$$(G.3) \quad \left\{ (x, \delta) \in \mathbb{R}^n \times \mathbb{R}^m : \alpha(V(x)) \geq 2 \frac{c_\delta}{c_V} \sum_{i=1}^m \mu_i(|\delta_i|) \right\} \\ \subseteq \left\{ (x, \delta) \in \mathbb{R}^n \times \mathbb{R}^m : \frac{\partial V}{\partial x}(x) f(x, \delta) \leq -\frac{c_V}{2} \alpha(V(x)) \right\}.$$

In the following, let  $t \in [0, T] \mapsto (x(t), \delta(t), z(t))$  be any function which satisfies (2.8) on  $[0, T]$  and (2.10) and (2.11) for all  $0 \leq s \leq t \leq T$ . From [32], we know the inclusion (G.3) implies the existence of a class  $\mathcal{KL}$  function  $\beta_V$  such that, for all  $0 \leq s \leq t \leq T$ ,

$$(G.4) \quad V(x(t)) \leq \max \left\{ \beta_V(V(x(s)), t-s), \sup_{s \leq \kappa \leq t} \left\{ \alpha^{-1} \left( \frac{2c_\delta}{c_V} \sum_{j=1}^m \mu_j(|\delta_j(\kappa)|) \right) \right\} \right\}.$$

With  $\alpha$  acting on both sides of inequality (G.4), (G.2) gives, for all  $0 \leq s \leq t \leq T$ ,

$$(G.5) \quad \mathfrak{H} \left( |x(t)|_{r_0}^{\mathfrak{d}_0 + d_{V_0}}, |x(t)|_{r_\infty}^{\mathfrak{d}_\infty + d_{V_\infty}} \right) \\ \leq \max \left\{ c_1 \alpha \circ \beta_V(V(x(s)), t-s), \frac{2c_1 c_\delta}{c_V} \sup_{s \leq \kappa \leq t} \left\{ \sum_{j=1}^m \mu_j(|\delta_j(\kappa)|) \right\} \right\}.$$

This is the linear gain property required. To conclude the proof it remains to show the existence of  $c_G$  such that a small gain property is satisfied.

First, note that the function  $x \mapsto \mathfrak{H}(|x|_{r_0}^{\mathfrak{d}_0 + d_{V_0}}, |x|_{r_\infty}^{\mathfrak{d}_\infty + d_{V_\infty}})$  is positive definite and homogeneous in the bi-limit with weights  $r_0$  and  $r_\infty$  and degrees  $\mathfrak{d}_0 + d_{V_0}$  and  $\mathfrak{d}_\infty + d_{V_\infty}$ . By Proposition 2.10, for  $i$  in  $\{1, \dots, m\}$  the same holds with the function  $x \mapsto \mu_i(\mathfrak{H}(|x|_{r_0}^{\mathfrak{r}_{0,i}}, |x|_{r_\infty}^{\mathfrak{r}_{\infty,i}}))$ . Hence, by Corollary 2.15, there exists a positive real number  $c_2$  satisfying

$$(G.6) \quad \mu_i(\mathfrak{H}(|x|_{r_0}^{\mathfrak{r}_{0,i}}, |x|_{r_\infty}^{\mathfrak{r}_{\infty,i}})) \leq c_2 \mathfrak{H}(|x|_{r_0}^{\mathfrak{d}_0 + d_{V_0}}, |x|_{r_\infty}^{\mathfrak{d}_\infty + d_{V_\infty}}) \quad \forall x \in \mathbb{R}^n.$$

Let  $C_i$  for  $i$  in  $\{1, \dots, m\}$  be the class  $\mathcal{K}_\infty$  functions defined as

$$C_i(c) = \max\{c^{q_i}, c^{p_i}\} + c^{\frac{p_i q_i}{q_i + p_i}} + c^{p_i + q_i}.$$

From (G.1), we get, for each  $s > 0$  and  $c > 0$ ,

$$\frac{\mu_i(cs)}{\mu_i(s)} = c^{q_i} \frac{(1 + s^{q_i})(1 + c^{p_i} s^{p_i})}{(1 + s^{p_i})(1 + c^{q_i} s^{q_i})} \leq c^{q_i} \left[ \frac{1 + c^{p_i} s^{p_i + q_i}}{1 + c^{q_i} s^{p_i + q_i}} + \frac{s^{q_i}}{1 + c^{q_i} s^{q_i + p_i}} + \frac{c^{p_i} s^{p_i}}{1 + s^{p_i}} \right],$$

where

$$c^{q_i} \frac{1 + c^{p_i} s^{p_i + q_i}}{1 + c^{q_i} s^{p_i + q_i}} \leq \max\{c^{q_i}, c^{p_i}\}, \quad \frac{c^{q_i} s^{q_i}}{1 + c^{q_i} s^{q_i + p_i}} \leq c^{\frac{p_i q_i}{q_i + p_i}}, \quad \frac{c^{q_i} c^{p_i} s^{p_i}}{1 + s^{p_i}} \leq c^{p_i + q_i}.$$

Hence, by continuity at 0, we have

$$(G.7) \quad \mu_i(cs) \leq C_i(c) \mu_i(s) \quad \forall (c, s) \in \mathbb{R}_+^2.$$

Consider the positive real numbers  $c_1$ ,  $c_2$ ,  $c_\delta$ , and  $c_V$  previously introduced, and select  $c_G$  in  $\mathbb{R}_+$  satisfying

$$(G.8) \quad c_G < \min_{1 \leq i \leq m} C_i^{-1} \left( \frac{c_V}{2m c_1 c_2 c_\delta} \right).$$

To show that such a selection for  $c_G$  is appropriate, observe that by (G.6) and (G.7) and  $\mu_i$  acting on both sides of the inequality (2.11), we get for each  $i$  in  $\{1, \dots, m\}$  and all  $0 \leq s \leq t \leq T$ ,

$$\mu_i(|\delta_i(t)|) \leq \max \left\{ \mu_i \circ \beta_\delta(|z(s)|, t-s), \right. \\ \left. C_i(c_G) c_2 \sup_{s \leq \kappa \leq t} \left\{ \mathfrak{H} \left( |x(\kappa)|_{r_0}^{\mathfrak{d}_0 + d_{V_0}}, |x(\kappa)|_{r_\infty}^{\mathfrak{d}_\infty + d_{V_\infty}} \right) \right\} \right\}.$$

Consequently

$$\sum_{i=1}^m \mu_i(|\delta_i(t)|) \leq \max \left\{ m \max_{1 \leq i \leq m} \{ \mu_i \circ \beta_\delta(|z(s)|, t-s) \}, \right. \\ (G.9) \quad \left. (m \max_{1 \leq i \leq m} C_i(c_G) c_2) \sup_{s \leq \kappa \leq t} \left\{ \mathfrak{H} \left( |x(\kappa)|_{r_0}^{\mathfrak{d}_0 + d_{V_0}}, |x(\kappa)|_{r_\infty}^{\mathfrak{d}_\infty + d_{V_\infty}} \right) \right\} \right\}.$$

Since (G.8) yields

$$\frac{2c_1 c_\delta}{c_V} m \max_{1 \leq i \leq m} C_i(c_G) c_2 < 1,$$

the existence of the function  $\beta_x$  follows from (2.10), (G.5), (G.9), and the (proof of the) small-gain theorem [11].

