]. Indeed, it suffices to consider the extended system  $(X, \epsilon)$  reflected at the boundary of  $\mathcal{O} \times \tilde{E}$  for some open ball  $\tilde{E} = B(0, \tilde{r})$ , which contains the compact set  $E$  along a smooth direction  $\tilde{\gamma}$  such that  $\tilde{\gamma} = (\gamma, 0)$  on  $\mathcal{O} \times E$  and  $\tilde{\gamma} = (\gamma, -e/\tilde{r})/\sqrt{2}$  on  $\mathcal{O} \times \partial \tilde{E}$ . This system satisfies the exterior cone condition of [6]. Since  $\epsilon$  takes values in  $E$ , the reflection does not operate on this component and we deduce the existence of a solution to (1.6) from the results of [6]. However, this formulation is quite restrictive and we are interested in a more general class of controls.

We therefore come back to the initial deterministic Skorokhod problem and follow the steps of [6], which are inspired by [12]. The existence of the Skorokhod problem with directions of reflection controlled by a continuous function  $\epsilon$  with bounded variations is deduced from [6] by using the above arguments, which consists of considering an extended system. We then use suitable estimates on a family of test functions introduced in [5] to prove the existence of a solution to (1.6) in our general setting. Moreover, by considering SDEs with random coefficients, we are able to incorporate another control on the direction which takes the form of an Itô process; see section 2.

We then introduce a control problem which generalizes (1.5) and prove that its value function is a viscosity solution of an equation of the form (1.2), for which we provide a comparison result. In the case where  $\gamma(x, e)$  does not depend on  $e$ , it essentially follows from the results of [5]. In this paper, we propose a new set of conditions which is more adapted to our setting and does not seem to be covered in the existing literature; see section 3.4 below.

In the last section, we discuss the link between (1.5) and the pricing of barrier options under portfolio constraints. In a particular setting, we prove that (1.5) coincides with the superhedging price of the option, when (1.2) admits a sufficiently smooth solution. This generalizes previous results of [14]. When  $E$  is reduced to a singleton, this leads to a natural Monte-Carlo approach for its estimation. We leave the discussion of more general cases for future research.

Also, we should point out that an extension of the results of [14] to American options was carried out by [11] within a similar model as in [14], but with infinite time horizon. In mathematical terms, it essentially corresponds to mixing the problem (1.5) with an optimal stopping one. We think that our approach could be used in this setting too. We also leave this for future research.

**Notation.** Given  $E \subset \mathbb{R}^m$ ,  $m \geq 1$ , and  $E_i \subset \mathbb{R}^{m_i}$ ,  $m_i \geq 1$ , for  $i \leq I$ , we denote by  $C^{k_1, \dots, k_I}(E_1 \times \dots \times E_I, E)$  (resp.,  $C_b^{k_1, \dots, k_I}(E_1 \times \dots \times E_I, E)$ ) the set of continuous maps  $\varphi$  from  $E_1 \times \dots \times E_I$  into  $E$  that admit continuous (resp., bounded) derivatives up to order  $k_i$  in their  $i$ th component  $x_i$ . We omit  $k_i$  when it is equal to 0 and only write  $C^{k_1}(E_1 \times \dots \times E_I, E)$  when  $k_1 = k_2 = \dots = k_I$ . We omit  $E$  when  $E = \mathbb{R}$ , and, in this case, we denote by  $D_{x_i}\varphi$  and  $D_{x_i}^2\varphi$  the (partial) Jacobian and Hessian matrices with respect to  $x_i$ . We simply write  $D\varphi$  and  $D^2\varphi$  for  $D_{x_2}\varphi$  and  $D_{x_2}^2\varphi$  if  $I = 2$ . For  $T > 0$ , we define  $BV([0, T], E)$  as the set of continuous maps from  $[0, T]$  into  $E$  with a bounded total variation. For  $\epsilon \in BV([0, T], E)$ , we set  $|\epsilon| := \sum_{i \leq m} |\epsilon^i|$ , where  $|\epsilon^i|(t)$  is the total variation of  $\epsilon^i$  on  $[0, t]$ ,  $t \geq 0$ . We write  $E^c$  for  $\mathbb{R}^m \setminus E$ ,  $\partial E$  and  $\bar{E}$  denote the boundary and the closure of  $E$ ,  $\mathbb{R}_+^m = [0, \infty)^m$ , and  $\mathbb{R}_-^m = -\mathbb{R}_+^m$ . The Euclidean norm of  $x = (x^1, \dots, x^m) \in \mathbb{R}^m$  is denoted by  $|x|$ ,  $B(x, r)$  is the open ball centered on  $x$  with radius  $r$ , and  $\langle \cdot, \cdot \rangle$  is the natural scalar product on  $\mathbb{R}^m$ . We denote by  $\mathbb{M}^m$  the set of square matrices of dimension  $m$  and we extend the definition of  $|\cdot|$  with  $\mathbb{M}^m$  by identifying  $\mathbb{M}^m$  with  $\mathbb{R}^{m \times m}$ . For  $x \in \mathbb{R}^m$ ,  $\text{diag } x$  is the diagonal matrix of  $\mathbb{M}^m$  whose  $i$ th diagonal element is  $x^i$ ,  $\text{Tr } M$  is the trace of  $M \in \mathbb{M}^m$ , and  $M^*$  its transposition. All inequalities between random variables have to be taken in the a.s. sense.

**2. SDEs with controlled reflecting directions.** The goal of this section is to construct an SDE which is reflected at the boundary of some bounded open set  $\mathcal{O} \subset \mathbb{R}^d$ ,  $d \geq 1$ , along a direction which is controlled by an adapted continuous process with bounded variations taking values in a compact subset  $E$  of  $\mathbb{R}^\ell$ ,  $\ell \geq 1$ . We follow the arguments of [6] and start with the resolution of the associated (deterministic) Skorokhod problem.

**2.1. The Skorokhod problem with controlled reflecting directions.** For the sake of completeness, we first recall one of the main results of [6] which provides a solution to the Skorokhod problem for oblique reflection on general bounded sets.

**THEOREM 2.1** (Dupuis and Ishii [6]). *Fix  $\gamma \in C^2(\mathbb{R}^d, \mathbb{R}^d)$  with  $|\gamma| = 1$ . Assume that there exists some  $r \in (0, 1)$  such that*

$$(2.1) \quad \bigcup_{0 \leq \lambda \leq r} B(x - \lambda\gamma(x), \lambda r) \subset \mathcal{O}^c \quad \text{for all } x \in \partial\mathcal{O}.$$

*Then, for all  $\psi \in C([0, T], \mathbb{R}^d)$  satisfying  $\psi(0) \in \bar{\mathcal{O}}$ , there exists  $(\phi, \eta) \in C([0, T], \bar{\mathcal{O}}) \times \text{BV}([0, T], \mathbb{R}_+)$  such that  $\eta$  is nondecreasing and*

$$\phi(t) = \psi(t) + \int_0^t \gamma(\phi(s)) d\eta(s), \quad \eta(t) = \int_0^t \mathbb{I}_{\{\phi(s) \in \partial\mathcal{O}\}} d\eta(s), \quad t \leq T.$$

*Moreover,  $(\phi(t), \eta(t)) \in \sigma(\psi(s), s \leq t)$  for all  $t \leq T$ , and uniqueness holds if  $\psi \in \text{BV}([0, T], \mathbb{R}^d)$ .*

*Proof.* See Theorem 4.8 and the discussion after Corollary 5.2 in [6].  $\square$

We now fix an open bounded set  $\mathcal{O} \subset \mathbb{R}^d$ , a compact set  $E \subset \mathbb{R}^\ell$ , and  $\gamma$  satisfying

$$(2.2) \quad \gamma \in C^2(\mathbb{R}^{d+\ell}, \mathbb{R}^d), \quad |\gamma| = 1,$$

$$(2.3) \quad \exists r \in (0, 1) \text{ s.t. } \bigcup_{0 \leq \lambda \leq r} B(x - \lambda\gamma(x, e), \lambda r) \subset \mathcal{O}^c \quad \text{for all } (x, e) \in \partial\mathcal{O} \times \mathbb{R}^\ell.$$

We then deduce from Theorem 2.1 the following result.

**COROLLARY 2.1.** *Let the conditions (2.2) and (2.3) hold. Then, for all  $\psi \in \text{BV}([0, T], \mathbb{R}^d)$  satisfying  $\psi(0) \in \bar{\mathcal{O}}$  and  $\epsilon \in \text{BV}([0, T], E)$ , there exists a unique pair  $(\phi, \eta) \in C([0, T], \bar{\mathcal{O}}) \times \text{BV}([0, T], \mathbb{R}_+)$  such that  $\eta$  is nondecreasing and*

$$(2.4) \quad \phi(t) = \psi(t) + \int_0^t \gamma(\phi(s), \epsilon(s)) d\eta(s) \quad \text{and} \quad \eta(t) = \int_0^t \mathbb{I}_{\{\phi(s) \in \partial\mathcal{O}\}} d\eta(s), \quad t \leq T.$$

*Moreover,  $(\phi(t), \eta(t)) \in \sigma((\psi(s), \epsilon(s)), s \leq t)$  for all  $t \leq T$ .*

*Proof.* This is an immediate consequence of Theorem 2.1. Since  $\epsilon$  is valued in a compact set, it suffices to apply the above result to an extended fictitious reflected system  $(\psi, \epsilon)$ . We detail the proof for completeness. Fix  $\tilde{r} > 0$  so that  $\tilde{E} := B(0, \tilde{r})$  strictly contains  $E$ . Fix  $\zeta \in C^2(\mathbb{R}^\ell, [0, 1])$  such that  $\zeta(e) = 0$  for  $e \in E$  and  $\zeta(e) = 1$  for  $e \in \partial\tilde{E}$  and set, on  $\mathbb{R}^{d+\ell}$ ,  $\tilde{\gamma}(x, e) = (\gamma(x, e), -e\zeta(e)/\tilde{r})/|(\gamma(x, e), -e\zeta(e)/\tilde{r})|$ . Since  $|\gamma| = 1$ ,  $|(\gamma(x, e), -e\zeta(e)/\tilde{r})| \geq 1$  and  $\tilde{\gamma} \in C^2(\mathbb{R}^{d+\ell}, \mathbb{R}^{d+\ell})$ . Moreover,  $|(\gamma(x, e), -e\zeta(e)/\tilde{r})|^2 \leq 2$  on the closure of  $\mathcal{O} \times \tilde{E}$ ,  $|(\gamma(x, e), -e\zeta(e)/\tilde{r})|^2 = 2$  if  $e \in \partial\tilde{E}$ , and  $B(e + \lambda e/\tilde{r}, \lambda r) \cap \tilde{E} = \emptyset$  for all  $e \in \partial\tilde{E}$  and  $\lambda > 0$ ; recall that  $r < 1$ . We then deduce from (2.3) that for  $(x, e) \in \partial(\mathcal{O} \times \tilde{E})$  and  $\lambda \in [0, r/\sqrt{2}]$ ,

$$|(y, f) - ((x, e) - \lambda\tilde{\gamma}(x, e))|^2 \leq \lambda^2(r/\sqrt{2})^2 \Rightarrow (y, f) \notin \mathcal{O} \times \tilde{E}.$$

We can therefore apply Theorem 2.1 to the pair  $(\psi, \epsilon)$  reflected at the boundary of  $\mathcal{O} \times \tilde{E}$ . Since  $\epsilon$  does not reach the boundary of  $\tilde{E}$ , this leads to the required result.  $\square$

**2.2. The stochastic Skorokhod problem with controlled reflecting direction.** We now consider some probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  supporting a  $d$ -dimensional standard Brownian motion  $W$ . We denote by  $\mathbb{F} = (\mathcal{F}_t)_{t \leq T}$  the natural filtration induced by  $W$ , satisfying the usual conditions, and assume that  $\mathcal{F} = \mathcal{F}_T$ . Given two uniformly Lipschitz functions  $\mu$  and  $\sigma$  from  $\mathbb{R}^d$  into  $\mathbb{R}^d$  and  $\mathbb{M}^d$ , respectively, it is shown in [6] that, under the condition (2.1), there exists a unique pair  $(X, L)$  of  $\mathbb{F}$ -adapted continuous processes such that  $L$  is real valued, nondecreasing and

$$(2.5) \quad X(t) = x + \int_0^t \mu(X(s))ds + \int_0^t \sigma(X(s))dW(s) + \int_0^t \gamma(X(s))dL(s),$$

$$X(t) \in \bar{\mathcal{O}} \text{ and } L(t) = \int_0^t \mathbb{I}_{\{X(s) \in \partial \mathcal{O}\}} dL(s), \quad t \leq T.$$

The aim of this section is to extend this result to the case where  $\mu$  and  $\sigma$  are random and  $\gamma$  is controlled by some continuous bounded variation process  $\epsilon$  taking values in the compact set  $E$ . We refer to Remarks 2.2 and 2.3 below for comments on this a priori strong regularity assumption on the control  $\epsilon$ .

In the following, given two subsets  $E_1$  and  $E_2$  of  $\mathbb{R}^{m_1}$  and  $\mathbb{R}^{m_2}$ ,  $m_1, m_2 \geq 1$ , we denote by  $L_{\mathbb{F}}(E_1, E_2)$  the set of measurable maps

$$f : (\omega, t, x) \in \Omega \times [0, T] \times E_1 \longrightarrow f_t(\omega, x) \in E_2$$

such that  $t \mapsto f_t(\cdot, x)$  is progressively measurable for each  $x \in E_1$ , and

$$|f_t(\omega, x) - f_t(\omega, y)| \leq K|x - y| \text{ for all } x, y \in E_1 \text{ } d\mathbb{P}(\omega)\text{-a.s.}$$

for some  $K > 0$  independent of  $(t, \omega) \in [0, T] \times \Omega$ . In what follows, we shall write only  $f_t(x)$  for  $f_t(\omega, x)$ .

We denote by  $BV_{\mathbb{F}}(E_2)$  the set of  $E_2$ -valued continuous adapted processes with bounded variations. For ease of notation, we write  $\mathcal{E}$  for  $BV_{\mathbb{F}}(E)$  and set

$$\mathcal{E}_m^b := \{\epsilon \in \mathcal{E} : |\epsilon|(T) \leq m \text{ } \mathbb{P}\text{-a.s.}\}, \quad m > 0.$$

In the rest of this section, we fix  $(\mu, \sigma) \in L_{\mathbb{F}}(\mathbb{R}^d, \mathbb{R}^d \times \mathbb{M}^d)$  and assume that the conditions (2.2) and (2.3) hold. Our first result extends Theorem 5.1 in [6].

**LEMMA 2.1.** *Let  $X$  be a continuous semimartingale with values in  $\bar{\mathcal{O}}$ . Fix  $m > 0$  and  $\epsilon \in \mathcal{E}_m^b$ . Assume that  $Y$  is a continuous semimartingale with values in  $\bar{\mathcal{O}}$  satisfying, for  $0 \leq t_0 \leq t \leq T$ ,*

$$Y(t) = X(t_0) + \int_{t_0}^t \mu_s(X(s))ds + \int_{t_0}^t \sigma_s(X(s))dW(s) + \int_{t_0}^t \gamma(Y(s), \epsilon(s))dL(s),$$

where  $L$  is a nondecreasing element of  $BV_{\mathbb{F}}(\mathbb{R}_+)$  such that

$$L(t) = \int_{t_0}^t \mathbb{I}_{\{Y(s) \in \partial \mathcal{O}\}} dL(s), \quad t_0 \leq t \leq T.$$

Let  $X'$  be another continuous semimartingale with values in  $\bar{\mathcal{O}}$  and assume that  $(Y', L')$  satisfies the same properties as  $(Y, L)$  with  $X'$  in place of  $X$ . Then, there is a constant  $C_m > 0$  such that

$$\mathbb{E} \left[ \sup_{t_0 \leq s \leq t} |\Delta Y(s)|^4 \right] \leq C_m \mathbb{E} \left[ |\Delta X(t_0)|^4 + \int_{t_0}^t \sup_{t_0 \leq s \leq u} |\Delta X(s)|^4 du \right], \quad t_0 \leq t \leq T,$$

where  $\Delta Y$  and  $\Delta X$  stand for  $Y - Y'$  and  $X - X'$ .

In order to prove Lemma 2.1, we shall appeal to the following technical result. It is a simple extension of Theorem 3.2 in [6], which is based on Theorem 4.1 in [5].

LEMMA 2.2. *Given  $\theta \in (0, 1)$  there exists a family of functions  $(f_\varepsilon)_{\varepsilon>0}$  in  $C^2(\bar{\mathcal{O}} \times \bar{\mathcal{O}} \times E)$  and a constant  $K > 0$  independent of  $\varepsilon > 0$  such that, for all  $(y, y', e) \in \bar{\mathcal{O}} \times \bar{\mathcal{O}} \times E$ ,*

$$(2.6) \quad \frac{|y - y'|^2}{\varepsilon} \leq f_\varepsilon(y, y', e) \leq K \left( \varepsilon + \frac{|y - y'|^2}{\varepsilon} \right),$$

$$(2.7) \quad \langle \gamma(y, e), D_y f_\varepsilon(y, y', e) \rangle \leq K \frac{|y - y'|^2}{\varepsilon} \quad \text{if} \quad \langle y' - y, \gamma(y, e) \rangle \geq -\theta |y - y'|,$$

$$(2.8) \quad \langle \gamma(y', e), D_{y'} f_\varepsilon(y, y', e) \rangle \leq K \frac{|y - y'|^2}{\varepsilon} \quad \text{if} \quad \langle y - y', \gamma(y', e) \rangle \geq -\theta |y - y'|,$$

$$(2.9) \quad |D_y f_\varepsilon(y, y', e) + D_{y'} f_\varepsilon(y, y', e)| \vee |D_e f_\varepsilon(y, y', e)| \leq K \frac{|y - y'|^2}{\varepsilon},$$

$$(2.10) \quad |D_y f_\varepsilon(y, y', e)| \vee |D_{y'} f_\varepsilon(y, y', e)| \leq K \frac{|y - y'|}{\varepsilon},$$

$$(2.11) \quad D_{(y, y')}^2 f_\varepsilon(y, y', e) \leq \frac{C}{\varepsilon} \begin{pmatrix} I_d & -I_d \\ -I_d & I_d \end{pmatrix} + K \frac{|y - y'|^2}{\varepsilon} I_{2d}.$$

Moreover, there is  $h \in C^2(\bar{\mathcal{O}} \times E)$  with nonnegative values such that

$$(2.12) \quad \langle D_y h(y, e), \gamma(y, e) \rangle \geq 1 \quad \text{for all } (y, e) \in \partial \mathcal{O} \times E.$$

*Proof.* This follows from the proof of Theorem 4.1 in [5]. Since it is long, we provide only the main arguments. Let  $g : (p, x) \in \mathbb{R}^d \times \mathbb{R}^d$  be as in Lemma 4.4 of [5]. In particular, it satisfies

$$(2.13) \quad |D_x g(p, x)| \leq C |p|^2$$

for some  $C > 0$ . Let  $\psi \in C^2(\mathbb{R})$  be a real nondecreasing function such that  $\psi(t) = t$  for  $t \geq 2$ ,  $\psi(t) = 1$  for  $t \leq 1/2$ , and  $\psi(t) \geq t$  for all  $t \in [1/2, 2]$ . For  $\varepsilon > 0$ , we then define

$$f_\varepsilon(x, y, e) := \varepsilon \tilde{g} \left( \frac{x - y}{\varepsilon}, x, e \right), \quad (x, y, e) \in \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^\ell,$$

with

$$\tilde{g}(p, x, e) := \psi(g(p, \gamma(x, e))), \quad (p, x, e) \in \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^\ell.$$

All the estimates, except the one on  $|D_e f_\varepsilon(y, y', e)|$ , follow directly from the property of  $g$  stated in Lemma 4.4 of [5], as in the proof of Theorem 4.1 in [5, pp. 1136–1137], for fixed values of  $e$ . Here, the constant  $K$  can be taken independent of  $e$  because  $E$  is bounded. The estimate on  $|D_e f_\varepsilon(y, y', e)|$  follows from (2.13), the smoothness condition on  $\gamma$ , and the boundedness of  $\mathcal{O}$ , and  $E$ . The existence of the function  $h$  follows from Theorem 3.2 in [6]; see (3.20) of this paper. It suffices to repeat the argument of the proof of Corollary 2.1; i.e., consider a fictitious extended reflected system  $(x, e)$ .  $\square$

*Remark 2.1.* Observe that given  $\theta \in (0, 1)$  such that  $\theta^2 > 1 - r^2$ , we can find  $\delta \in (0, r)$  for which  $\langle y' - y, \gamma(y, e) \rangle \geq -\theta|y - y'|$  for all  $e \in E$ ,  $y \in \partial\mathcal{O}$ , and  $y' \in \bar{\mathcal{O}}$  such that  $|y - y'| \leq \delta$ . This follows from (2.3) and the observation that  $\langle y' - y, \gamma(y, e) \rangle \leq -\theta|y - y'|$ ,  $|y - y'| \leq \delta$ , and  $|\gamma| = 1$  imply that

$$|y' - (y - \lambda\gamma(y, e))|^2 \leq |y' - y|^2 - 2\lambda\theta|y - y'| + \lambda^2 = \lambda^2(1 - \theta^2) \leq \lambda^2 r^2$$

for  $\lambda := |y - y'|/\theta \leq \delta/(1 - r^2)^{\frac{1}{2}}$  with  $\delta$  small enough so that  $\lambda \leq r$ .

*Proof of Lemma 2.1.* As in [6], we first observe that we can restrict our attention to the case  $|Y - Y'| \leq \delta$ , where  $\delta$  is defined as in Remark 2.1 for  $\theta := (1 + \sqrt{1 - r^2})/2$ . Indeed, since  $\mathcal{O}$  is bounded, there is  $\tilde{r} > 0$  such that  $B(0, \tilde{r}/2) \supset \bar{\mathcal{O}}$ , and if  $\tau$  is the first time after  $t_0$  when  $|Y - Y'| \geq \delta$ , then

$$\mathbb{E} \left[ \sup_{t_0 \leq s \leq T} |\Delta Y(s)|^4 \right] \leq \frac{\tilde{r}^4}{\delta^4} \mathbb{E} \left[ \sup_{t_0 \leq s \leq \tau} |\Delta Y(s)|^4 \right].$$

From now on, we therefore assume that  $|Y - Y'| \leq \delta$ . For ease of notation, we also restrict our attention to the case where  $t_0 = 0$ ; the general case is handled similarly.

Recall from Lemma 2.2 the definitions of  $h$  and  $f_\varepsilon$  for  $\theta$  defined as above. We fix  $\varepsilon, \lambda > 0$  and define the smooth function  $\tilde{f}_\varepsilon$  on  $\bar{\mathcal{O}} \times \bar{\mathcal{O}} \times E$  by

$$(2.14) \quad \tilde{f}_\varepsilon(y, y', e) := e^{-\lambda(h(y, e) + h(y', e))} f_\varepsilon(y, y', e).$$

Fix  $\bar{K} > 0$ . Set

$$A_t := \int_0^t e^{-\bar{K}|\epsilon|(s)} \left( \left| D_e \tilde{f}_\varepsilon(Y(s), Y'(s), \epsilon(s)) \right| - \bar{K} \tilde{f}_\varepsilon(Y(s), Y'(s), \epsilon(s)) \right) d|\epsilon|(s)$$

and  $\beta_s := e^{-\bar{K}|\epsilon|(s)} e^{-\lambda(h(Y(s), \epsilon(s)) + h(Y'(s), \epsilon(s)))}$ . Since, by the estimates of Lemma 2.2,

$$\begin{aligned} & e^{-\bar{K}|\epsilon|(s)} \left| D_e \tilde{f}_\varepsilon(Y(s), Y'(s), \epsilon(s)) \right| \\ & \leq \beta_s \left( 2\lambda \sup_{(y, e) \in \bar{\mathcal{O}} \times E} |D_e h(y, e)| + 1 \right) K \left( \varepsilon + \frac{|Y(s) - Y'(s)|^2}{\varepsilon} \right) \end{aligned}$$

and

$$e^{-\bar{K}|\epsilon|(s)} \bar{K} \tilde{f}_\varepsilon(Y(s), Y'(s), \epsilon(s)) \geq \beta_s \bar{K} \frac{|Y(s) - Y'(s)|^2}{\varepsilon},$$

we can find  $C > 0$ , independent of  $\lambda$  and  $\varepsilon$ , such that  $A_t \leq \lambda C \varepsilon$  for  $\bar{K}$  large enough with respect to  $K$ ,  $\lambda$ , and  $|D_e h|$ .

Thus, applying Itô's lemma to  $\xi := (e^{-\bar{K}|\epsilon|(t)} \tilde{f}_\varepsilon(Y(t), Y'(t), \epsilon(t)))_{t \leq T}$  leads to

$$(2.15) \quad \xi_t \leq \xi_0 + T\lambda C \varepsilon + G_t + G'_t + H_t,$$

where

$$\begin{aligned} G_t &:= \int_0^t e^{-\bar{K}|\epsilon|(s)} \langle D_y \tilde{f}_\varepsilon(Y(s), Y'(s), \epsilon(s)), \gamma(Y(s), \epsilon(s)) \rangle dL(s), \\ G'_t &:= \int_0^t e^{-\bar{K}|\epsilon|(s)} \langle D_{y'} \tilde{f}_\varepsilon(Y(s), Y'(s), \epsilon(s)), \gamma(Y'(s), \epsilon(s)) \rangle dL'(s), \end{aligned}$$

and

$$\begin{aligned}
 H_t := & \int_0^t e^{-\bar{K}|\epsilon|(s)} \langle D_y \tilde{f}_\epsilon(Y(s), Y'(s), \epsilon(s)), \mu_s(X(s)) - \mu_s(X'(s)) \rangle ds \\
 & + \int_0^t e^{-\bar{K}|\epsilon|(s)} \langle D_y \tilde{f}_\epsilon(Y(s), Y'(s), \epsilon(s)), [\sigma_s(X(s)) - \sigma_s(X'(s))] dW_s \rangle \\
 & + \int_0^t e^{-\bar{K}|\epsilon|(s)} \langle D_{y'} \tilde{f}_\epsilon(Y(s), Y'(s), \epsilon(s)) + D_y \tilde{f}_\epsilon(Y(s), Y'(s), \epsilon(s)), \mu_s(X'(s)) \rangle ds \\
 & + \int_0^t e^{-\bar{K}|\epsilon|(s)} \langle D_{y'} \tilde{f}_\epsilon(Y(s), Y'(s), \epsilon(s)) + D_y \tilde{f}_\epsilon(Y(s), Y'(s), \epsilon(s)), \sigma_s(X'(s)) dW_s \rangle \\
 & + \frac{1}{2} \int_0^t e^{-\bar{K}|\epsilon|(s)} \text{Tr} \left[ D_{(y, y')}^2 \tilde{f}_\epsilon(Y(s), Y'(s), \epsilon(s)) a_s(X(s), X'(s)) \right] ds
 \end{aligned}$$

with

$$a_s(x, x') = \begin{bmatrix} \sigma_s(x) \sigma_s(x)^* & \sigma_s(x) \sigma_s(x')^* \\ \sigma_s(x') \sigma_s(x)^* & \sigma_s(x') \sigma_s(x')^* \end{bmatrix},$$

where  $*$  denotes the transposition.

Now, observe that the estimates (2.6), (2.7), and (2.12) of Lemma 2.2, Remark 2.1, and the assumption  $|Y - Y'| \leq \delta$  imply that

$$\begin{aligned}
 G_t &= \int_0^t \beta_s \langle D_y f_\epsilon(Y(s), Y'(s), \epsilon(s)), \gamma(Y(s), \epsilon(s)) \rangle dL(s) \\
 &\quad - \lambda \int_0^t \beta_s f_\epsilon(Y(s), Y'(s), \epsilon(s)) \langle D_y h(Y(s), \epsilon(s)), \gamma(Y(s), \epsilon(s)) \rangle dL(s) \\
 &\leq (K - \lambda) \int_0^t \beta_s \frac{|\Delta Y(s)|^2}{\epsilon} dL(s).
 \end{aligned}$$

Similarly,

$$G'_t \leq (K - \lambda) \int_0^t \beta_s \frac{|\Delta Y(s)|^2}{\epsilon} dL'(s).$$

Taking  $\lambda = K$ , it then follows from (2.15) that

$$(2.16) \quad \xi_t \leq \xi_0 + T\lambda C\epsilon + H_t.$$

Moreover, it follows from Doob's inequality, the estimates of Lemma 2.2, the a.s. Lipschitz continuity of  $\mu$  and  $\sigma$ , the fact that  $Y$ ,  $Y'$ ,  $X$ , and  $X'$  are bounded, and the inequality  $\alpha^2 \beta^2 \leq \alpha^4 + \beta^4$ ,  $\alpha, \beta \in \mathbb{R}$ , that

$$\mathbb{E} \left[ \sup_{s \leq t} H_s^2 \right] \leq C' \mathbb{E} \left[ \int_0^t \frac{e^{-2\bar{K}|\epsilon|(s)}}{\epsilon^2} (\epsilon^4 + |\Delta Y(s)|^4 + |\Delta X(s)|^4) ds \right],$$

where  $C'$  is a positive constant which does not depend on  $\varepsilon$ . Since  $|\epsilon|(T) \leq m$ , it follows from (2.16) and the left-hand side of (2.6) of Lemma 2.2 that

$$\mathbb{E} \left[ \sup_{s \leq t} |\Delta Y(s)|^4 \right] \leq C_m \left( \varepsilon^4 + |\Delta X(0)|^4 + \int_0^t \mathbb{E} \left[ \sup_{r \leq s} |\Delta Y(r)|^4 + \sup_{r \leq s} |\Delta X(r)|^4 \right] ds \right),$$

where  $C_m$  is a positive constant independent of  $\varepsilon$ . The required result is then obtained by sending  $\varepsilon \rightarrow 0$  and using Gronwall's lemma.  $\square$

We can now provide the main result of this section, which ensures the strong existence and uniqueness of an SDE with random coefficients and controlled reflecting directions.

**THEOREM 2.2.** *Fix  $\epsilon \in \mathcal{E}$ ,  $t \in [0, T]$ , and  $\xi$  a  $\mathcal{F}_t$ -measurable random variable with values in  $\mathcal{O}$ . Then, there exists a unique continuous adapted process  $(X, L)$  such that  $L$  is a nondecreasing element of  $\text{BV}_{\mathbb{F}}(\mathbb{R}_+)$  and*

$$(2.17) \quad \begin{aligned} X(s) &= \xi + \int_t^s \mu_r(X(r))dr + \int_t^s \sigma_r(X(r))dW(r) + \int_t^s \gamma(X(r), \epsilon(r))dL(r), \\ L(s) &= \int_t^s \mathbb{I}_{\{X(r) \in \partial \mathcal{O}\}} dL(r), \quad t \leq s \leq T. \end{aligned}$$

*Proof.* Observe that Lemma 4.7 in [6] can be easily extended to our setting by appealing to the arguments already used in the proof of Corollary 2.1. The existence and uniqueness when  $|\epsilon|(T)$  is uniformly bounded then follow from Corollary 2.1, Lemma 2.1, and the same arguments as in [6] (see the discussion after their Corollary 5.2), or as in the proof of Proposition 4.1 in [12]. In the case where  $|\epsilon|(T)$  is not uniformly bounded, we use a localization argument. For each  $m \geq 1$ , we define  $\tau_m := \inf\{s \geq t : |\epsilon|(s) \geq m\}$  and let  $(X^m, L^m)$  be the unique solution of (2.17) associated with  $\epsilon^m(\cdot) := \epsilon(\cdot \wedge \tau_m)$ . We then define  $(X, L)$  by

$$(X, L)(s) := (X^1, L^1)(s) \mathbb{I}_{\{t \leq s \leq \tau_1\}} + \sum_{m \geq 2} (X^m, L^m)(s) \mathbb{I}_{\{\tau_{m-1} < s \leq \tau_m\}}.$$

It solves (2.17) associated with  $\epsilon$ . The same argument provides uniqueness.  $\square$

**Remark 2.2.** The presence of the control  $\epsilon$  in  $\gamma$  plays a similar role as the time dependence in nonlinear Neumann-type boundary conditions of the form  $L(t, x, u, Du) = 0$  in the viscosity literature. To the best of our knowledge the papers dealing with such a time dependence impose rather strong regularity conditions. The less stringent seem to appear in [3] where, for fixed  $(x, u, p)$ , the map  $t \mapsto L(t, x, u, p)$  is absolutely continuous with respect to the Lebesgue measure; see condition (H6) of this paper. In particular,  $t \mapsto L(t, x, u, p)$  has bounded variations. It is therefore not surprising to retrieve such a condition in the definition of the set of controls  $\mathcal{E}$ .

**Remark 2.3.** Let  $(a, b)$  be a progressively measurable process with values in  $\mathbb{M}^\ell \times \mathbb{R}^\ell$  satisfying

$$\int_0^t (|b(s)| + |a(s)|^2) < \infty \quad \mathbb{P}\text{-a.s.},$$

and assume that the process  $Z$  defined on  $[t, T]$  by

$$Z(s) := z + \int_t^s b(r)dr + \int_t^s a(r)dW(r)$$

takes values in a compact set  $F$  of  $\mathbb{R}^\ell$ . Then, it follows from Theorem 2.2 that existence and uniqueness hold for

$$X(s) = x + \int_t^s \mu_r(X(r))dr + \int_t^s \sigma_r(X(r))dW(r) + \int_t^s \tilde{\gamma}(X(r), Z(r), \epsilon(r))dL(r),$$

$$L(s) = \int_t^s \mathbb{I}_{\{X(r) \in \partial\mathcal{O}\}} d|L|(r), \quad t \leq s \leq T,$$

when  $\tilde{\gamma} \in C^2(\mathbb{R}^d \times \mathbb{R}^\ell \times \mathbb{R}^\ell, \mathbb{R}^d)$  satisfies

$$\bigcup_{0 \leq \lambda \leq r} B(x - \lambda \tilde{\gamma}(x, z, e), \lambda r) \subset \mathcal{O}^c \quad \text{for all } (x, z, e) \in \partial\mathcal{O} \times \mathbb{R}^{2\ell}$$

for some  $r \in (0, 1)$ . This is easily checked by arguing as in the proof of Corollary 2.1; i.e., introduce the fictitious reflected system  $(X, Z)$  and apply Theorem 2.2. This allows us to introduce a new control on the direction of reflection which corresponds to an Itô process.

**3. Optimal control.** As in the previous section, we consider a bounded open set  $\mathcal{O} \subset \mathbb{R}^d$  and  $\gamma \in C^2(\mathbb{R}^{d+\ell}, \mathbb{R}^d)$  such that  $|\gamma| = 1$  and (2.3) holds.

**3.1. Definitions and assumptions.** We fix a compact subset  $A$  of  $\mathbb{R}^\ell$  and denote by  $\mathcal{A}$  the set of progressively measurable processes with values in  $A$ .

Let  $\mu$  and  $\sigma$  be two continuous maps on  $\mathbb{R}^d \times A$  with values in  $\mathbb{R}^d$  and  $\mathbb{M}^d$ , respectively. We assume that both are Lipschitz with respect to their first variable, uniformly in the other ones, so that  $(\mu^\alpha, \sigma^\alpha)$  defined by

$$(\mu_t^\alpha, \sigma_t^\alpha)(\cdot) := (\mu, \sigma)(\cdot, \alpha(t)), \quad t \leq T,$$

belongs to  $L_{\mathbb{F}}(\mathbb{R}^d; \mathbb{R}^d \times \mathbb{M}^d)$  for all  $\alpha \in \mathcal{A}$ . It then follows from Theorem 2.2 that, for all  $(t, x) \in [0, T] \times \bar{\mathcal{O}}$ , there exists a unique solution  $(X_{t,x}^{\alpha, \epsilon}, L_{t,x}^{\alpha, \epsilon})$  to (2.17) associated with  $(\mu^\alpha, \sigma^\alpha)$  with initial conditions given by  $(X_{t,x}^{\alpha, \epsilon}, L_{t,x}^{\alpha, \epsilon})(t) = (x, 0)$ .

The goal of this section is to provide a PDE characterization for the control problem

$$(3.1) \quad v(t, x) := \sup_{(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}} J(t, x; \alpha, \epsilon),$$

where

$$J(t, x; \alpha, \epsilon) := \mathbb{E} \left[ \beta_{t,x}^{\alpha, \epsilon}(T) g(X_{t,x}^{\alpha, \epsilon}(T)) + \int_t^T \beta_{t,x}^{\alpha, \epsilon}(s) f(X_{t,x}^{\alpha, \epsilon}(s), \alpha(s)) ds \right],$$

$$\beta_{t,x}^{\alpha, \epsilon}(s) := e^{-\int_t^s \rho(X_{t,x}^{\alpha, \epsilon}(r), \epsilon(r)) dL_{t,x}^{\alpha, \epsilon}(r)},$$

and  $\rho, g, f$  are continuous real valued maps on  $\bar{\mathcal{O}} \times E$ ,  $\bar{\mathcal{O}}$  and  $\bar{\mathcal{O}} \times A$ , respectively. In order to ensure that  $J$  is well defined, we assume that  $\rho \geq 0$ . We also assume that

- (i)  $g$  is Lipschitz continuous;
- (ii)  $f$  is Lipschitz continuous in its first variable, uniformly in its second one;
- (iii)  $\rho$  is  $C^1$  with Lipschitz first derivative in its first variable, uniformly in its second one, and Lipschitz in its second variable, uniformly in the first one.

**3.2. Dynamic programming.** We first provide some useful estimates on  $X_{t,x}^{\alpha,\epsilon}$  and  $J$  which will be used to derive the dynamic programming principle of Lemma 3.2 below.

PROPOSITION 3.1. *For each  $m > 0$ , there is a constant  $C_m > 0$  such that for all  $(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}_m^b$ ,  $t \leq t' \leq T$ , and  $x, x' \in \bar{\mathcal{O}}$ , we have*

$$(3.2) \quad \mathbb{E} \left[ \sup_{t' \leq s \leq T} |X_{t,x}^{\alpha,\epsilon}(s) - X_{t',x'}^{\alpha,\epsilon}(s)|^4 \right]^{\frac{1}{4}} \leq C_m \left( |x - x'| + |t' - t|^{\frac{1}{4}} \right),$$

$$(3.3) \quad \mathbb{E} \left[ \sup_{t \leq s \leq t'} |X_{t,x}^{\alpha,\epsilon}(s) - x|^4 \right]^{\frac{1}{4}} + \mathbb{E} [L_{t,x}^{\alpha,\epsilon}(t')^2]^{\frac{1}{2}} \leq C_m |t' - t|^{\frac{1}{4}},$$

$$(3.4) \quad \mathbb{E} \left[ \sup_{t' \leq s \leq T} |\ln(\beta_{t,x}^{\alpha,\epsilon}(s)) - \ln(\beta_{t',x'}^{\alpha,\epsilon}(s))| \right] \leq C_m \left( |x - x'| + |t' - t|^{\frac{1}{4}} \right).$$

*Proof.* We write  $(X, L, \beta)$  and  $(X', L', \beta')$  for  $(X_{t,x}^{\alpha,\epsilon}, L_{t,x}^{\alpha,\epsilon}, \beta_{t,x}^{\alpha,\epsilon})$  and  $(X_{t',x'}^{\alpha,\epsilon}, L_{t',x'}^{\alpha,\epsilon}, \beta_{t',x'}^{\alpha,\epsilon})$ .

1. It follows from Lemma 2.1 and Gronwall's lemma that

$$\mathbb{E} \left[ \sup_{t' \leq s \leq T} |X(s) - X'(s)|^4 \right] \leq C_m \mathbb{E} [|X(t') - x'|^4],$$

where  $C_m > 0$  denotes a generic constant independent of  $(t, t', x, x')$ . Choosing some large  $\bar{K} > 0$ , applying Itô's lemma to  $(e^{-\bar{K}|\epsilon|(t)} \tilde{f}_\epsilon(X(t), y, \epsilon(t)))_{t \leq T}$ ,  $y \in \bar{\mathcal{O}}$ , and  $\tilde{f}_\epsilon$  defined as in (2.14), and using the same arguments as in Lemma 2.1 (the terms corresponding to  $A_t$  and  $G_t$  are treated similarly; the term corresponding to  $H_t$  is bounded by using the fact that the integrands are bounded by  $C/\epsilon$  for some  $C > 0$  by Lemma 2.2), leads to

$$(3.5) \quad \mathbb{E} \left[ \sup_{t \leq s \leq t'} |X(s) - y|^4 \right] \leq C_m (|t' - t| + |x - y|^4).$$

This proves (3.2) and the bound for the first term in (3.3).

2. We now provide the bound for the second term in (3.3). Let  $h$  be defined as in Lemma 2.2. Applying Itô's lemma to  $h(X, \epsilon) - h(x, \epsilon)$  and using (2.12) leads to

$$\begin{aligned} 0 \leq L(t') &\leq \int_t^{t'} \langle D_x h(X(s), \epsilon(s)), \gamma(X(s), \epsilon(s)) \rangle dL(s) \\ &= h(X(t'), \epsilon(t')) - h(x, \epsilon(t')) \\ &\quad - \int_t^{t'} \left( \langle D_x h(X(s), \epsilon(s)), \mu_s(X(s)) \rangle + \frac{1}{2} \text{Tr}[D_x^2 h(X(s), \epsilon(s)) \sigma_s \sigma_s^*(X(s))] \right) ds \\ &\quad - \int_t^{t'} \langle D_x h(X(s), \epsilon(s)), \sigma_s(X(s)) dW_s \rangle \\ &\quad - \int_t^{t'} \langle D_\epsilon h(X(s), \epsilon(s)) - D_\epsilon h(x, \epsilon(s)), d\epsilon(s) \rangle, \end{aligned}$$

where, by the Lipschitz continuity of  $D_e h$ ,

$$\left| \int_t^{t'} \langle D_e h(X(s), \epsilon(s)) - D_e h(x, \epsilon(s)), d\epsilon(s) \rangle \right| \leq C \sup_{t \leq s \leq t'} |X(s) - x| |\epsilon|(T)$$

for some  $C > 0$  which depends only on  $h$ . Since  $|\epsilon|(T) \leq m$ , the bound for the second term in (3.3) then follows from the Lipschitz continuity of the coefficients, the previous estimates, and the boundedness of  $\mathcal{O}$  and  $E$ .

3. We finally prove (3.4). Since  $|\gamma| = 1$  and  $\rho|\gamma|^2$  is bounded, we have for  $s \in [t', T]$

$$\begin{aligned} & |\ln \beta(s) - \ln \beta'(s)| \\ &= \left| \int_t^s (\rho|\gamma|^2)(X(r), \epsilon(r)) dL(r) - \int_{t'}^s (\rho|\gamma|^2)(X'(r), \epsilon(r)) dL'(r) \right| \\ &\leq \left| \int_t^s \langle (\rho\gamma)(X(r), \epsilon(r)), \gamma(X(r), \epsilon(r)) \rangle dL(r) \right. \\ &\quad \left. - \int_{t'}^s \langle (\rho\gamma)(X(r), \epsilon(r)), \gamma(X'(r), \epsilon(r)) \rangle dL'(r) \right| \\ &\quad + \left| \int_{t'}^s \langle (\rho\gamma)(X(r), \epsilon(r)) - (\rho\gamma)(X'(r), \epsilon(r)), \gamma(X'(r), \epsilon(r)) \rangle dL'(r) \right| \\ &\leq \left| \int_{t'}^s \langle \rho\gamma(X(r), \epsilon(r)), \gamma(X(r), \epsilon(r)) \rangle dL(r) \right. \\ &\quad \left. - \int_{t'}^s \langle \rho\gamma(X(r), \epsilon(r)), \gamma(X'(r), \epsilon(r)) \rangle dL'(r) \right| \\ &\quad + C \left( L(t') + \sup_{t' \leq s \leq T} |X(s) - X'(s)| L'(T) \right) \end{aligned}$$

for some  $C > 0$  independent of  $(s, x, x', t, t')$ . If we assume that  $\rho \in C^{2,1}(\mathbb{R}^{d+\ell}, \mathbb{R})$ , then applying Itô's lemma to  $\langle X - X', \gamma(X, \epsilon) \rho(X, \epsilon) \rangle$  on  $[t', s]$  leads to

$$\begin{aligned} & \langle X(s) - X'(s), \gamma(X(s), \epsilon(s)) \rho(X(s), \epsilon(s)) \rangle \\ &= \langle X(t') - X'(t'), \gamma(X(t'), \epsilon(t')) \rho(X(t'), \epsilon(t')) \rangle \\ &\quad + \int_{t'}^s \langle \gamma(X(r), \epsilon(r)) \rho(X(r), \epsilon(r)), \mu_r(X(r)) - \mu_r(X'(r)) \rangle dr \\ &\quad + \int_{t'}^s \sum_{i \leq d} (\gamma(X(r), \epsilon(r)) \rho(X(r), \epsilon(r)))^i (\sigma_r(X(r)) - \sigma_r(X'(r)))^i dW_r \\ &\quad + \int_{t'}^s \langle \rho\gamma(X(r), \epsilon(r)), \gamma(X(r), \epsilon(r)) \rangle dL(r) \\ &\quad - \int_{t'}^s \langle \rho\gamma(X(r), \epsilon(r)), \gamma(X'(r), \epsilon(r)) \rangle dL'(r) \end{aligned}$$

$$\begin{aligned}
& + \int_{t'}^s \sum_{i \leq d} (X(r) - X'(r))^i \left( \langle D_x([\gamma\rho]^i)(X(r), \epsilon(r)), \mu_r(X(r)) \rangle \right) dr \\
& + \int_{t'}^s \sum_{i \leq d} (X(r) - X'(r))^i \left( \frac{1}{2} \text{Tr}[D_x^2([\gamma\rho]^i)(X(r), \epsilon(r)) \sigma_r \sigma_r^*(X(r))] \right) dr \\
& + \int_{t'}^s \sum_{i \leq d} (X(r) - X'(r))^i \left( \langle D_x([\gamma\rho]^i)(X(r), \epsilon(r)), \gamma(X(r), \epsilon(r)) \rangle \right) dL(r) \\
& + \int_{t'}^s \sum_{i \leq d} (X(r) - X'(r))^i \langle D_x([\gamma\rho]^i)(X(r), \epsilon(r)), \sigma_r(X(r)) dW_r \rangle \\
& + \int_{t'}^s \sum_{i \leq d} (X(r) - X'(r))^i \langle D_e([\gamma\rho]^i)(X(r), \epsilon(r)), d\epsilon(r) \rangle \\
& + \int_{t'}^s \sum_{i \leq d} \langle \sigma_r(X(r)) - (\sigma_r(X'(r)))^i, \sum_{k \leq d} (D_x([\gamma\rho]^i)(X(r), \epsilon(r)))^k \sigma_r^{k\cdot}(X(r)) \rangle dr,
\end{aligned}$$

where  $M^{j\cdot}$  denotes the  $j$ th column of a matrix  $M$ . Using the Lipschitz continuity of the coefficients and the bound  $|\epsilon|(T) \leq m$  thus leads to

$$\begin{aligned}
& \mathbb{E} \left[ \sup_{t' \leq s \leq T} \left| \int_{t'}^s \langle \rho \gamma(X(r), \epsilon(r)), \gamma(X(r), \epsilon(r)) \rangle dL(r) \right. \right. \\
& \quad \left. \left. - \int_{t'}^s \langle \rho \gamma(X(r), \epsilon(r)), \gamma(X'(r), \epsilon(r)) \rangle dL'(r) \right| \right] \\
& \leq C_m \mathbb{E} \left[ \sup_{t' \leq s \leq T} |X(s) - X'(s)|^2 \right]^{\frac{1}{2}} \left( 1 + \mathbb{E} [L(T)^2]^{\frac{1}{2}} \right),
\end{aligned}$$

where  $C_m$  depends on  $\rho$  only through the bounds on  $|\rho|$ , on the first and second derivatives in its first variable, and on the first derivative in its second variable. Thus, by the previous inequality and the Cauchy–Schwarz inequality,

$$\begin{aligned}
& \mathbb{E} \left[ \sup_{t' \leq s \leq T} |\ln \beta(s) - \ln \beta'(s)| \right] \\
& \leq C_m \left( \mathbb{E} [L(t')] + \mathbb{E} \left[ \sup_{t' \leq s \leq T} |X(s) - X'(s)|^2 \right]^{\frac{1}{2}} \left( \mathbb{E} [(L'(T))^2]^{\frac{1}{2}} + \mathbb{E} [(L(T))^2]^{\frac{1}{2}} + 1 \right) \right)
\end{aligned}$$

for some  $C_m > 0$  as above. In view of the previous estimates, the result follows for  $\rho$  smooth enough. Since the estimate of (3.3) clearly does not depend on  $\rho$ , this result is easily extended to the general case by a standard approximation argument.  $\square$

*Remark 3.1.* It follows from the pathwise uniqueness result of Theorem 2.2 and standard arguments (see, e.g., Theorems 5.3.19 and 5.4.20 of [10]), that  $X_{t,x}^{\alpha,\epsilon}$  is a strong Markov process.

LEMMA 3.1. Fix  $m > 0$  and set

$$v_m(t, x) := \sup_{(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}_m^b} J(t, x; \alpha, \epsilon), \quad (t, x) \in [0, T] \times \bar{\mathcal{O}}.$$

Then, there is  $C_m > 0$  such that

$$|J(t, x; \alpha, \epsilon) - J(t', x'; \alpha, \epsilon)| + |v_m(t, x) - v_m(t', x')| \leq C_m \left( |t - t'|^{\frac{1}{4}} + |x - x'| \right)$$

for all  $(t, t', x, x') \in [0, T]^2 \times \bar{\mathcal{O}}^2$  and  $(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}_m^b$ . Moreover,  $v = \lim_{m \rightarrow \infty} \uparrow v_m = \sup_{m > 0} v_m$  on  $[0, T] \times \bar{\mathcal{O}}$  and  $v$  is lower semicontinuous.

*Proof.* Since

$$|v_m(t, x) - v_m(t', x')| \leq \sup_{(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}_m^b} |J(t, x; \alpha, \epsilon) - J(t', x'; \alpha, \epsilon)|,$$

the first assertion follows from the uniform estimates of Proposition 3.1, the Lipschitz continuity assumptions on the parameters  $g$  and  $f$ , and the fact that  $\rho \geq 0$  so that  $\beta_{t,x}^{\alpha,\epsilon} \leq 1$  for all  $(t, x) \in [0, T] \times \bar{\mathcal{O}}$  and  $(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}$ . Clearly  $(v_m)_{m>0}$  is nondecreasing and  $v \geq \sup_{m>0} v_m$ . Thus, it remains to prove that when  $v \leq \sup_{m>0} v_m$ , the lower semicontinuity of  $v$  will then follow from the continuity of each  $v_m$ . To see this, fix  $(t, x) \in [0, T] \times \bar{\mathcal{O}}$ ,  $(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}$  and set  $\tau_m := \inf\{s \in [t, T] : |\epsilon|(s) \geq m\}$  and  $\epsilon_m := \epsilon(\cdot \wedge \tau_m)$ ,  $m > 0$ . Since  $\tau_m \rightarrow \infty$ , we have  $\beta_{t,x}^{\alpha,\epsilon_m} f(X_{t,x}^{\alpha,\epsilon_m}, \alpha) \rightarrow \beta_{t,x}^{\alpha,\epsilon} f(X_{t,x}^{\alpha,\epsilon}, \alpha)$   $dt \times d\mathbb{P}$ -a.e. on  $[t, T]$  and  $(X_{t,x}^{\alpha,\epsilon_m}, \beta_{t,x}^{\alpha,\epsilon_m})(T) \rightarrow (X_{t,x}^{\alpha,\epsilon}, \beta_{t,x}^{\alpha,\epsilon})(T)$   $\mathbb{P}$ -a.s. as  $m \rightarrow \infty$ . By dominated convergence and the continuity of  $g$ , we then deduce that  $J(t, x; \alpha, \epsilon_m) \rightarrow J(t, x; \alpha, \epsilon)$ . This implies that, for each  $\varepsilon > 0$ , we can find  $m > 0$  such that  $v(t, x) - \varepsilon \leq v_m(t, x)$  and therefore  $v(t, x) \leq \sup_{m>0} v_m(t, x)$ .  $\square$

We can now prove the following dynamic programming principle.

LEMMA 3.2. Fix  $(t, x) \in [0, T] \times \bar{\mathcal{O}}$ . For all  $[t, T]$ -valued stopping times  $\theta$ , we have

$$v(t, x) = \sup_{(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}} \mathbb{E} \left[ \beta_{t,x}^{\alpha,\epsilon}(\theta) v(\theta, X_{t,x}^{\alpha,\epsilon}(\theta)) + \int_t^\theta \beta_{t,x}^{\alpha,\epsilon}(s) f(X_{t,x}^{\alpha,\epsilon}(s), \alpha(s)) ds \right].$$

*Proof.* Fix  $(t_0, x_0) \in [0, T] \times \bar{\mathcal{O}}$  (the case  $t_0 = T$  is trivial). The fact that  $v(t_0, x_0)$  is bounded from above by

$$\sup_{(\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}} \mathbb{E} \left[ \beta_{t_0,x_0}^{\alpha,\epsilon}(\theta) v(\theta, X_{t_0,x_0}^{\alpha,\epsilon}(\theta)) + \int_{t_0}^\theta \beta_{t_0,x_0}^{\alpha,\epsilon}(s) f(X_{t_0,x_0}^{\alpha,\epsilon}(s), \alpha(s)) ds \right]$$

follows from the Markov feature of our model; see Remark 3.1. We now prove the converse inequality.

1. Fix  $m > 0$ . Let  $(B_n)_{n \geq 1}$  be a partition of  $[0, T] \times \bar{\mathcal{O}}$  and  $(t_n, x_n)_{n \geq 1}$  be a sequence such that  $(t_n, x_n) \in B_n$  for each  $n \geq 1$ . By definition, we can find  $\xi^n := (\alpha^n, \epsilon^n) \in \mathcal{A} \times \mathcal{E}_m^b$  such that

$$(3.6) \quad J(t_n, x_n; \xi^n) \geq v_m(t_n, x_n) - \varepsilon/3,$$

where  $\varepsilon > 0$  is a fix parameter. Moreover, by the uniform continuity of  $v_m$  and  $J(\cdot; \xi)$  for  $\xi \in \mathcal{A} \times \mathcal{E}_m^b$  (see Lemma 3.1), we can choose  $(B_n, t_n, x_n)_{n \geq 1}$  in such a way that

$$(3.7) \quad |J(\cdot; \xi^n) - J(t_n, x_n; \xi^n)| + |v_m - v_m(t_n, x_n)| \leq \varepsilon/3 \quad \text{on } B_n.$$

2. Given  $\xi \in \mathcal{A} \times \mathcal{E}_m^b$  and  $\theta$  a stopping time with values in  $[t_0, T]$ , we define  $\bar{\xi} \in \mathcal{A} \times \mathcal{E}_m^b$  by

$$\bar{\xi}(t) := \xi(t) \mathbb{I}_{\{t < \theta\}} + \mathbb{I}_{\{t \geq \theta\}} \sum_{n \geq 1} \xi^n(t) \mathbb{I}_{\{(\theta, X_{t_0,x_0}^{\xi^n}(\theta)) \in B_n\}}.$$

Using successively the Markov feature of our model (see Remark 3.1, (3.7), (3.6), (3.7)) again and the fact that  $\rho \geq 0$  (which implies that  $\beta_{t_0, x_0}(\theta) \leq 1$ ), we deduce that, for all  $\xi = (\alpha, \epsilon) \in \mathcal{A} \times \mathcal{E}^b$ ,

$$\begin{aligned}
 J(t_0, x_0; \bar{\xi}) &\geq \mathbb{E} \left[ \beta_{t_0, x_0}^\xi(\theta) J(\theta, X_{t_0, x_0}^\xi(\theta); \bar{\xi}) + \int_t^\theta \beta_{t_0, x_0}^\xi(s) f(X_{t_0, x_0}^\xi(s), \alpha(s)) ds \right] \\
 &= \mathbb{E} \left[ \beta_{t_0, x_0}^\xi(\theta) \sum_{n \geq 1} J(\theta, X_{t_0, x_0}^\xi(\theta); \xi^n) \mathbb{I}_{\{(\theta, X_{t_0, x_0}^\xi(\theta)) \in B_n\}} \right] \\
 &\quad + \mathbb{E} \left[ \int_t^\theta \beta_{t_0, x_0}^\xi(s) f(X_{t_0, x_0}^\xi(s), \alpha(s)) ds \right] \\
 &\geq \mathbb{E} \left[ \beta_{t_0, x_0}^\xi(\theta) \sum_{n \geq 1} J(t_n, x_n; \xi^n) \mathbb{I}_{\{(\theta, X_{t_0, x_0}^\xi(\theta)) \in B_n\}} \right] \\
 &\quad + \mathbb{E} \left[ \int_t^\theta \beta_{t_0, x_0}^\xi(s) f(X_{t_0, x_0}^\xi(s), \alpha(s)) ds \right] - \varepsilon/3 \\
 &\geq \mathbb{E} \left[ \beta_{t_0, x_0}^\xi(\theta) \left( \sum_{n \geq 1} v_m(t_n, x_n; \xi^n) \mathbb{I}_{\{(\theta, X_{t_0, x_0}^\xi(\theta)) \in B_n\}} \right) \right] \\
 &\quad + \mathbb{E} \left[ \int_t^\theta \beta_{t_0, x_0}^\xi(s) f(X_{t_0, x_0}^\xi(s), \alpha(s)) ds \right] - 2\varepsilon/3 \\
 &\geq \mathbb{E} \left[ \beta_{t_0, x_0}^\xi(\theta) v_m(\theta, X_{t_0, x_0}^\xi(\theta)) + \int_t^\theta \beta_{t_0, x_0}^\xi(s) f(X_{t_0, x_0}^\xi(s), \alpha(s)) ds \right] - \varepsilon.
 \end{aligned}$$

By arbitrariness of  $\varepsilon > 0$ , this shows that

$$(3.8) \quad v(t_0, x_0) \geq \mathbb{E} \left[ \beta_{t_0, x_0}^\xi(\theta) v_m(\theta, X_{t_0, x_0}^\xi(\theta)) + \int_t^\theta \beta_{t_0, x_0}^\xi(s) f(X_{t_0, x_0}^\xi(s), \alpha(s)) ds \right].$$

Since  $v_m \rightarrow v$  as  $m \rightarrow \infty$  by Lemma 3.1, it follows by dominated convergence that, for all  $\xi \in \mathcal{A} \times \mathcal{E}^b$ ,

$$v(t_0, x_0) \geq \mathbb{E} \left[ \beta_{t_0, x_0}^\xi(\theta) v(\theta, X_{t_0, x_0}^\xi(\theta)) + \int_t^\theta \beta_{t_0, x_0}^\xi(s) f(X_{t_0, x_0}^\xi(s), \alpha(s)) ds \right].$$

The same localization argument as in the proofs of Theorem 2.2 and Lemma 3.1 then implies that the above inequality actually holds for all  $\xi \in \mathcal{A} \times \mathcal{E}$ .  $\square$

**3.3. PDE characterization for the optimal control problem.** In this section, we show that  $v$  is a solution of

$$\mathcal{K}\varphi = 0,$$

where

$$\mathcal{K}\varphi := \begin{cases} \min_{a \in A} (-\mathcal{L}^a \varphi - f(\cdot, a)) = 0 & \text{on } [0, T] \times \mathcal{O}, \\ \min_{e \in E} \mathcal{H}^e \varphi = 0 & \text{on } [0, T] \times \partial \mathcal{O}, \\ \varphi - g = 0 & \text{on } \{T\} \times \bar{\mathcal{O}}, \end{cases}$$

and, for a smooth function  $\varphi$  on  $[0, T] \times \bar{\mathcal{O}}$  and  $(a, e) \in A \times E$ , we set

$$\begin{aligned} \mathcal{L}^a \varphi &:= \frac{\partial}{\partial t} \varphi + \langle \mu(\cdot, a), D\varphi \rangle + \frac{1}{2} \text{Tr} \sigma(\cdot, a) \sigma(\cdot, a)^* D^2 \varphi, \\ \mathcal{H}^e \varphi &:= \rho(\cdot, e) \varphi - \langle \gamma(\cdot, e), D\varphi \rangle. \end{aligned}$$

**3.3.1. Definitions.** Since  $v$  may not be smooth, we need to consider the above equation in the viscosity sense. Moreover, the boundary conditions may not be satisfied in a strong sense and, as usual, we have to consider a relaxed version; see, e.g., [4]. We therefore introduce the operator  $\mathcal{K}_+$  and  $\mathcal{K}_-$  defined as

$$\mathcal{K}_+ \varphi := \begin{cases} \mathcal{K}\varphi & \text{on } [0, T] \times \mathcal{O}, \\ \max \left\{ \min_{a \in A} -\mathcal{L}^a \varphi - f(\cdot, a), \min_{e \in E} \mathcal{H}^e \varphi \right\} & \text{on } [0, T] \times \partial \mathcal{O}, \\ \varphi - g & \text{on } \{T\} \times \partial \mathcal{O} \end{cases}$$

and

$$\mathcal{K}_- \varphi := \begin{cases} \mathcal{K}\varphi & \text{on } [0, T] \times \mathcal{O}, \\ \min \left\{ \min_{a \in A} -\mathcal{L}^a \varphi - f(\cdot, a), \min_{e \in E} \mathcal{H}^e \varphi \right\} & \text{on } [0, T] \times \partial \mathcal{O}, \\ \min \left\{ \varphi - g, \min_{e \in E} \mathcal{H}^e \varphi \right\} & \text{on } \{T\} \times \partial \mathcal{O}. \end{cases}$$

**DEFINITION 3.1.** We say that a lower-semicontinuous (resp., upper-semicontinuous) function  $w$  on  $[0, T] \times \bar{\mathcal{O}}$  is a viscosity supersolution (resp., subsolution) of

$$(3.9) \quad \mathcal{K}\varphi = 0$$

if for all  $\varphi \in C^{1,2}([0, T] \times \bar{\mathcal{O}})$  and all  $(t, x) \in [0, T] \times \bar{\mathcal{O}}$ , which realizes a local minimum (resp., maximum) of  $w - \varphi$  equal to 0, we have  $\mathcal{K}_+ \varphi \geq 0$  (resp.,  $\mathcal{K}_- \varphi \leq 0$ ). We say that a locally bounded function  $w$  is a (discontinuous) viscosity solution of (3.9) if  $w_*$  (resp.,  $w^*$ ) is a supersolution (resp., subsolution) of (3.9), where

$$\begin{aligned} w^*(t, x) &:= \limsup_{(t', x') \rightarrow (t, x), (t', x') \in D} w(t', x'), \\ w_*(t, x) &:= \liminf_{(t', x') \rightarrow (t, x), (t', x') \in D} w(t', x'), \quad (t, x) \in [0, T] \times \bar{\mathcal{O}}, \end{aligned}$$

with  $D := [0, T] \times \mathcal{O}$ .

**Remark 3.2.** Take  $E = \tilde{K}_1 := \tilde{K} \cap \partial B(0, 1)$ , where  $\tilde{K}$  is the domain of the support function  $\delta$  of a closed convex set  $K \subset \mathbb{R}^\ell$ , i.e.,

$$\delta(e) := \sup_{y \in K} \langle y, e \rangle, \quad e \in \mathbb{R}^\ell,$$

and assume that  $\rho(x, e) = \delta(e)$  and  $\gamma(x, e) = e$  on  $\partial\mathcal{O} \times E$ . Then, for  $\varphi \in C^1(\bar{\mathcal{O}}, (0, \infty))$ , the constraint

$$\min_{e \in E} \mathcal{H}^e \varphi = \min_{e \in E} (\delta(e) \varphi - \langle e, D\varphi \rangle) \geq 0$$

means that  $D\varphi/\varphi \in K$ ; see, e.g., [13]. In this case, the term  $\mathcal{H}^e \varphi \geq 0$  can be assimilated into a constraint on the gradient of the logarithm of the solution at the boundary of  $\mathcal{O}$ . A similar constraint appears in [2], but in the whole domain.