**Appendix H. Proof of Corollary 2.24.** First, observe that the continuity of  $f_0$ , at least, on  $\mathbb{R}^n \setminus \{0\}$  implies

$$|\mathfrak{d}_0| = -\mathfrak{d}_0 \leq \min_{1 \leq i \leq n} r_{0,i} \leq \max_{1 \leq i \leq n} r_{0,i} < d_{V_0}.$$

Then, let  $V$  be the function given in Theorem 2.20 and, since  $\mathfrak{d}_0 < 0 < \mathfrak{d}_\infty$ , the function  $\phi(x) = V(x)^{\frac{d_{V_0} + \mathfrak{d}_0}{d_{V_0}}} + V(x)^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{d_{V_\infty}}}$  is homogeneous in the bi-limit with weights  $r_0$  and  $r_\infty$ , degrees  $d_{V_0} + \mathfrak{d}_0$  and  $d_{V_\infty} + \mathfrak{d}_\infty$ , and approximating functions  $V(x)^{\frac{d_{V_0} + \mathfrak{d}_0}{d_{V_0}}}$  and  $V(x)^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{d_{V_\infty}}}$ . Moreover, the function  $\zeta(x) = -\frac{\partial V}{\partial x}(x) f(x)$  is homogeneous in the bi-limit with the same weights and degrees as  $\phi$ . Furthermore, since the function  $\zeta$  and its homogeneous approximations are positive definite, Corollary 2.15 yields a strictly positive real number  $c$  such that

$$(H.1) \quad \frac{\partial V}{\partial x}(x) f(x) \leq -c \left( V(x)^{\frac{d_{V_0} + \mathfrak{d}_0}{d_{V_0}}} + V(x)^{\frac{d_{V_\infty} + \mathfrak{d}_\infty}{d_{V_\infty}}} \right) \quad \forall x \in \mathbb{R}^n.$$

Let  $x_{ic}$  in  $\mathbb{R}^n \setminus \{0\}$  be the initial condition of a solution of the system  $\dot{x} = f(x)$ , and let  $V_{x_{ic}} : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  be the function of time given by the evaluation of  $V$  along this solution. Then

$$\overline{V_{x_{ic}}(t)} \leq -c V_{x_{ic}}(t)^{\frac{d_{V_\infty} + \vartheta_\infty}{d_{V_\infty}}} \quad \forall t \geq 0 ,$$

from which we get

$$V_{x_{ic}}(t) \leq \frac{1}{\left(\frac{\vartheta_\infty}{d_{V_\infty}} ct + V(x_{ic})^{-\frac{\vartheta_\infty}{d_{V_\infty}}}\right)^{\frac{d_{V_\infty}}{\vartheta_\infty}}} \leq \frac{1}{\left(\frac{\vartheta_\infty}{d_{V_\infty}} ct\right)^{\frac{d_{V_\infty}}{\vartheta_\infty}}} \quad \forall t > 0 .$$

Therefore, setting  $T_1 = \frac{d_{V_\infty}}{c\vartheta_\infty}$ , we have

$$V_{x_{ic}}(t) \leq 1 \quad \forall t \geq T_1, \quad \forall x_{ic} \in \mathbb{R}^n$$

and

$$\overline{V_{x_{ic}}(t)} \leq -c V_{x_{ic}}(t)^{\frac{d_{V_0} - |\vartheta_0|}{d_{V_0}}} \quad \forall t \geq 0 .$$

As a result, we get

$$\begin{aligned} V_{x_{ic}}(t) &\leq \max \left\{ \left( -\frac{|\vartheta_0|}{d_{V_0}} c(t - T_1) + V_{x_{ic}}(T_1)^{\frac{|\vartheta_0|}{d_{V_0}}} \right)^{\frac{d_{V_0}}{|\vartheta_0|}}, 0 \right\} , \\ &\leq \max \left\{ \left( 1 - \frac{|\vartheta_0|}{d_{V_0}} c(t - T_1) \right)^{\frac{d_{V_0}}{|\vartheta_0|}}, 0 \right\} \quad \forall t \geq T_1 . \end{aligned}$$

Therefore, setting  $T_2 = \frac{d_{V_0}}{c|\vartheta_0|}$  yields

$$V_{x_{ic}}(t) = 0 \quad \forall t \geq T_1 + T_2 = \frac{1}{c} \left( \frac{d_{V_\infty}}{\vartheta_\infty} + \frac{d_{V_0}}{|\vartheta_0|} \right), \quad \forall x_{ic} \in \mathbb{R}^n ,$$

hence the claim.

**Acknowledgments.** The second author is extremely grateful to Wilfrid Perruquetti and Emmanuel Moulay for the many discussions about the notion of homogeneity in the bi-limit. Also, all the authors would like to thank the anonymous reviewers for their comments, which were extremely helpful in improving the quality of the paper.

# INVARIANT CARNOT–CARATHEODORY METRICS ON $S^3$ , $SO(3)$ , $SL(2)$ , AND LENS SPACES\*

UGO BOSCAIN<sup>†</sup> AND FRANCESCO ROSSI<sup>‡</sup>

**Abstract.** In this paper we study the Carnot–Caratheodory metrics on  $SU(2) \simeq S^3$ ,  $SO(3)$ , and  $SL(2)$  induced by their Cartan decomposition and by the Killing form. Besides computing explicitly geodesics and conjugate loci, we compute the cut loci (globally), and we give the expression of the Carnot–Caratheodory distance as the inverse of an elementary function. We then prove that the metric given on  $SU(2)$  projects on the so-called lens spaces  $L(p, q)$ . Also for lens spaces, we compute the cut loci (globally). For  $SU(2)$  the cut locus is a maximal circle without one point. In all other cases the cut locus is a stratified set. To our knowledge, this is the first explicit computation of the whole cut locus in sub-Riemannian geometry, except for the trivial case of the Heisenberg group.

**Key words.** left-invariant sub-Riemannian geometry, Carnot–Caratheodory distance, global structure of the cut locus, lens spaces

**DOI.** 10.1137/070703727

**1. Introduction.** In this paper we study the global structure of the cut locus (the set of points reached optimally by more than one geodesic) for the simplest sub-Riemannian structures on three-dimensional simple Lie groups (i.e.,  $SU(2)$ ,  $SO(3)$ , and  $SL(2)$ ), namely, the left-invariant sub-Riemannian structures induced by their Cartan decomposition and by the Killing form.

Let  $G$  be a simple real Lie group of matrices with associated Lie algebra  $\mathbf{L}$  and Killing form  $\text{Kil}(\cdot, \cdot)$ . Let  $\mathbf{L} = \mathbf{k} \oplus \mathbf{p}$  be its Cartan decomposition with the usual commutation relations  $[\mathbf{k}, \mathbf{k}] \subseteq \mathbf{k}$ ,  $[\mathbf{p}, \mathbf{p}] \subseteq \mathbf{k}$ ,  $[\mathbf{k}, \mathbf{p}] \subseteq \mathbf{p}$ . If  $\mathbf{L}$  is noncompact, we also require  $\mathbf{k}$  to be the maximal compact subalgebra of  $\mathbf{L}$ . The most natural left-invariant sub-Riemannian structure that one can define on  $G$  is the one in which the distribution is generated by left translations of  $\mathbf{p}$ , and the sub-Riemannian metric  $\langle \cdot, \cdot \rangle$  at the identity is generated by a scalar multiple of the Killing form restricted to  $\mathbf{p}$ . The scalar must be chosen positive or negative in such a way that the scalar product is positive definite. We call  $G$ , endowed with such a sub-Riemannian structure, a  **$\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold**.

$\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifolds have very special features: there are no strict abnormal minimizers, and the Hamiltonian system given by the Pontryagin maximum principle (PMP) is integrable in terms of elementary functions (products of exponentials). More precisely, if we write the distribution at a point  $g \in G$  as  $\Delta(g) = g\mathbf{p}$ , we have the following expression for geodesics parametrized by arclength, starting at time zero from  $g_0$  (see [3, 10, 14, 22, 23]):

$$(1) \quad g(t) = g_0 e^{(A_k + A_p)t} e^{-A_k t},$$

where  $A_k \in \mathbf{k}$ ,  $A_p \in \mathbf{p}$ , and we have  $\langle A_p, A_p \rangle = 1$ . Thanks to left-invariance, without loss of generality we can always assume that  $g_0$  is the identity, and we will do so throughout the paper.

FIG. 1. Local structure of sub-Riemannian spheres and of cut and conjugate loci for 3-dim  $\mathfrak{k} \oplus \mathfrak{p}$  sub-Riemannian manifolds.