*Remark 3.3.* Assume that  $\mathcal{O}$  is  $C^2$  and that  $\sigma$  satisfies the noncharacteristic boundary condition

$$(3.10) \quad \min_{a \in A} |\sigma(x, a)\xi| > 0 \text{ for all } x \in \partial\mathcal{O} \text{ and } \xi \in \mathbb{R}^d \setminus \{0\}.$$

Then, it follows from the same arguments as in step 2 of the proof of Proposition 6.3 of [2] that  $w$  is a supersolution of  $\mathcal{K}_+\varphi = 0$  only if it is a supersolution of  $\bar{\mathcal{K}}_+\varphi = 0$ , where

$$\bar{\mathcal{K}}_+\varphi := \begin{cases} \mathcal{K}_+\varphi & \text{on } ([0, T] \times \mathcal{O}) \cup (\{T\} \times \bar{\mathcal{O}}), \\ \min_{e \in E} \mathcal{H}^e \varphi & \text{on } [0, T) \times \partial\mathcal{O}. \end{cases}$$

Similarly, it follows from the same arguments as in step 2 of Proposition 6.6 in [2] that  $w$  is a subsolution of  $\mathcal{K}_-\varphi = 0$  only if it is a subsolution of  $\bar{\mathcal{K}}_-\varphi = 0$ , where

$$\bar{\mathcal{K}}_-\varphi := \begin{cases} \mathcal{K}_-\varphi & \text{on } ([0, T] \times \mathcal{O}) \cup (\{T\} \times \bar{\mathcal{O}}), \\ \min_{e \in E} \mathcal{H}^e \varphi & \text{on } [0, T) \times \partial\mathcal{O}. \end{cases}$$

### 3.3.2. Super- and subsolution properties.

PROPOSITION 3.2. *The function  $v_*$  is a viscosity supersolution of (3.9).*

*Proof.* The fact that  $v_* \geq g$  on  $\{T\} \times \bar{\mathcal{O}}$  is a direct consequence of the lower semi-continuity of  $v$ ; see Lemma 3.1. Fix  $(t_0, x_0) \in [0, T) \times \bar{\mathcal{O}}$  and  $\varphi \in C^{1,2}([0, T] \times \bar{\mathcal{O}})$  such that

$$0 = (v_* - \varphi)(t_0, x_0) = \min_{[0, T] \times \bar{\mathcal{O}}} (v_* - \varphi).$$

1. We first assume that  $(t_0, x_0) \in [0, T) \times \partial\mathcal{O}$  and that

$$\max \left\{ \min_{a \in A} -\mathcal{L}^a \varphi(t_0, x_0) - f(x_0, a), \min_{e \in E} \mathcal{H}^e \varphi(t_0, x_0) \right\} =: -2\varepsilon < 0$$

and work toward a contradiction. Under the above assumption, we can find  $(a_0, e_0) \in A \times E$  and  $\delta \in (t_0, T - t_0)$  for which

$$(3.11) \quad \max \{ -\mathcal{L}^{a_0} \varphi - f(\cdot, a_0), \mathcal{H}^{e_0} \varphi \} \leq -\varepsilon$$

on  $\bar{B}_0 \cap \bar{D}_0$  where  $B_0 := B(t_0, \delta) \times B(x_0, \delta)$  and  $D_0 := (t_0 - \delta, t_0 + \delta) \times \mathcal{O}$ . Observe that we can assume, without loss of generality, that  $(t_0, x_0)$  achieves a strict local minimum so that

$$(3.12) \quad \inf_{\partial_p B_0 \cap \bar{D}_0} (v_* - \varphi) =: \zeta > 0,$$

where  $\partial_p B_0 = ([t_0 - \delta, t_0 + \delta] \times \partial B(x_0, \delta)) \cup (\{t_0 + \delta\} \times B(x_0, \delta))$ . Let  $(t_k, x_k)_{k \geq 1}$  be a sequence in  $B_0 \cap D_0$  satisfying

$$(t_k, x_k) \longrightarrow (t_0, x_0) \text{ and } v(t_k, x_k) \longrightarrow v_*(t_0, x_0) \text{ as } k \longrightarrow \infty$$

so that

$$(3.13) \quad \eta_k := v(t_k, x_k) - \varphi(t_k, x_k) \longrightarrow 0 \text{ as } k \longrightarrow \infty.$$

Let us write  $(X^k, L^k, \beta^k)$  for  $(X_{t_k, x_k}^{a_0, e_0}, L_{t_k, x_k}^{a_0, e_0}, \beta_{t_k, x_k}^{a_0, e_0})$ , where  $(a_0, e_0)$  is viewed as an element of  $\mathcal{A} \times \mathcal{E}$ . Set

$$\theta^k := \inf \{s \geq t_k : (s, X^k(s)) \notin B_0\}, \vartheta^k := \inf \{s \geq t_k : X^k(s) \notin \mathcal{O}\}.$$

It then follows from Itô's lemma, (3.11), and (3.12) that

$$\begin{aligned} v(t_k, x_k) &\leq \eta_k + \mathbb{E} \left[ \beta^k(\theta^k) v(\theta^k, X^k(\theta^k)) + \int_{t_k}^{\theta^k} \beta^k(s) f(X^k(s), a_0) ds \right] \\ &\quad - \mathbb{E} [\zeta \mathbb{I}_{\{\theta^k < \vartheta^k\}} + (\beta^k(\theta^k) \zeta + \varepsilon L^k(\theta^k)) \mathbb{I}_{\{\theta^k \geq \vartheta^k\}}], \end{aligned}$$

where we used the fact that  $\beta^k(\theta^k) = 1$  on  $\{\theta^k < \vartheta^k\}$ . Let  $c > 0$  be such that  $|\rho| \leq c$  on  $\bar{\mathcal{O}} \times E$  and observe that

$$\nu := \inf_{\ell \in [0, \infty)} e^{-c\ell} \zeta + \varepsilon \ell > 0.$$

It follows that

$$v(t_k, x_k) \leq \eta_k - \zeta \wedge \nu + \mathbb{E} \left[ \beta^k(\theta^k) v(\theta^k, X^k(\theta^k)) + \int_{t_k}^{\theta^k} \beta^k(s) f(X^k(s), a_0) ds \right],$$

which leads to a contradiction to Lemma 3.2 for  $k$  large enough; recall (3.13).

2. The case where  $(t_0, x_0) \in [0, T) \times \mathcal{O}$  is treated similarly. We assume that

$$\min_{a \in A} -\mathcal{L}^a \varphi(t_0, x_0) - f(x_0, a) =: -2\varepsilon < 0$$

and repeat the above argument with  $\delta$  small enough so that  $B(x_0, \delta) \subset \mathcal{O}$  and therefore  $\theta^k < \vartheta^k$  (so that the reflection does not operate on  $[t_0, \theta^k]$ ).  $\square$

**PROPOSITION 3.3.** *The function  $v^*$  is a viscosity subsolution of (3.9).*

*Proof.* Fix  $(t_0, x_0) \in [0, T) \times \bar{\mathcal{O}}$  and  $\varphi \in C^{1,2}([0, T] \times \bar{\mathcal{O}})$  such that

$$0 = (v^* - \varphi)(t_0, x_0) = \max_{[0, T] \times \bar{\mathcal{O}}} (v^* - \varphi).$$

The case where  $(t_0, x_0) \in [0, T) \times \bar{\mathcal{O}}$  is treated by similar arguments as in the proof of Proposition 3.2; see also what follows. We therefore assume that  $t_0 = T$ .

1. We first consider the case where  $x_0 \in \partial \mathcal{O}$ . We assume that

$$\min \left\{ \varphi - g, \min_{e \in E} \mathcal{H}^e \varphi \right\} =: 2\varepsilon > 0.$$

Set  $\phi(t, x) = \varphi(t, x) + \sqrt{T - t}$  so that  $(\partial/\partial t)\phi(t, x) \rightarrow -\infty$  as  $t \rightarrow T$  and observe that  $(T, x_0)$  also achieves a maximum for  $v^* - \phi$ . Without loss of generality, we can therefore

assume that  $(\partial/\partial t)\varphi(t, x) \rightarrow -\infty$  as  $t \rightarrow T$  and that we can find  $\delta \in (t_0, T - t_0)$  for which

$$(3.14) \quad \min \left\{ \min_{a \in A} -\mathcal{L}^a \varphi - f(\cdot, a), \varphi - g, \min_{e \in E} \mathcal{H}^e \varphi \right\} \geq \varepsilon$$

on  $\bar{B}_0 \cap \bar{D}_0$  where  $B_0 := [t_0 - \delta, T] \times B(x_0, \delta)$  and  $D_0 := (t_0 - \delta, T) \times \mathcal{O}$ . Observe that we can assume, without loss of generality, that  $(t_0, x_0)$  achieves a strict local maximum so that

$$(3.15) \quad \max_{\partial_p B_0 \cap \bar{D}_0} (v^* - \varphi) =: -\zeta < 0,$$

where  $\partial_p B_0 = ([t_0 - \delta, T] \times \partial B(x_0, \delta)) \cup (\{T\} \times B(x_0, \delta))$ . Let  $(t_k, x_k)_{k \geq 1}$  be a sequence in  $B_0 \cap D_0$  satisfying

$$(t_k, x_k) \longrightarrow (t_0, x_0) \quad \text{and} \quad v(t_k, x_k) \longrightarrow v^*(t_0, x_0) \quad \text{as } k \longrightarrow \infty$$

so that

$$(3.16) \quad \eta_k := v(t_k, x_k) - \varphi(t_k, x_k) \longrightarrow 0 \quad \text{as } k \longrightarrow \infty.$$

Let us write  $(X^k, L^k, \beta^k)$  for  $(X_{t_k, x_k}^{\alpha, \epsilon}, L_{t_k, x_k}^{\alpha, \epsilon}, \beta_{t_k, x_k}^{\alpha, \epsilon})$ , where  $(\alpha, \epsilon)$  is a given element of  $\mathcal{A} \times \mathcal{E}$ . Set

$$\theta^k := \inf \{s \geq t_k : (s, X^k(s)) \notin B_0\}, \quad \vartheta^k := \inf \{s \geq t_k : X^k(s) \notin \mathcal{O}\}.$$

It follows from Itô's lemma, (3.14), (3.15), and the identity  $v(T, \cdot) = g$  that

$$\begin{aligned} v(t_k, x_k) &\geq \eta_k + \mathbb{E} \left[ \beta^k(\theta^k) v(\theta^k, X^k(\theta^k)) + \int_{t_k}^{\theta^k} \beta^k(s) f(X^k(s), \alpha(s)) ds \right] \\ &\quad + \mathbb{E} [\zeta \mathbb{I}_{\{\theta^k < \vartheta^k\}} + (\beta^k(\theta^k)(\zeta \wedge \varepsilon) + \varepsilon L^k(\theta^k)) \mathbb{I}_{\{\theta^k \geq \vartheta^k\}}]. \end{aligned}$$

Arguing as in step 1 of the proof of Proposition 3.2, this implies that

$$\begin{aligned} v(t_k, x_k) &\geq \eta_k + \zeta \wedge \nu \\ &\quad + \mathbb{E} \left[ \beta^k(\theta^k) v(\theta^k, X^k(\theta^k)) + \int_{t_k}^{\theta^k} \beta^k(s) f(X^k(s), \alpha(s)) ds \right] \end{aligned}$$

for some  $\nu > 0$  independent of  $(\alpha, \epsilon)$ . By arbitrariness of  $(\alpha, \epsilon)$  and (3.16), this leads to a contradiction to Lemma 3.2 for  $k$  large enough.

2. The case where  $x_0 \in \mathcal{O}$  is treated similarly. It suffices to take  $\delta$  small enough so that  $B(x_0, \delta) \subset \mathcal{O}$  and therefore  $\theta^k < \vartheta^k$ .  $\square$

**3.4. A comparison result.** A lot of work has been done so far on comparison results for quasi-linear second-order parabolic PDEs with nonlinear or oblique derivative Neumann conditions; see, e.g., [1], [9], [3], or [5] and the references therein. However, as in the first three papers, they usually require additional smoothness conditions on  $\mathcal{O}$  or, as in [5], do not allow for nonlinearities at the boundary.

In this section, we provide a comparison theorem for (3.9) in the case where there exist  $\bar{e}$  and  $\underline{e}$  in  $E$  such that

$$(3.17) \quad \underline{e} \in \arg \min \{\rho(x, e), e \in E\}, \quad \bar{e} \in \arg \max \{\rho(x, e), e \in E\} \quad \text{for all } x \in \partial \mathcal{O}$$

and additional conditions on the directions of reflection are imposed as follows:

1. As in section 7.B of [4], we first make a uniform exterior ball assumption in the direction  $\gamma$ :

$$(3.18) \quad \exists b > 0 \text{ s.t. } B(x - b\gamma(x, e), b) \cap \mathcal{O} = \emptyset \text{ for all } (x, e) \in \partial\mathcal{O} \times E.$$

2. We then assume that there is a  $C^2(\bar{\mathcal{O}})$  function  $\hat{h}$  such that

$$(3.19) \quad \langle \gamma(x, e), D\hat{h}(x) \rangle \geq 1 \text{ for all } x \in \partial\mathcal{O} \text{ and } e \in E.$$

3. The direction  $\gamma(\cdot, \bar{e})$  satisfies

$$(3.20) \quad \inf_{e \in E} \langle \gamma(x, e), \gamma(x, \bar{e}) \rangle > 0 \text{ for all } x \in \partial\mathcal{O}.$$

*Remark 3.4.* The condition (3.19) holds in the case where  $E$  is a singleton; see (2.12). When  $\partial\mathcal{O}$  is  $C^2$ , i.e., the algebraic distance  $d$  to  $\partial\mathcal{O}$  is  $C^2$ , and

$$\min_{e \in E} \langle \gamma(x, e), Dd(x) \rangle \geq \varepsilon \text{ for all } x \in \partial\mathcal{O}$$

for some  $\varepsilon > 0$ , then we can choose  $\hat{h} = \varepsilon^{-1}d$ . This imposes a restriction on the direction of reflection with respect to the unit normal inward vector at  $x \in \partial\mathcal{O}$ .

Under these conditions, we can state the following comparison theorem for super- and subsolutions of (3.9).

**PROPOSITION 3.4.** *Assume that (3.17), (3.18), (3.19), and (3.20) hold. Let  $u$  (resp.,  $w$ ) be a bounded upper-semicontinuous viscosity subsolution (resp., lower-semicontinuous viscosity supersolution) of (3.9). Then,  $u \leq w$  on  $[0, T] \times \bar{\mathcal{O}}$ .*

*Proof.* We argue by contradiction and assume that  $\max_{\bar{D}}(u - w) > 0$ , with  $D := [0, T] \times \mathcal{O}$ . We can then find  $\varepsilon > 0$  small enough and  $(t_0, x_0) \in \bar{D}$  such that

$$(3.21) \quad \max_{\bar{D}}(\tilde{u} - \tilde{w} - 2\varepsilon H) = (\tilde{u} - \tilde{w} - 2\varepsilon H)(t_0, x_0) =: \eta > 0,$$

where  $\tilde{u}(t, x) = e^{\kappa t}u(t, x)$ ,  $\tilde{w}(t, x) = e^{\kappa t}w(t, x)$ , and  $H(t, x) := e^{-\kappa t - \hat{h}(x)}$ , where  $\hat{h}$  is defined as in (3.19) and  $\kappa > 0$  is a constant parameter such that

$$(3.22) \quad -\mathcal{L}^a H \geq 0 \text{ on } \bar{D} \text{ for all } a \in A.$$

We first assume that

$$(3.23) \quad u(t_0, x_0) \geq 0.$$

The case  $u(t_0, x_0) < 0$  will be treated in step 4 below.

Given  $\lambda \in \mathbb{N}$ , we next define

$$\Phi_\lambda(t, x, y) := \tilde{u}(t, x) - \tilde{w}(t, y) - \Psi_\lambda(t, x, y),$$

where

$$\begin{aligned} \Psi_\lambda(t, x, y) &:= \varepsilon(H(t, x) + H(t, y)) + \rho(x_0, \underline{e})u(t_0, x_0)\langle \gamma(x_0, \underline{e}), x - y \rangle \\ &\quad + \frac{\lambda}{2}|x - y|^2 + |t - t_0|^2 + |x - x_0|^4 \end{aligned}$$

for some  $\zeta > 0$ .

Let  $(t_\lambda, x_\lambda, y_\lambda)$  be a global maximum point for  $\Phi_\lambda$  on  $\bar{D}$ . Using standard arguments, one easily checks that

$$(3.24) \quad (t_\lambda, x_\lambda) \rightarrow (t_0, x_0), \quad \lambda |x_\lambda - y_\lambda|^2 \rightarrow 0, \quad (\tilde{u}(t_\lambda, x_\lambda), \tilde{w}(t_\lambda, y_\lambda)) \rightarrow (\tilde{u}(t_0, x_0), \tilde{w}(t_0, x_0))$$

as  $\lambda \rightarrow \infty$ ; see, e.g., Lemma 3.1 and Proposition 3.7 in [4].

Moreover, Ishii's lemma (see Theorem 8.3 in [4]) implies that we can find  $p_{\lambda,1}$ ,  $p_{\lambda,2} \in \mathbb{R}$ , and two symmetric matrices  $X_{\alpha,\lambda}$  and  $Y_{\alpha,\lambda}$ , depending on a parameter  $\alpha > 0$ , such that

$$(3.25) \quad \begin{aligned} (p_{\lambda,1}, D_x \Psi_\lambda(t_\lambda, x_\lambda, y_\lambda), X_{\alpha,\lambda}) &\in \bar{\mathcal{P}}_{\mathcal{O}}^{2,+} \tilde{u}(t_\lambda, x_\lambda), \\ (p_{\lambda,2}, -D_y \Psi_\lambda(t_\lambda, x_\lambda, y_\lambda), Y_{\alpha,\lambda}) &\in \bar{\mathcal{P}}_{\mathcal{O}}^{2,-} \tilde{w}(t_\lambda, y_\lambda) \end{aligned}$$

and

$$(3.26) \quad p_{\lambda,1} - p_{\lambda,2} = 2(t_\lambda - t_0) - \kappa \varepsilon (H(t_\lambda, x_\lambda) + H(t_\lambda, y_\lambda)),$$

$$(3.27) \quad \begin{pmatrix} X_{\alpha,\lambda} & 0 \\ 0 & -Y_{\alpha,\lambda} \end{pmatrix} \leq (A_\lambda + B_\lambda) + \alpha (A_\lambda + B_\lambda)^2,$$

where

$$\begin{aligned} A_\lambda &:= \varepsilon \begin{pmatrix} D^2 H(t_\lambda, x_\lambda) & 0 \\ 0 & D^2 H(t_\lambda, y_\lambda) \end{pmatrix} + 12(x_\lambda - x_0) \otimes (x_\lambda - x_0), \\ B_\lambda &:= \lambda \begin{pmatrix} I_d & -I_d \\ -I_d & I_d \end{pmatrix}, \end{aligned}$$

see [4] for the notations  $\bar{\mathcal{P}}_{\mathcal{O}}^{2,+}$  and  $\bar{\mathcal{P}}_{\mathcal{O}}^{2,-}$ .

1. Assume that  $x_\lambda \in \partial \mathcal{O}$ . Fix  $e \in E$ . Since  $y_\lambda \in \bar{\mathcal{O}}$ , it follows from (3.18) that  $|x_\lambda - b\gamma(x_\lambda, e) - y_\lambda|^2 \geq b^2$ . Since  $|\gamma| = 1$ , this implies

$$(3.28) \quad 2\langle \gamma(x_\lambda, e), y_\lambda - x_\lambda \rangle \geq -b^{-1}|x_\lambda - y_\lambda|^2.$$

Then, it follows from the definition of  $\varepsilon$ , the fact that  $|\gamma| = 1$ , the assumptions  $\rho \geq 0$ , (3.23), (3.17), (3.19), (3.24), and (3.28) that

$$\begin{aligned} &\rho(x_\lambda, e)u(t_\lambda, x_\lambda) - \langle \gamma(x_\lambda, e), D_x \Psi_\lambda(t_\lambda, x_\lambda, y_\lambda) \rangle \\ &= (\rho(x_0, e) - \rho(x_0, \underline{e}))u(t_0, x_0) + \rho(x_0, \underline{e})u(t_0, x_0)(1 - \langle \gamma(x_0, e), \gamma(x_0, \underline{e}) \rangle) \\ &\quad + O(\lambda^{-1}) - \langle \gamma(x_\lambda, e), \lambda(x_\lambda - y_\lambda) - \varepsilon D\hat{h}(x_\lambda)H(t_\lambda, x_\lambda) \rangle \\ &\geq O(\lambda^{-1}) + \varepsilon H(t_0, x_0). \end{aligned}$$

Arguing as above, using the inequalities  $\rho \geq 0$ , and  $u(t_0, x_0) \geq w(t_0, x_0)$ , and observing that  $\langle \gamma(y_\lambda, \underline{e}), \gamma(x_0, \underline{e}) \rangle \rightarrow 1$ , we also deduce that, if  $y_\lambda \in \partial \mathcal{O}$ ,

$$\begin{aligned} &\rho(y_\lambda, \underline{e})w(t_\lambda, y_\lambda) - \langle \gamma(y_\lambda, \underline{e}), -D_y \Psi_\lambda(t_\lambda, x_\lambda, y_\lambda) \rangle \\ &\leq \rho(x_0, \underline{e})(w(t_0, x_0) - u(t_0, x_0)) - \varepsilon H(t_0, x_0) + O(\lambda^{-1}) \\ &\leq -\varepsilon H(t_0, x_0) + O(\lambda^{-1}). \end{aligned}$$

2. We now assume that, up to a subsequence,  $t_\lambda = T$  for all  $\lambda \in \mathbb{N}$ . By step 1 and the fact that  $H(t_0, x_0) > 0$ , we must have  $u(t_\lambda, x_\lambda) \leq g(x_\lambda)$  and  $g(y_\lambda) \leq w(t_\lambda, y_\lambda)$ . Since  $g$  is continuous, we deduce from (3.24) that  $u(t_0, x_0) \leq w(t_0, w_0)$ , which contradicts (3.21); recall that  $H > 0$ .

3. The rest of the proof is standard. We first observe that  $\tilde{u}$  and  $\tilde{w}$  are viscosity super- and subsolutions of  $\tilde{\mathcal{K}}_+\varphi = 0$  and  $\tilde{\mathcal{K}}_-\varphi = 0$ , where  $\tilde{\mathcal{K}}_+$  and  $\tilde{\mathcal{K}}_-$  are defined as  $\mathcal{K}_+$  and  $\mathcal{K}_-$  with  $\mathcal{L}^a$  replaced by  $\tilde{\mathcal{L}}^a$  defined by

$$\tilde{\mathcal{L}}^a\varphi = -\kappa\varphi + \mathcal{L}^a\varphi.$$

In view of steps 1 and 2 and  $H(t_0, x_0) > 0$ , we may find  $a_\lambda$  in the compact set  $A$  such that, after possibly passing to a subsequence,

$$\begin{aligned} 0 &\geq \kappa\tilde{u}(t_\lambda, x_\lambda) - p_{\lambda,1} - \langle \mu(t_\lambda, x_\lambda, a_\lambda), D_x\Psi_\lambda(t_\lambda, x_\lambda, y_\lambda) \rangle \\ &\quad - \frac{1}{2}\text{Tr}\sigma\sigma^*(t_\lambda, x_\lambda, a_\lambda)X_{\eta,\lambda} - f(t_\lambda, x_\lambda, a_\lambda) \\ 0 &\leq \kappa\tilde{w}(t_\lambda, y_\lambda) - p_{\lambda,2} - \langle \mu(t_\lambda, y_\lambda, a_\lambda), -D_y\Psi_\lambda(t_\lambda, x_\lambda, y_\lambda) \rangle \\ &\quad - \frac{1}{2}\text{Tr}\sigma\sigma^*(t_\lambda, y_\lambda, a_\lambda)Y_{\eta,\lambda} - f(t_\lambda, y_\lambda, a_\lambda). \end{aligned}$$

Taking the difference of these two equations and using (3.21) and (3.22), the Lipschitz continuity of the coefficients, and the fact that  $A$  and  $\mathcal{O}$  are bounded, (3.26) and (3.27) leads to

$$\begin{aligned} \kappa\eta + O(\lambda^{-1}) &\leq \kappa(\tilde{u}(t_\lambda, x_\lambda) - \tilde{w}(t_\lambda, y_\lambda)) \\ &\leq O(|t_\lambda - t_0| + \lambda|x_\lambda - y_\lambda|^2 + |x_\lambda - x_0|^2 + C_\lambda\alpha), \end{aligned}$$

where  $C > 0$  is independent of  $\lambda$  and  $\alpha$ , and  $C_\lambda$  depends only on  $\lambda$ . Sending  $\alpha \rightarrow 0$  and then  $\lambda \rightarrow \infty$  thus leads to a contradiction; recall (3.24).

4. The case  $u(t_0, x_0) < 0$  is treated similarly. It suffices to consider the test function

$$\begin{aligned} \Psi_\lambda(t, x, y) &:= \varepsilon(H(t, x) + H(t, y)) + \tilde{b}^{-1}\rho(x_0, \bar{e})u(t_0, x_0)\langle \gamma(x_0, \bar{e}), x - y \rangle \\ &\quad + \frac{\lambda}{2}|x - y|^2 + |t - t_0|^2 + |x - x_0|^4, \end{aligned}$$

where  $\bar{e}$  is defined in (3.17), and  $\tilde{b} > 0$  and  $\bar{e} \in E$  satisfy

$$\min_{e \in E} \langle \gamma(x_0, \bar{e}), \gamma(x_0, e) \rangle = \langle \gamma(x_0, \bar{e}), \gamma(x_0, \tilde{e}) \rangle = \tilde{b};$$

recall (3.20). With this modification, the arguments of step 1 becomes

$$\begin{aligned} &\rho(x_\lambda, e)u(t_\lambda, x_\lambda) - \langle \gamma(x_\lambda, e), D_x\Psi_\lambda(t_\lambda, x_\lambda, y_\lambda) \rangle \\ &= (\rho(x_0, e) - \rho(x_0, \bar{e}))u(t_0, x_0) + \rho(x_0, \bar{e})u(t_0, x_0)(1 - \tilde{b}^{-1}\langle \gamma(x_0, e), \gamma(x_0, \tilde{e}) \rangle) \\ &\quad + O(\lambda^{-1}) - \langle \gamma(x_\lambda, e), \lambda(x_\lambda - y_\lambda) - \varepsilon D\hat{h}(x_\lambda)H(t_\lambda, x_\lambda) \rangle \\ &\geq O(\lambda^{-1}) + \varepsilon H(t_0, x_0) \end{aligned}$$

in the case where  $x_\lambda \in \partial\mathcal{O}$ , and becomes

$$\begin{aligned} & \rho(y_\lambda, \bar{e})w(t_\lambda, y_\lambda) - \langle \gamma(y_\lambda, \bar{e}), -D_y \Psi_\lambda(t_\lambda, x_\lambda, y_\lambda) \rangle \\ & \leq \rho(x_0, \bar{e})(w(t_0, x_0) - u(t_0, x_0)) \\ & \quad + \rho(x_0, \bar{e})u(t_0, x_0)(1 - \tilde{b}^{-1} \langle \gamma(x_0, \bar{e}), \gamma(x_0, \tilde{e}) \rangle) - \varepsilon H(t_0, x_0) + O(\lambda^{-1}) \\ & \leq -\varepsilon H(t_0, x_0) + O(\lambda^{-1}) \end{aligned}$$

in the case where  $y_\lambda \in \partial\mathcal{O}$ . The rest of the proof is similar to the above.  $\square$

*Remark 3.5.* Observe that the right-hand sides of conditions (3.17) and (3.20) are only used in step 4 of the above proof to treat the case  $u(t_0, x_0) < 0$ . It is therefore not required if  $u \geq 0$  on  $[0, T] \times \partial\mathcal{O}$ . Similarly, it can be dropped if  $w \geq 0$  on  $[0, T] \times \partial\mathcal{O}$  since, in this case, (3.21) also implies that  $u(t_0, x_0) \geq 0$ .

*Remark 3.6.* Assume that

$$\mu(x, a) = \text{diag } x\bar{\mu}(x, a), \quad \sigma(x, a) = \text{diag } x\bar{\sigma}(x, a) \quad \text{on } \mathbb{R}_+^d \times A$$

and

$$\gamma(x, e) = \text{diag } x\bar{\gamma}(x, e) \quad \text{on } (\partial\mathcal{O} \cap (0, \infty)^d) \times E$$

with  $\bar{\mu}$ ,  $\bar{\sigma}$ , and  $\bar{\gamma}$  such that  $\mu$ ,  $\sigma$ , and  $\gamma$  satisfy the general assumptions of this section. Then, the process  $X_{t,x}^{\alpha,\epsilon}$  takes values in  $(0, \infty)^d$  whenever  $x \in (0, \infty)^d$ . It is therefore natural to consider the PDE  $\mathcal{K}\varphi = 0$  on  $[0, T] \times (\bar{\mathcal{O}} \cap (0, \infty)^d)$ , with a notion of viscosity solution similar to the one of Definition 3.1 with  $\mathcal{O}$ ,  $\partial\mathcal{O}$ , and  $\bar{\mathcal{O}}$  replaced by  $\mathcal{O}^* := \mathcal{O} \cap (0, \infty)^d$ ,  $\partial\mathcal{O}^* := \partial\mathcal{O} \cap (0, \infty)^d$ , and  $\bar{\mathcal{O}}^* := \bar{\mathcal{O}} \cap (0, \infty)^d$ .

The proofs of Propositions 3.2 and 3.3 are easily adapted to this context. We therefore obtain that  $v$  is a viscosity solution of  $\mathcal{K}\varphi = 0$  on  $[0, T] \times \bar{\mathcal{O}}^*$ . Moreover, the proof of the comparison principle of Proposition 3.4 can also be extended. It suffices to add an additional penalty function of the form  $k \sum_{i \leq d} |x^i|^{-1}$ , with  $k \rightarrow \infty$ , as in [2].

*Remark 3.7.* The smoothness assumptions on  $\rho$  and  $\gamma$  are only used either to construct  $(X_{t,x}^{\alpha,\epsilon}, L_{t,x}^{\alpha,\epsilon})$  or to prove the dynamic programming principle of Lemma 3.2. We shall see, through an example in section 4.3 below, how they can be relaxed.

**4. Application to the pricing of barrier options under constraints.** As already stated in the introduction, our main motivation comes from applications in mathematical finance. More precisely, [2] provides a PDE characterization of the superhedging price of barrier options under portfolio constraints, which is very similar to the equation  $\mathcal{K}\varphi = 0$  up to an additional term inside the domain  $\mathcal{O}$  which imposes a constraint on the gradient of the logarithm of the solution.

The aim of this section is to show that the superhedging price of barrier options under portfolio constraints can actually admit a dual formulation in terms of an optimal control problem for a reflected diffusion in which the direction of reflection is controlled. Due to the additional term, which appears in the PDE of [2], we cannot expect this result to be general and we shall restrict our attention to a Black-Scholes type model; see below.

In order to simplify the presentation, we shall work under quite restrictive conditions, assuming, for instance, that the equation  $\mathcal{K}\varphi = 0$  admits a sufficiently smooth solution for a suitable choice of parameters. The general case is left for future research.

**4.1. Problem formulation.** We briefly present the hedging problem. Details can be found in [2] and the references contained in this paper.

We consider a financial market which consists of one nonrisky asset, whose price process is normalized to unity, and  $d$  risky assets  $S_{t,x} = (S_{t,x}^i)_{i \leq d}$  which solve on  $[t, T]$

$$S_{t,x}(s) = x + \int_t^s \text{diag } S_{t,x}(r) \Sigma \, dW(r),$$

where  $\Sigma$  is a  $d$ -dimensional invertible matrix. A financial strategy is described by a  $d$ -dimensional predictable process  $\pi = (\pi^1, \dots, \pi^d)$  (viewed as a line vector) satisfying the integrability condition

$$(4.1) \quad \int_0^T |\pi(s)|^2 ds < \infty \quad \mathbb{P}\text{-a.s.},$$

where  $\pi^i(s)$  is the proportion of wealth invested at time  $s$  in the risky asset  $S_{t,x}^i$ . We associate with an initial capital  $y \in \mathbb{R}$  and a financial strategy  $\pi$  the induced wealth process  $Y_{t,y}^\pi$  which solves on  $[t, T]$

$$(4.2) \quad Y(s) = y + \int_t^s Y(r) \pi(r) \text{diag } S_{t,x}(r)^{-1} dS_{t,x}(r) = y + \int_t^s Y(r) \pi(r) \Sigma \, dW(r).$$

In this paper, we restrict our attention to the case where the proportions invested in the risky asset are constrained to be bounded from below. Given  $m^i > 0$ ,  $i \leq d$ , we set

$$K := \prod_{i=1}^d [-m^i, \infty)$$

and denote by  $\Pi_K$  the set of financial strategies  $\pi$  satisfying

$$(4.3) \quad \pi \in K \quad dt \times d\mathbb{P}\text{-a.e.}$$

We consider an up-and-out type option. More precisely, we take  $\mathcal{O}$  such that

$$\mathcal{O}^* := \mathcal{O} \cap (0, \infty)^d = \left\{ x \in (0, \infty)^d : \sum_{i=1}^d x^i < \kappa \right\}, \quad \kappa > 0.$$

The “payoff” of the barrier option is a continuous map  $g$  defined on  $\mathbb{R}_+^d$  satisfying

$$(4.4) \quad g \geq 0 \quad \text{on } \mathcal{O}^* \text{ and } g = 0 \quad \text{on } \partial\mathcal{O}^* := \partial\mathcal{O} \cap (0, \infty)^d.$$

In order to apply the general results of [2], we assume that the map  $\hat{g}$  defined by

$$\hat{g}(x) = \sup_{y \in \mathbb{R}_-^d} e^{-\delta(y)} g(x^1 e^{y^1}, \dots, x^d e^{y^d}), \quad x \in \bar{\mathcal{O}}^* := \bar{\mathcal{O}} \cap (0, \infty)^d$$

is continuous. Here,  $\delta$  is the support function of  $K$ ; see Remark 3.2. We also assume that  $\hat{g}$  is almost everywhere differentiable on  $\bar{\mathcal{O}}^*$  and we denote by  $D\hat{g}$  its gradient when it is well defined.

*Remark 4.1.* One easily checks that

$$\hat{g}(x) = \sup_{y \in \mathbb{R}_-^d} e^{-\delta(y)} \hat{g}(x^1 e^{y^1}, \dots, x^d e^{y^d}), \quad x \in \bar{\mathcal{O}}^*;$$

see [2], which implies

$$\inf \left\{ \delta(e)\hat{g}(x) - \langle e, \text{diag } x D\hat{g}(x) \rangle, e \in \tilde{K}_1 \right\} \geq 0$$

for all  $x \in \bar{\mathcal{O}}^*$  where  $D\hat{g}$  is well defined. Here,  $\tilde{K}_1 := \mathbb{R}_-^d \cap \partial B(0, 1)$  is the set of unit elements of the domain of  $\delta$ ; see Remark 3.2.

The option pays  $g(S_{t,x}(T))$  at  $T$  if and only if  $S_{t,x}$  does not exit  $\mathcal{O}^*$  before  $T$ . Since  $S_{t,x}$  has positive components, this corresponds to the situation where

$$\tau_{t,x} := \inf \{s \in [t, T] : S_{t,x}(s) \notin \mathcal{O}\} > T,$$

with the usual convention  $\inf \emptyset = \infty$ .

The super-replication cost of the barrier option is then defined as the minimal initial wealth  $y$  such that  $Y_{t,y}^\pi(T) \geq g(S_{t,x}(T))\mathbb{I}_{\{T < \tau_{t,x}\}}$  for some suitable strategy  $\pi \in \Pi_K$ . This leads to the introduction of the value function defined on  $[0, T] \times \bar{\mathcal{O}}^*$  by

$$(4.5) \quad w(t, x) := \inf \{y \in \mathbb{R} : Y_{t,y}^\pi(T) \geq g(S_{t,x}(T))\mathbb{I}_{\{T < \tau_{t,x}\}} \text{ for some } \pi \in \Pi_K\}.$$

**4.2. PDE characterization.** We define  $\mathcal{L}$  as  $\mathcal{L}^0$  with  $A = \{0\}$ ,  $\mu = 0$ ,  $\sigma(x, \cdot) = \text{diag } x \Sigma$ , and  $f = 0$ . The next result is a consequence of [2].

**THEOREM 4.1** (see Bentahar and Bouchard [2]). *The value function  $w$  is the unique viscosity solution in the class of bounded functions on  $[0, T] \times (\bar{\mathcal{O}} \cap \mathbb{R}_+^d)$  of  $\mathcal{G}\varphi = 0$ , where  $\mathcal{G}\varphi$  equals*

$$\begin{cases} \min \left\{ -\mathcal{L}\varphi(t, x), \min_{e \in \tilde{K}_1} (\delta(e)\varphi(t, x) - \langle e, \text{diag } x D\varphi(t, x) \rangle) \right\} & \text{on } [0, T] \times \mathcal{O}^*, \\ \min \left\{ \varphi, \min_{e \in \tilde{K}_1} (\delta(e)\varphi(t, x) - \langle e, \text{diag } x D\varphi(t, x) \rangle) \right\} & \text{on } [0, T] \times \partial\mathcal{O}^*, \\ \varphi - \hat{g} & \text{on } \{T\} \times \bar{\mathcal{O}}^*. \end{cases}$$

In the above theorem, the notion of viscosity solution has to be taken in the classical sense.

When (4.6), (4.7), (4.8) below admit a sufficiently smooth solution, the above equation can be simplified as follows.

**PROPOSITION 4.1.** *Assume that there is a bounded nonnegative  $C^{1,3}([0, T] \times \mathcal{O}^*) \cap C^{0,1}([0, T] \times \bar{\mathcal{O}}^*) \cap C([0, T] \times \bar{\mathcal{O}}^*)$  function  $\psi$  such that  $\partial\psi/\partial t \in C^{0,1}([0, T] \times \bar{\mathcal{O}}^*)$  and satisfying*

$$(4.6) \quad -\mathcal{L}\psi(t, x) = 0 \text{ on } [0, T] \times \mathcal{O}^*,$$

$$(4.7) \quad \min_{e \in \tilde{K}_1} (\delta(e)\psi(t, x) - \langle e, \text{diag } x D\psi(t, x) \rangle) = 0 \text{ on } [0, T] \times \partial\mathcal{O}^*,$$

$$(4.8) \quad \psi = \hat{g} \text{ on } \{T\} \times \bar{\mathcal{O}}^*,$$

$$(4.9) \quad \lim_{\substack{(t', x') \rightarrow (T, x) \\ (t', x') \in [0, T] \times \mathcal{O}^*}} D\psi(t', x') = D\hat{g}(x) \text{ almost everywhere on } \bar{\mathcal{O}}^*.$$

Then,  $\psi = w$  on  $[0, T] \times \mathcal{O}^*$  and  $\psi$  is the unique bounded solution to (4.6)-(4.7)-(4.8) on  $[0, T] \times \bar{\mathcal{O}}^*$ .

*Proof.* In view of Theorem 4.1, it suffices to show that  $\psi$  is a solution of  $\mathcal{G}\varphi = 0$ . Clearly, it is a subsolution. Since  $\psi \geq 0$ , the supersolution property holds if, in addition to (4.6), (4.7), (4.8), we have

$$(4.10) \quad \min_{e \in \tilde{K}_1} (\delta(e)\psi(t, x) - \langle e, \text{diag } x D\psi(t, x) \rangle) \geq 0 \text{ on } [0, T] \times \mathcal{O}^* .$$

To see this, observe that (4.6) implies that each component  $\phi^k := (D\psi)^k$  of  $D\psi$  solves, on  $[0, T] \times \mathcal{O}^*$ ,

$$-\frac{\partial}{\partial t} \phi^k(t, x) - \frac{1}{2} \text{Tr} \text{diag } x \Sigma \Sigma' \text{diag } x D^2 \phi^k(t, x) - \langle D\phi^k(t, x)^* \text{diag } x \Sigma, \Sigma^k \rangle = 0,$$

where  $\Sigma^k$  denotes the  $k$ th line of  $\Sigma$ . Applying Itô's lemma to  $\langle e, \text{diag } S_{t,x} D\psi(\cdot, S_{t,x}) \rangle$ ,  $e \in \tilde{K}_1$ , and  $(t, x) \in [0, T] \times \mathcal{O}^*$ , and using (4.9), we deduce that

$$\begin{aligned} \langle e, \text{diag } x D\psi(t, x) \rangle &= \mathbb{E} [\langle e, \text{diag } S_{t,x}(\tau_{t,x}) D\psi(\tau_{t,x}, S_{t,x}(\tau_{t,x})) \rangle \mathbb{I}_{\{\tau_{t,x} < T\}}] \\ &\quad + \mathbb{E} [\langle e, \text{diag } S_{t,x}(T) D\hat{g}(S_{t,x}(T)) \rangle \mathbb{I}_{\{\tau_{t,x} \geq T\}}] . \end{aligned}$$

Since by (4.6) and (4.8),

$$\psi(t, x) = \mathbb{E} [\psi(\tau_{t,x}, S_{t,x}(\tau_{t,x})) \mathbb{I}_{\{\tau_{t,x} < T\}} + \hat{g}(S_{t,x}(T)) \mathbb{I}_{\{\tau_{t,x} \geq T\}}] ,$$

it follows from (4.7) and Remark 4.1 that

$$\delta(e)\psi(t, x) - \langle e, \text{diag } x D\psi(t, x) \rangle \geq 0$$

which, by arbitrariness of  $e$ , provides the required result.  $\square$

**4.3. Dual formulation.** Equations (4.6), (4.7), (4.8) are very similar to  $\mathcal{K}\varphi = 0$  with  $E = \tilde{K}_1$  and

$$\rho(x, e) := \delta(e)/|\text{diag } xe|, \quad \gamma(x, e) = \text{diag } xe/|\text{diag } xe| .$$

However, the gradient of  $\text{diag } xe/|\text{diag } xe|$  may blow up near  $\partial(0, \infty)^d$ , and it is not possible to consider a smooth extension of  $\gamma$  on  $\mathbb{R}^{2d}$  (even on  $\mathbb{R}_+^d \times \tilde{K}_1$ ).

In order to overcome this difficulty, we use the following construction. First, we define  $\mathcal{O}$  as

$$\mathcal{O} := \left\{ x \in \mathbb{R}^d : \sum_{i=1}^d |x^i| < \kappa \right\}$$

so that  $\mathcal{O}^* = \{x \in (0, \infty)^d : \sum_{i=1}^d x^i < \kappa\}$ . Let  $r \in (0, 1/2)$  be such that  $B(0, 2r) \subset \mathcal{O}$ . Then, given a nonincreasing  $C^2(\mathbb{R}, [0, 1])$  function  $\phi$  such that  $\phi(y) = 1$  if  $y \leq 1$  and  $\phi(y) = 0$  if  $y \geq 3/2$ , we set, for  $n \geq 1$ ,

$$z_n(e) := (e^i \phi(ne^i + 2) - (1 - \phi(ne^i + 2)))_{i \leq d} .$$

Observe that  $z_n(e) = e$  on  $E_n := \{e \in \tilde{K}_1 : e^i \leq -n^{-1} \text{ for all } i \leq d\}$ ,  $z_n(e) \in (-\infty, -1/(2n)]^d$  for all  $e \in \mathbb{R}^d$ , and

$$(4.11) \quad |\text{diag } xe| \geq r/(2n) := \eta_n \text{ for } (x, e) \in B(0, r)^c \times (-\infty, -1/(2n)]^d .$$

We then set (with  $1_d = (1, \dots, 1) \in \mathbb{R}^d$ )

$$\begin{aligned}\bar{\gamma}_n(x, e) &:= \text{diag } xz_n(e) \left( 1 - \phi \left( \frac{3}{2} |\text{diag } xe| / \eta_n \right) \right) - 1_d \phi \left( \frac{3}{2} |\text{diag } xe| / \eta_n \right), \\ \gamma_n(x, e) &:= \bar{\gamma}_n(x, e) / |\bar{\gamma}_n(x, e)|.\end{aligned}$$

Using (4.11), one easily checks that  $\gamma_n \in C^2(\mathbb{R}^{2d}, \mathbb{R}^d)$ . Moreover,  $\gamma_n(x, e) = \gamma(x, e) = \text{diag } xe / |\text{diag } xe|$  on  $B(0, r)^c \times E_n$ , and (2.3) holds for  $(\mathcal{O}, \gamma_n)$ .

For  $\epsilon \in \mathcal{E}_0 := \cup_{n \geq 1} \text{BV}_{\mathbb{F}}(E_n)$  and  $(t, x) \in [0, T] \times \bar{\mathcal{O}}^*$ , we can then define  $(X_{t,x}^\epsilon, L_{t,x}^\epsilon) := (X_{t,x}^{0,\epsilon}, L_{t,x}^{0,\epsilon})$  as in section 3 with  $\mu = 0$ ,  $\sigma(x, a) = \text{diag } x \Sigma$ , and  $\gamma$  defined as above. Clearly,  $X_{t,x}^\epsilon$  takes values in  $(0, \infty)^d$ .

We next define  $\rho$  on  $\mathbb{R}^d \times \tilde{K}_1$  as

$$\rho(x, e) = (\delta(e) / |\text{diag } xe|) (1 - \phi(|x|/r + 1/2))$$

so that  $\rho$  is continuous on  $\mathbb{R}^d \times \tilde{K}_1$ , satisfies the assumption of section 3 as a function on  $\mathbb{R}^d \times E_n$  for all  $n \geq 1$ , and

$$\rho(x, e) = \delta(e) / |\text{diag } xe| \quad \text{on } \partial \mathcal{O}^* \times (\cup_{n \geq 1} E_n).$$

With this construction, we can now consider the control problem

$$v(t, x) := \sup_{\epsilon \in \mathcal{E}_0} \mathbb{E} \left[ e^{-\int_t^T \rho(X_{t,x}^\epsilon(s), \epsilon(s)) dL_{t,x}^\epsilon(s)} \hat{g}(X_{t,x}^\epsilon(T)) \right], \quad (t, x) \in [0, T] \times \bar{\mathcal{O}}^*.$$

**PROPOSITION 4.2.** *The function  $v$  is a bounded viscosity solution on  $[0, T] \times \bar{\mathcal{O}}^*$  of (4.6), (4.7), (4.8).*

*Proof.* For  $n \geq 1$  and  $(t, x) \in [0, T] \times \bar{\mathcal{O}}^*$ , set

$$v_n(t, x) := \sup_{\epsilon \in \mathcal{E}_n} \mathbb{E} \left[ e^{-\int_t^T \rho(X_{t,x}^\epsilon(s), \epsilon(s)) dL_{t,x}^\epsilon(s)} \hat{g}(X_{t,x}^\epsilon(T)) \right],$$

where  $\mathcal{E}_n := \text{BV}_{\mathbb{F}}(E_n)$ . It follows from the previous discussion that we can apply Lemma 3.2 to  $v_n$ . Since  $v = \sup_{n \geq 1} v_n = \lim_{n \rightarrow \infty} \uparrow v_n$ , a monotone convergence argument shows that the dynamic programming principle of Lemma 3.2 holds for  $v$ . Following the arguments used in Propositions 3.2 and 3.3, and using the continuity of  $\rho$  and  $\gamma$  on  $(B(0, r)^c \cap (0, \infty)^d) \times \tilde{K}_1 \supset \partial \mathcal{O}^* \times \tilde{K}_1$ , we deduce that  $v$  is a viscosity solution of  $\mathcal{K}\varphi = 0$  on  $[0, T] \times \bar{\mathcal{O}}^*$ ; see Remark 3.6. Since

$$\delta(e)y - \langle e, \text{diag } xp \rangle \geq 0 \Leftrightarrow |\text{diag } xe|^{-1} (\delta(e)y - \langle e, \text{diag } xp \rangle) \geq 0$$

for  $(x, e, y, p) \in \partial \mathcal{O}^* \times \tilde{K}_1 \times \mathbb{R} \times \mathbb{R}^d$ , this implies that  $v$  is a viscosity solution on  $[0, T] \times \bar{\mathcal{O}}^*$  of (4.6), (4.7), (4.8).  $\square$

In view of Proposition 4.1, we finally obtain the main result of this section, which provides a dual formulation for the superhedging price  $w$ .

**THEOREM 4.2.** *Let the conditions of Proposition 4.1 hold. Then, for all  $(t, x) \in [0, T] \times \mathcal{O}^*$ ,*

$$(4.12) \quad w(t, x) = \sup_{\epsilon \in \mathcal{E}_0} \mathbb{E} \left[ e^{-\int_t^T \rho(X_{t,x}^\epsilon(s), \epsilon(s)) dL_{t,x}^\epsilon(s)} \hat{g}(X_{t,x}^\epsilon(T)) \right].$$

**Remark 4.2.** It follows from Theorem 4.1, Proposition 4.2, and Theorem 7.1 in [2] that

$$w(t, x) \geq \sup_{\epsilon \in \mathcal{E}_0} \mathbb{E} \left[ e^{-\int_t^T \rho(X_{t,x}^\epsilon(s), \epsilon(s)) dL_{t,x}^\epsilon(s)} \hat{g}(X_{t,x}^\epsilon(T)) \right]$$

even if the conditions of Proposition 4.1 are not satisfied.

*Remark 4.3.* When  $d = 1$ , we retrieve the results of [14]; see also [15]. In this case,  $\mathcal{E}_0 = \{-1\}$  and the right-hand side quantity in (4.12) can be computed by using Monte-Carlo methods.

*Remark 4.4.* It follows from [2] that  $w$  admits the dual formulation

$$w(t, x) = \sup_{\vartheta \in \Theta} \mathbb{E}^\vartheta \left[ e^{-\int_t^T \delta(\vartheta(s)) ds} \hat{g}(S_{t,x}(T)) \mathbb{I}_{\{\tau_{t,x} > T\}} \right],$$

where  $\Theta$  denotes the set of bounded adapted processes with values in  $\mathbb{R}_-^d$ , and  $\mathbb{E}^\vartheta$  is the expectation operator under the equivalent probability measure  $\mathbb{Q}^\vartheta$  under which the process  $W^\vartheta$  defined by

$$W^\vartheta(t) = W(t) - \int_0^t \Sigma^{-1} \vartheta(s) ds, \quad t \leq T,$$

is a Brownian motion. Since

$$S_{t,x}(s) = x + \int_t^s \text{diag } S_{t,x}(r) \Sigma dW^\vartheta(r) + \int_t^s \text{diag } S_{t,x}(r) \vartheta(r) dr,$$

and  $W^\vartheta$  has the same law under  $\mathbb{Q}^\vartheta$  as  $W$  under  $\mathbb{P}$ , this is, at least formally, equivalent to

$$w(t, x) = \sup_{\vartheta \in \Theta} \mathbb{E} \left[ e^{-\int_t^T \delta(\vartheta(s)) ds} \hat{g}(S_{t,x}^\vartheta(T)) \mathbb{I}_{\{\tau_{t,x}^\vartheta > T\}} \right]$$

with  $S_{t,x}^\vartheta$  now defined as the solution of

$$S_{t,x}^\vartheta(s) = x + \int_t^s \text{diag } S_{t,x}^\vartheta(r) \Sigma dW(r) + \int_t^s \text{diag } S_{t,x}^\vartheta(r) \vartheta(r) dr.$$

A formal change of variable ( $\vartheta = |\tilde{\vartheta}| \tilde{\vartheta} / |\text{diag } S_{t,x}^{\tilde{\vartheta}} \tilde{\vartheta}|$ ) then leads to

$$(4.13) \quad w(t, x) = \sup_{\tilde{\vartheta} \in \Theta} \mathbb{E} \left[ e^{-\int_t^T |\tilde{\vartheta}(s)| \rho(S_{t,x}^{\tilde{\vartheta}}(s), \tilde{\vartheta}(s)) ds} \hat{g}(S_{t,x}^{\tilde{\vartheta}}(T)) \mathbb{I}_{\{\tau_{t,x}^{\tilde{\vartheta}} > T\}} \right],$$

where

$$S_{t,x}^{\tilde{\vartheta}}(s) = x + \int_t^s \text{diag } S_{t,x}^{\tilde{\vartheta}}(r) \Sigma dW(r) + \int_t^s |\tilde{\vartheta}(s)| \gamma(S_{t,x}^{\tilde{\vartheta}}(r), \tilde{\vartheta}(r)) dr,$$

$\rho(x, e) = \delta(e) / |\text{diag } xe|$ ,  $\gamma(x, e) = \text{diag } xe / |\text{diag } xe|$ ,  $\tilde{\tau}_{t,x}^{\tilde{\vartheta}}$  is the first exit time of  $S_{t,x}^{\tilde{\vartheta}}$  from  $\mathcal{O}^*$ , and we use the convention  $0/0 = 0$ .

For very large values of  $|\tilde{\vartheta}|$ , the process  $S^{\tilde{\vartheta}}$  is “essentially” reflected in the direction  $\gamma(S_{t,x}^{\tilde{\vartheta}}, \tilde{\vartheta})$ .

Moreover, since  $\hat{g} \geq 0$ , we should seek a control  $\tilde{\vartheta}$  such that  $\tilde{\tau}_{t,x}^{\tilde{\vartheta}} > T$ , i.e., which “causes reflection” of  $S^{\tilde{\vartheta}}$  at least at the boundary  $\partial\mathcal{O}^*$ . The “reflection” should also be optimal so that the right-hand side of (4.13) is maximal. If  $d = 1$  and  $\hat{g}$  is non-decreasing on  $\mathcal{O}^*$ , the action of  $\tilde{\vartheta}$  should then be minimal since it decreases the value of  $S_{t,x}^{\tilde{\vartheta}}(T)$  and  $\rho(x, e) > 0$  if  $e \neq 0$ . Thus, at the limit, the process should be reflected only at the boundary  $\partial\mathcal{O}^*$ . This phenomenon, which was already observed in [14] in the one-dimensional case, naturally leads to the formulation (4.12).

## HOMOGENEOUS APPROXIMATION, RECURSIVE OBSERVER DESIGN, AND OUTPUT FEEDBACK\*

VINCENT ANDRIEU<sup>†</sup>, LAURENT PRALY<sup>‡</sup>, AND ALESSANDRO ASTOLFI<sup>§</sup>

**Abstract.** We introduce two new tools that can be useful in nonlinear observer and output feedback design. The first one is a simple extension of the notion of homogeneous approximation to make it valid both at the origin and at infinity (homogeneity in the bi-limit). Exploiting this extension, we give several results concerning stability and robustness for a homogeneous in the bi-limit vector field. The second tool is a new recursive observer design procedure for a chain of integrator. Combining these two tools, we propose a new global asymptotic stabilization result by output feedback for feedback and feedforward systems.

**Key words.** homogeneous approximation, output feedback and observer

**DOI.** 10.1137/060675861

**1. Introduction.** The problems of designing globally convergent observers and globally asymptotically stabilizing output feedback control laws for nonlinear systems have been addressed by many authors following different routes. Many of these approaches exploit domination ideas and robustness of stability and/or convergence. In view of possibly clarifying and developing further these techniques we introduce two new tools. The first one is a simple extension of the technique of homogeneous approximation to make it valid both at the origin and at infinity. The second tool is a new recursive observer design procedure for a chain of integrator. Combining these two tools, we propose a new global asymptotic stabilization result by output feedback for feedback and feedforward systems.

To place our contribution in perspective, we consider the following system, for which we want to design a global asymptotic stabilizing output feedback:

$$(1.1) \quad \dot{x}_1 = x_2, \quad \dot{x}_2 = u + \delta_2(x_1, x_2), \quad y = x_1,$$

where (see notation (1.4))

$$(1.2) \quad \delta_2(x_1, x_2) = c_0 x_2^q + c_\infty x_2^p, \quad (c_0, c_\infty) \in \mathbb{R}^2, \quad p > q > 0.$$

In the domination's approach, the nonlinear function  $\delta_2$  is not treated per se in the design but considered as a perturbation. In this framework the output feedback controller is designed on the linear system

$$(1.3) \quad \dot{x}_1 = x_2, \quad \dot{x}_2 = u, \quad y = x_1,$$

and will be suitable for the nonlinear system (1.1), provided the global asymptotic stability obtained for the origin of the closed-loop system is robust to the nonlinear disturbance  $\delta_2$ . For instance, the design given in [13, 27] provides a linear output feedback controller which is suitable for the nonlinear system (1.1) when  $q = 1$  and  $c_\infty = 0$ . This result has been extended recently in [26] employing a homogeneous output feedback controller which allows us to deal with  $p \geq 1$  and  $c_0 = 0$ .

Homogeneity in the bi-limit and the novel recursive observer design proposed in this paper allow us to deal with the case in which  $c_0 \neq 0$  and  $c_\infty \neq 0$ . In this case, the function  $\delta_2$  is such that

1. when  $|x_2|$  is small and  $q = 1$ ,  $\delta_2(x_2)$  can be approximated by  $c_0 x_2$  and the nonlinearity can be approximated by a linear function;
2. when  $|x_2|$  is large,  $\delta_2(x_2)$  can be approximated by  $c_\infty x_2^p$ , and hence we have a polynomial growth which can be handled by a weighted homogeneous controller as in [26].

To deal with both linear and polynomial terms we introduce a generalization of weighted homogeneity which highlights the fact that a function becomes homogeneous as the state tends to the origin or to infinity but with different weights and degrees.

The paper is organized as follows. Section 2 is devoted to general properties related to homogeneity. After giving the definition of homogeneous approximation we introduce homogeneous in the bi-limit functions and vector fields (section 2.1) and list some of their properties (section 2.2). Various results concerning stability and robustness for homogeneous in the bi-limit vector fields are given in section 2.3. In section 3 we introduce a novel recursive observer design method for a chain of integrator. Section 4 is devoted to the homogeneous in the bi-limit state feedback. Finally, in section 5, using the previous tools, we establish new results on stabilization by output feedback.

### Notation.

- $\mathbb{R}_+$  denotes the set  $[0, +\infty)$ .
- For any nonnegative real number  $r$  the function  $w \mapsto w^r$  is defined as

$$(1.4) \quad w^r = \text{sign}(w) |w|^r \quad \forall w \in \mathbb{R}.$$

According to this definition,

$$(1.5) \quad \frac{dw^r}{dw} = r|w|^{r-1}, \quad w^2 = w|w|, \quad (w_1 > w_2 \text{ and } r > 0) \Rightarrow w_1^r > w_2^r.$$

- The function  $\mathfrak{H} : \mathbb{R}_+^2 \rightarrow \mathbb{R}_+$  is defined as

$$(1.6) \quad \mathfrak{H}(a, b) = \frac{a}{1+a} [1 + b].$$

- Given  $r = (r_1, \dots, r_n)^T$  in  $\mathbb{R}_+^n$  and  $\lambda$  in  $\mathbb{R}_+$ ,  $\lambda^r \diamond x = (\lambda^{r_1} x_1, \dots, \lambda^{r_n} x_n)^T$  is the dilation of a vector  $x$  in  $\mathbb{R}^n$  with weight  $r$ . Note that

$$\lambda_1^r \diamond (\lambda_2^r \diamond x) = (\lambda_1 \lambda_2)^r \diamond x.$$

- Given  $r = (r_1, \dots, r_n)^T$  in  $(\mathbb{R}_+ \setminus \{0\})^n$ ,  $|x|_r = |x_1|^{\frac{1}{r_1}} + \dots + |x_n|^{\frac{1}{r_n}}$  is the homogeneous norm with weight  $r$  and degree 1. Note that

$$|\lambda^r \diamond x|_r = \lambda |x|_r, \quad \left| \left( \frac{1}{|x|_r} \right)^r \diamond x \right|_r = 1.$$

- Given  $r$  in  $(\mathbb{R}_+ \setminus \{0\})^n$ ,  $S_r = \{x \in \mathbb{R}^n \mid |x|_r = 1\}$  is the unity homogeneous sphere. Note that each  $x$  in  $\mathbb{R}^n$  can be decomposed in polar coordinates; i.e., there exist  $\lambda$  in  $\mathbb{R}_+$  and  $\theta$  in  $S_r$  satisfying

$$(1.7) \quad x = \lambda^r \diamond \theta \quad \text{with} \quad \begin{cases} \lambda &= |x|_r, \\ \theta &= \left(\frac{1}{|x|_r}\right)^r \diamond x. \end{cases}$$

## 2. Homogeneous approximation.

**2.1. Definitions.** The use of homogeneous approximations has a long history in the study of stability of an equilibrium. It can be traced back to the Lyapunov first order approximation theorem and has been pursued by many authors; see, for example, Massera [16], Hahn [8], Hermes [9], and Rosier [29]. Similarly, this technique has been used to investigate the behavior of the solutions of dynamical systems at infinity; see, for instance, Lefschetz in [14, Chapter IX.5] and Orsi, Praly, and Mareels in [20]. In this section, we recall the definitions of homogeneous approximation at the origin and at infinity and restate and/or complete some related results.

DEFINITION 2.1 (homogeneity in the 0-limit).

- A function  $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$  is said to be homogeneous in the 0-limit with associated triple  $(r_0, d_0, \phi_0)$ , where  $r_0$  in  $(\mathbb{R}_+ \setminus \{0\})^n$  is the weight,  $d_0$  in  $\mathbb{R}_+$  the degree, and  $\phi_0 : \mathbb{R}^n \rightarrow \mathbb{R}$  the approximating function, if  $\phi$  is continuous,  $\phi_0$  is continuous and not identically zero, and, for each compact set  $C$  in  $\mathbb{R}^n \setminus \{0\}$  and each  $\varepsilon > 0$ , there exists  $\lambda_0$  such that

$$\max_{x \in C} \left| \frac{\phi(\lambda^{r_0} \diamond x)}{\lambda^{d_0}} - \phi_0(x) \right| \leq \varepsilon \quad \forall \quad \lambda \in (0, \lambda_0] .$$

- A vector field  $f = \sum_{i=1}^n f_i \frac{\partial}{\partial x_i}$  is said to be homogeneous in the 0-limit with associated triple  $(r_0, \mathfrak{d}_0, f_0)$ , where  $r_0$  in  $(\mathbb{R}_+ \setminus \{0\})^n$  is the weight,  $\mathfrak{d}_0$  in  $\mathbb{R}$  is the degree, and  $f_0 = \sum_{i=1}^n f_{0,i} \frac{\partial}{\partial x_i}$  is the approximating vector field, if, for each  $i$  in  $\{1, \dots, n\}$ ,  $\mathfrak{d}_0 + r_{0,i} \geq 0$  and the function  $f_i$  is homogeneous in the 0-limit with associated triple  $(r_0, \mathfrak{d}_0 + r_{0,i}, f_{0,i})$ .

This notion of local approximation of a function or of a vector field can be found in [9, 29, 2, 10].

*Example 2.2.* The function  $\delta_2 : \mathbb{R} \rightarrow \mathbb{R}$  introduced in the illustrative system (1.1) is homogeneous in the 0-limit with associated triple  $(r_0, d_0, \delta_{2,0}) = (1, q, c_0 x_2^q)$ . Furthermore, if  $q < 2$ , then the vector field  $f(x_1, x_2) = (x_2, \delta_2(x_2))$  is homogeneous in the 0-limit with associated triple

$$(2.1) \quad (r_0, \mathfrak{d}_0, f_0) = \left( (2 - q, 1), q - 1, (x_2, c_0 x_2^q) \right) .$$

DEFINITION 2.3 (homogeneity in the  $\infty$ -limit).

- A function  $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$  is said to be homogeneous in the  $\infty$ -limit with associated triple  $(r_\infty, d_\infty, \phi_\infty)$ , where  $r_\infty$  in  $(\mathbb{R}_+ \setminus \{0\})^n$  is the weight,  $d_\infty$  in

$\mathbb{R}_+$  is the degree, and  $\phi_\infty : \mathbb{R}^n \rightarrow \mathbb{R}$  is the approximating function, if  $\phi$  is continuous,  $\phi_\infty$  is continuous and not identically zero, and, for each compact set  $C$  in  $\mathbb{R}^n \setminus \{0\}$  and each  $\varepsilon > 0$ , there exists  $\lambda_\infty$  such that

$$\max_{x \in C} \left| \frac{\phi(\lambda^{r_\infty} \diamond x)}{\lambda^{d_\infty}} - \phi_\infty(x) \right| \leq \varepsilon \quad \forall \lambda \geq \lambda_\infty.$$

- A vector field  $f = \sum_{i=1}^n f_i \frac{\partial}{\partial x_i}$  is said to be homogeneous in the  $\infty$ -limit with associated triple  $(r_\infty, \mathfrak{d}_\infty, f_\infty)$ , where  $r_\infty$  in  $(\mathbb{R}_+ \setminus \{0\})^n$  is the weight,  $\mathfrak{d}_\infty$  in  $\mathbb{R}$  is the degree, and  $f_\infty = \sum_{i=1}^n f_{\infty,i} \frac{\partial}{\partial x_i}$  is the approximating vector field, if, for each  $i$  in  $\{1, \dots, n\}$ ,  $\mathfrak{d}_\infty + r_{\infty,i} \geq 0$  and the function  $f_i$  is homogeneous in the  $\infty$ -limit with associated triple  $(r_\infty, \mathfrak{d}_\infty + r_{\infty,i}, f_{\infty,i})$ .

*Example 2.4.* The function  $\delta_2 : \mathbb{R} \rightarrow \mathbb{R}$  given in the illustrative system (1.1) is homogeneous in the  $\infty$ -limit with associated triple  $(r_\infty, d_\infty, \delta_{2,\infty}) = (1, p, c_\infty x_2^p)$ . Furthermore, when  $p < 2$ , the vector field  $f(x_1, x_2) = (x_2, \delta_2(x_2))$  is homogeneous in the  $\infty$ -limit with associated triple

$$(2.2) \quad (r_\infty, \mathfrak{d}_\infty, f_\infty) = ((2-p, 1), p-1, (x_2, c_\infty x_2^p)).$$

**DEFINITION 2.5** (homogeneity in the bi-limit). A function  $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$  (or a vector field  $f : \mathbb{R}^n \rightarrow \mathbb{R}^n$ ) is said to be homogeneous in the bi-limit if it is homogeneous in the 0-limit and homogeneous in the  $\infty$ -limit.

*Remark 2.6.* If a function  $\phi$  (resp., a vector field  $f$ ) is homogeneous in the bi-limit, then the approximating function  $\phi_0$  or  $\phi_\infty$  (resp., the approximating vector field  $f_0$  or  $f_\infty$ ) is homogeneous in the standard sense<sup>1</sup> (with the same weight and degree).

*Example 2.7.* As a consequence of Examples 2.2 and 2.4, the vector field  $f(x_1, x_2) = (x_2, \delta_2(x_2))$  is homogeneous in the bi-limit with the associated triples given in (2.1) and (2.2) as long as  $0 < q < p < 2$ .

*Example 2.8.* The function  $x \mapsto |x|_{r_0}^{d_0} + |x|_{r_\infty}^{d_\infty}$ , where  $(d_0, d_\infty)$  are in  $\mathbb{R}_+^2$  and  $(r_0, r_\infty)$  are in  $(\mathbb{R}_+ \setminus \{0\})^{2n}$ , is homogeneous in the bi-limit with associated triples  $(r_0, d_0, |x|_{r_0}^{d_0})$  and  $(r_\infty, d_\infty, |x|_{r_\infty}^{d_\infty})$ , provided that

$$(2.3) \quad \frac{d_\infty}{r_{\infty,i}} > \frac{d_0}{r_{0,i}} \quad \forall i \in \{1, \dots, n\}.$$

*Example 2.9.* We recall (1.6) and consider two homogeneous and positive definite functions  $\phi_0 : \mathbb{R}^n \rightarrow \mathbb{R}_+$  and  $\phi_\infty : \mathbb{R}^n \rightarrow \mathbb{R}_+$  with weights  $(r_0, r_\infty)$  in  $(\mathbb{R}_+ \setminus \{0\})^{2n}$  and degrees  $(d_0, d_\infty)$  in  $(\mathbb{R}_+ \setminus \{0\})^2$ . The function  $x \mapsto \mathfrak{H}(\phi_0(x), \phi_\infty(x))$  is positive definite and homogeneous in the bi-limit with associated triples  $(r_0, d_0, \phi_0)$  and  $(r_\infty, d_\infty, \phi_\infty)$ . This way of constructing a homogeneous in the bi-limit function from two positive definite homogeneous functions is extensively used in this paper.

**2.2. Properties of homogeneous approximations.** To begin, we note that the weight and degree of a homogeneous in the 0- (resp.,  $\infty$ -) limit function are

<sup>1</sup>This is proved by noting that, for all  $x$  in  $\mathbb{R}^n$  and all  $\mu$  in  $\mathbb{R}_+ \setminus \{0\}$ ,

$$\frac{\phi_0(\mu^{r_0} \diamond x)}{\mu^{d_0}} = \frac{1}{\mu^{d_0}} \lim_{\lambda \rightarrow 0} \frac{\phi(\lambda^{r_0} \diamond (\mu^{r_0} \diamond x))}{\lambda^{d_0}} = \lim_{\lambda \rightarrow 0} \frac{\phi((\lambda\mu)^{r_0} \diamond x)}{(\lambda\mu)^{d_0}} = \phi_0(x),$$

and similarly for the homogeneous in the  $\infty$ -limit function.

not uniquely defined. Indeed, if  $\phi$  is homogeneous in the 0- (resp.,  $\infty$ -) limit with associated triple  $(r_0, d_0, \phi_0)$  (resp.,  $(r_\infty, d_\infty, \phi_\infty)$ ), then it is also homogeneous in the 0- (resp.,  $\infty$ -) limit with associated triple  $(k r_0, k d_0, \phi_0)$  (resp.,  $(k r_\infty, k d_\infty, \phi_\infty)$ ) for all  $k > 0$ . (Simply change  $\lambda$  into  $\lambda^k$ .)