In all three-dimensional cases (i.e.,  $SU(2)$ ,  $SO(3)$ , and  $SL(2)$ ),  $\mathfrak{p}$  has dimension 2, while  $\mathfrak{k}$  has dimension 1. Writing  $\mathfrak{p} = \text{span}\{p_1, p_2\}$ , where  $\{p_1, p_2\}$  is an orthonormal frame for the sub-Riemannian structure (i.e.,  $\langle p_i, p_j \rangle = \delta_{ij}$ ) and  $\mathfrak{k} = \text{span}\{k\}$ , we can write  $A_p = \cos(\theta)p_1 + \sin(\theta)p_2$  and  $A_k = ck$  with  $\theta \in \mathbb{R}/2\pi$ ,  $c \in \mathbb{R}$ . The map associating to the triple  $(\theta, c, t)$  the final point of the corresponding geodesic starting from the identity is called the *exponential map*,

$$\begin{aligned} \text{Exp} : S^1 \times \mathbb{R} \times \mathbb{R}^+ &\rightarrow G, \\ (\theta, c, t) &\mapsto \text{Exp}(\theta, c, t) = e^{(A_k + A_p)t} e^{-A_k t}. \end{aligned}$$

For three-dimensional  $\mathfrak{k} \oplus \mathfrak{p}$  sub-Riemannian manifolds, the local structure of the sub-Riemannian spheres, cut loci, and conjugate loci starting from the identity has been described by Agrachev (unpublished), and, due to cylindrical symmetry of the Killing form in the  $\mathfrak{p}$  subspace, it is very similar to that of the Heisenberg group. Indeed, locally, the cut locus coincides with the first conjugate locus (i.e., the set where local optimality is lost) and is made by two connected one-dimensional manifolds adjacent to the identity and transversal to the distribution; see Figure 1.

However, the global structure of the cut locus was still unknown. Indeed, to our knowledge, no global structure of the cut locus is known in sub-Riemannian geometry apart from that of the Heisenberg group.

The main result of our paper is the following.

**THEOREM 1.** *Let  $K_{\text{Id}}$  be the cut locus starting from the identity. We have the following:*

- (i) *For  $SU(2)$ ,  $K_{\text{Id}}$  is a maximal circle  $S^1$  without one point (the identity).*
- (ii) *For  $SO(3)$ ,  $K_{\text{Id}}$  is a stratified set made by two manifolds glued in one point. The first manifold is  $\mathbb{RP}^2$ ; the second manifold is a maximal circle  $S^1$  without one point (the identity).*
- (iii) *For  $SL(2)$ ,  $K_{\text{Id}}$  is a stratified set made by two manifolds glued in one point. The first manifold is  $\mathbb{R}^2$ ; the second manifold is a circle  $S^1$  without one point (the identity).*

A picture of the three cut loci is given in Figure 2.

For all cases, the one-dimensional strata contain the cut locus appearing in the local analysis.

Notice that the  $\mathfrak{k} \oplus \mathfrak{p}$  sub-Riemannian manifold  $SU(2)$  has the structure of a CR (Cauchy–Riemann) manifold and is a tight structure [7, 16].

Once the cut locus is computed, one can obtain the expression of the sub-Riemannian distance from the identity. The following theorem gives the sub-Riemannian distance for  $SU(2)$ . The proof, given in section 5.1.1, can be adapted

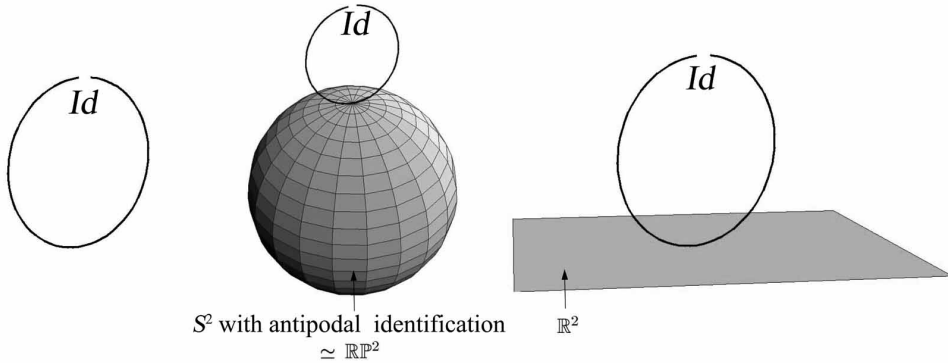

FIG. 2. The cut loci for the  $\mathfrak{k} \oplus \mathfrak{p}$  sub-Riemannian manifolds  $SU(2)$ ,  $SO(3)$ , and  $SL(2)$ .

to get similar results in the cases of  $SO(3)$  and  $SL(2)$ .

THEOREM 2. *Let*

$$SU(2) = \left\{ \begin{pmatrix} \alpha & \beta \\ -\bar{\beta} & \bar{\alpha} \end{pmatrix} \mid \alpha, \beta \in \mathbb{C}, |\alpha|^2 + |\beta|^2 = 1 \right\}.$$

Consider the sub-Riemannian distance from  $\text{Id}$  defined by

$$\begin{aligned} \dot{g} &= g \left( \frac{u_1}{2} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} + \frac{u_2}{2} \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix} \right), \\ d(\text{Id}, g_1) &:= \inf \left\{ \int_0^T \sqrt{u_1^2 + u_2^2} \mid g(0) = \text{Id}, g(T) = g_1 \right\}. \end{aligned}$$

It holds that

$$(2) \quad d \left( \text{Id}, \begin{pmatrix} \alpha & \beta \\ -\bar{\beta} & \bar{\alpha} \end{pmatrix} \right) = \begin{cases} 2\sqrt{\arg(\alpha)(2\pi - \arg(\alpha))} & \text{if } \beta = 0, \\ \psi(\alpha) & \text{if } \beta \neq 0, \end{cases}$$

where  $\arg(\alpha) \in [0, 2\pi]$  and  $\psi(\alpha) = t$  is the unique solution of

$$(3) \quad \begin{cases} -\frac{ct}{2} + \arctan \left( \frac{c}{\sqrt{1+c^2}} \tan \left( \frac{\sqrt{1+c^2}t}{2} \right) \right) = \arg(\alpha), \\ \frac{\sin \left( \frac{\sqrt{1+c^2}t}{2} \right)}{\sqrt{1+c^2}} = \sqrt{1-|\alpha|^2}, \\ t \in \left( 0, \frac{2\pi}{\sqrt{1+c^2}} \right). \end{cases}$$

This theorem and its analogues for  $SO(3)$  and  $SL(2)$  are useful to give estimates for the fundamental solutions of the hypoelliptic heat equation induced by the sub-Riemannian structure (see [5, 12, 17, 19]). Moreover, this theorem can be seen as the answer, in the case of  $SU(2)$ , to the question (formulated in [14]) about the possibility of inverting the matrix equation (1); i.e., for every matrix  $g \in SU(2)$ , find a matrix  $A = A_k + A_p$ , with  $\langle A_p, A_p \rangle = 1$ , being a solution to the equation  $g = g_0 e^{(A_k + A_p)t} e^{-A_k t}$ . If  $\beta \neq 0$ , then this equation has one and only one solution; otherwise it has more than one solution (indeed, infinitely many; see sections 3 and 5).

Then we study the most natural sub-Riemannian structures on the lens spaces  $L(p, q)$  induced by the one on  $SU(2)$ . The lens space  $L(p, q)$  (with  $p, q$  coprime integers,  $p, q \neq 0$ ) is the quotient of  $SU(2)$  by the equivalence relation

$$\begin{pmatrix} \alpha_1 & \beta_1 \\ -\beta_1 & \alpha_1 \end{pmatrix} \sim \begin{pmatrix} \alpha_2 & \beta_2 \\ -\beta_2 & \alpha_2 \end{pmatrix} \text{ if } \exists \omega \in \mathbb{C} \text{ } p\text{th root of unity such that}$$

$$\begin{pmatrix} \alpha_2 \\ \beta_2 \end{pmatrix} = \begin{pmatrix} \omega & 0 \\ 0 & \omega^q \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \beta_1 \end{pmatrix}.$$

The lens spaces are three-dimensional manifolds, but they are neither Lie groups nor homogeneous spaces of  $SU(2)$ , except for the case  $L(2, 1) \simeq SO(3)$ .