It is straightforward to show that if  $\phi$  and  $\zeta$  are two functions homogeneous in the 0- (resp.,  $\infty$ -) limit, with weights  $r_{\phi,0}$  and  $r_{\zeta,0}$  (resp.,  $r_{\phi,\infty}$  and  $r_{\zeta,\infty}$ ), degrees  $d_{\phi,0}$  and  $d_{\zeta,0}$  (resp.,  $d_{\phi,\infty}$  and  $d_{\zeta,\infty}$ ), and approximating functions  $\phi_0$  and  $\zeta_0$  (resp.,  $\phi_\infty$  and  $\zeta_\infty$ ), then the following hold:

- P1: If there exists  $k \in \mathbb{R}_+$  such that  $k r_{\phi,0} = r_{\zeta,0}$  (resp.,  $k r_{\phi,\infty} = r_{\zeta,\infty}$ ), then the function  $x \mapsto \phi(x) \zeta(x)$  is homogeneous in the 0- (resp.,  $\infty$ -) limit with weight  $r_{\zeta,0}$ , degree  $k d_{\phi,0} + d_{\zeta,0}$  (resp.,  $r_{\zeta,\infty}$ ,  $k d_{\phi,\infty} + d_{\zeta,\infty}$ ) and approximating function  $x \mapsto \phi_0(x) \zeta_0(x)$  (resp.,  $x \mapsto \phi_\infty(x) \zeta_\infty(x)$ ).
- P2: If, for each  $j$  in  $\{1, \dots, n\}$ ,  $\frac{d_{\phi,0}}{r_{\phi,0,j}} < \frac{d_{\zeta,0}}{r_{\zeta,0,j}}$  (resp.,  $\frac{d_{\phi,\infty}}{r_{\phi,\infty,j}} > \frac{d_{\zeta,\infty}}{r_{\zeta,\infty,j}}$ ), then the function  $x \mapsto \phi(x) + \zeta(x)$  is homogeneous in the 0- (resp.,  $\infty$ -) limit with degree  $d_{\phi,0}$  and weight  $r_{\phi,0}$  (resp.,  $d_{\phi,\infty}$  and  $r_{\phi,\infty}$ ) and approximating function  $x \mapsto \phi_0(x)$  (resp.,  $x \mapsto \phi_\infty(x)$ ). In this case we say that the function  $\phi$  *dominates* the function  $\zeta$  in the 0-limit (resp., in the  $\infty$ -limit).
- P3: If the function  $\phi_0 + \zeta_0$  (resp.,  $\phi_\infty + \zeta_\infty$ ) is not identically zero and, for each  $j$  in  $\{1, \dots, n\}$ ,  $\frac{d_{\phi,0}}{r_{\phi,0,j}} = \frac{d_{\zeta,0}}{r_{\zeta,0,j}}$  (resp.,  $\frac{d_{\phi,\infty}}{r_{\phi,\infty,j}} = \frac{d_{\zeta,\infty}}{r_{\zeta,\infty,j}}$ ), then the function  $x \mapsto \phi(x) + \zeta(x)$  is homogeneous in the 0- (resp.,  $\infty$ -) limit with degree  $d_{\phi,0}$  and weight  $r_{\phi,0}$  (resp.,  $d_{\phi,\infty}$  and  $r_{\phi,\infty}$ ) and approximating function  $x \mapsto \phi_0(x) + \zeta_0(x)$  (resp.,  $x \mapsto \phi_\infty(x) + \zeta_\infty(x)$ ).

Some properties of the composition or inverse of functions are given in the following two propositions, the proofs of which are given in Appendices A and B.

**PROPOSITION 2.10** (composition function). *If  $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$  and  $\zeta : \mathbb{R} \rightarrow \mathbb{R}$  are homogeneous in the 0- (resp.,  $\infty$ -) limit functions, with weights  $r_{\phi,0}$  and  $r_{\zeta,0}$  (resp.,  $r_{\phi,\infty}$  and  $r_{\zeta,\infty}$ ), degrees  $d_{\phi,0} > 0$  and  $d_{\zeta,0} \geq 0$  (resp.,  $d_{\phi,\infty} > 0$  and  $d_{\zeta,\infty} \geq 0$ ), and approximating functions  $\phi_0$  and  $\zeta_0$  (resp.,  $\phi_\infty$  and  $\zeta_\infty$ ), then  $\zeta \circ \phi$  is homogeneous in the 0- (resp.,  $\infty$ -) limit with weight  $r_{\phi,0}$  (resp.,  $r_{\phi,\infty}$ ), degree  $\frac{d_{\zeta,0} d_{\phi,0}}{r_{\zeta,0}}$  (resp.,  $\frac{d_{\zeta,\infty} d_{\phi,\infty}}{r_{\zeta,\infty}}$ ), and approximating function  $\zeta_0 \circ \phi_0$  (resp.,  $\zeta_\infty \circ \phi_\infty$ ).*

**PROPOSITION 2.11** (inverse function). *Let  $\phi : \mathbb{R} \rightarrow \mathbb{R}$  be a bijective homogeneous in the 0- (resp.,  $\infty$ -) limit function with associated triple  $(1, d_0, \varphi_0 x^{d_0})$  with  $\varphi_0 \neq 0$  and  $d_0 > 0$  (resp.,  $(1, d_\infty, \varphi_\infty x^{d_\infty})$  with  $\varphi_\infty \neq 0$  and  $d_\infty > 0$ ). Then the inverse function  $\phi^{-1} : \mathbb{R} \rightarrow \mathbb{R}$  is a homogeneous in the 0- (resp.,  $\infty$ -) limit function with associated triple  $(1, \frac{1}{d_0}, (\frac{x}{\varphi_0})^{\frac{1}{d_0}})$  (resp.,  $(1, \frac{1}{d_\infty}, (\frac{x}{\varphi_\infty})^{\frac{1}{d_\infty}})$ .*

Despite the existence of well-known results concerning the derivative of a homogeneous function, it is not possible to say anything, in general, when dealing with homogeneity in the limit. For example, the function

$$\phi(x) = x^3 + x^2 \sin(x^2) + x^3 \sin(1/x) + x^2, \quad x \in \mathbb{R},$$

is homogeneous in the bi-limit with associated triples

$$(1, 2, x^2), \quad (1, 3, x^3).$$

However, its derivative is homogeneous in neither the 0-limit nor the  $\infty$ -limit. Nevertheless the following result holds, the proof of which is elementary.

**PROPOSITION 2.12** (integral function). *If the function  $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$  is homogeneous in the 0- (resp.,  $\infty$ -) limit with associated triple  $(r_0, d_0, \phi_0)$  (resp.,  $(r_\infty, d_\infty, \phi_\infty)$ ),*

then the function  $\Phi_i(x) = \int_0^{x_i} \phi(x_1, \dots, x_{i-1}, s, x_{i+1}, \dots, x_n) ds$  is homogeneous in the 0- (resp.,  $\infty$ -) limit with associated triple  $(r_0, d_0 + r_{0,i}, \Phi_{i,0})$  (resp.,  $(r_\infty, d_\infty + r_{\infty,i}, \Phi_{i,\infty})$ ), with  $\Phi_{i,0}(x) = \int_0^{x_i} \phi_0(x_1, \dots, x_{i-1}, s, x_{i+1}, \dots, x_n) ds$  (resp.,  $\Phi_{i,\infty}(x) = \int_0^{x_i} \phi_\infty(x_1, \dots, x_{i-1}, s, x_{i+1}, \dots, x_n) ds$ ).

By exploiting the definition of homogeneity in the bi-limit, it is possible to establish results which are straightforward extensions of well-known results based on the standard notion of homogeneity. These results are given as corollaries of the following key technical lemma, the proof of which is given in Appendix C.

LEMMA 2.13 (key technical lemma). *Let  $\eta : \mathbb{R}^n \rightarrow \mathbb{R}$  and  $\gamma : \mathbb{R}^n \rightarrow \mathbb{R}_+$  be two functions homogeneous in the bi-limit, with weights  $r_0$  and  $r_\infty$ , degrees  $d_0$  and  $d_\infty$ , and approximating functions,  $\eta_0, \eta_\infty$  and  $\gamma_0, \gamma_\infty$  such that the following hold:*

$$\begin{aligned} \{x \in \mathbb{R}^n \setminus \{0\} : \gamma(x) = 0\} &\subseteq \{x \in \mathbb{R}^n : \eta(x) < 0\}, \\ \{x \in \mathbb{R}^n \setminus \{0\} : \gamma_0(x) = 0\} &\subseteq \{x \in \mathbb{R}^n : \eta_0(x) < 0\}, \\ \{x \in \mathbb{R}^n \setminus \{0\} : \gamma_\infty(x) = 0\} &\subseteq \{x \in \mathbb{R}^n : \eta_\infty(x) < 0\}. \end{aligned}$$

Then there exists a real number  $c^*$  such that, for all  $c \geq c^*$  and for all  $x$  in  $\mathbb{R}^n \setminus \{0\}$ ,

$$(2.4) \quad \eta(x) - c\gamma(x) < 0, \quad \eta_0(x) - c\gamma_0(x) < 0, \quad \eta_\infty(x) - c\gamma_\infty(x) < 0.$$

Example 2.14. To illustrate the importance of this lemma, consider, for  $(x_1, x_2)$  in  $\mathbb{R}^2$ , the functions

$$\eta(x_1, x_2) = x_1 x_2 - |x_1|^{\frac{r_1+r_2}{r_1}}, \quad \gamma(x_1, x_2) = |x_2|^{\frac{r_1+r_2}{r_2}},$$

with  $r_1 > 0$  and  $r_2 > 0$ . They are homogeneous in the standard sense, and therefore in the bi-limit, with the same weight  $r = (r_1, r_2)$  and the same degree  $d = r_1 + r_2$ . Furthermore, the function  $\gamma$  takes positive values, and for all  $(x_1, x_2)$  in  $\{(x_1, x_2) \in \mathbb{R}^2 \setminus \{0\} : \gamma(x_1, x_2) = 0\}$  we have

$$\eta(x_1, x_2) = -|x_1|^{\frac{r_1+r_2}{r_1}} < 0.$$

Thus Lemma 2.13 yields the existence of a positive real number  $c^*$  such that for all  $c \geq c^*$ , we have

$$(2.5) \quad x_1 x_2 - |x_1|^{\frac{r_1+r_2}{r_1}} - c|x_2|^{\frac{r_1+r_2}{r_2}} < 0 \quad \forall (x_1, x_2) \in \mathbb{R}^2 \setminus \{0\}.$$

This is a generalization of the procedure known as the completion of the squares in which, however, the constant  $c_1^*$  is not specified.

COROLLARY 2.15. *Let  $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$  and  $\zeta : \mathbb{R}^n \rightarrow \mathbb{R}_+$  be two homogeneous in the bi-limit functions with the same weights  $r_0$  and  $r_\infty$ , degrees  $d_{\phi,0}, d_{\phi,\infty}$  and  $d_{\zeta,0}, d_{\zeta,\infty}$ , and approximating functions  $\eta_0, \phi_\infty$  and  $\zeta_0, \zeta_\infty$ . If the degrees satisfy  $d_{\phi,0} \geq d_{\zeta,0}$  and  $d_{\phi,\infty} \leq d_{\zeta,\infty}$ , and the functions  $\zeta, \zeta_0$  and  $\zeta_\infty$  are positive definite, then there exists a positive real number  $c$  satisfying*

$$\phi(x) \leq c\zeta(x) \quad \forall x \in \mathbb{R}^n.$$

*Proof.* Consider the two functions

$$\eta(x) := \phi(x) + \zeta(x), \quad \gamma(x) := \zeta(x).$$

By property P2 (or P3)<sup>2</sup> in section 2.2, they are homogeneous in the bi-limit with degrees  $d_{\zeta,0}$  and  $d_{\zeta,\infty}$ . The function  $\gamma$  and its homogeneous approximations being positive definite, all assumptions of Lemma 2.13 are satisfied. Therefore there exists a positive real number  $c$  such that

$$c\gamma(x) > \eta(x) > \phi(x) \quad \forall x \in \mathbb{R}^n \setminus \{0\}.$$

Finally, by continuity of the functions  $\phi$  and  $\zeta$  at zero, we can obtain the claim.  $\square$

**2.3. Stability and homogeneous approximation.** A very basic property of asymptotic stability is its robustness. This fact was already known to Lyapunov, who proposed his second method, in which (local) asymptotic stability of an equilibrium is established by looking at the first order approximation of the system. The case of local homogeneous approximations of higher degree has been investigated by Massera [16], Hermes [9], Rosier [29], and Kawski [12].

PROPOSITION 2.16 (see [29]). *Consider a homogeneous in the 0-limit vector field  $f : \mathbb{R}^n \rightarrow \mathbb{R}^n$  with associated triple  $(r_0, \mathfrak{d}_0, f_0)$ . If the origin of the system*

$$\dot{x} = f_0(x)$$

*is locally asymptotically stable, then the origin of*

$$\dot{x} = f(x)$$

*is locally asymptotically stable.*

Consequently, a natural strategy to ensure local asymptotic stability of an equilibrium of a system is to design a stabilizing homogeneous control law for the homogeneous approximation in the 0-limit (see [9, 12, 5], for instance).

Example 2.17. Consider the system (1.1), with  $q = 1$  and  $p > q$ , and the linear control law

$$u = -(c_0 + 1)x_2 - x_1.$$

The closed-loop vector field is homogeneous in the 0-limit with degree  $\mathfrak{d}_0 = 0$ , weight  $(1, 1)$  (i.e., we are in the linear case), and associated vector field  $f_0(x_1, x_2) = (x_2, -x_1 - x_2)^T$ . Selecting the Lyapunov function of degree 2,

$$V_0(x_1, x_2) = \frac{1}{2}|x_1|^2 + \frac{1}{2}|x_2 + x_1|^2,$$

yields

$$\frac{\partial V_0}{\partial x}(x) f_0(x) = -|x_1|^2 - |x_2 + x_1|^2.$$

It follows, from Lyapunov's second method, that the control law locally asymptotically stabilizes the equilibrium of the system. Furthermore, local asymptotic stability is preserved in the presence of any perturbation which does not change the approximating homogeneous function, i.e., in the presence of perturbations which are dominated by the linear part (see P2 in section 2.2).

---

<sup>2</sup>If  $\phi_0(x) + \zeta_0(x) = 0$  (resp.,  $\phi_\infty(x) + \zeta_\infty(x) = 0$ ), the proof can be completed by replacing  $\zeta$  with  $2\zeta$ .

In the context of homogeneity in the  $\infty$ -limit, we have the following result.

**PROPOSITION 2.18.** *Consider a homogeneous in the  $\infty$ -limit vector field  $f : \mathbb{R}^n \rightarrow \mathbb{R}^n$  with associated triple  $(r_\infty, \mathfrak{d}_\infty, f_\infty)$ . If the origin of the system*

$$\dot{x} = f_\infty(x)$$

*is globally asymptotically stable, then there exists an invariant compact subset of  $\mathbb{R}^n$ , denoted  $C_\infty$ , which is globally asymptotically stable<sup>3</sup> for the system*

$$\dot{x} = f(x).$$

The proof of the proposition is given in Appendix D.

As in the case of homogeneity in the 0-limit, this property can be used to design a feedback, ensuring boundedness of solutions.

*Example 2.19.* Consider the system (1.1) with  $0 < q < p < 2$  and the control law

$$(2.6) \quad u = -\frac{1}{2-p} x_1^{\frac{p-1}{2-p}} x_2 - x_1^{\frac{p}{2-p}} - c_\infty x_2^p - \left(x_2 + x_1^{\frac{1}{2-p}}\right)^p.$$

This control law is such that the closed-loop vector field is homogeneous in the  $\infty$ -limit with degree  $\mathfrak{d}_\infty = p - 1$ , weight  $(2 - p, 1)$ , and associated vector field  $f_\infty(x_1, x_2) = (x_2, -\frac{1}{2-p} x_1^{\frac{p-1}{2-p}} x_2 - x_1^{\frac{p}{2-p}} - (x_2 + x_1^{\frac{1}{2-p}})^p)^T$ . For the homogeneous Lyapunov function of degree 2,

$$V_\infty(x_1, x_2) = \frac{2-p}{2} |x_1|^{\frac{2}{2-p}} + \frac{1}{2} \left| x_2 + x_1^{\frac{1}{2-p}} \right|^2,$$

we get

$$\frac{\partial V_\infty}{\partial x}(x) f_\infty(x) = -|x_1|^{\frac{p+1}{2-p}} - \left| x_2 + x_1^{\frac{1}{2-p}} \right|^{p+1}.$$

It follows that the control law (2.6) guarantees boundedness of the solutions of the closed-loop system. Furthermore, boundedness of solutions is preserved in the presence of any perturbation which does not change the approximating homogeneous function in the  $\infty$ -limit, i.e., in the presence of perturbations which are negligible with respect to the dominant homogeneous part (see P2 in section 2.2).

The key step in the proof of Propositions 2.16 and 2.18 is the converse Lyapunov theorem given by Rosier in [29]. This result can also be extended to the case of homogeneity in the bi-limit.

**THEOREM 2.20** (homogeneous in the bi-limit Lyapunov functions). *Consider a homogeneous in the bi-limit vector field  $f : \mathbb{R}^n \rightarrow \mathbb{R}^n$ , with associated triples  $(r_\infty, \mathfrak{d}_\infty, f_\infty)$  and  $(r_0, \mathfrak{d}_0, f_0)$  such that the origins of the systems*

$$(2.7) \quad \dot{x} = f(x), \quad \dot{x} = f_\infty(x), \quad \dot{x} = f_0(x)$$

*are globally asymptotically stable equilibria. Let  $d_{V_\infty}$  and  $d_{V_0}$  be real numbers such that  $d_{V_\infty} > \max_{1 \leq i \leq n} r_{\infty,i}$  and  $d_{V_0} > \max_{1 \leq i \leq n} r_{0,i}$ . Then there exists a  $C^1$ , positive definite, and proper function  $V : \mathbb{R}^n \rightarrow \mathbb{R}_+$  such that, for each  $i$  in  $\{1, \dots, n\}$ ,*

<sup>3</sup>See [34] for the definition of global asymptotical stability for invariant compact sets.

the function  $x \mapsto \frac{\partial V}{\partial x_i}$  is homogeneous in the bi-limit with associated triples  $(r_0, d_{V_0} - r_{0,i}, \frac{\partial V_0}{\partial x_i})$  and  $(r_\infty, d_{V_\infty} - r_{\infty,i}, \frac{\partial V_\infty}{\partial x_i})$ , and the functions  $x \mapsto \frac{\partial V}{\partial x}(x) f(x)$ ,  $x \mapsto \frac{\partial V_0}{\partial x}(x) f_0(x)$ , and  $x \mapsto \frac{\partial V_\infty}{\partial x}(x) f_\infty(x)$  are negative definite.

The proof is given in Appendix E. A direct consequence of this result is an input-to-state stability (ISS) property with respect to disturbances (see [31]). To illustrate this property, consider the system with exogenous disturbance  $\delta = (\delta_1, \dots, \delta_m)$  in  $\mathbb{R}^m$ ,

$$(2.8) \quad \dot{x} = f(x, \delta) ,$$

with  $f : \mathbb{R}^n \times \mathbb{R}^m$  a continuous vector field homogeneous in the bi-limit with associated triples  $(\mathfrak{d}_0, (r_0, \mathfrak{r}_0), f_0)$  and  $(\mathfrak{d}_\infty, (r_\infty, \mathfrak{r}_\infty), f_\infty)$ , where  $\mathfrak{r}_0$  and  $\mathfrak{r}_\infty$  in  $(\mathbb{R}_+ \setminus \{0\})^m$  are the weights associated with the disturbance  $\delta$ .

COROLLARY 2.21 (ISS property). *If the origins of the systems*

$$\dot{x} = f(x, 0), \quad \dot{x} = f_0(x, 0), \quad \dot{x} = f_\infty(x, 0)$$

*are globally asymptotically stable equilibria, then under the hypotheses of Theorem 2.20 the function  $V$  given by Theorem 2.20 satisfies,<sup>4</sup> for all  $\delta = (\delta_1, \dots, \delta_m)$  in  $\mathbb{R}^m$  and  $x$  in  $\mathbb{R}^n$ ,*

$$(2.9) \quad \begin{aligned} \frac{\partial V}{\partial x}(x) f(x, \delta) \leq & -c_V \mathfrak{H} \left( V(x)^{\frac{d_{V_0} + d_0}{d_{V_0}}}, V(x)^{\frac{d_{V_\infty} + d_\infty}{d_{V_\infty}}} \right) \\ & + c_\delta \sum_{j=1}^m \mathfrak{H} \left( |\delta_j|^{\frac{d_{V_0} + d_0}{\mathfrak{r}_{0,j}}}, |\delta_j|^{\frac{d_{V_\infty} + d_\infty}{\mathfrak{r}_{\infty,j}}} \right) , \end{aligned}$$

where  $c_V$  and  $c_\delta$  are positive real numbers.

In other words, system (2.8) with  $\delta$  as input satisfies an ISS property. The proof of this corollary is given in Appendix F.

Finally, we have also the following small-gain result for homogeneous in the bi-limit vector fields.

COROLLARY 2.22 (small-gain). *Under the hypotheses of Corollary 2.21, there exists a real number  $c_G > 0$  such that, for each class  $\mathcal{K}$  function  $\gamma_z$  and  $\mathcal{KL}$  function  $\beta_\delta$ , there exists a class  $\mathcal{KL}$  function  $\beta_x$  such that, for each function  $t \in [0, T) \mapsto (x(t), \delta(t), z(t))$ ,  $T \leq +\infty$ , with  $x$   $C^1$  and  $\delta$  and  $z$  continuous, which satisfy (2.8) on  $[0, T)$  and, for all  $0 \leq s \leq t \leq T$ ,*

$$(2.10) \quad |z(t)| \leq \max \left\{ \beta_\delta(|z(s)|, t-s), \sup_{s \leq \kappa \leq t} \gamma_z(|x(\kappa)|) \right\} ,$$

$$(2.11) \quad |\delta_i(t)| \leq \max \left\{ \beta_\delta(|z(s)|, t-s), c_G \sup_{s \leq \kappa \leq t} \left\{ \mathfrak{H}(|x(\kappa)|_{r_0}^{\mathfrak{r}_{0,i}}, |x(\kappa)|_{r_\infty}^{\mathfrak{r}_{\infty,i}}) \right\} \right\} ,$$

we have

$$(2.12) \quad |x(t)| \leq \beta_x(|(x(s), z(s))|, t-s), \quad 0 \leq s \leq t \leq T .$$

<sup>4</sup>The function  $\mathfrak{H}$  is defined in (1.6).

The proof is given in Appendix G.

*Example 2.23.* An interesting case, which can be dealt with by Corollary 2.22, is when the  $\delta_i$ 's are outputs of auxiliary systems with state  $z_i$  in  $\mathbb{R}^{n_i}$ , i.e.,

$$(2.13) \quad \delta_i(t) := \delta_i(z_i(t), x(t)), \quad \dot{z}_i = g_i(z_i, x) .$$

It can be checked that the bounds (2.11) and (2.10) are satisfied by all the solutions of (2.8) and (2.13) if there exist positive definite and radially unbounded functions  $Z_i : \mathbb{R}^{n_i} \rightarrow \mathbb{R}_+$ ; class  $\mathcal{K}$  functions  $\omega_1$ ,  $\omega_2$ , and  $\omega_3$ ; and a positive real number  $\epsilon$  in  $(0, 1)$  such that for all  $x$  in  $\mathbb{R}^n$ , for all  $i$  in  $\{1, \dots, m\}$ , and  $z_i$  in  $\mathbb{R}^{n_i}$ , we have

$$\begin{aligned} |\delta_i(z_i, x)| &\leq \omega_1(x) + \omega_2(Z_i(z_i)), & \frac{\partial Z_i}{\partial z_i}(z_i) g_i(z_i, x) &\leq -Z_i(z_i) + \omega_3(|x|) , \\ \omega_1(x) + \omega_2([1 + \epsilon] \omega_3(|x|)) &\leq c_G \mathfrak{H}(|x|_{r_0}^{r_{0,i}}, |x|_{r_\infty}^{r_{\infty,i}}) . \end{aligned}$$

Another important result exploiting Theorem 2.20 deals with finite time convergence of solutions toward a globally asymptotically stable equilibrium (see [4]). It is well known that when the origin of the homogeneous approximation in the 0-limit is globally asymptotically stable with a strictly negative degree, then solutions converge to the origin in finite time (see [3]). We extend this result by showing that if, furthermore, the origin of the homogeneous approximation in the  $\infty$ -limit is globally asymptotically stable with strictly positive degree, then the convergence time doesn't depend on the initial condition. This is expressed by the following corollary.

**COROLLARY 2.24** (uniform and finite time convergence). *Under the hypotheses of Theorem 2.20, if we have  $\mathfrak{d}_\infty > 0 > \mathfrak{d}_0$ , then all solutions of the system  $\dot{x} = f(x)$  converge in finite time to the origin, uniformly in the initial condition.*

The proof is given in Appendix H.

**3. Recursive observer design for a chain of integrators.** The notion of homogeneity in the bi-limit is instrumental in introducing a new observer design method. Throughout this section we consider a chain of integrators, with state  $\mathfrak{X}_n = (x_1, \dots, x_n)$  in  $\mathbb{R}^n$ , namely,

$$(3.1) \quad \dot{x}_1 = x_2, \dots, \dot{x}_n = u, \quad \text{or in compact form,} \quad \dot{\mathfrak{X}}_n = \mathcal{S}_n \mathfrak{X}_n + B_n u ,$$

where  $\mathcal{S}_n$  is the shift matrix of order  $n$ , i.e.,  $\mathcal{S}_n \mathfrak{X}_n = (x_2, \dots, x_n, 0)^T$  and  $B_n = (0, \dots, 0, 1)^T$ . By selecting arbitrary vector field degrees  $\mathfrak{d}_0$  and  $\mathfrak{d}_\infty$  in  $(-1, \frac{1}{n-1})$ , we see that, to possibly obtain homogeneity in the bi-limit of the associated vector field, we must choose the weights  $r_0 = (r_{0,1}, \dots, r_{0,n})$  and  $r_\infty = (r_{\infty,1}, \dots, r_{\infty,n})$  as

$$(3.2) \quad \begin{aligned} r_{0,n} &= 1, & r_{0,i} &= r_{0,i+1} - \mathfrak{d}_0 &= 1 - \mathfrak{d}_0(n-i), \\ r_{\infty,n} &= 1, & r_{\infty,i} &= r_{\infty,i+1} - \mathfrak{d}_\infty &= 1 - \mathfrak{d}_\infty(n-i). \end{aligned}$$

The goal of this section is to introduce a global homogeneous in the bi-limit observer for the system (3.1). This design follows a recursive method, which constitutes one of the main contributions of this paper.

The idea of designing an observer recursively starting from  $x_n$  and going backwards towards  $x_1$  is not new. It can be found, for instance, in [28, 26, 23, 30, 35] and in [7, Lemma 6.2.1]. Nevertheless, the procedure we propose is new and extends the results in [23, Lemmas 1 and 2] to the homogeneous in the bi-limit case.

Also, as opposed to what is proposed in [28, 26],<sup>5</sup> this observer is an exact observer (with any input  $u$ ) for a chain of integrators. The observer is given by the system<sup>6</sup>

$$(3.3) \quad \dot{\hat{\mathbf{x}}}_n = \mathcal{S}_n \hat{\mathbf{x}}_n + B_n u + K_1(\hat{x}_1 - x_1),$$

with state  $\hat{\mathbf{x}}_n = (\hat{x}_1, \dots, \hat{x}_n)$ , and where  $K_1 : \mathbb{R}^n \rightarrow \mathbb{R}^n$  is a homogeneous in the bi-limit vector field with weights  $r_0, r_\infty$  and degrees  $\mathfrak{d}_0, \mathfrak{d}_\infty$ . The output injection vector field  $K_1$  has to be selected such that the origin is a globally asymptotically stable equilibrium for the system

$$(3.4) \quad \dot{E}_1 = \mathcal{S}_n E_1 + K_1(e_1), \quad E_1 = (e_1, \dots, e_n)^T,$$

and also for its homogeneous approximations. The construction of  $K_1$  is performed via a recursive procedure whose induction argument is as follows.

Consider the system on  $\mathbb{R}^{n-i}$  given by

$$(3.5) \quad \dot{E}_{i+1} = \mathcal{S}_{n-i} E_{i+1} + K_{i+1}(e_{i+1}), \quad E_{i+1} = (e_{i+1}, \dots, e_n)^T,$$

with  $\mathcal{S}_{n-i}$  the shift matrix of order  $n-i$ , i.e.,  $\mathcal{S}_{n-i} E_{i+1} = (e_{i+2}, \dots, e_n, 0)^T$ , and  $K_{i+1} : \mathbb{R}^{n-i} \rightarrow \mathbb{R}^{n-i}$  a homogeneous in the bi-limit vector field, whose associated triples are  $((r_{0,i+1}, \dots, r_{0,n}), \mathfrak{d}_0, K_{i+1,0})$  and  $((r_{\infty,i+1}, \dots, r_{\infty,n}), \mathfrak{d}_\infty, K_{i+1,\infty})$ .

**THEOREM 3.1** (homogeneous in the bi-limit observer design). *Consider the system (3.5) and its homogeneous approximation at infinity and around the origin,*

$$\dot{E}_{i+1} = \mathcal{S}_{n-i} E_{i+1} + K_{i+1,0}(e_{i+1}), \quad \dot{E}_{i+1} = \mathcal{S}_{n-i} E_{i+1} + K_{i+1,\infty}(e_{i+1}).$$

*Suppose the origin is a globally asymptotically stable equilibrium for these systems. Then there exists a homogeneous in the bi-limit vector field  $K_i : \mathbb{R}^{n-i+1} \rightarrow \mathbb{R}^{n-i+1}$ , with associated triples  $((r_{0,i}, \dots, r_{0,n}), \mathfrak{d}_0, K_{i,0})$  and  $((r_{\infty,i}, \dots, r_{\infty,n}), \mathfrak{d}_\infty, K_{i,\infty})$ , such that the origin is a globally asymptotically stable equilibrium for the systems*

$$(3.6) \quad \begin{aligned} \dot{E}_i &= \mathcal{S}_{n-i+1} E_i + K_i(e_i), \\ \dot{E}_i &= \mathcal{S}_{n-i+1} E_i + K_{i,0}(e_i), \quad E_i = (e_i, \dots, e_n)^T, \\ \dot{E}_i &= \mathcal{S}_{n-i+1} E_i + K_{i,\infty}(e_i). \end{aligned}$$

*Proof.* We prove this result in two steps. First, we define a homogeneous in the bi-limit Lyapunov function. Then we construct the vector field  $K_i$ , depending on a parameter  $\ell$  which, if sufficiently large, renders negative definite the derivative of this Lyapunov function along the solutions of the system.

**Step 1. Definition of the Lyapunov function.** Let  $d_{W_0}$  and  $d_{W_\infty}$  be positive real numbers satisfying

$$(3.7) \quad d_{W_0} > 2 \max_{1 \leq j \leq n} r_{0,j} + \mathfrak{d}_0, \quad d_{W_\infty} > 2 \max_{1 \leq j \leq n} r_{\infty,j} + \mathfrak{d}_\infty,$$

and

$$(3.8) \quad \frac{d_{W_\infty}}{r_{\infty,i}} \geq \frac{d_{W_0}}{r_{0,i}}.$$

<sup>5</sup>Note the term  $x_i$  in (3.15) of [28], for instance.

<sup>6</sup>To simplify the presentation, we use the compact notation  $K_1(\hat{x}_1 - x_1)$  for  $K_1(\hat{x}_1 - x_1, 0, \dots, 0)$ .

The selection (3.2) implies  $r_{0,j} + \mathfrak{d}_0 > 0$  and  $r_{\infty,j} + \mathfrak{d}_\infty > 0$  for each  $j$  in  $\{1, \dots, n\}$ . Hence,

$$d_{W_0} > \max_{1 \leq j \leq n} r_{0,j}, \quad d_{W_\infty} > \max_{1 \leq j \leq n} r_{\infty,j},$$

and we can invoke Theorem 2.20 for the system (3.4) and its homogeneous approximations given in (3.5). This implies that there exists a  $C^1$ , positive definite, and proper function  $W_{i+1} : \mathbb{R}^{n-i} \rightarrow \mathbb{R}_+$  such that, for each  $j$  in  $\{i+1, \dots, n\}$ , the function  $\frac{\partial W_{i+1}}{\partial e_j}$  is homogeneous in the bi-limit with associated triples

$$\left( (r_{0,i+1}, \dots, r_{0,n}), d_{W_0} - r_{0,j}, \frac{\partial W_{i+1,0}}{\partial e_j} \right) \quad \text{and} \\ \left( (r_{\infty,i+1}, \dots, r_{\infty,n}), d_{W_\infty} - r_{\infty,j}, \frac{\partial W_{i+1,\infty}}{\partial e_j} \right).$$

Moreover, for all  $E_{i+1} \in \mathbb{R}^{n-i} \setminus \{0\}$ , we have

$$(3.9) \quad \begin{aligned} & \frac{\partial W_{i+1}}{\partial E_{i+1}}(E_{i+1}) (\mathcal{S}_{n-i} E_{i+1} + K_{i+1}(e_{i+1})) < 0, \\ & \frac{\partial W_{i+1,0}}{\partial E_{i+1}}(E_{i+1}) (\mathcal{S}_{n-i} E_{i+1} + K_{i+1,0}(e_{i+1})) < 0, \\ & \frac{\partial W_{i+1,\infty}}{\partial E_{i+1}}(E_{i+1}) (\mathcal{S}_{n-i} E_{i+1} + K_{i+1,\infty}(e_{i+1})) < 0. \end{aligned}$$

Consider the function  $q_i : \mathbb{R} \rightarrow \mathbb{R}$  defined as

$$(3.10) \quad q_i(s) = \begin{cases} \frac{r_{0,i}}{r_{0,i} + \mathfrak{d}_0} s^{\frac{r_{0,i} + \mathfrak{d}_0}{r_{0,i}}}, & |s| \leq 1, \\ \frac{r_{\infty,i}}{r_{\infty,i} + \mathfrak{d}_\infty} s^{\frac{r_{\infty,i} + \mathfrak{d}_\infty}{r_{\infty,i}}} + \frac{r_{0,i}}{r_{0,i} + \mathfrak{d}_0} - \frac{r_{\infty,i}}{r_{\infty,i} + \mathfrak{d}_\infty}, & |s| \geq 1. \end{cases}$$

Since we have  $0 < r_{0,i} + \mathfrak{d}_0$  and  $0 < r_{\infty,i} + \mathfrak{d}_\infty$ , this function is well defined and continuous on  $\mathbb{R}$ , strictly increasing and onto, and  $C^1$  on  $\mathbb{R} \setminus \{0\}$ . Furthermore, it is by construction homogeneous in the bi-limit with approximating continuous functions  $\frac{r_{0,i}}{r_{0,i} + \mathfrak{d}_0} s^{\frac{r_{0,i} + \mathfrak{d}_0}{r_{0,i}}}$  and  $\frac{r_{\infty,i}}{r_{\infty,i} + \mathfrak{d}_\infty} s^{\frac{r_{\infty,i} + \mathfrak{d}_\infty}{r_{\infty,i}}}$ . The inverse function  $q_i^{-1}$  of  $q_i$  is defined as

$$q_i^{-1}(s) = \begin{cases} \left( \frac{r_{0,i} + \mathfrak{d}_0}{r_{0,i}} s \right)^{\frac{r_{0,i}}{r_{0,i} + \mathfrak{d}_0}}, & |s| \leq \frac{r_{0,i} + \mathfrak{d}_0}{r_{0,i}}, \\ \left( \left( s - \frac{r_{0,i}}{r_{0,i} + \mathfrak{d}_0} + \frac{r_{\infty,i}}{r_{\infty,i} + \mathfrak{d}_\infty} \right) \frac{r_{\infty,i} + \mathfrak{d}_\infty}{r_{\infty,i}} \right)^{\frac{r_{\infty,i}}{r_{\infty,i} + \mathfrak{d}_\infty}}, & |s| \geq \frac{r_{0,i} + \mathfrak{d}_0}{r_{0,i}}. \end{cases}$$

By (3.8), the function

$$(3.11) \quad s \mapsto q_i^{-1}(s) \frac{d_{W_0} - r_{0,i}}{r_{0,i}} + q_i^{-1}(s) \frac{d_{W_\infty} - r_{\infty,i}}{r_{\infty,i}}$$

is homogeneous in the bi-limit with associated approximating functions  $\left( \frac{r_{0,i} + \mathfrak{d}_0}{r_{0,i}} s \right)^{\frac{d_{W_0} - r_{0,i}}{r_{0,i} + \mathfrak{d}_0}}$  and  $\left( \frac{r_{\infty,i} + \mathfrak{d}_\infty}{r_{\infty,i}} s \right)^{\frac{d_{W_\infty} - r_{\infty,i}}{r_{\infty,i} + \mathfrak{d}_\infty}}$ . Furthermore, by (3.7), it is  $C^1$  on  $\mathbb{R}$ , and its derivative is homogeneous in the bi-limit with continuous approximating functions

$$s \mapsto \frac{d_{W_0} - r_{0,i}}{r_{0,i}} \left| \frac{d_{W_0} - r_{0,i}}{r_{0,i} + \mathfrak{d}_0} s \right|^{\frac{d_{W_0} - 2r_{0,i} - \mathfrak{d}_0}{r_{0,i} + \mathfrak{d}_0}} \quad \text{and} \quad s \mapsto \frac{d_{W_\infty} - r_{\infty,i}}{r_{\infty,i}} \left| \frac{d_{W_\infty} - r_{\infty,i}}{r_{\infty,i} + \mathfrak{d}_\infty} s \right|^{\frac{d_{W_\infty} - 2r_{\infty,i} - \mathfrak{d}_\infty}{r_{\infty,i} + \mathfrak{d}_\infty}}.$$

Let  $\mathfrak{W}_i : \mathbb{R}^{n-i+1} \rightarrow \mathbb{R}_+$  be defined by

$$\begin{aligned} \mathfrak{W}_i(E_{i+1}, s) = & W_{i+1}(E_{i+1}) + \int_{q_i^{-1}(e_{i+1})}^s \left( h^{\frac{dW_0 - r_{0,i}}{r_{0,i}}} + h^{\frac{dW_\infty - r_{\infty,i}}{r_{\infty,i}}} \right) dh \\ & - \int_{q_i^{-1}(e_{i+1})}^s \left( q_i^{-1}(e_{i+1})^{\frac{dW_0 - r_{0,i}}{r_{0,i}}} + q_i^{-1}(e_{i+1})^{\frac{dW_\infty - r_{\infty,i}}{r_{\infty,i}}} \right) dh . \end{aligned}$$

This function is  $C^1$ , and by (3.8), Proposition 2.12 yields that it is homogeneous in the bi-limit with weights  $(r_{0,i+1}, \dots, r_{0,n})$  and  $(r_{\infty,i+1}, \dots, r_{\infty,n})$  for  $E_{i+1}$ ,  $r_{0,i}$  and  $r_{\infty,i}$  for  $s$ , and degrees  $d_{W_0}$  and  $d_{W_\infty}$ . Furthermore, for each  $j$  in  $\{i+1, \dots, n\}$ , the functions  $\frac{\partial \mathfrak{W}_i}{\partial e_j}(E_{i+1}, s)$  are also homogeneous in the bi-limit with the same weights and with degrees  $d_{W_0} - r_{0,j}$  and  $d_{W_\infty} - r_{\infty,j}$ .

*Step 2. Construction of the vector field  $K_i$ .* Given a positive real number  $\ell$ , we define the vector field  $K_i : \mathbb{R}^{n-i} \rightarrow \mathbb{R}^{n-i}$  as

$$K_i(e_i) = \begin{pmatrix} -q_i(\ell e_i) \\ K_{i+1}(q_i(\ell e_i)) \end{pmatrix} .$$

By Proposition 2.10 and the properties we have established for  $q_i$ ,  $K_i$  is a homogeneous in the bi-limit vector field. We show now that selecting  $\ell$  large enough yields the asymptotic stability properties. To begin with, note that for all  $E_i = (E_{i+1}, e_i)$  in  $\mathbb{R}^{n-i}$ ,

$$\frac{\partial \mathfrak{W}_i(E_{i+1}, \ell e_i)}{\partial E_i}(E_i) (\mathcal{S}_{n-i+1} E_i + K_i(e_i)) \leq T_1(E_{i+1}, \ell e_i) - \ell T_2(E_{i+1}, \ell e_i) ,$$

with the functions  $T_1$  and  $T_2$  defined as

$$\begin{aligned} T_1(E_{i+1}, \vartheta_i) &= \frac{\partial \mathfrak{W}_i}{\partial E_{i+1}}(E_{i+1}, \vartheta_i) (\mathcal{S}_{n-i} E_{i+1} + K_{i+1}(q_i(\vartheta_i))) , \\ T_2(E_{i+1}, \vartheta_i) &= \left( \vartheta_i^{\frac{dW_0 - r_{0,i}}{r_{0,i}}} - q_i^{-1}(e_{i+1})^{\frac{dW_0 - r_{0,i}}{r_{0,i}}} + \vartheta_i^{\frac{dW_\infty - r_{\infty,i}}{r_{\infty,i}}} - q_i^{-1}(e_{i+1})^{\frac{dW_\infty - r_{\infty,i}}{r_{\infty,i}}} \right) \\ &\quad \times (q_i(\vartheta_i) - e_{i+1}) . \end{aligned}$$

These functions are homogeneous in the bi-limit with weights  $(r_{\infty,i}, \dots, r_{\infty,n})$  and  $(r_{0,i}, \dots, r_{0,n})$ , degrees  $\mathfrak{d}_0 + d_{W_0}$  and  $\mathfrak{d}_\infty + d_{W_\infty}$ , and continuous approximating functions

$$\begin{aligned} T_{1,0}(E_{i+1}, \vartheta_i) &= \frac{\partial \mathfrak{W}_{i,0}}{\partial E_{i+1}}(E_{i+1}, \vartheta_i) (\mathcal{S}_{n-i} E_{i+1} + K_{i+1,0}(q_{i,0}(\vartheta_i))) , \\ T_{1,\infty}(E_{i+1}, \vartheta_i) &= \frac{\partial \mathfrak{W}_{i,\infty}}{\partial E_{i+1}}(E_{i+1}, \vartheta_i) (\mathcal{S}_{n-i} E_{i+1} + K_{i+1,\infty}(q_{i,\infty}(\vartheta_i))) , \\ T_{2,0}(E_{i+1}, \vartheta_i) &= \left( \vartheta_i^{\frac{dW_0 - r_{0,i}}{r_{0,i}}} - q_{i,0}^{-1}(e_{i+1})^{\frac{dW_0 - r_{0,i}}{r_{0,i}}} \right) (q_{i,0}(\vartheta_i) - e_{i+1}) , \end{aligned}$$

and

$$T_{2,\infty}(E_{i+1}, \vartheta_i) = \left( \vartheta_i^{\frac{dW_\infty - r_{\infty,i}}{r_{\infty,i}}} - q_{i,\infty}^{-1}(e_{i+1})^{\frac{dW_\infty - r_{\infty,i}}{r_{\infty,i}}} \right) (q_{i,\infty}(\vartheta_i) - e_{i+1}) .$$

As the function  $q_i^{-1}$  is continuous, strictly increasing and onto, the function

$$\vartheta_i^{\frac{dW_0 - r_{0,i}}{r_{0,i}}} - q_i^{-1}(e_{i+1})^{\frac{dW_0 - r_{0,i}}{r_{0,i}}} + \vartheta_i^{\frac{dW_\infty - r_{\infty,i}}{r_{\infty,i}}} - q_i^{-1}(e_{i+1})^{\frac{dW_\infty - r_{\infty,i}}{r_{\infty,i}}}$$

has a unique zero at  $q_i(\vartheta_i) = e_{i+1}$  and has the same sign as  $q_i(\vartheta_i) - e_{i+1}$ . It follows that

$$\begin{aligned} T_2(E_{i+1}, \vartheta_i) &\geq 0 & \forall (E_{i+1}, \vartheta_i) \in \mathbb{R}^{n-i}, \\ T_2(E_{i+1}, \vartheta_i) &= 0 & \Rightarrow q_i(\vartheta_i) = e_{i+1}. \end{aligned}$$

On the other hand, for all  $E_i \neq 0$ ,

$$T_1(E_{i+1}, q_i^{-1}(e_{i+1})) = \frac{\partial W_{i+1}}{\partial E_{i+1}}(E_{i+1}) (\mathcal{S}_{n-i} E_{i+1} + K_{i+1}(e_{i+1})) < 0.$$

Hence (3.9) yields

$$\begin{aligned} \{(E_{i+1}, \vartheta_i) \in \mathbb{R}^{n-i+1} \setminus \{0\} : T_2(E_{i+1}, \vartheta_i) = 0\} \\ \subseteq \{(E_{i+1}, \vartheta_i) \in \mathbb{R}^{n-i+1} : T_1(E_{i+1}, \vartheta_i) < 0\}. \end{aligned}$$

By following the same argument, it can be shown that this property holds also for the homogeneous approximations, i.e.,

$$\begin{aligned} \{(E_{i+1}, \vartheta_i) \in \mathbb{R}^{n-i+1} \setminus \{0\} : T_{2,0}(E_{i+1}, \vartheta_i) = 0\} \\ \subseteq \{(E_{i+1}, \vartheta_i) \in \mathbb{R}^{n-i+1} : T_{1,0}(E_{i+1}, \vartheta_i) < 0\}, \\ \{(E_{i+1}, \vartheta_i) \in \mathbb{R}^{n-i+1} \setminus \{0\} : T_{2,\infty}(E_{i+1}, \vartheta_i) = 0\} \\ \subseteq \{(E_{i+1}, \vartheta_i) \in \mathbb{R}^{n-i+1} : T_{1,\infty}(E_{i+1}, \vartheta_i) < 0\}. \end{aligned}$$

Therefore, by Lemma 2.13, there exists  $\ell^*$  such that, for all  $\ell \geq \ell^*$  and all  $(E_{i+1}, \vartheta_i) \neq 0$ ,

$$\begin{aligned} T_1(E_{i+1}, \vartheta_i) - \ell T_2(E_{i+1}, \vartheta_i) &< 0, \\ T_{1,0}(E_{i+1}, \vartheta_i) - \ell T_{2,0}(E_{i+1}, \vartheta_i) &< 0, \\ T_{1,\infty}(E_{i+1}, \vartheta_i) - \ell T_{2,\infty}(E_{i+1}, \vartheta_i) &< 0. \end{aligned}$$

This implies that the origin is a globally asymptotically stable equilibrium of the systems (3.6), which concludes the proof.  $\square$

To construct the function  $K_1$ , which defines the observer (3.3), it is sufficient to iterate the construction proposed in Theorem 3.1 starting from

$$K_n(e_n) = - \begin{cases} \frac{1}{1+\vartheta_0} (\ell_n e_n)^{1+\vartheta_0}, & |\ell_n e_n| \leq 1, \\ \frac{1}{1+\vartheta_\infty} (\ell_n e_n)^{1+\vartheta_\infty} + \frac{1}{1+\vartheta_0} - \frac{1}{1+\vartheta_\infty}, & |\ell_n e_n| \geq 1, \end{cases}$$

where  $\ell_n$  is any strictly positive real number. Indeed,  $K_n$  is a homogeneous in the bi-limit vector field with approximating functions  $K_{n,0}(e_n) = \frac{1}{1+\vartheta_0} (\ell_n e_n)^{1+\vartheta_0}$  and  $K_{n,\infty}(e_n) = \frac{1}{1+\vartheta_\infty} (\ell_n e_n)^{1+\vartheta_\infty}$ . This selection implies that the origin is a globally asymptotically stable equilibrium for the systems  $\dot{e}_n = K_n(e_n)$ ,  $\dot{e}_n = K_{n,0}(e_n)$ , and  $\dot{e}_n = K_{n,\infty}(e_n)$ .

Consequently the assumptions of Theorem 3.1 are satisfied for  $i + 1 = n$ . We can apply it recursively up to  $i = 1$ , obtaining the vector field  $K_1$ .

As a result of this procedure we obtain a homogeneous in the bi-limit observer, which globally asymptotically observes the state of the system (3.1), and also the state for its homogeneous approximations around the origin and at infinity. In other words, the origin is a globally asymptotically stable equilibrium of the systems

$$(3.12) \quad \dot{E}_1 = \mathcal{S}_n E_1 + K_1(e_1), \quad \dot{\bar{E}}_1 = \mathcal{S}_n E_1 + K_{1,0}(e_1), \quad \dot{\hat{E}}_1 = \mathcal{S}_n E_1 + K_{1,\infty}(e_1).$$

*Remark 3.2.* Note that when  $0 \leq \mathfrak{d}_0 \leq \mathfrak{d}_\infty$ , we have  $1 \leq \frac{r_{0,i} + \mathfrak{d}_0}{r_{0,i}} \leq \frac{r_{\infty,i} + \mathfrak{d}_\infty}{r_{\infty,i}}$  for  $i = 1, \dots, n$  and we can replace the function  $q_i$  in (3.10) by the simpler function

$$q_i(s) = s^{\frac{r_{0,i} + \mathfrak{d}_0}{r_{0,i}}} + s^{\frac{r_{\infty,i} + \mathfrak{d}_\infty}{r_{\infty,i}}},$$

which has been used already in [1].

*Example 3.3.* Consider a chain of integrators of dimension two, with the following weights and degrees:

$$(r_0, \mathfrak{d}_0) = ((2 - q, 1), q - 1), \quad (r_\infty, \mathfrak{d}_\infty) = ((2 - p, 1), p - 1).$$

When  $q \geq p$  (i.e.,  $\mathfrak{d}_0 \leq \mathfrak{d}_\infty$ ), by following the above recursive observer design we obtain two positive real numbers  $\ell_1$  and  $\ell_2$  such that the system

$$\dot{\hat{x}}_1 = \hat{x}_2 - q_1(\ell_1 e_1), \quad \dot{\hat{x}}_2 = u - q_2(\ell_2 q_1(\ell_1 e_1)), \quad e_1 = \hat{x}_1 - y,$$

with

$$(3.13) \quad q_2(s) = \begin{cases} \frac{1}{q} s^q, & |s| \leq 1, \\ \frac{1}{p} s^p + \frac{1}{q} - \frac{1}{p}, & |s| \geq 1, \end{cases} \quad q_1(s) = \begin{cases} (2 - q) s^{\frac{1}{2-q}}, & |s| \leq 1, \\ (2 - p) s^{\frac{1}{2-p}} + p - q, & |s| \geq 1, \end{cases}$$

is a global observer for the system  $\dot{x}_1 = x_2$ ,  $\dot{x}_2 = u$ ,  $y = x_1$ . Furthermore, its homogeneous approximations around the origin and at infinity are also global observers for the same system.

#### 4. Recursive design of a homogeneous in the bi-limit state feedback.

It is well known that the system (3.1) can be rendered homogeneous by using a stabilizing homogeneous state feedback which can be designed by backstepping (see [21, 25, 19, 26, 33, 10], for instance). We show in this section that this property can be extended to the case of homogeneity in the bi-limit. More precisely, we show that there exists a homogeneous in the bi-limit function  $\phi_n$  such that the system (3.1) with  $u = \phi_n(\mathfrak{X}_n)$  is homogeneous in the bi-limit, with weights  $r_0$  and  $r_\infty$  and degrees  $\mathfrak{d}_0$  and  $\mathfrak{d}_\infty$ . Furthermore, its origin and the origin of the approximating systems in the 0-limit and in the  $\infty$ -limit are globally asymptotically stable equilibria.

To design the state feedback we follow the approach of Praly and Mazenc [25]. To this end, consider the auxiliary system with state  $\mathfrak{X}_i = (x_1, \dots, x_i)$  in  $\mathbb{R}^i$ ,  $1 \leq i < n$ , and dynamics

$$(4.1) \quad \dot{x}_1 = x_2, \dots, \dot{x}_i = u \quad \text{or in compact form} \quad \dot{\mathfrak{X}}_i = \mathcal{S}_i \mathfrak{X}_i + B_i u,$$

where  $u$  is the input in  $\mathbb{R}$ ,  $\mathcal{S}_i$  is the shift matrix of order  $i$ , i.e.,  $\mathcal{S}_i \mathfrak{X}_i = (x_2, \dots, x_i, 0)^T$ , and  $B_i = (0, \dots, 1)^T$  is in  $\mathbb{R}^i$ . We show that, if there exists a homogeneous in the

bi-limit stabilizing control law for the origin of the system (4.1), then there is one for the origin of the system with state  $\mathfrak{X}_{i+1} = (x_1, \dots, x_{i+1})$  in  $\mathbb{R}^{i+1}$  defined by

$$(4.2) \quad \dot{x}_1 = x_2, \dots, \dot{x}_{i+1} = u, \text{ i.e., } \quad \dot{\mathfrak{X}}_{i+1} = \mathcal{S}_{i+1} \mathfrak{X}_{i+1} + B_{i+1} u .$$

Let  $\mathfrak{d}_0$  and  $\mathfrak{d}_\infty$  be in  $(-1, \frac{1}{n-1})$  and consider the weights and degrees defined in (3.2).

**THEOREM 4.1** (homogeneous in the bi-limit backstepping). *Suppose there exists a homogeneous in the bi-limit function  $\phi_i : \mathbb{R}^i \rightarrow \mathbb{R}$  with associated triples  $(r_0, \mathfrak{d}_0 + r_{0,i}, \phi_{i,0})$  and  $(r_\infty, \mathfrak{d}_\infty + r_{\infty,i}, \phi_{i,\infty})$  such that the following hold:*

1. *There exists  $\alpha_i \geq 1$  such that the function  $\psi_i(\mathfrak{X}_i) = \phi_i(\mathfrak{X}_i)^{\alpha_i}$  is  $C^1$  and for each  $j$  in  $\{1, \dots, i\}$  the function  $\frac{\partial \psi_i}{\partial x_j}$  is homogeneous in the bi-limit with weights  $(r_{0,1}, \dots, r_{0,i})$ ,  $(r_{\infty,1}, \dots, r_{\infty,i})$ , degrees  $\alpha_i(r_{0,i} + \mathfrak{d}_0) - r_{0,j}$ ,  $\alpha_i(r_{\infty,i} + \mathfrak{d}_\infty) - r_{\infty,j}$ , and approximating functions  $\frac{\partial \psi_{i,0}}{\partial x_j}$ ,  $\frac{\partial \psi_{i,\infty}}{\partial x_j}$ .*
2. *The origin is a globally asymptotically stable equilibrium of the systems*

(4.3)

$$\dot{\mathfrak{X}}_i = \mathcal{S}_i \mathfrak{X}_i + B_i \phi_i(\mathfrak{X}_i) , \quad \dot{\mathfrak{X}}_i = \mathcal{S}_i \mathfrak{X}_i + B_i \phi_{i,0}(\mathfrak{X}_i) , \quad \dot{\mathfrak{X}}_i = \mathcal{S}_i \mathfrak{X}_i + B_i \phi_{i,\infty}(\mathfrak{X}_i) .$$

Then there exists a homogeneous in the bi-limit function  $\phi_{i+1} : \mathbb{R}^{i+1} \rightarrow \mathbb{R}$  with associated triples  $(r_0, \mathfrak{d}_0 + r_{0,i+1}, \phi_{i+1,0})$  and  $(r_\infty, \mathfrak{d}_\infty + r_{\infty,i+1}, \phi_{i+1,\infty})$  such that the same properties hold, i.e.,

1. *there exists a real number  $\alpha_{i+1} > 1$  such that the function  $\psi_{i+1}(\mathfrak{X}_{i+1}) = \phi_{i+1}(\mathfrak{X}_{i+1})^{\alpha_{i+1}}$  is  $C^1$  and for each  $j$  in  $\{1, \dots, i+1\}$  the function  $\frac{\partial \psi_{i+1}}{\partial x_j}$  is homogeneous in the bi-limit with weights  $(r_{0,1}, \dots, r_{0,i+1})$ ,  $(r_{\infty,1}, \dots, r_{\infty,i+1})$ , degrees  $\alpha_{i+1}(r_{0,i+1} + \mathfrak{d}_0) - r_{0,j}$ ,  $\alpha_{i+1}(r_{\infty,i+1} + \mathfrak{d}_\infty) - r_{\infty,j}$ , and approximating functions  $\frac{\partial \psi_{i+1,0}}{\partial x_j}$ ,  $\frac{\partial \psi_{i+1,\infty}}{\partial x_j}$ ;*
2. *the origin is a globally asymptotically stable equilibrium of the systems*

$$(4.4) \quad \begin{aligned} \mathfrak{X}_{i+1} &= \mathcal{S}_{i+1} \mathfrak{X}_{i+1} + B_{i+1} \phi_{i+1}(\mathfrak{X}_{i+1}) , \\ \mathfrak{X}_{i+1} &= \mathcal{S}_{i+1} \mathfrak{X}_{i+1} + B_{i+1} \phi_{i+1,0}(\mathfrak{X}_{i+1}) , \\ \mathfrak{X}_{i+1} &= \mathcal{S}_{i+1} \mathfrak{X}_{i+1} + B_{i+1} \phi_{i+1,\infty}(\mathfrak{X}_{i+1}) . \end{aligned}$$

*Proof.* We prove this result in three steps. First, we construct a homogeneous in the bi-limit Lyapunov function; then we define a control law parametrized by a real number  $k$ . Finally, we show that there exists  $k$  such that the time derivative, along the trajectories of systems (4.4), of the Lyapunov function and of its approximating functions is negative definite.

*Step 1. Construction of the Lyapunov function.* Let  $d_{V_0}$  and  $d_{V_\infty}$  be positive real numbers satisfying

$$(4.5) \quad d_{V_0} > \max_{j \in \{1, \dots, n\}} \{r_{0,j}\}, \quad d_{V_\infty} > \max_{j \in \{1, \dots, n\}} \{r_{\infty,j}\} ,$$

and

$$(4.6) \quad \frac{d_{V_\infty}}{r_{\infty,i+1}} \geq \frac{d_{V_0}}{r_{0,i+1}} > 1 + \alpha_i .$$

With this selection, Theorem 2.20 gives the existence of a  $C^1$ , proper, and positive definite function  $V_i : \mathbb{R}^i \rightarrow \mathbb{R}_+$  such that, for each  $j$  in  $\{1, \dots, n\}$ , the function  $\frac{\partial V_i}{\partial x_j}$

is homogeneous in the bi-limit with weights  $(r_{0,1}, \dots, r_{0,i})$ ,  $(r_{\infty,1}, \dots, r_{\infty,i})$ , degrees  $d_{V_0} - r_{0,j}$ ,  $d_{V_\infty} - r_{\infty,j}$ , and approximating functions  $\frac{\partial V_{i,0}}{\partial x_j}$ ,  $\frac{\partial V_{i,\infty}}{\partial x_j}$ . Moreover, we have for all  $\mathfrak{X}_i \in \mathbb{R}^i \setminus \{0\}$ ,

$$(4.7) \quad \begin{aligned} \frac{\partial V_i}{\partial \mathfrak{X}_i}(\mathfrak{X}_i) [\mathcal{S}_i \mathfrak{X}_i + B_i \phi_i(\mathfrak{X}_i)] &< 0, \\ \frac{\partial V_{i,0}}{\partial \mathfrak{X}_i}(\mathfrak{X}_i) [\mathcal{S}_i \mathfrak{X}_i + B_i \phi_{i,0}(\mathfrak{X}_i)] &< 0, \\ \frac{\partial V_{i,\infty}}{\partial \mathfrak{X}_i}(\mathfrak{X}_i) [\mathcal{S}_i \mathfrak{X}_i + B_i \phi_{i,\infty}(\mathfrak{X}_i)] &< 0. \end{aligned}$$

Following [21], consider the Lyapunov function  $V_{i+1} : \mathbb{R}^{i+1} \rightarrow \mathbb{R}_+$  defined by

$$\begin{aligned} V_{i+1}(\mathfrak{X}_{i+1}) = V_i(\mathfrak{X}_i) &+ \int_{\phi_i(\mathfrak{X}_i)}^{\mathcal{X}_{i+1}} \left( h^{\frac{d_{V_0}-r_{0,i+1}}{r_{0,i+1}}} - \phi_i(\mathfrak{X}_i)^{\frac{d_{V_0}-r_{0,i+1}}{r_{0,i+1}}} \right) dh \\ &+ \int_{\phi_i(\mathfrak{X}_i)}^{\mathcal{X}_{i+1}} \left( h^{\frac{d_{V_\infty}-r_{\infty,i+1}}{r_{\infty,i+1}}} - \phi_i(\mathfrak{X}_i)^{\frac{d_{V_\infty}-r_{\infty,i+1}}{r_{\infty,i+1}}} \right) dh. \end{aligned}$$

This function is positive definite and proper. Furthermore, as  $d_{V_\infty}$  and  $d_{V_0}$  satisfy (4.6), we have

$$\frac{d_{V_\infty} - r_{\infty,i+1}}{r_{\infty,i+1}} \geq \frac{d_{V_0} - r_{0,i+1}}{r_{0,i+1}} > \alpha_i \geq 1.$$

Since the function  $\psi_i(\mathfrak{X}_i) = \phi_i(\mathfrak{X}_i)^{\alpha_i}$  is  $C^1$ , this inequality yields that the function  $V_{i+1}$  is  $C^1$ . Finally, for each  $j$  in  $\{1, \dots, n\}$ , the function  $\frac{\partial V_{i+1}}{\partial x_j}$  is homogeneous in the bi-limit with associated triples

$$\left( (r_{0,1}, \dots, r_{0,i+1}), d_{V_0} - r_{0,j}, \frac{\partial V_{i+1,0}}{\partial x_j} \right), \quad \left( (r_{\infty,1}, \dots, r_{\infty,i+1}), d_{V_\infty} - r_{\infty,j}, \frac{\partial V_{i+1,\infty}}{\partial x_j} \right).$$

*Step 2. Definition of the control law.* Recall (1.6) and consider the function  $\psi_{i+1} : \mathbb{R}^{i+1} \rightarrow \mathbb{R}$  defined by

$$\psi_{i+1}(\mathfrak{X}_{i+1}) = -k \int_0^{\mathcal{X}_{i+1}^{\alpha_{i+1}} - \phi_i(\mathfrak{X}_i)^{\alpha_i}} \mathfrak{H} \left( |s|^{\alpha_{i+1} \frac{\mathfrak{d}_0 + r_{0,i+1}}{\alpha_i r_{0,i+1}} - 1}, |s|^{\alpha_{i+1} \frac{\mathfrak{d}_\infty + r_{\infty,i+1}}{\alpha_i r_{\infty,i+1}} - 1} \right) ds,$$

where  $k$  in  $\mathbb{R}_+$  is a design parameter and  $\alpha_{i+1}$  is selected as

$$\alpha_{i+1} \geq \max \left\{ \frac{\alpha_i r_{0,i+1}}{\mathfrak{d}_0 + r_{0,i+1}}, \frac{\alpha_i r_{\infty,i+1}}{\mathfrak{d}_\infty + r_{\infty,i+1}}, 1 \right\}.$$

$\psi_{i+1}$  takes values with the same sign as  $\mathcal{X}_{i+1} - \phi_i(\mathfrak{X}_i)$ , is  $C^1$ , and, by Proposition 2.12, is homogeneous in the bi-limit. Furthermore, by Proposition 2.10, for each  $j$  in  $\{1, \dots, i+1\}$ , the function  $\frac{\partial \psi_{i+1}}{\partial x_j}$  is homogeneous in the bi-limit, with weights  $(r_{0,1}, \dots, r_{0,i+1})$ ,  $(r_{\infty,1}, \dots, r_{\infty,i+1})$ , degrees  $\alpha_{i+1}(r_{0,i+1} + \mathfrak{d}_0) - r_{0,j}$ ,  $\alpha_{i+1}(r_{\infty,i+1} + \mathfrak{d}_\infty) - r_{\infty,j}$ , and approximating functions  $\frac{\partial \psi_{i+1,0}}{\partial x_j}$ ,  $\frac{\partial \psi_{i+1,\infty}}{\partial x_j}$ . With this at hand, we choose the control law  $\phi_{i+1}$  as

$$\phi_{i+1}(\mathfrak{X}_{i+1}) = \psi_{i+1}(\mathfrak{X}_{i+1})^{\frac{1}{\alpha_{i+1}}}.$$

*Step 3. Selection of  $k$ .* Note that

$$(4.8) \quad \frac{\partial V_{i+1}}{\partial \mathfrak{X}_{i+1}}(\mathfrak{X}_{i+1}) [\mathcal{S}_{i+1} \mathfrak{X}_{i+1} + B_{i+1} \phi_{i+1}(\mathfrak{X}_{i+1})] = T_1(\mathfrak{X}_{i+1}) - k T_2(\mathfrak{X}_{i+1}) ,$$

with the functions  $T_1$  and  $T_2$  defined as

$$\begin{aligned} T_1(\mathfrak{X}_{i+1}) &= \frac{\partial V_{i+1}}{\partial \mathfrak{X}_i}(\mathfrak{X}_{i+1}) [\mathcal{S}_i \mathfrak{X}_i + B_i \mathfrak{X}_{i+1}] \\ T_2(\mathfrak{X}_{i+1}) &= \left( \mathfrak{X}_{i+1}^{\frac{dV_0 - r_{0,i+1}}{r_{0,i+1}}} - \phi_i(\mathfrak{X}_i)^{\frac{dV_0 - r_{0,i+1}}{r_{0,i+1}}} \right. \\ &\quad \left. + \mathfrak{X}_{i+1}^{\frac{dV_\infty - r_{\infty,i+1}}{r_{\infty,i+1}}} - \phi_i(\mathfrak{X}_i)^{\frac{dV_\infty - r_{\infty,i+1}}{r_{\infty,i+1}}} \right) \phi_{i+1}(\mathfrak{X}_{i+1}) . \end{aligned}$$

By the definition of homogeneity in the bi-limit and Proposition 2.10, these functions are homogeneous in the bi-limit with weights  $(r_{0,1}, \dots, r_{0,i+1})$  and  $(r_{\infty,1}, \dots, r_{\infty,i+1})$  and degrees  $dV_0 + \mathfrak{d}_0$  and  $dV_\infty + \mathfrak{d}_\infty$ . Moreover, since  $\phi_{i+1}(\mathfrak{X}_{i+1})$  has the same sign as  $\mathfrak{X}_{i+1} - \phi_i(\mathfrak{X}_i)$ ,  $T_2(\mathfrak{X}_{i+1})$  is nonnegative for all  $\mathfrak{X}_{i+1}$  in  $\mathbb{R}^{i+1}$  and, as  $\phi_{i+1}(\mathfrak{X}_{i+1}) = 0$  only if  $\mathfrak{X}_{i+1} - \phi_i(\mathfrak{X}_i) = 0$ , we get

$$\begin{aligned} T_2(\mathfrak{X}_{i+1}) = 0 &\implies \mathfrak{X}_{i+1} = \phi_i(\mathfrak{X}_i) , \\ \mathfrak{X}_{i+1} = \phi_i(\mathfrak{X}_i) &\implies T_1(\mathfrak{X}_{i+1}) = \frac{\partial V_i}{\partial \mathfrak{X}_i}(\mathfrak{X}_i) [\mathcal{S}_i \mathfrak{X}_i + B_i \phi_i(\mathfrak{X}_i)] . \end{aligned}$$

Consequently, equations (4.7) yield

$$\{\mathfrak{X}_{i+1} \in \mathbb{R}^{i+1} \setminus \{0\} : T_2(\mathfrak{X}_{i+1}) = 0\} \subseteq \{\mathfrak{X}_{i+1} \in \mathbb{R}^{i+1} : T_1(\mathfrak{X}_{i+1}) < 0\} .$$

The same implication holds for the homogeneous approximations of the two functions at infinity and around the origin, i.e.,

$$\begin{aligned} \{\mathfrak{X}_{i+1} \in \mathbb{R}^{i+1} \setminus \{0\} : T_{2,0}(\mathfrak{X}_{i+1}) = 0\} &\subseteq \{\mathfrak{X}_{i+1} \in \mathbb{R}^{i+1} : T_{1,0}(\mathfrak{X}_{i+1}) < 0\} , \\ \{\mathfrak{X}_{i+1} \in \mathbb{R}^{i+1} \setminus \{0\} : T_{2,\infty}(\mathfrak{X}_{i+1}) = 0\} &\subseteq \{\mathfrak{X}_{i+1} \in \mathbb{R}^{i+1} : T_{1,\infty}(\mathfrak{X}_{i+1}) < 0\} . \end{aligned}$$

Hence, by Lemma 2.13, there exists  $k^* > 0$  such that, for all  $k \geq k^*$ , we have for all  $\mathfrak{X}_{i+1} \neq 0$ ,

$$\begin{aligned} \frac{\partial V_{i+1}}{\partial \mathfrak{X}_{i+1}}(\mathfrak{X}_{i+1}) [\mathcal{S}_{i+1} \mathfrak{X}_{i+1} + B_{i+1} \phi_{i+1}(\mathfrak{X}_{i+1})] &< 0 , \\ \frac{\partial V_{i+1,0}}{\partial \mathfrak{X}_{i+1}}(\mathfrak{X}_{i+1}) [\mathcal{S}_{i+1} \mathfrak{X}_{i+1} + B_{i+1} \phi_{i+1,0}(\mathfrak{X}_{i+1})] &< 0 , \\ \frac{\partial V_{i+1,\infty}}{\partial \mathfrak{X}_{i+1}}(\mathfrak{X}_{i+1}) [\mathcal{S}_{i+1} \mathfrak{X}_{i+1} + B_{i+1} \phi_{i+1,\infty}(\mathfrak{X}_{i+1})] &< 0 . \end{aligned}$$

This implies that the origin is a globally asymptotically stable equilibrium of the systems (4.4).  $\square$

To construct the function  $\phi_n$  it is sufficient to iterate the construction in Theorem 4.1 starting from

$$\phi_1(x_1) = \psi_1(x_1)^{\frac{1}{\alpha_1}}, \quad \psi_1(x_1) = -k_1 \int_0^{x_1} \mathfrak{H} \left( |s|^{\alpha_1 \frac{r_{0,2}}{r_{0,1}} - 1}, |s|^{\alpha_1 \frac{r_{\infty,2}}{r_{\infty,1}} - 1} \right) ds ,$$

with  $k_1 > 0$ .