In the case of lens spaces, we get that the cut locus is much more complicated with respect to those on  $SU(2)$  and  $SL(2)$ . It is still a stratified set, but in general with more strata. The precise description is given in section 5.2.

Sub-Riemannian structures on the lens space  $L(4, 1)$  are particularly interesting for mechanical applications and for problems of geometry of vision on the two-dimensional sphere. Indeed,  $L(4, 1) \simeq PTS^2$ , the bundle of directions of  $S^2$ . These applications are the subject of a forthcoming paper.

The structure of this paper is the following. In section 2 we recall the definition of sub-Riemannian manifold, state the PMP (that is a first order necessary condition for optimality for problems of calculus of variations with nonholonomic constraints), and define the cut and conjugate loci. Then we define  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifolds. In section 3 we define  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian structures on  $SU(2)$ ,  $SO(3)$ , and  $SL(2)$  and compute the corresponding geodesics and conjugate loci. In section 4 we give sub-Riemannian structures on lens spaces as quotients of the  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian structure on  $SU(2)$ . The core of the paper is section 5, where we compute the cut loci and the sub-Riemannian distance. The general idea is the following: we first identify the prolongation of the cut locus arising locally, then we compute the part of the cut locus due to the symmetries of the problem, and finally, we show that there is no other cut point.

## 2. Basic definitions.

**2.1. Sub-Riemannian manifold.** An  $(n, m)$ -sub-Riemannian manifold is a triple  $(M, \Delta, \mathbf{g})$ , where

- (i)  $M$  is a connected smooth manifold of dimension  $n$ ;
- (ii)  $\Delta$  is a Lie bracket generating smooth distribution of constant rank  $m < n$ ; i.e.,  $\Delta$  is a smooth map that associates to  $q \in M$  an  $m$ -dim subspace  $\Delta(q)$  of  $T_q M$ , and  $\forall q \in M$ , we have

$$(4) \quad \text{span} \{[f_1, [\dots [f_{k-1}, f_k] \dots]](q) \mid f_i \in \text{Vec}(M) \text{ and } f_i(p) \in \Delta(p) \forall p \in M\} = T_q M.$$

Here  $\text{Vec}(M)$  denotes the set of smooth vector fields on  $M$ .

- (iii)  $\mathbf{g}_q$  is a Riemannian metric on  $\Delta(q)$ , that is, smooth as a function of  $q$ .

The Lie bracket generating condition (4) is also known as the Hörmander condition.

A Lipschitz continuous curve  $\gamma : [0, T] \rightarrow M$  is said to be *horizontal* if  $\dot{\gamma}(t) \in \Delta(\gamma(t))$  for almost every  $t \in [0, T]$ . Given a horizontal curve  $\gamma : [0, T] \rightarrow M$ , the

length of  $\gamma$  is

$$(5) \quad l(\gamma) = \int_0^T \sqrt{\mathbf{g}_{\gamma(t)}(\dot{\gamma}(t), \dot{\gamma}(t))} \, dt.$$

The distance induced by the sub-Riemannian structure on  $M$  is the function

$$(6) \quad d(q_0, q_1) = \inf\{l(\gamma) \mid \gamma(0) = q_0, \gamma(T) = q_1, \gamma \text{ horizontal}\}.$$

The hypothesis of connectedness of  $M$  and the Lie bracket generating assumption for the distribution guarantee the finiteness and the continuity of  $d(\cdot, \cdot)$  with respect to the topology of  $M$  (Chow's theorem; see, for instance, [3]).

The function  $d(\cdot, \cdot)$  is called the Carnot-Caratheodory distance and gives to  $M$  the structure of metric space (see [6, 18]).

It is a standard fact that  $l(\gamma)$  is invariant under reparametrization of the curve  $\gamma$ . Moreover, if an admissible curve  $\gamma$  minimizes the so-called *energy functional*

$$E(\gamma) = \int_0^T \mathbf{g}_{\gamma(t)}(\dot{\gamma}(t), \dot{\gamma}(t)) \, dt$$

with  $T$  fixed (and fixed initial and final point), then  $v = \sqrt{\mathbf{g}_{\gamma(t)}(\dot{\gamma}(t), \dot{\gamma}(t))}$  is constant and  $\gamma$  is also a minimizer of  $l(\cdot)$ . On the other hand, a minimizer  $\gamma$  of  $l(\cdot)$  such that  $v$  is constant is a minimizer of  $E(\cdot)$  with  $T = l(\gamma)/v$ .

A *geodesic* for the sub-Riemannian manifold is a curve  $\gamma : [0, T] \rightarrow M$  such that for every sufficiently small interval  $[t_1, t_2] \subset [0, T]$ ,  $\gamma|_{[t_1, t_2]}$  is a minimizer of  $E(\cdot)$ . A geodesic for which  $\mathbf{g}_{\gamma(t)}(\dot{\gamma}(t), \dot{\gamma}(t))$  is (constantly) equal to one is said to be parametrized by arclength.

Locally, the pair  $(\Delta, \mathbf{g})$  can be given by assigning a set of  $m$  smooth vector fields that are orthonormal for  $\mathbf{g}$ , i.e.,

$$(7) \quad \Delta(q) = \text{span}\{F_1(q), \dots, F_m(q)\}, \quad \mathbf{g}_q(F_i(q), F_j(q)) = \delta_{ij}.$$

When  $(\Delta, \mathbf{g})$  can be defined as in (7) by  $m$  vector fields defined globally, we say that the sub-Riemannian manifold is *trivializable*.

Given a  $(n, m)$ -trivializable sub-Riemannian manifold, the problem of finding a curve minimizing the energy between two fixed points  $q_0, q_1 \in M$  is naturally formulated as the optimal control problem

$$(8) \quad \dot{q} = \sum_{i=1}^m u_i F_i(q), \quad u_i \in \mathbb{R}, \quad \int_0^T \sum_{i=1}^m u_i^2(t) \, dt \rightarrow \min, \quad q(0) = q_0, \quad q(T) = q_1.$$

It is a standard fact that this optimal control problem is equivalent to the minimum time problem with controls  $u_1, \dots, u_m$  satisfying  $u_1^2 + \dots + u_m^2 \leq 1$ .

When the manifold is analytic and the orthonormal frame can be assigned through  $m$  analytic vector fields, we say that the sub-Riemannian manifold is *analytic*.

In this paper we are concerned with sub-Riemannian manifolds that are trivializable and analytic since they are given in terms of left-invariant vector fields on Lie groups.

## 2.2. First order necessary conditions, cut locus, and conjugate locus.

Consider a trivializable  $(n, m)$ -sub-Riemannian manifold. Solutions to the optimal control problem (8) are computed via the PMP (see, for instance, [3, 11, 21, 24]) that is a first order necessary condition for optimality and generalizes the Weierstraß conditions of the calculus of variations. For each optimal curve, the PMP provides a lift to the cotangent bundle that is a solution to a suitable pseudo-Hamiltonian system.