At the end of the recursive procedure, we have that the origin is a globally asymptotically stable equilibrium of the systems

$$(4.9) \quad \begin{aligned} \mathfrak{X}_n &= \mathcal{S}_n \mathfrak{X}_n + B_n \phi_n(\mathfrak{X}_n) , \\ \mathfrak{X}_n &= \mathcal{S}_n \mathfrak{X}_n + B_n \phi_{n,0}(\mathfrak{X}_n) , \\ \mathfrak{X}_n &= \mathcal{S}_n \mathfrak{X}_n + B_n \phi_{n,\infty}(\mathfrak{X}_n) . \end{aligned}$$

*Remark 4.2.* Note that if  $\mathfrak{d}_0 \geq 0$  and  $\mathfrak{d}_\infty \geq 0$ , then we can select  $\alpha_i = 1$  for all  $1 \leq i \leq n$ , and if  $\mathfrak{d}_0 \leq 0$  and  $\mathfrak{d}_\infty \geq \mathfrak{d}_0$ , then we can select  $\alpha_i = \frac{r_{0,1}}{r_{0,i+1}}$ . Finally, if  $\mathfrak{d}_\infty \leq 0$  and  $\mathfrak{d}_0 \geq \mathfrak{d}_\infty$ , then we can select  $\alpha_i = \frac{r_{\infty,1}}{r_{\infty,i+1}}$ .

*Remark 4.3.* As in the observer design, when  $\mathfrak{d}_0 \leq \mathfrak{d}_\infty$ , we have  $\frac{r_{0,i+1} + \mathfrak{d}_0}{r_{0,i+1}} \leq \frac{r_{\infty,i+1} + \mathfrak{d}_\infty}{r_{\infty,i+1}}$  for  $i = 1, \dots, n$  and we can replace the function  $\psi_i$  by the simpler function

$$(4.10) \quad \psi_{i+1}(\mathfrak{X}_{i+1}) = -k \left( |\mathfrak{X}_{i+1}^{\alpha_i} - \phi_i(\mathfrak{X}_i)|^{\alpha_{i+1} \frac{\mathfrak{d}_0 + r_{0,i+1}}{\alpha_i r_{0,i+1}}} + |\mathfrak{X}_{i+1}^{\alpha_i} - \phi_i(\mathfrak{X}_i)|^{\alpha_{i+1} \frac{\mathfrak{d}_\infty + r_{\infty,i+1}}{\alpha_i r_{\infty,i+1}}} \right) .$$

Finally, if  $0 \leq \mathfrak{d}_0 \leq \mathfrak{d}_\infty$ , then by taking  $\alpha_i = 1$  (see Remark 4.2) and  $\phi(\mathfrak{X}_{i+1}) = \psi_{i+1}(\mathfrak{X}_{i+1})$  as defined in (4.10), we recover the design in [1].

*Example 4.4.* Consider a chain of integrators of dimension two with weights and degrees

$$(r_0, \mathfrak{d}_0) = \left( (2 - q, 1), q - 1 \right), \quad (r_\infty, \mathfrak{d}_\infty) = \left( (2 - p, 1), p - 1 \right) ,$$

with  $2 > p > q > 0$ . Given  $k_1 > 0$ , using the proposed backstepping procedure we obtain a positive real number  $k_2$  such that the feedback

$$(4.11) \quad \phi_2(x_1, x_2) = -k_2 \int_0^{x_1 - \phi_1(x_1)} \mathfrak{H}(|s|^{q-1}, |s|^{p-1}) \, ds ,$$

with  $\phi_1(x_1) = -k_1 \int_0^{x_1} \mathfrak{H}(|s|^{\frac{q-1}{2-q}}, |s|^{\frac{p-1}{2-p}}) \, ds$ , renders the origin a globally asymptotically stable equilibrium of the closed-loop system. Furthermore, as a consequence of the robustness result in Corollary 2.22, there is a positive real number  $c_G$  such that, if the positive real numbers  $|c_0|$  and  $|c_\infty|$  associated with  $\delta_i$  in (1.2) are smaller than  $c_G$ , then the control law  $\phi_2$  globally asymptotically stabilizes the origin of system (1.1).

## 5. Application to nonlinear output feedback design.

**5.1. Results on output feedback.** The tools presented in the previous sections can be used to derive two new results on stabilization by output feedback for the origin of nonlinear systems. The output feedback is designed for a simple chain of integrators,

$$(5.1) \quad \dot{x} = \mathcal{S}_n x + B_n u, \quad y = x_1 ,$$

where  $x$  is in  $\mathbb{R}^n$ ,  $y$  is the output in  $\mathbb{R}$ , and  $u$  is the control input in  $\mathbb{R}$ . It is then shown to be adequate to solve the output feedback stabilization problem for the origin of systems for which this chain of integrators can be considered as the dominant part of the dynamics.

Such a domination approach has a long history. It is the cornerstone of the results in [13] (see also [27] and [24]), where a linear controller was introduced to deal with nonlinear systems. This approach has also been followed with nonlinear controllers in [22] and more recently in combination with weighted homogeneity in [35, 26, 28] and the references therein.

In the context of homogeneity in the bi-limit, we use this approach exploiting the proposed backstepping and recursive observer designs. Following the idea introduced by Qian in [26] (see also [27]), the output feedback we proposed is given by

$$(5.2) \quad \dot{\hat{\mathbf{x}}}_n = L \left( \mathcal{S}_n \hat{\mathbf{x}}_n + B_n \phi_n(\hat{\mathbf{x}}_n) + K_1(x_1 - \hat{x}_1) \right), \quad u = L^n \phi_n(\hat{\mathbf{x}}_n),$$

with  $\hat{\mathbf{x}}_n$  in  $\mathbb{R}^n$  and where  $\phi_n$  and  $K_1$  are continuous functions and  $L$  is a positive real number. Employing the recursive procedure given in sections 3 and 4, we get the following theorem, whose proof is in section 5.2.

**THEOREM 5.1.** *For all real numbers  $\mathfrak{d}_0$  and  $\mathfrak{d}_\infty$  in  $(-1, \frac{1}{n-1})$ , there exists a homogeneous in the bi-limit function  $\phi_n : \mathbb{R}^n \rightarrow \mathbb{R}$  with associated triples  $(r_0, 1 + \mathfrak{d}_0, \phi_{n,0})$  and  $(r_\infty, 1 + \mathfrak{d}_\infty, \phi_{n,\infty})$  and a homogeneous in the bi-limit vector field  $K_1 : \mathbb{R}^n \rightarrow \mathbb{R}^n$  with associated triples  $(r_0, \mathfrak{d}_0, K_{1,0})$  and  $(r_\infty, \mathfrak{d}_\infty, K_{1,\infty})$  such that for all real numbers  $L > 0$  the origin is a globally asymptotically stable equilibrium of the systems (5.1) and (5.2) and their homogeneous approximations.*

We can then apply Corollary 2.22 to get an output feedback result for nonlinear systems described by

$$(5.3) \quad \dot{x} = \mathcal{S}_n x + B_n u + \delta(t), \quad y = x_1,$$

where  $\delta : \mathbb{R}_+ \rightarrow \mathbb{R}^n$  is a continuous function related to the solutions as described in the two corollaries below and proved in section 5.2. Depending on whether  $\mathfrak{d}_0 \leq \mathfrak{d}_\infty$  or  $\mathfrak{d}_\infty \leq \mathfrak{d}_0$ , we get an output feedback result for systems in feedback or feedforward form.

**COROLLARY 5.2 (feedback form).** *If, in the design of  $\phi_n$  and  $K_1$ , we select  $\mathfrak{d}_0 \leq \mathfrak{d}_\infty$ , then for all positive real numbers  $c_0$  and  $c_\infty$  there exists a real number  $L^* > 0$  such that for every  $L$  in  $[L^*, +\infty)$ , the following holds:*

• *For every class  $\mathcal{K}$  function  $\gamma_z$  and class  $\mathcal{KL}$  function  $\beta_\delta$ , we can find two class  $\mathcal{KL}$  functions  $\beta_x$  and  $\hat{\beta}_x$  such that, for each function  $t \in [0, T) \mapsto (x(t), \hat{\mathbf{x}}_n(t), \delta(t), z(t))$ ,  $T \leq +\infty$ , with  $(x, \hat{\mathbf{x}}_n)$   $C^1$  and  $\delta$  and  $z$  continuous, which satisfies (5.3), (5.2), and for  $i$  in  $\{1, \dots, n\}$  and  $0 \leq s \leq t < T$ ,*

$$(5.4) \quad \begin{aligned} |z(t)| &\leq \max \left\{ \beta_\delta(|z(s)|, t-s), \sup_{s \leq \kappa \leq t} \gamma_z(|x(\kappa)|) \right\}, \\ |\delta_i(t)| &\leq \max \left\{ \beta_\delta(|z(s)|, t-s), \right. \\ &\quad \left. \sup_{s \leq \kappa \leq t} \left\{ c_0 \sum_{j=1}^i |x_j(\kappa)|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} + c_\infty \sum_{j=1}^i |x_j(\kappa)|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}} \right\} \right\}, \end{aligned}$$

we have for all  $0 \leq s \leq t \leq T$ ,

$$|x(t)| \leq \beta_x(|(x(s), \hat{\mathbf{x}}_n(s), z(s))|, t-s), \quad |\hat{\mathbf{x}}_n(t)| \leq \hat{\beta}_x(|(x(s), \hat{\mathbf{x}}_n(s), z(s))|, t-s).$$

COROLLARY 5.3 (feedforward form). *If, in the design of  $\phi_n$  and  $K_1$ , we select  $\mathfrak{d}_\infty \leq \mathfrak{d}_0$ , then for all positive real numbers  $c_0$  and  $c_\infty$  there exists a real number  $L^* > 0$  such that for every  $L$  in  $(0, L^*]$ , the following holds:*

• *For every class  $\mathcal{K}$  function  $\gamma_z$  and class  $\mathcal{KL}$  function  $\beta_\delta$ , we can find two class  $\mathcal{KL}$  functions  $\beta_x$  and  $\beta_{\hat{x}}$  such that, for each function  $t \in [0, T) \mapsto (x(t), \hat{x}_n(t), \delta(t), z(t))$ ,  $T \leq +\infty$ , with  $(x, \hat{x}_n)$   $C^1$  and  $\delta$  and  $z$  continuous, which satisfies (5.3), (5.2), and for  $i$  in  $\{1, \dots, n\}$  and  $0 \leq s \leq t < T$ ,*

$$(5.5) \quad \begin{aligned} |z(t)| &\leq \max \left\{ \beta_\delta(|z(s)|, t-s), \sup_{s \leq \kappa \leq t} \gamma_z(|x(\kappa)|) \right\}, \\ |\delta_i(t)| &\leq \max \left\{ \beta_\delta(|z(s)|, t-s), \right. \\ &\quad \left. \sup_{s \leq \kappa \leq t} \left\{ c_0 \sum_{j=i+2}^n |x_j(\kappa)|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} + c_\infty \sum_{j=i+2}^n |x_j(\kappa)|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}} \right\} \right\}, \end{aligned}$$

we have for all  $0 \leq s \leq t \leq T$ ,

$$|x(t)| \leq \beta_x(|(x(s), \hat{x}_n(s), z(s))|, t-s), \quad |\hat{x}_n(t)| \leq \beta_{\hat{x}}(|(x(s), \hat{x}_n(s), z(s))|, t-s).$$

*Example 5.4.* Following Example 2.23, we can consider the case where the  $\delta_i$ 's are outputs of auxiliary systems given in (2.13). Suppose there exist  $n$  positive definite and radially unbounded functions  $Z_i : \mathbb{R}^{n_i} \rightarrow \mathbb{R}_+$ , three class  $\mathcal{K}$  functions  $\omega_1, \omega_2, \omega_3$ , and a positive real number  $\epsilon$  in  $(0, 1)$  such that

$$|\delta_i(z_i, x)| \leq \omega_1(x) + \omega_2(Z_i(z_i)), \quad \frac{\partial Z_i}{\partial z_i}(z_i) g_i(z_i, x) \leq -Z_i(z_i) + \omega_3(|x|);$$

then, if there exist two real numbers  $\mathfrak{d}_0$  and  $\mathfrak{d}_\infty$  satisfying  $-1 < \mathfrak{d}_0 \leq \mathfrak{d}_\infty < \frac{1}{n-1}$  and

$$(5.6) \quad \omega_1(x) + \omega_2([1 + \epsilon] \omega_3(|x|)) \leq \left( \sum_{j=1}^i |x_j|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} + \sum_{j=1}^i |x_j|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}} \right),$$

then Corollary 5.2 gives  $L^* > 0$  such that for all  $L$  in  $[L^*, +\infty)$ , the output feedback (5.2) is globally asymptotically stabilizing. Compared to already published results (see [13] and [26], for instance), the novelty of this case is in the simultaneous presence of the terms  $|x_j|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}}$  and  $|x_j|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}}$ .

On the other hand, if there exist two real numbers  $\mathfrak{d}_0$  and  $\mathfrak{d}_\infty$  satisfying  $-1 < \mathfrak{d}_\infty \leq \mathfrak{d}_0 < \frac{1}{n-1}$  and

$$\omega_1(x) + \omega_2([1 + \epsilon] \omega_3(|x|)) \leq \left( \sum_{j=i+2}^n |x_j|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} + \sum_{j=i+2}^n |x_j|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}} \right),$$

then Corollary 5.3 gives  $L^* > 0$  such that for all  $L$  in  $(0, L^*]$ , the output feedback (5.2) is globally asymptotically stabilizing.

*Example 5.5.* Consider the illustrative system (1.1). The bound (5.6) gives the condition

$$(5.7) \quad 0 < q < p < 2 .$$

This is almost the least conservative condition we can obtain with the domination approach. Specifically, it is shown in [18] that, when  $p > 2$ , there is no stabilizing output feedback. However, when  $p = 2$ , (5.6) is not satisfied, although the stabilization problem is solvable (see [18]).

By Corollary 2.24, when (5.7) holds, the output feedback

$$u = L^2 \phi_2(\hat{x}_1, \hat{x}_2), \quad \begin{cases} \dot{\hat{x}}_1 &= L \hat{x}_2 - L q_1(\ell_1 e_1) , \\ \dot{\hat{x}}_2 &= \frac{u}{L} - L q_2(\ell_2 q_1(\ell_1 e_1)) , \\ e_1 &= \hat{x}_1 - y , \end{cases}$$

with  $\ell_1, \ell_2, \phi_2, q_1$ , and  $q_2$  defined in (3.13) and (4.11) and with picking  $\mathfrak{d}_0$  in  $(-1, q-1]$  and  $\mathfrak{d}_\infty$  in  $[p-1, 1)$ , globally asymptotically stabilizes the origin of the system (1.1), with  $L$  chosen sufficiently large. Furthermore, if  $\mathfrak{d}_0$  is chosen strictly negative and  $\mathfrak{d}_\infty$  strictly positive, by Corollary 2.24, convergence to the origin occurs in finite time, uniformly in the initial conditions.

*Example 5.6.* To illustrate the feedforward result consider the system<sup>7</sup>

$$\dot{x}_1 = x_2 + x_3^{\frac{3}{2}} + z^3, \quad \dot{x}_2 = x_3, \quad \dot{x}_3 = u, \quad \dot{z} = -z^4 + x_3, \quad y = x_1 .$$

For any  $\varepsilon > 0$ , there exists a class  $\mathcal{KL}$  function  $\beta_\delta$  such that

$$|z(t)|^3 \leq \max \left\{ \beta_\delta(|z(s)|, t-s), \quad (1+\varepsilon) \sup_{s \leq \kappa \leq t} |x_3(\kappa)|^{\frac{3}{4}} \right\} .$$

Therefore by letting  $\delta_1 = x_3^{\frac{3}{2}} + z^3$  we get, for all  $0 \leq s \leq t < T$  on the time of existence of the solutions,

$$|\delta_1(t)| \leq \max \left\{ \beta_\delta(|z(s)|, t-s), \quad \sup_{s \leq \kappa \leq t} (1+\varepsilon) |x_3(\kappa)|^{\frac{3}{4}} + |x_3(\kappa)|^{\frac{3}{2}} \right\} .$$

This is inequality (5.5) with  $\mathfrak{d}_0 = -\frac{1}{2}$  and  $\mathfrak{d}_\infty = \frac{1}{4}$ . Consequently, Corollary 5.3 says that it is possible to design a globally asymptotically stabilizing output feedback.

## 5.2. Proofs of output feedback results.

*Proof of Theorem 5.1.* The homogeneous in the bi-limit state feedback  $\phi_n$  and the homogeneous in the bi-limit vector field  $K_1$  involved in this feedback are obtained by following the procedures given in sections 3 and 4. They are such that the origin is a globally asymptotically stable equilibrium of the systems given in (4.9) and (3.12). To this end, as in [26], we write the dynamics of this system in the coordinates  $\hat{\mathbf{x}}_n = (\hat{x}_1, \dots, \hat{x}_n)$  and  $E_1 = (e_1, \dots, e_n)$  and in the time  $\tau$  defined by

$$(5.8) \quad e_i = \hat{x}_i - \frac{x_i}{L^{i-1}}, \quad \frac{d}{d\tau} = \frac{1}{L} \frac{d}{dt} .$$

<sup>7</sup>Recall the notation (1.4).

This yields

$$(5.9) \quad \begin{cases} \frac{d}{d\tau} \hat{\mathbf{x}}_n &= \mathcal{S}_n \hat{\mathbf{x}}_n + B_n \phi_n(\hat{\mathbf{x}}_n) + K_1(e_1), \\ \frac{d}{d\tau} E_1 &= \mathcal{S}_n E_1 + K_1(e_1) \end{cases}$$

with  $E_1 = (e_1, \dots, e_n)$ ,  $\hat{\mathbf{x}}_n = (\hat{x}_1, \dots, \hat{x}_n)$ . The right-hand side of (5.9) is a vector field which is homogeneous in the bi-limit with weights  $(r_0, r_0), (r_\infty, r_\infty)$ .

Given  $d_U > \max_j \{r_{0,j}, r_{\infty,j}\}$ , by applying Theorem 2.20 twice, we get two  $C^1$ , proper, and positive definite functions  $V : \mathbb{R}^n \rightarrow \mathbb{R}_+$  and  $W : \mathbb{R}^n \rightarrow \mathbb{R}_+$  such that for each  $i$  in  $\{1, \dots, n\}$ , the functions  $\frac{\partial V}{\partial x_i}$  and  $\frac{\partial W}{\partial e_i}$  are homogeneous in the bi-limit, with weights  $r_0$  and  $r_\infty$ , degrees  $d_U - r_{0,i}$  and  $d_U - r_{\infty,i}$ , and approximating functions  $\frac{\partial V_0}{\partial \hat{x}_j}$ ,  $\frac{\partial V_\infty}{\partial \hat{x}_j}$  and  $\frac{\partial W_0}{\partial e_j}$ ,  $\frac{\partial W_\infty}{\partial e_j}$ . Moreover, for all  $\hat{\mathbf{x}}_n \neq 0$ ,

$$(5.10) \quad \begin{aligned} \frac{\partial V}{\partial \hat{\mathbf{x}}}(\hat{\mathbf{x}}_n) [\mathcal{S}_n \hat{\mathbf{x}}_n + B_n \phi_n(\hat{\mathbf{x}}_n)] &< 0, \\ \frac{\partial V_0}{\partial \hat{\mathbf{x}}_n}(\hat{\mathbf{x}}_n) [\mathcal{S}_n \hat{\mathbf{x}}_n + B_n \phi_{n,0}(\hat{\mathbf{x}}_n)] &< 0, \\ \frac{\partial V_\infty}{\partial \hat{\mathbf{x}}_n}(\hat{\mathbf{x}}_n) [\mathcal{S}_n \hat{\mathbf{x}}_n + B_n \phi_{n,\infty}(\hat{\mathbf{x}}_n)] &< 0, \end{aligned}$$

and for all  $E_1 \neq 0$ ,

$$(5.11) \quad \begin{aligned} \frac{\partial W}{\partial E_1}(E_1) (\mathcal{S}_n E_1 + K_1(e_1)) &< 0, \\ \frac{\partial W_0}{\partial E_1}(E_1) (\mathcal{S}_n E_1 + K_{1,0}(e_1)) &< 0, \\ \frac{\partial W_\infty}{\partial E_1}(E_1) (\mathcal{S}_n E_1 + K_{1,\infty}(e_1)) &< 0. \end{aligned}$$

Consider now the Lyapunov function candidate

$$(5.12) \quad U(\hat{\mathbf{x}}_n, E_1) = V(\hat{\mathbf{x}}_n) + \mathfrak{c} W(E_1),$$

where  $\mathfrak{c}$  is a positive real number to be specified. Let

$$\begin{aligned} \eta(\hat{\mathbf{x}}_n, E_1) &= \frac{\partial V}{\partial \hat{\mathbf{x}}_n}(\hat{\mathbf{x}}_n) (\mathcal{S}_n \hat{\mathbf{x}}_n + B_n \phi_n(\hat{\mathbf{x}}_n) + K_1(e_1)), \\ \gamma(E_1) &= -\frac{\partial W}{\partial E_1}(E_1) (\mathcal{S}_n E_1 + K_1(e_1)). \end{aligned}$$

These two functions are continuous and homogeneous in the bi-limit with associated triples  $((r_0, r_0), d_U + \mathfrak{d}_0, \eta_0)$ ,  $((r_\infty, r_\infty), d_U + \mathfrak{d}_\infty, \eta_\infty)$  and  $((r_0, r_0), d_U + \mathfrak{d}_0, \gamma_0)$ ,  $((r_\infty, r_\infty), d_U + \mathfrak{d}_\infty, \gamma_\infty)$ , where  $\gamma_0, \gamma_\infty$  and  $\eta_0, \eta_\infty$  are continuous functions. Furthermore, by (5.11),  $\gamma(E_1)$  is negative definite. Hence, by (5.10), we have

$$\begin{aligned} \{(\hat{\mathbf{x}}_n, E_1) \in \mathbb{R}^{2n} \setminus \{0\} : \gamma(E_1) = 0\} &\subseteq \{(\hat{\mathbf{x}}_n, E_1) \in \mathbb{R}^{2n} : \eta(\hat{\mathbf{x}}_n, E_1) < 0\}, \\ \{(\hat{\mathbf{x}}_n, E_1) \in \mathbb{R}^{2n} \setminus \{0\} : \gamma_0(E_1) = 0\} &\subseteq \{(\hat{\mathbf{x}}_n, E_1) \in \mathbb{R}^{2n} : \eta_0(\hat{\mathbf{x}}_n, E_1) < 0\}, \\ \{(\hat{\mathbf{x}}_n, E_1) \in \mathbb{R}^{2n} \setminus \{0\} : \gamma_\infty(E_1) = 0\} &\subseteq \{(\hat{\mathbf{x}}_n, E_1) \in \mathbb{R}^{2n} : \eta_\infty(\hat{\mathbf{x}}_n, E_1) < 0\}. \end{aligned}$$

Consequently, by Lemma 2.13, there exists a positive real number  $c^*$  such that, for all  $c > c^*$  and all  $(\hat{\mathbf{x}}_n, E_1) \neq (0, 0)$ , the Lyapunov function  $U$ , defined in (5.12), satisfies

$$\begin{aligned} \frac{\partial U}{\partial \hat{\mathbf{x}}_n}(\hat{\mathbf{x}}_n, E_1) \left( \mathcal{S}_n \hat{\mathbf{x}}_n + B_n \phi_n(\hat{\mathbf{x}}_n) + K_1(e_1) \right) \\ + \frac{\partial U}{\partial E_1}(\hat{\mathbf{x}}_n, E_1)(E_1) (\mathcal{S}_n E_1 + K_1(e_1)) < 0 \end{aligned}$$

and the same holds for the homogeneous approximations in the 0-limit and in the  $\infty$ -limit; hence the claim.  $\square$

*Proof of Corollary 5.2.* We write the dynamics of the system (5.3) in the coordinates  $\hat{\mathbf{x}}_n$  and  $E_1$  and in the time  $\tau$  given in (5.8). This yields

$$(5.13) \quad \begin{cases} \frac{d}{d\tau} \hat{\mathbf{x}}_n &= \mathcal{S}_n \hat{\mathbf{x}}_n + B_n \phi_n(\hat{\mathbf{x}}_n) + K_1(e_1), \\ \frac{d}{d\tau} E_1 &= \mathcal{S}_n E_1 + K_1(e_1) + \mathfrak{D}(L) \end{cases}$$

with

$$\mathfrak{D}(L) = \left( \frac{\delta_1}{L}, \dots, \frac{\delta_n}{L^n} \right).$$

We denote the solution of this system, starting from  $(\hat{\mathbf{x}}_n(0), E_1(0))$  in  $\mathbb{R}^{2n}$  at time  $\tau$ , by  $(\hat{\mathbf{x}}_{\tau,n}(\tau), E_{\tau,1}(\tau))$ . We have

$$(5.14) \quad x_i(t) = L^{i-1} (\hat{x}_{\tau,i}(Lt) - e_{\tau,i}(Lt)).$$

The right-hand side of (5.13) is a vector field which is homogeneous in the bi-limit with weights  $(r_0, r_0), (r_\infty, r_\infty)$  for  $(\hat{\mathbf{x}}_n, E_1)$  and  $(\mathfrak{r}_0, \mathfrak{r}_\infty)$  for  $\mathfrak{D}(L)$ , where  $\mathfrak{r}_{0,i} = r_{0,i} + \mathfrak{d}_0$  and  $\mathfrak{r}_{\infty,i} = r_{\infty,i} + \mathfrak{d}_\infty$  for each  $i$  in  $\{1, \dots, n\}$ .

The time function  $\tau \mapsto \delta(\frac{\tau}{L})$  is considered as an input, and when  $\mathfrak{D}(L) = 0$ , Theorem 5.1 implies global asymptotic stability of the origin of the system (5.13) and of its homogeneous approximations. To complete the proof we show that there exists  $L^*$  such that the “input”  $\mathfrak{D}(L)$  satisfies the small-gain condition (2.11) of Corollary 2.22 for all  $L > L^*$ . Using (5.8) and (5.14), assumption (5.4) becomes, for all  $0 \leq \sigma \leq \tau < LT$  and all  $i$  in  $\{1, \dots, n\}$ ,

$$(5.15) \quad \begin{aligned} \left| \frac{\delta_i(\frac{\tau}{L})}{L^i} \right| &\leq \max \left\{ \frac{1}{L^i} \beta_\delta \left( \left| z\left(\frac{\sigma}{L}\right) \right|, \frac{\tau - \sigma}{L} \right), \right. \\ &\quad L^{-i} \sup_{\sigma \leq \kappa \leq \tau} \left\{ c_0 \sum_{j=1}^i \left| L^{(j-1)} (\hat{x}_{\tau,j}(\kappa) - e_{\tau,j}(\kappa)) \right|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} \right. \\ &\quad \left. \left. + c_\infty \sum_{j=1}^i \left| L^{(j-1)} (\hat{x}_{\tau,j}(\kappa) - e_{\tau,j}(\kappa)) \right|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}} \right\} \right\}. \end{aligned}$$

Note that when  $1 \leq j \leq i \leq n$ , the function  $s \mapsto \frac{1-(n-i-1)s}{1-(n-j)s}$  is strictly increasing, mapping  $(-1, \frac{1}{n-1})$  in  $(\frac{n-i}{n+1-j}, \frac{i}{j-1})$ . As  $\mathfrak{d}_0 \leq \mathfrak{d}_\infty < \frac{1}{n-1}$ , we have for all  $1 \leq j \leq i \leq n$ ,

$$\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)} \leq \frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)} < \frac{i}{j-1}.$$

Hence, selecting  $L \geq 1$ , there exists a real number  $\epsilon > 0$  such that

$$L^{-\epsilon} \geq L^{(j-1)\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_0(n-j)}-i} \geq L^{(j-1)\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}-i}.$$

This implies

$$\begin{aligned} \frac{|\delta_i(\frac{\tau}{L})|}{L^i} &\leq \max \left\{ \frac{1}{L^i} \beta_\delta \left( \left| z \left( \frac{\sigma}{L} \right) \right|, \frac{\tau - \sigma}{L} \right), \right. \\ &\quad \left. L^{-\epsilon} \sup_{\sigma \leq \kappa \leq \tau} \left\{ c_0 \sum_{j=1}^i |(\hat{\chi}_{\tau,j}(\kappa) - e_{\tau,j}(\kappa))|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} \right. \right. \\ &\quad \left. \left. + c_\infty \sum_{j=1}^i |(\hat{\chi}_{\tau,j}(\kappa) - e_{\tau,j}(\kappa))|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}} \right\} \right\}. \end{aligned}$$

On the other hand, the function

$$(\hat{\mathfrak{X}}_n, E_1) \mapsto c_0 \sum_{j=1}^i |\hat{\chi}_j - e_j|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} + c_\infty \sum_{j=1}^i |\hat{\chi}_j - e_j|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}}$$

is homogeneous in the bi-limit with weights  $(r_0, r_0)$  and  $(r_\infty, r_\infty)$  and degrees  $1 - \mathfrak{d}_0(n-i-1) = r_{0,i} + \mathfrak{d}_0$  and  $1 - \mathfrak{d}_\infty(n-i-1) = r_{\infty,i} + \mathfrak{d}_\infty$  (see (3.2)). Hence, by Corollary 2.15, there exists a positive real number  $c_1$  such that

$$\begin{aligned} c_0 \sum_{j=1}^i |\hat{\chi}_j - e_j|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} + c_\infty \sum_{j=1}^i |\hat{\chi}_j - e_j|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}} \\ (5.16) \quad \leq c_1 \mathfrak{H} \left( |(\hat{\mathfrak{X}}_n, E_1)|_{(r_0, r_0)}^{\mathfrak{d}_0 + r_{0,i}}, |(\hat{\mathfrak{X}}_n, E_1)|_{(r_\infty, r_\infty)}^{\mathfrak{d}_\infty + r_{\infty,i}} \right). \end{aligned}$$

Hence, by Corollary 2.22 (applied in the  $\tau$  time-scale), there exists  $c_G$  such that for any  $L^*$  large enough such that  $c_1 L^{*- \epsilon} \leq c_G$ , the conclusion holds.  $\square$

*Proof of Corollary 5.3.* The proof is similar to the previous one with the only difference being that, when  $i$  and  $j$  satisfy  $3 \leq i+2 \leq j \leq n$ , the function  $s \mapsto \frac{1-(n-i-1)s}{1-(n-j)s}$  is strictly decreasing, mapping  $(-1, \frac{1}{n-1})$  in  $(\frac{i}{j-1}, \frac{n-i}{n+1-j})$ . Moreover the condition  $-1 < \mathfrak{d}_\infty \leq \mathfrak{d}_0 < \frac{1}{n-1}$  gives the inequalities

$$\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)} \geq \frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)} > \frac{i}{j-1}.$$

Hence (5.16) holds, and by selecting  $L < 1$  we obtain the existence of a positive real number  $\epsilon$  such that

$$L^\epsilon \geq L^{(j-1)\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}-i} \geq L^{(j-1)\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}-i}.$$

From (5.5), this yields, for all  $0 \leq \sigma \leq \tau < LT$  and all  $i$  in  $\{1, \dots, n\}$ ,

$$\begin{aligned} \frac{|\delta_i(\frac{\tau}{L})|}{L^i} &\leq \max \left\{ \frac{1}{L^i} \beta_\delta \left( \left| z \left( \frac{\sigma}{L} \right) \right|, \frac{\tau - \sigma}{L} \right), \right. \\ &\quad L^\epsilon \sup_{\sigma \leq \kappa \leq \tau} \left\{ c_0 \sum_{j=i+2}^n |(\hat{\chi}_{\tau,j}(\kappa) - e_{\tau,j}(\kappa))|^{\frac{1-\mathfrak{d}_0(n-i-1)}{1-\mathfrak{d}_0(n-j)}} \right. \\ &\quad \left. \left. + c_\infty \sum_{j=i+2}^n |(\hat{\chi}_{\tau,j}(\kappa) - e_{\tau,j}(\kappa))|^{\frac{1-\mathfrak{d}_\infty(n-i-1)}{1-\mathfrak{d}_\infty(n-j)}} \right\} \right\}. \end{aligned}$$

From Corollary 2.22, the result holds for all  $L^*$  small enough to satisfy  $c_1 L^{*\varepsilon} \leq c_G$ .  $\square$

**6. Conclusion.** We have presented two new tools that can be useful in nonlinear control design. The first one is introduced to formalize the notion of homogeneous approximation valid both at the origin and at infinity. With this formalism we have given several novel results concerning asymptotic stability, robustness analysis, and also finite time convergence (uniformly in the initial conditions). The second one is a new recursive design for an observer for a chain of integrators. The combination of these two tools allows us to obtain a new result on stabilization by output feedback for systems whose dominant homogeneous in the bi-limit part is a chain of integrators.