**THEOREM 3** (PMP for the problem (8)). *Let  $M$  be an  $n$ -dimensional smooth manifold, and consider the minimization problem (8), in the class of Lipschitz continuous curves, where  $F_i$ ,  $i = 1, \dots, m$  are smooth vector fields on  $M$  and the final time  $T$  is fixed. Consider the map  $\mathbf{H} : T^*M \times \mathbb{R} \times \mathbb{R}^m \rightarrow \mathbb{R}$  defined by*

$$\mathbf{H}(q, \lambda, p_0, u) := \left\langle \lambda, \sum_{i=1}^m u_i F_i(q) \right\rangle + p_0 \sum_{i=1}^m u_i^2(t).$$

*If the curve  $q(\cdot) : [0, T] \rightarrow M$  corresponding to the control  $u(\cdot) : [0, T] \rightarrow \mathbb{R}^m$  is optimal, then there exist a never vanishing Lipschitz continuous covector  $\lambda(\cdot) : t \in [0, T] \mapsto \lambda(t) \in T_{q(t)}^*M$  and a constant  $p_0 \leq 0$  such that, for a.e.  $t \in [0, T]$ ,*

- (i)  $\dot{q}(t) = \frac{\partial \mathbf{H}}{\partial \lambda}(q(t), \lambda(t), p_0, u(t))$ ,
- (ii)  $\dot{\lambda}(t) = -\frac{\partial \mathbf{H}}{\partial q}(q(t), \lambda(t), p_0, u(t))$ , and
- (iii)  $\frac{\partial \mathbf{H}}{\partial u}(q(t), \lambda(t), p_0, u(t)) = 0$ .

**Remark 1.** A curve  $q(\cdot) : [0, T] \rightarrow M$  satisfying the PMP is said to be an *extremal*. In general, an extremal may correspond to more than one pair  $(\lambda(\cdot), p_0)$ . If an extremal satisfies the PMP with  $p_0 \neq 0$ , then it is called a *normal extremal*. If it satisfies the PMP with  $p_0 = 0$  it is called an *abnormal extremal*. An extremal can be both normal and abnormal. For normal extremals one can normalize  $p_0 = -1/2$ .

If an extremal satisfies the PMP only with  $p_0 = 0$ , then it is called a *strict abnormal extremal*. If a strict abnormal extremal is optimal, then it is called a *strict abnormal minimizer*. For a deep analysis of abnormal extremals in sub-Riemannian geometry, see [8, 15].

It is well known that all normal extremals are geodesics (see, for instance, [3]). Moreover, if there are no strict abnormal minimizers, then all geodesics are normal extremals for some fixed final time  $T$ . This always will be the case in this paper; indeed, we are concerned with sub-Riemannian manifolds of dimension 3, defined by a pair of vector fields  $F_1$  and  $F_2$  such that  $\forall q \in M$ ,  $\text{span}\{F_1(q), F_2(q), [F_1(q), F_2(q)]\} = T_q M$ , i.e., the so called three-dimensional *contact case*, for which there are no abnormal extremals (not even nonstrict).

In this case, from (iii) one gets  $u_i(t) = \langle \lambda(t), F_i(t) \rangle$ ,  $i = 1, \dots, m$ , and the PMP becomes much simpler: a curve  $q(\cdot)$  is a geodesic if and only if it is the projection on  $M$  of a solution  $(\lambda(t), q(t))$  for the Hamiltonian system on  $T^*M$  corresponding to

$$H(\lambda, q) = \frac{1}{2} \left( \sum_{i=1}^m \langle \lambda, F_i(q) \rangle^2 \right), \quad q \in M, \quad \lambda \in T_q^*M$$

satisfying  $H(\lambda(0), q(0)) \neq 0$ .

**Remark 2.** Notice that  $H$  is constant along any given solution of the Hamiltonian system. Moreover,  $H = \frac{1}{2}$  if and only if the geodesic is parametrized by arclength. In the following, for simplicity of notation we assume that all geodesics are defined for  $t \in [0, +\infty)$ .

Fix  $q_0 \in M$ . For every  $\lambda_0 \in T_{q_0}^*M$  satisfying

$$(9) \quad H(\lambda_0, q_0) = 1/2$$

and every  $t > 0$ , define the *exponential map*  $\text{Exp}(\lambda_0, t)$  as the projection on  $M$  of the solution, evaluated at time  $t$ , of the Hamiltonian system associated with  $H$ , with initial condition  $\lambda(0) = \lambda_0$  and  $q(0) = q_0$ . Notice that condition (9) defines a hypercylinder  $\Lambda_{q_0} \simeq S^{m-1} \times \mathbb{R}^{n-m}$  in  $T_{q_0}^* M$ .

**DEFINITION 4.** *The **conjugate locus from**  $q_0$  is the set  $C_{q_0}$  of critical values of the map*

$$\begin{aligned} \text{Exp} : \Lambda_{q_0} \times \mathbb{R}^+ &\rightarrow M, \\ (\lambda_0, t) &\mapsto \text{Exp}(\lambda_0, t). \end{aligned}$$

For every  $\bar{\lambda}_0 \in \Lambda_{q_0}$ , let  $t(\bar{\lambda}_0)$  be the  $n$ th positive time, if it exists, for which the map  $(\lambda_0, t) \mapsto \text{Exp}(\lambda_0, t)$  is singular at  $(\bar{\lambda}_0, t(\bar{\lambda}_0))$ . The  **$n$ th conjugate locus from**  $q_0$   $C_{q_0}^n$  is the set  $\{\text{Exp}(\bar{\lambda}_0, t(\bar{\lambda}_0)) \mid t(\bar{\lambda}_0) \text{ exists}\}$ .

The **cut locus** from  $q_0$  is the set  $K_{q_0}$  of points reached optimally by more than one geodesic, i.e., the set

$$K_{q_0} = \left\{ q \in M \mid \exists \begin{array}{l} \lambda_1, \lambda_2 \in \Lambda_{q_0}, \lambda_1 \neq \lambda_2, \\ t \in \mathbb{R}^+ \end{array} \text{ such that } \begin{array}{l} q = \text{Exp}(\lambda_1, t), \\ q = \text{Exp}(\lambda_2, t), \\ \text{Exp}(\lambda_1, \cdot) \text{ optimal in } [0, t], \\ \text{Exp}(\lambda_2, \cdot) \text{ optimal in } [0, t]. \end{array} \right\}$$

**Remark 3.** It is a standard fact that for every  $\bar{\lambda}_0$  satisfying (9), the set  $T(\bar{\lambda}_0) = \{\bar{t} > 0 \mid \text{Exp}(\lambda, t) \text{ is singular at } (\bar{\lambda}_0, \bar{t})\}$  is a discrete set (see, for instance, [3]).

**Remark 4.** Let  $(M, \Delta, \mathbf{g})$  be a sub-Riemannian manifold. Fix  $q_0 \in M$  and assume that

- (i) Each point of  $M$  is reached by an optimal geodesic starting from  $q_0$ ;
- (ii) there are no abnormal minimizers.

The following facts are well known (a proof in the three-dimensional contact case can be found in [4]):

(i) The first conjugate locus  $C_{q_0}^1$  is the set of points where the geodesics starting from  $q_0$  lose local optimality;

(ii) if  $q(\cdot)$  is a geodesic starting from  $q_0$ , and  $\bar{t}$  is the first positive time such that  $q(\bar{t}) \in K_{q_0} \cup C_{q_0}^1$ , then  $q(\cdot)$  loses optimality in  $\bar{t}$ ; i.e., it is optimal in  $[0, \bar{t}]$  and not optimal in  $[0, t]$  for any  $t > \bar{t}$ ;

(iii) if a geodesic  $q(\cdot)$  starting from  $q_0$  loses optimality at  $\bar{t} > 0$ , then  $q(\bar{t}) \in K_{q_0} \cup C_{q_0}^1$ .

As a consequence, when the first conjugate locus is included in the cut locus (as in our cases; see section 5), the cut locus is the set of points where the geodesics lose optimality.

**Remark 5.** It is well known that, while in Riemannian geometry  $K_{q_0}$  is never adjacent to  $q_0$ , in sub-Riemannian geometry this is always the case. See [2].

**2.3.  $\mathfrak{k} \oplus \mathfrak{p}$  sub-Riemannian manifolds.** For the sake of simplicity in the exposition, throughout the paper, when we deal with Lie groups and Lie algebras, we always consider that they are groups and algebras of matrices.