**Appendix A. Proof of Proposition 2.10.** We give the proof only in the 0-limit case since the  $\infty$ -limit case is similar. Let  $C$  be an arbitrary compact subset of  $\mathbb{R}^n \setminus \{0\}$  and  $\epsilon$  any strictly positive real number. By the definition of homogeneity in the 0-limit, there exists  $\lambda_1 > 0$  such that we have

$$\left| \frac{\phi(\lambda^{r_{\phi,0}} \diamond x)}{\lambda^{d_{\phi,0}}} - \phi_0(x) \right| \leq 1 \quad \forall x \in C, \quad \forall \lambda \in (0, \lambda_1].$$

Hence, as  $\phi_0$  is a continuous function on  $\mathbb{R}^n$ , for all  $\lambda$  in  $(0, \lambda_1]$ , the function  $x \mapsto \frac{\phi(\lambda^{r_{\phi,0}} \diamond x)}{\lambda^{d_{\phi,0}}}$  takes its values in a compact set  $C_\phi = \phi_0(C) + B_1$ , where  $B_1$  is the unity ball.

Now, as  $\zeta_0$  is continuous on the compact subset  $C_\phi$ , it is uniformly continuous; i.e., there exists  $\nu > 0$  such that

$$|z_1 - z_2| < \nu \quad \implies \quad |\zeta_0(z_1) - \zeta_0(z_2)| < \epsilon.$$

Also there exists  $\mu_\epsilon > 0$  satisfying

$$\left| \frac{\zeta(\mu^{r_{\zeta,0}} z)}{\mu^{d_{\zeta,0}}} - \zeta_0(z) \right| \leq \epsilon \quad \forall z \in C_\phi, \quad \forall \mu \in (0, \mu_\epsilon],$$

or equivalently, since  $d_{\phi,0} > 0$ ,

$$\left| \frac{\zeta(\lambda^{d_{\phi,0}} z)}{\lambda^{\frac{d_{\phi,0} d_{\zeta,0}}{r_{\zeta,0}}}} - \zeta_0(z) \right| \leq \epsilon \quad \forall z \in C_\phi, \quad \forall \lambda \in \left(0, \mu_\epsilon^{\frac{r_{\zeta,0}}{d_{\phi,0}}}\right].$$

Similarly, there exists  $\lambda_\nu$  such that

$$\left| \frac{\phi(\lambda^{r_{\phi,0}} \diamond x)}{\lambda^{d_{\phi,0}}} - \phi_0(x) \right| \leq \nu \quad \forall x \in C, \quad \forall \lambda \in (0, \lambda_\nu].$$

It follows that

$$\begin{aligned} \left| \frac{\zeta(\phi(\lambda^{r_{\phi,0}} \diamond x))}{\lambda^{\frac{d_{\phi,0} d_{\zeta,0}}{r_{\zeta,0}}}} - \zeta_0(\phi_0(x)) \right| &\leq \left| \frac{\zeta(\phi(\lambda^{r_{\phi,0}} \diamond x))}{\lambda^{\frac{d_{\phi,0} d_{\zeta,0}}{r_{\zeta,0}}}} - \zeta_0\left(\frac{\phi(\lambda^{r_{\phi,0}} \diamond x)}{\lambda^{d_{\phi,0}}}\right) \right| \\ &\quad + \left| \zeta_0\left(\frac{\phi(\lambda^{r_{\phi,0}} \diamond x)}{\lambda^{d_{\phi,0}}}\right) - \zeta_0(\phi_0(x)) \right| \\ &\leq 2\epsilon \quad \forall x \in C, \quad \forall \lambda \in \min\left\{\lambda_1, \lambda_\nu, \mu_\epsilon^{\frac{r_{\zeta,0}}{d_{\phi,0}}}\right\}. \end{aligned}$$

This establishes homogeneity in the 0-limit of the function  $\zeta \circ \phi$ .

**Appendix B. Proof of Proposition 2.11.** We give the proof only in the 0-limit case since the  $\infty$ -limit case is similar. The function  $\phi$  being a bijection, we can assume without loss of generality that it is a strictly increasing function (otherwise we take  $-\phi$ ). This, together with homogeneity in the 0-limit, implies that  $\varphi_0$  is strictly positive. Moreover, for each  $\delta > 0$ , there exists  $t_0(\delta) > 0$  such that

$$\left| \frac{\phi(t)}{t^{d_0}} - \varphi_0 \right| \leq \delta \quad \forall t \in (0, t_0(\delta)) .$$

By letting  $\lambda = \phi(t)$ , this gives

$$\varphi_0 - \delta \leq \frac{\lambda}{\phi^{-1}(\lambda)^{d_0}} \leq \varphi_0 + \delta \quad \forall \lambda \in (0, \phi(t_0(\delta))) , \quad \forall \delta > 0 .$$

Since for  $\delta < \varphi_0$  the term on the left is strictly positive, these inequalities give

$$\left( \frac{1}{\varphi_0 + \delta} \right)^{\frac{1}{d_0}} \leq \frac{\phi^{-1}(\lambda)}{\lambda^{\frac{1}{d_0}}} \leq \left( \frac{1}{\varphi_0 - \delta} \right)^{\frac{1}{d_0}} \quad \forall \lambda \in (0, \phi^{-1}(t_0(\delta))) , \quad \forall \delta \in (0, \varphi_0) .$$

Then since the function  $\delta \mapsto \left( \frac{1}{\varphi_0 - \delta} \right)^{\frac{1}{d_0}}$  is continuous at zero, for every  $\epsilon_1 > 0$  there exists  $\delta_1(\epsilon_1) > 0$  satisfying

$$\left( \frac{1}{\varphi_0} \right)^{\frac{1}{d_0}} - \epsilon_1 \leq \left( \frac{1}{\varphi_0 + \delta_1(\epsilon_1)} \right)^{\frac{1}{d_0}} \leq \left( \frac{1}{\varphi_0 - \delta_1(\epsilon_1)} \right)^{\frac{1}{d_0}} \leq \left( \frac{1}{\varphi_0} \right)^{\frac{1}{d_0}} + \epsilon_1 .$$

This yields

$$\left| \frac{\phi^{-1}(\lambda)}{\lambda^{\frac{1}{d_0}}} - \left( \frac{1}{\varphi_0} \right)^{\frac{1}{d_0}} \right| \leq \epsilon_1 \quad \forall \lambda \in (0, \lambda_-(\epsilon_1)) ,$$

with  $\lambda_-(\epsilon_1) = \phi(t_0(\delta_1(\epsilon_1)))$ . With a similar argument, we get

$$\left| \frac{\phi^{-1}(-\lambda)}{\lambda^{\frac{1}{d_0}}} + \left( \frac{1}{\varphi_0} \right)^{\frac{1}{d_0}} \right| \leq \epsilon_1 \quad \forall \lambda \in (0, \lambda_+(\epsilon_1))$$

for some  $\lambda_+ > 0$ . Let  $\lambda_0 = \min\{\lambda_-, \lambda_+\}$ .

Now, for  $x \neq 0$  and  $\lambda > 0$ , we have

$$\left| \frac{\phi^{-1}(\lambda x)}{\lambda^{\frac{1}{d_0}}} - \left( \frac{x}{\varphi_0} \right)^{\frac{1}{d_0}} \right| = |x|^{\frac{1}{d_0}} \left| \frac{\phi^{-1}(\lambda x)}{(\lambda x)^{\frac{1}{d_0}}} - \left( \frac{1}{\varphi_0} \right)^{\frac{1}{d_0}} \right| .$$

Therefore, for any compact set  $C$  of  $\mathbb{R} \setminus \{0\}$  and any  $\epsilon > 0$ , by letting  $\epsilon_1 = \frac{\epsilon}{\max_{x \in C} |x|^{\frac{1}{d_0}}}$ , we have

$$|x|^{\frac{1}{d_0}} \epsilon_1 \leq \epsilon, \quad 0 < |\lambda x| \leq \lambda_0(\epsilon_1) \quad \forall \lambda \in \left( 0, \frac{\lambda_0(\epsilon_1)}{\max_{x \in C} |x|} \right] , \quad \forall x \in C ,$$

and therefore

$$\left| \frac{\phi^{-1}(\lambda x)}{\lambda^{\frac{1}{d_0}}} - \left( \frac{x}{\varphi_0} \right)^{\frac{1}{d_0}} \right| \leq \epsilon \quad \forall \lambda \in \left( 0, \frac{\lambda_0(\epsilon_1)}{\max_{x \in C} |x|} \right] , \quad \forall x \in C .$$

This establishes homogeneity in the 0-limit of the function  $\phi^{-1}$ .

**Appendix C. Proof of Lemma 2.13.** The proof of this lemma is divided into three parts.

1. We first show, by contradiction, that there exists a real number  $c_0$  satisfying

$$\eta_0(\theta) - c\gamma_0(\theta) < 0 \quad \forall \theta \in S_{r_0}, \quad \forall c \geq c_0.$$

Suppose there is no such  $c_0$ . This means there is a sequence  $(\theta_i)_{i \in \mathbb{N}}$  in  $S_{r_0}$  which satisfies

$$\eta_0(\theta_i) - i\gamma_0(\theta_i) \geq 0 \quad \forall i \in \mathbb{N}.$$

The sequence  $(\theta_i)_{i \in \mathbb{N}}$  lives in a compact set. Thus we can extract a convergent subsequence  $(\theta_{i_\ell})_{\ell \in \mathbb{N}}$  which converges to a point denoted  $\theta_\infty$ .

As the functions  $\eta_0$  and  $\gamma_0$  are bounded on  $S_{r_0}$  and  $\gamma_0$  takes nonnegative values,<sup>8</sup>  $\gamma_0(\theta_{i_\ell})$  must go to 0 as  $i_\ell$  goes to infinity. Since the functions  $\eta_0$  and  $\gamma_0$  are continuous, we get  $\gamma_0(\theta_\infty) = 0$  and  $\eta_0(\theta_\infty) \geq 0$ , which is impossible. Consequently, there exist  $c_0$  and  $\varepsilon_0 > 0$  such that

$$(C.1) \quad \eta_0(\theta) - c\gamma_0(\theta) \leq -\varepsilon_0 < 0 \quad \forall \theta \in S_{r_0}, \quad \forall c \geq c_0.$$

Moreover, since the functions  $\eta_0$  and  $\gamma_0$  are homogeneous in the standard sense (see Remark 2.6), we have the second inequality in (2.4).

Following the same argument, we can find positive real numbers  $c_\infty$  and  $\varepsilon_\infty$  such that

$$(C.2) \quad \eta_\infty(\theta) - c\gamma_\infty(\theta) < -\varepsilon_\infty \quad \forall \theta \in S_{r_\infty}, \quad \forall c \geq c_\infty,$$

and the third inequality in (2.4) holds.

In the rest of the proof, let

$$c_1 = \max\{c_0, c_\infty\}, \quad \varepsilon_1 = \min\{\varepsilon_0, \varepsilon_\infty\}.$$

2. Since  $\eta$  and  $\gamma$  are homogeneous in the 0-limit, there exists  $\lambda_0$  such that, for all  $\lambda \in (0, \lambda_0]$  and all  $\theta \in S_{r_0}$ , we have

$$\eta(\lambda^{r_0} \diamond \theta) \leq \lambda^{d_0} \eta_0(\theta) + \lambda^{d_0} \frac{\varepsilon_1}{4}, \quad \lambda^{d_0} \gamma_0(\theta) - \lambda^{d_0} \frac{\varepsilon_1}{4c_1} \leq \gamma(\lambda^{r_0} \diamond \theta),$$

which readily gives

$$\eta(\lambda^{r_0} \diamond \theta) - c_1 \gamma(\lambda^{r_0} \diamond \theta) \leq \lambda^{d_0} \eta_0(\theta) + \lambda^{d_0} \frac{\varepsilon_1}{2} - c_1 \lambda^{d_0} \gamma_0(\theta).$$

Using (C.1), we get

$$\eta(\lambda^{r_0} \diamond \theta) - c_1 \gamma(\lambda^{r_0} \diamond \theta) \leq -\lambda^{d_0} \frac{\varepsilon_1}{2} \quad \forall \lambda \in (0, \lambda_0], \quad \forall \theta \in S_{r_0},$$

and therefore, since  $\gamma$  takes nonnegative values,

$$\eta(\lambda^{r_0} \diamond \theta) - c\gamma(\lambda^{r_0} \diamond \theta) \leq -\lambda^{d_0} \frac{\varepsilon_1}{2} \quad \forall \lambda \in (0, \lambda_0], \quad \forall \theta \in S_{r_0}, \quad \forall c \geq c_1.$$

---

<sup>8</sup>Indeed, if we had  $\gamma_0(x) < 0$  for some  $x$  in  $\mathbb{R}^n \setminus \{0\}$ , by letting  $\epsilon = -\frac{\gamma_0(x)}{2}$ , the homogeneity in the 0-limit of  $\gamma$  would give a real number  $\lambda > 0$  satisfying  $\frac{\gamma(\lambda^{r_0} \diamond x)}{\lambda^{d_0}} \leq \gamma_0(x) + \epsilon = \frac{\gamma_0(x)}{2} < 0$ . This contradicts the fact that  $\gamma$  takes nonnegative values only. Also by continuity we have  $\gamma_0(0) \geq 0$ .

Similarly, there exists  $\lambda_\infty$  satisfying

$$\eta(\lambda^{r_\infty} \diamond \theta) - c \gamma(\lambda^{r_\infty} \diamond \theta) \leq -\lambda^{d_\infty} \frac{\varepsilon_1}{2} \quad \forall \lambda \in [\lambda_\infty, +\infty), \forall \theta \in S_{r_\infty}, \forall c \geq c_1.$$

Consequently, for each  $c \geq c_1$ , the set

$$\{x \in \mathbb{R}^n \setminus \{0\} \mid \eta(x) - c \gamma(x) \geq 0\},$$

if not empty, must be a subset of

$$C = \{x \in \mathbb{R}^n : |x|_{r_0} \geq \lambda_0\} \cup \{x \in \mathbb{R}^n : |x|_{r_\infty} \leq \lambda_\infty\},$$

which is compact and does not contain the origin.

3. Suppose now that for all  $c$  the first inequality in (2.4) is not true. This means that, for all integers  $c$  larger than  $c_1$ , there exists  $x_c$  in  $\mathbb{R}^n$  satisfying

$$\eta(x_c) - c \gamma(x_c) \geq 0,$$

and therefore  $x_c$  is in  $C$ . Since  $C$  is a compact set, there is a convergent subsequence  $(x_{c_\ell})_{\ell \in \mathbb{N}}$  which converges to a point denoted  $x^*$  different from zero. Also as above, we must have  $\gamma(x^*) = 0$  and  $\eta(x^*) \geq 0$ . But this contradicts the assumption, namely,

$$\{x \in \mathbb{R}^n \setminus \{0\}, \gamma(x) = 0\} \Rightarrow \eta(x) < 0.$$

**Appendix D. Proof of Proposition 2.18.** Because the vector field  $f$  is homogeneous in the  $\infty$ -limit, its approximating vector field  $f_\infty$  is homogeneous in the standard sense (see Remark 2.6). Let  $d_{V_\infty}$  be a positive real number larger than  $r_{\infty,i}$  for all  $i$  in  $\{1, \dots, n\}$ . Following Rosier [29], there exists a  $C^1$ , positive definite, proper, and homogeneous function  $V_\infty : \mathbb{R}^n \rightarrow \mathbb{R}_+$ , with weight  $r_\infty$  and degree  $d_{V_\infty}$ , satisfying

$$(D.1) \quad \frac{\partial V_\infty}{\partial x}(x) f_\infty(x) < 0 \quad \forall x \neq 0.$$

From P1 in section 2.2, we know that the function  $x \mapsto \frac{\partial V_\infty}{\partial x}(x) f(x)$  is homogeneous in the  $\infty$ -limit with associated triple  $(r_\infty, \mathfrak{d}_\infty + d_{V_\infty}, \frac{\partial V_\infty}{\partial x}(x) f_\infty(x))$ . Let

$$\epsilon_\infty = -\frac{1}{2} \max_{\theta \in S_{r_\infty}} \left\{ \frac{\partial V_\infty}{\partial x}(\theta) f_\infty(\theta) \right\},$$

and note that, by inequality (D.1),  $\epsilon_\infty$  is a strictly positive real number. By the definition of homogeneity in the  $\infty$ -limit, there exists  $\lambda_\infty$  such that

$$\left| \frac{\frac{\partial V_\infty}{\partial x}(\lambda^{r_\infty} \diamond \theta) f(\lambda^{r_\infty} \diamond \theta)}{\lambda^{d_{V_\infty} + \mathfrak{d}_\infty}} - \frac{\partial V_\infty}{\partial x}(\theta) f_\infty(\theta) \right| \leq \epsilon_\infty \quad \forall \theta \in S_{r_\infty}, \forall \lambda \geq \lambda_\infty.$$

This yields

$$\begin{aligned} \frac{\partial V_\infty}{\partial x}(\lambda^{r_\infty} \diamond \theta) f(\lambda^{r_\infty} \diamond \theta) &\leq \lambda^{d_{V_\infty} + \mathfrak{d}_\infty} \left( \frac{\partial V_\infty}{\partial x}(\theta) f_\infty(\theta) + \epsilon_\infty \right) \\ &\leq -\lambda^{d_{V_\infty} + \mathfrak{d}_\infty} \epsilon_\infty \quad \forall \theta \in S_{r_\infty}, \forall \lambda \geq \lambda_\infty, \end{aligned}$$

or in other words,

$$(D.2) \quad \frac{\partial V_\infty}{\partial x}(x) f(x) < 0 \quad \forall x : |x|_{r_\infty} \geq \lambda_\infty .$$

This establishes global asymptotic stability of the compact set

$$\mathcal{C}_\infty = \{x : V_\infty(x) \leq v_\infty\} ,$$

where  $v_\infty$  is given by

$$v_\infty = \max_{|x|_{r_\infty} = \lambda_\infty} \{V_\infty(x)\} .$$

**Appendix E. Proof of Theorem 2.20.** The proof is divided into three steps. First, we define three Lyapunov functions  $V_0$ ,  $V_m$ , and  $V_\infty$ . Then we build another Lyapunov function  $V$  from these three. Finally, we show that its derivative along the trajectories of the system (2.7) and its homogeneous approximations are negative definite.

1. As established in the proof of Proposition 2.18, there exist a positive real number  $\lambda_\infty$  and a  $C^1$  positive definite, proper, and homogeneous function  $V_\infty : \mathbb{R}^n \rightarrow \mathbb{R}_+$ , with weight  $r_\infty$  and degree  $d_{V_\infty}$  satisfying (D.2). Similarly, there exist a number  $\lambda_0 > 0$  and a  $C^1$  positive definite, proper, and homogeneous function  $V_0 : \mathbb{R}^n \rightarrow \mathbb{R}_+$ , with weight  $r_0$  and degree  $d_{V_0}$ , satisfying

$$(E.1) \quad \frac{\partial V_0}{\partial x}(x) f(x) < 0 \quad \forall x : 0 < |x|_{r_0} \leq \lambda_0 .$$

Finally, the global asymptotic stability of the origin of the system  $\dot{x} = f(x)$  implies the existence of a  $C^1$ , positive definite, and proper function  $V_m : \mathbb{R}^n \rightarrow \mathbb{R}_+$  satisfying

$$(E.2) \quad \frac{\partial V_m}{\partial x}(x) f(x) < 0 \quad \forall x \neq 0 .$$

2. Now we build a function  $V$  from the functions  $V_m$ ,  $V_\infty$ , and  $V_0$ . For this, we follow a technique used by Mazenc in [17] (see also [15]). Let  $v_\infty$  and  $v_0$  be two strictly positive real numbers such that  $v_0 < v_\infty$  and

$$v_\infty \geq \max_{x: |x|_{r_\infty} \leq \lambda_\infty} V_m(x), \quad v_0 \leq \min_{x: |x|_{r_0} \geq \lambda_0} V_m(x) .$$

This implies

$$\begin{aligned} \{x \in \mathbb{R}^n : V_m(x) \geq v_\infty\} &\subseteq \{x \in \mathbb{R}^n : |x|_{r_\infty} \geq \lambda_\infty\} , \\ \{x \in \mathbb{R}^n : V_m(x) \leq v_0\} &\subseteq \{x \in \mathbb{R}^n : |x|_{r_0} \leq \lambda_0\} . \end{aligned}$$

Let  $\omega_0$  and  $\omega_\infty$  be defined as

$$\omega_0 = \min_{x: \frac{1}{2} v_0 \leq V_m(x) \leq v_0} \frac{V_m(x)}{V_0(x)}, \quad \omega_\infty = \max_{x: v_\infty \leq V_m(x) \leq 2 v_\infty} \frac{V_m(x)}{V_\infty(x)} .$$

We have

$$\begin{aligned} \omega_\infty V_\infty(x) - V_m(x) &\geq 0 \quad \forall x : v_\infty \leq V_m(x) \leq 2 v_\infty , \\ V_m(x) - \omega_0 V_0(x) &\geq 0 \quad \forall x : \frac{1}{2} v_0 \leq V_m(x) \leq v_0 . \end{aligned}$$

Let

$$V(x) = \omega_\infty \varphi_\infty(V_m(x)) V_\infty(x) \\ + [1 - \varphi_\infty(V_m(x))] \varphi_0(V_m(x)) V_m(x) + \omega_0 [1 - \varphi_0(V_m(x))] V_0(x) ,$$

where  $\varphi_0$  and  $\varphi_\infty$  are  $C^1$  nondecreasing functions satisfying

$$(E.3) \quad \varphi_0(s) = 0 \quad \forall s \leq \frac{1}{2} v_0, \quad \varphi_0(s) = 1 \quad \forall s \geq v_0 ,$$

$$(E.4) \quad \varphi_\infty(s) = 0 \quad \forall s \leq v_\infty, \quad \varphi_\infty(s) = 1 \quad \forall s \geq 2v_\infty .$$

Then  $V$  is  $C^1$ , positive definite, and proper. Moreover, by construction,

$$V(x) = \begin{cases} \omega_0 V_0(x) & \forall x : V_m(x) \leq \frac{1}{2} v_0 , \\ \varphi_0(V_m(x)) V_m(x) + \omega_0 [1 - \varphi_0(V_m(x))] V_0(x) & \forall x : \frac{1}{2} v_0 \leq V_m(x) \leq v_0 , \\ V_m(x) & \forall x : v_0 \leq V_m(x) \leq v_\infty , \\ \omega_\infty \varphi_\infty(V_m(x)) V_\infty(x) + [1 - \varphi_\infty(V_m(x))] V_m(x) & \forall x : v_\infty \leq V_m(x) \leq 2v_\infty , \\ \omega_\infty V_\infty(x) & \forall x : V_m(x) \geq 2v_\infty . \end{cases}$$

Thus for each  $i$  in  $\{1, \dots, n\}$ ,

$$(E.5) \quad \frac{\partial V}{\partial x_i}(x) = \omega_\infty \frac{\partial V_\infty}{\partial x_i}(x) \quad \forall x : V_m(x) > 2v_\infty$$

and

$$(E.6) \quad \frac{\partial V}{\partial x_i}(x) = \omega_0 \frac{\partial V_0}{\partial x_i}(x) \quad \forall x : V_m(x) < \frac{1}{2} v_0 .$$

Since  $\frac{\partial V_\infty}{\partial x_i}$  and  $\frac{\partial V_0}{\partial x_i}$  are homogeneous in the standard sense, this proves that for each  $i$  in  $\{1, \dots, n\}$ ,  $\frac{\partial V}{\partial x_i}$  is homogeneous in the bi-limit, with weights  $r_0$  and  $r_\infty$  and degrees  $d_{V_0} - r_{0,i}$  and  $d_{V_\infty} - r_{\infty,i}$ .

3. It remains to show that the Lie derivative of  $V$  along  $f$  is negative definite. To this end note that, for all  $x$  such that  $\frac{1}{2} v_0 \leq V_m(x) \leq v_0$ ,

$$\frac{\partial V}{\partial x}(x) f(x) = \varphi'_0(V_m(x)) [V_m(x) - \omega_0 V_0(x)] \frac{\partial V_m}{\partial x}(x) f(x) \\ + \omega_0 [1 - \varphi_0(V_m(x))] \frac{\partial V_0}{\partial x}(x) f(x) + \varphi_0(V_m(x)) \frac{\partial V_m}{\partial x}(x) f(x)$$

and, for all  $x$  such that  $v_\infty \leq V_m(x) \leq 2v_\infty$ ,

$$\frac{\partial V}{\partial x}(x) f(x) = \varphi'_\infty(V_m(x)) [\omega_\infty V_\infty(x) - V_m(x)] \frac{\partial V_m}{\partial x}(x) f(x) \\ + \omega_\infty \varphi_\infty(V_m(x)) \frac{\partial V_\infty}{\partial x}(x) f(x) + [1 - \varphi_\infty(V_m(x))] \frac{\partial V_m}{\partial x}(x) f(x) .$$

By (D.2), (E.1), (E.2), (E.3), and (E.4), these inequalities imply

$$\frac{\partial V}{\partial x}(x) f(x) < 0 \quad \forall x \neq 0 ,$$

which proves the claim.

**Appendix F. Proof of Corollary 2.21.** Recall (1.6) and consider the functions  $\eta_1 : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$  and  $\gamma_1 : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}_+$  defined as

$$\eta_1(x, \delta) = \frac{\partial V}{\partial x}(x) \left[ f(x, \delta) - \frac{1}{2} f(x, 0) \right], \quad \gamma_1(x, \delta) = \sum_{j=1}^m \mathfrak{H} \left( |\delta_j|^{\frac{d_{V_0} + \mathfrak{d}_0}{\mathfrak{r}_{0,j}}}, |\delta_j|^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{\mathfrak{r}_{\infty,j}}} \right).$$

These functions are homogeneous in the bi-limit with weights  $r_0$  and  $r_\infty$  for  $x$  and  $\mathfrak{r}_0$  and  $\mathfrak{r}_\infty$  for  $\delta$  and degrees  $d_{V_0} + \mathfrak{d}_0$  and  $d_{V_\infty} + \mathfrak{d}_\infty$ . Since the function  $x \mapsto \frac{\partial V}{\partial x}(x) f(x, 0)$  is negative definite, then

$$\{(x, \delta) \in \mathbb{R}^{n+m} \setminus \{0\} : \gamma_1(x, \delta) = 0\} \subseteq \{(x, \delta) \in \mathbb{R}^{n+m} : \eta_1(x, \delta) < 0\}.$$

Moreover, since the homogeneous approximations of  $\eta$  are negative definite, we get

$$\begin{aligned} \{(x, \delta) \in \mathbb{R}^{n+m} \setminus \{0\} : \gamma_{1,0}(x, \delta) = 0\} &\subseteq \{(x, \delta) \in \mathbb{R}^{n+m} : \eta_{1,0}(x, \delta) < 0\}, \\ \{(x, \delta) \in \mathbb{R}^{n+m} \setminus \{0\} : \gamma_{1,\infty}(x, \delta) = 0\} &\subseteq \{(x, \delta) \in \mathbb{R}^{n+m} : \eta_{1,\infty}(x, \delta) < 0\}. \end{aligned}$$

Hence, by Lemma 2.13, there exists a positive real number  $c_\delta$  such that

$$(F.1) \quad \frac{\partial V}{\partial x}(x) \left[ f(x, \delta) - \frac{1}{2} f(x, 0) \right] \leq c_\delta \sum_{j=1}^m \mathfrak{H} \left( |\delta_j|^{\frac{d_{V_0} + \mathfrak{d}_0}{\mathfrak{r}_{0,j}}}, |\delta_j|^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{\mathfrak{r}_{\infty,j}}} \right).$$

Consider now the functions  $\eta_2 : \mathbb{R}^n \rightarrow \mathbb{R}_+$  and  $\gamma_2 : \mathbb{R}^n \rightarrow \mathbb{R}_+$  defined as

$$\eta_2(x) = \mathfrak{H} \left( V(x)^{\frac{d_{V_0} + \mathfrak{d}_0}{d_{V_0}}}, V(x)^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{d_{V_\infty}}} \right), \quad \gamma_2(x) = -\frac{1}{2} \frac{\partial V}{\partial x}(x) f(x, 0).$$

They are homogeneous in the bi-limit with weights  $r_0$  and  $r_\infty$  and degrees  $d_{V_0} + \mathfrak{d}_0$  and  $d_{V_\infty} + \mathfrak{d}_\infty$ . Since  $\gamma_2$  and its homogeneous approximations are positive definite, by Corollary 2.15 there exists a positive real number  $c_V$  such that

$$(F.2) \quad \frac{1}{2} \frac{\partial V}{\partial x}(x) f(x, 0) \leq -c_V \mathfrak{H} \left( V(x)^{\frac{d_{V_0} + \mathfrak{d}_0}{d_{V_0}}}, V(x)^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{d_{V_\infty}}} \right).$$

The two inequalities (F.1) and (F.2) yield the claim.

**Appendix G. Proof of Corollary 2.22.** Let  $d_{V_0}$  and  $d_{V_\infty}$  be such that the assumption of Theorem 2.20 holds. For each  $i$  in  $\{1, \dots, m\}$ , let  $\mu_i : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  be the strictly increasing function defined as (see (1.6))

$$(G.1) \quad \mu_i(s) = \mathfrak{H}(s^{q_i}, s^{p_i}),$$

where

$$p_i = \frac{\mathfrak{d}_\infty + d_{V_\infty}}{\mathfrak{r}_{\infty,i}}, \quad q_i = \frac{\mathfrak{d}_0 + d_{V_0}}{\mathfrak{r}_{0,i}}.$$

We first prove that the inequality given by Corollary 2.21 implies that the system (2.8), with  $\delta$  as input and  $x$  as output, is ISS with a linear gain between  $\sum_{i=1}^m \mu_i(|\delta_i|)$  and  $\mathfrak{H}(|x|_{r_0}^{\mathfrak{d}_0 + d_{V_0}}, |x|_{r_\infty}^{\mathfrak{d}_\infty + d_{V_\infty}})$ . To do so we introduce the function  $\alpha : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  as

$$\alpha(s) = \mathfrak{H} \left( s^{\frac{\mathfrak{d}_0 + d_{V_0}}{d_{V_0}}}, s^{\frac{\mathfrak{d}_\infty + d_{V_\infty}}{d_{V_\infty}}} \right), \quad s \geq 0.$$

This function is a bijection, strictly increasing, and homogeneous in the bi-limit with approximating functions  $s^{\frac{d_{V_0} + \mathfrak{d}_0}{d_{V_0}}}$  and  $s^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{d_{V_\infty}}}$ . Moreover, from Proposition 2.10, the function  $x \mapsto \alpha(V(x))$  is positive definite and homogeneous in the bi-limit with associated weights  $r_0$  and  $r_\infty$  and degrees  $\mathfrak{d}_0 + d_{V_0}$  and  $\mathfrak{d}_\infty + d_{V_\infty}$ . Moreover, its approximating homogeneous functions  $V_0(x)^{\frac{d_{V_0} + \mathfrak{d}_0}{d_{V_0}}}$  and  $V_\infty(x)^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{d_{V_\infty}}}$  are positive definite as well. Hence, we get from Corollary 2.15 the existence of a positive real number  $c_1$  satisfying

$$(G.2) \quad \mathfrak{H} \left( |x|_{r_0}^{\mathfrak{d}_0 + d_{V_0}}, |x|_{r_\infty}^{\mathfrak{d}_\infty + d_{V_\infty}} \right) \leq c_1 \alpha(V(x)) \quad \forall x \in \mathbb{R}^n.$$

On the other hand, from inequality (2.9) in Corollary 2.21, we have the property