Let  $\mathbf{L}$  be a simple Lie algebra and  $\text{Kil}(X, Y) = \text{Tr}(ad_X \circ ad_Y)$  its Killing form. Recall that the Killing form defines a nondegenerate pseudoscalar product on  $\mathbf{L}$ . In the following we recall what we mean by a Cartan decomposition of  $\mathbf{L}$ .

**DEFINITION 5.** *A Cartan decomposition of a simple Lie algebra  $\mathbf{L}$  is any decomposition of the form*

$$(10) \quad \mathbf{L} = \mathfrak{k} \oplus \mathfrak{p}, \text{ where } [\mathfrak{k}, \mathfrak{k}] \subseteq \mathfrak{k}, \quad [\mathfrak{p}, \mathfrak{p}] \subseteq \mathfrak{k}, \quad [\mathfrak{k}, \mathfrak{p}] \subseteq \mathfrak{p}.$$

DEFINITION 6. Let  $G$  be a simple Lie group with Lie algebra  $\mathbf{L}$ . Let  $\mathbf{L} = \mathbf{k} \oplus \mathbf{p}$  be a Cartan decomposition of  $\mathbf{L}$ . In the case in which  $G$  is noncompact, assume that  $\mathbf{k}$  is the maximal compact subalgebra of  $\mathbf{L}$ .

On  $G$ , consider the distribution  $\Delta(g) = g\mathbf{p}$  endowed with the Riemannian metric  $\mathbf{g}_g(v_1, v_2) = \langle g^{-1}v_1, g^{-1}v_2 \rangle$ , where  $\langle \cdot, \cdot \rangle := \alpha \operatorname{Kil}|_{\mathbf{p}}(\cdot, \cdot)$  and  $\alpha < 0$  (resp.,  $\alpha > 0$ ) if  $G$  is compact (resp., noncompact).

In this case we say that  $(G, \Delta, \mathbf{g})$  is a  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold.

The constant  $\alpha$  is clearly not relevant. It is chosen just to obtain good normalizations.

Remark 6. In the compact (resp., noncompact) case, the fact that  $\mathbf{g}$  is positive definite on  $\Delta$  is guaranteed by the requirement  $\alpha < 0$  (resp., by the requirements  $\alpha > 0$  and  $\mathbf{k}$  maximal compact subalgebra).

Let  $\{X_j\}$  be an orthonormal frame for the subspace  $\mathbf{p} \subset \mathbf{L}$ , with respect to the metric defined in Definition 6. Then the problem of finding the minimal energy between the identity and a point  $g_1 \in G$  in fixed time  $T$  becomes the left-invariant optimal control problem

$$\dot{g} = g \left( \sum_j u_j X_j \right), \quad u_j \in L^\infty(0, T), \quad \int_0^T \sum_j u_j^2(t) dt \rightarrow \min, \quad g(0) = \operatorname{Id}, \quad g(T) = g_1.$$

This problem admits a solution; see, for instance, Chapter 5 of [13].

For  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifolds, one can prove that strict abnormal extremals are never optimal, since the *Goh condition* (see [3]) is never satisfied. Moreover, the Hamiltonian system given by the PMP is integrable and the explicit expression of geodesics starting from the identity and parametrized by arclength is

$$(11) \quad g(t) = e^{(A_k + A_p)t} e^{-A_k t},$$

where  $A_k \in \mathbf{k}$ ,  $A_p \in \mathbf{p}$ , and  $\langle A_p, A_p \rangle = 1$ . This formula is well known in the community. It was used independently by Agrachev [1], Brockett [14], and Kupka (oral communication). The first complete proof was written by Jurdjevic in [22]. The proof that strict abnormal extremals are never optimal was first written in [10]. See also [3, 23].

Remark 7. In the three-dimensional case, the Hamiltonian system given by the PMP is indeed integrable even if the cost is not built with the Killing form (biinvariant) but is only left-invariant. For the case of  $SO(3)$  see [9].

**3.  $SU(2)$ ,  $SO(3)$ ,  $SL(2)$ , their geodesics, and their conjugate loci.** In this section we fix coordinates on  $SU(2)$ ,  $SO(3)$ ,  $SL(2)$ , and we apply formula (11) in order to get the explicit expressions for geodesics and conjugate loci.

**3.1. The  $\mathbf{k} \oplus \mathbf{p}$  problem on  $SU(2)$ .** The Lie group  $SU(2)$  is the group of unitary unimodular  $2 \times 2$  complex matrices

$$SU(2) = \left\{ \begin{pmatrix} \alpha & \beta \\ -\bar{\beta} & \bar{\alpha} \end{pmatrix} \in \operatorname{Mat}(2, \mathbb{C}) \mid |\alpha|^2 + |\beta|^2 = 1 \right\}.$$

It is compact and simply connected. The Lie algebra of  $SU(2)$  is the algebra of anti-Hermitian traceless  $2 \times 2$  complex matrices

$$su(2) = \left\{ \begin{pmatrix} i\alpha & \beta \\ -\bar{\beta} & -i\alpha \end{pmatrix} \in \operatorname{Mat}(2, \mathbb{C}) \mid \alpha \in \mathbb{R}, \beta \in \mathbb{C} \right\}.$$

A basis of  $su(2)$  is  $\{p_1, p_2, k\}$ , where

$$(12) \quad p_1 = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad p_2 = \frac{1}{2} \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \quad k = \frac{1}{2} \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix},$$

whose commutation relations are  $[p_1, p_2] = k$ ,  $[p_2, k] = p_1$ , and  $[k, p_1] = p_2$ . Recall that for  $su(n)$  we have  $\text{Kil}(X, Y) = 2n\text{Tr}(XY)$  (see [20, pp. 186, 516]); thus for  $su(2)$ ,  $\text{Kil}(X, Y) = 4\text{Tr}(XY)$  and, in particular,  $\text{Kil}(p_i, p_j) = -2\delta_{ij}$ . The choice of the subspaces

$$\mathbf{k} = \text{span}\{k\} \quad \mathbf{p} = \text{span}\{p_1, p_2\}$$

provides a *Cartan decomposition* for  $su(2)$ . Moreover,  $\{p_1, p_2\}$  is an orthonormal frame for the inner product  $\langle \cdot, \cdot \rangle = -\frac{1}{2}\text{Kil}(\cdot, \cdot)$  restricted to  $\mathbf{p}$ .

Defining  $\Delta(g) = g\mathbf{p}$  and  $\mathbf{g}_g(v_1, v_2) = \langle g^{-1}v_1, g^{-1}v_2 \rangle$ , we have that  $(SU(2), \Delta, \mathbf{g})$  is a  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold.

*Remark 8.* Observe that all the  $\mathbf{k} \oplus \mathbf{p}$  structures that one can define on  $SU(2)$  are equivalent. For instance, one could set  $\mathbf{k} = \text{span}\{p_1\}$  and  $\mathbf{p} = \text{span}\{p_2, k\}$ .

Recall that

$$SU(2) \simeq S^3 = \left\{ \begin{pmatrix} \alpha \\ \beta \end{pmatrix} \in \mathbb{C}^2 \mid |\alpha|^2 + |\beta|^2 = 1 \right\}$$

via the isomorphism

$$\phi : \begin{pmatrix} SU(2) & \rightarrow & S^3, \\ \begin{pmatrix} \alpha & \beta \\ -\bar{\beta} & \bar{\alpha} \end{pmatrix} & \mapsto & \begin{pmatrix} \alpha \\ \beta \end{pmatrix}. \end{pmatrix}$$

In the following we always write elements of  $SU(2)$  as pairs of complex numbers.

**3.1.1. Expression of geodesics.** We compute the explicit expression of geodesics using the formula (11). Consider an initial covector  $\lambda = \lambda(\theta, c) = \cos(\theta)p_1 + \sin(\theta)p_2 + ck \in \Lambda_{\text{Id}}$ . The corresponding exponential map is

$$\text{Exp}(\theta, c, t) := \text{Exp}(\lambda(\theta, c), t) = e^{(\cos(\theta)p_1 + \sin(\theta)p_2 + ck)t} e^{-ckt} = \begin{pmatrix} \alpha \\ \beta \end{pmatrix}$$

with

$$\begin{aligned} \alpha &= \frac{c \sin(\frac{ct}{2}) \sin(\sqrt{1+c^2}\frac{t}{2})}{\sqrt{1+c^2}} + \cos\left(\frac{ct}{2}\right) \cos\left(\sqrt{1+c^2}\frac{t}{2}\right) \\ &\quad + i \left( \frac{c \cos(\frac{ct}{2}) \sin(\sqrt{1+c^2}\frac{t}{2})}{\sqrt{1+c^2}} - \sin\left(\frac{ct}{2}\right) \cos\left(\sqrt{1+c^2}\frac{t}{2}\right) \right), \\ \beta &= \frac{\sin(\sqrt{1+c^2}\frac{t}{2})}{\sqrt{1+c^2}} \left( \cos\left(\frac{ct}{2} + \theta\right) + i \sin\left(\frac{ct}{2} + \theta\right) \right). \end{aligned}$$

We have the following symmetry properties:

(i) *cylindrical symmetry*:

$$\text{Exp}(\theta, c, t) = \begin{pmatrix} 1 & 0 \\ 0 & e^{i\theta} \end{pmatrix} \text{Exp}(0, c, t);$$

FIG. 3. Left: construction of the 2-dim picture of  $S^2$ . Right: the 3-dim picture of  $S^3$ .

(ii) *central symmetry*: Set  $\begin{pmatrix} \alpha \\ \beta \end{pmatrix} = \text{Exp}(\theta, c, t)$ . We have

$$\text{Exp}(\theta, -c, t) = \begin{cases} \begin{pmatrix} \bar{\alpha} \\ e^{2i(\theta - \arg(\beta))}\beta \end{pmatrix} & \text{if } \beta \neq 0, \\ \begin{pmatrix} \bar{\alpha} \\ 0 \end{pmatrix} & \text{if } \beta = 0. \end{cases}$$

**3.1.2. Pictures of  $S^2$  and  $S^3$ .** We recall a standard construction for representing  $S^2$  in a two-dimensional space and  $S^3$  in a three-dimensional space. For more details, see, e.g., [26]. Consider  $S^2 \subset \mathbb{R}^3$  and flatten it on the equator plane, pushing the northern hemisphere down and the southern hemisphere up, getting two superimposed disks  $D^2$  joined along their circular boundaries. The construction is drawn in Figure 3 (left). Similarly, consider  $S^3 \subset \mathbb{C}^2 \simeq \mathbb{R}^4$ : it can be viewed as two superimposed balls joined along their boundaries. In this case the boundaries are two spheres  $S^2$ . A picture of  $S^3$  is given in Figure 3 (right).

**3.1.3. The conjugate locus.** Recall that all the partial derivatives of  $\text{Exp}$  evaluated in  $(\theta, c, t)$  lie in  $T_g SU(2) = g \cdot su(2)$  with  $g = \text{Exp}(\theta, c, t)$ . One can easily check that the three vectors  $g^{-1} \cdot \frac{\partial \text{Exp}}{\partial \theta} \big|_{(\theta, c, t)}$ ,  $g^{-1} \cdot \frac{\partial \text{Exp}}{\partial c} \big|_{(\theta, c, t)}$ ,  $g^{-1} \cdot \frac{\partial \text{Exp}}{\partial t} \big|_{(\theta, c, t)} \in su(2)$  are linearly dependent (hence  $g$  is a conjugate point) if and only if

$$\sin\left(\sqrt{1+c^2}\frac{t}{2}\right)\left(2\sin\left(\sqrt{1+c^2}\frac{t}{2}\right)-\sqrt{1+c^2}t\cos\left(\sqrt{1+c^2}\frac{t}{2}\right)\right)=0.$$

The first term is 0 if and only if  $g \in e^{\mathbf{k}} = \left\{ \begin{pmatrix} \alpha \\ 0 \end{pmatrix} \mid |\alpha| = 1 \right\}$ , while the second vanishes if and only if  $\sqrt{1+c^2}\frac{t}{2} = \tan\left(\sqrt{1+c^2}\frac{t}{2}\right)$ ; hence we have two series of conjugate

 FIG. 4.  $\mathfrak{k} \oplus \mathfrak{p}$  problem on  $SU(2)$ : projection of the odd conjugate loci.

 FIG. 5.  $\mathfrak{k} \oplus \mathfrak{p}$  problem on  $SU(2)$ : projection of the 2nd, 4th, and 6th conjugate loci.

times as follows:

(i) first series:  $t_{2n-1} = \frac{2n\pi}{\sqrt{1+c^2}}$ , to which correspond the conjugate loci  $C_{\text{Id}}^{2n-1} = e^{\mathbf{k}} \setminus \text{Id}$ ;

(ii) second series:  $t_{2n} = \frac{2x_n}{\sqrt{1+c^2}}$ , where  $\{x_1, x_2, \dots\}$  is the ordered set of the strictly positive solutions of  $x = \tan(x)$ , to which correspond the conjugate loci

$$C_{\text{Id}}^{2n} = \left\{ \left( \begin{array}{c} \frac{c \sin(x_n)}{\sqrt{1+c^2}} e^{i(\frac{\pi}{2}-y_n)} + \cos(x_n) e^{-iy_n} \\ \frac{\sin(x_n)}{\sqrt{1+c^2}} e^{i\theta} \end{array} \right) \mid \begin{array}{l} c \in \mathbb{R}, \\ \theta \in \mathbb{R}/2\pi \end{array} \right\},$$

where  $y_n = \frac{cx_n}{\sqrt{1+c^2}}$ .

*Remark 9.* Notice that all the geodesics have a countable number of conjugate times.

We present some images of conjugate loci (Figures 4 and 5). For simplicity we present images of their sections with the plane  $\text{Re}(\beta) = 0$ . The complete images can be recovered using cylindrical symmetry.

*Remark 10.* Notice that the second conjugate locus is a two-dimensional submanifold of  $SU(2)$ , while the other even conjugate loci have self-intersections.

**3.2. The  $\mathfrak{k} \oplus \mathfrak{p}$  problem on  $SO(3)$ .** The Lie group  $SO(3)$  is the group of special orthogonal  $3 \times 3$  real matrices

$$SO(3) = \{g \in \text{Mat}(3, \mathbb{R}) \mid gg^T = \text{Id}, \det(g) = 1\}.$$

It is compact and its fundamental group is  $\mathbb{Z}_2$ . The Lie algebra of  $SO(3)$  is the algebra of skew-symmetric  $3 \times 3$  real matrices

$$\mathfrak{so}(3) = \left\{ \begin{pmatrix} 0 & -a & b \\ a & 0 & -c \\ -b & c & 0 \end{pmatrix} \in \text{Mat}(3, \mathbb{R}) \right\}.$$

A basis of  $so(3)$  is  $\{p_1, p_2, k\}$ , where

$$p_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \quad p_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad k = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

whose commutation relations are  $[p_1, p_2] = k$ ,  $[p_2, k] = p_1$ , and  $[k, p_1] = p_2$ . Recall that  $so(3)$  and  $su(2)$  are isomorphic as Lie algebras, while  $SU(2)$  is a double covering of  $SO(3)$ .

For  $so(3)$  we have  $\text{Kil}(X, Y) = \text{Tr}(XY)$  so, in particular,  $\text{Kil}(p_i, p_j) = -2\delta_{ij}$ . The choice of the subspaces

$$\mathbf{k} = \text{span}\{k\}, \quad \mathbf{p} = \text{span}\{p_1, p_2\}$$

gives a *Cartan decomposition* for  $so(3)$ . Moreover,  $\{p_1, p_2\}$  is an orthonormal frame for the inner product  $\langle \cdot, \cdot \rangle = -\frac{1}{2}\text{Kil}(\cdot, \cdot)$  restricted to  $\mathbf{p}$ .

Defining  $\Delta(g) = g\mathbf{p}$  and  $\mathbf{g}_g(v_1, v_2) = \langle g^{-1}v_1, g^{-1}v_2 \rangle$ , we have that  $(SO(3), \Delta, \mathbf{g})$  is a  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold. As for  $SU(2)$ , all the  $\mathbf{k} \oplus \mathbf{p}$  structures that one can define on  $SO(3)$  are equivalent.

**3.2.1. Expression of geodesics.** Consider an initial covector  $\lambda = \lambda(\theta, c) = \cos(\theta)p_1 + \sin(\theta)p_2 + ck \in \Lambda_{\text{Id}}$ . Using formula (11), we have that the exponential map is

$$\text{Exp}(\theta, c, t) := \text{Exp}(\lambda(\theta, c), t) = e^{(\cos(\theta)p_1 + \sin(\theta)p_2 + ck)t} e^{-ckt} = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix}$$

with

$$\begin{aligned} a_{11} &= K_1 \cos(ct) + K_2 \cos(2\theta + ct) + K_3 c \sin(ct), \\ a_{12} &= K_1 \sin(ct) + K_2 \sin(2\theta + ct) - K_3 c \cos(ct), & a_{13} &= K_4 \cos(\theta) + K_3 \sin(\theta), \\ a_{21} &= -K_1 \sin(ct) + K_2 \sin(2\theta + ct) + K_3 c \cos(ct), \\ a_{22} &= K_1 \cos(ct) - K_2 \cos(2\theta + ct) + K_3 c \sin(ct), & a_{23} &= -K_3 \cos(\theta) + K_4 \sin(\theta), \\ a_{21} &= K_4 \cos(\theta + ct) - K_3 \sin(\theta + ct), & a_{22} &= K_3 \cos(\theta + ct) + K_4 \sin(\theta + ct), \\ a_{23} &= \frac{\cos(\sqrt{1+c^2}t) + c^2}{1+c^2}, \\ K_1 &= \frac{1 + (1+2c^2)\cos(\sqrt{1+c^2}t)}{2(1+c^2)}, & K_2 &= \frac{1 - \cos(\sqrt{1+c^2}t)}{2(1+c^2)}, \\ K_3 &= \frac{\sin(\sqrt{1+c^2}t)}{\sqrt{1+c^2}}, & K_4 &= \frac{c(1 - \cos(\sqrt{1+c^2}t))}{1+c^2}. \end{aligned}$$

The set of geodesics has symmetry properties similar to the  $SU(2)$  case. The conjugate locus can be obtained from that of the  $SU(2)$  by the canonical projection  $SU(2) \rightarrow SO(3)$ . As for  $SU(2)$ , all the geodesics have a countable number of conjugate points.

**3.3. The  $\mathbf{k} \oplus \mathbf{p}$  problem on  $SL(2)$ .** The Lie group  $SL(2)$  is the group of  $2 \times 2$  real matrices with determinant 1,

$$SL(2) = \{g \in \text{Mat}(2, \mathbb{R}) \mid \det(g) = 1\}.$$

It is a noncompact group and its fundamental group is  $\mathbb{Z}$ . The Lie algebra of  $SL(2)$  is the algebra of traceless  $2 \times 2$  real matrices

$$sl(2) = \left\{ \begin{pmatrix} a & b \\ c & -a \end{pmatrix} \in \text{Mat}(2, \mathbb{R}) \right\}.$$

A basis of  $sl(2)$  is  $\{p_1, p_2, k\}$ , where

$$p_1 = \frac{1}{2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad p_2 = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad k = \frac{1}{2} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$$

whose commutation relations are  $[p_1, p_2] = -k$ ,  $[p_2, k] = p_1$ , and  $[k, p_1] = p_2$ . For  $sl(n)$  we have  $\text{Kil}(X, Y) = 2n\text{Tr}(XY)$  (see [20]); hence for  $sl(2)$ ,  $\text{Kil}(X, Y) = 4\text{Tr}(XY)$  and, in particular,  $\text{Kil}(p_i, p_j) = 2\delta_{ij}$ . The choice of the subspaces

$$\mathbf{k} = \text{span}\{k\}, \quad \mathbf{p} = \text{span}\{p_1, p_2\}$$

provides a *Cartan decomposition* for  $sl(2)$ . For  $sl(2)$  the Cartan decomposition is unique, since  $\mathbf{k}$  must be the maximal compact subalgebra. Moreover,  $\{p_1, p_2\}$  is a orthonormal frame for the inner product  $\langle \cdot, \cdot \rangle = \frac{1}{2}\text{Kil}(\cdot, \cdot)$  restricted to  $\mathbf{p}$ .

Defining  $\Delta(g) = g\mathbf{p}$  and  $\mathbf{g}_g(v_1, v_2) = \langle g^{-1}v_1, g^{-1}v_2 \rangle$ , we have that  $(SL(2), \Delta, \mathbf{g})$  is a  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold.

**3.3.1. Expression of geodesics.** Consider an initial covector  $\lambda = \lambda(\theta, c) = \cos(\theta)p_1 + \sin(\theta)p_2 + ck \in \Lambda_{\text{Id}}$ . Using formula (11), we have that the exponential map is

$$\text{Exp}(\theta, c, t) := \text{Exp}(\lambda(\theta, c), t) = e^{(\cos(\theta)p_1 + \sin(\theta)p_2 + ck)t} e^{-ckt} = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

with

$$\begin{aligned} a_{11} &= K_1 \cos\left(c\frac{t}{2}\right) + K_2 \left( \cos\left(\theta + c\frac{t}{2}\right) + c \sin\left(c\frac{t}{2}\right) \right), \\ a_{12} &= K_1 \sin\left(c\frac{t}{2}\right) + K_2 \left( \sin\left(\theta + c\frac{t}{2}\right) - c \cos\left(c\frac{t}{2}\right) \right), \\ a_{21} &= -K_1 \sin\left(c\frac{t}{2}\right) + K_2 \left( \sin\left(\theta + c\frac{t}{2}\right) + c \cos\left(c\frac{t}{2}\right) \right), \\ a_{22} &= K_1 \cos\left(c\frac{t}{2}\right) + K_2 \left( -\cos\left(\theta + c\frac{t}{2}\right) + c \sin\left(c\frac{t}{2}\right) \right), \\ K_1 &= \begin{cases} \text{Cosh}\left(\sqrt{1-c^2}\frac{t}{2}\right), & c \in [-1, 1], \\ \cos\left(\sqrt{c^2-1}\frac{t}{2}\right), & c \in (-\infty, -1) \cup (1, +\infty), \end{cases} \\ K_2 &= \begin{cases} \frac{\text{Sinh}\left(\sqrt{1-c^2}\frac{t}{2}\right)}{\sqrt{1-c^2}}, & c \in (-1, 1), \\ \frac{t}{2}, & c \in \{-1, 1\}, \\ \frac{\sin\left(\sqrt{c^2-1}\frac{t}{2}\right)}{\sqrt{c^2-1}}, & c \in (-\infty, -1) \cup (1, +\infty). \end{cases} \end{aligned}$$

### 3.3.2. A useful decomposition of $SL(2)$ .

**PROPOSITION 7.** *For every  $g \in SL(2)$ , there exists a unique pair  $r \in e^{\mathbf{k}}$ ,  $s \in e^{\mathbf{p}}$  such that  $g = rs$ .*

FIG. 6. A picture of  $SL(2)$ .

*Proof.* First, notice that  $e^{\mathbf{K}} = SO(2)$  and that  $e^{\mathbf{P}}$  is the set of  $2 \times 2$  symmetric matrices with determinant 1 and positive trace.

Take

$$r = \begin{pmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{pmatrix} \in e^{\mathbf{K}} \quad \text{and} \quad g = \begin{pmatrix} \alpha + \delta & \beta - \gamma \\ \beta + \gamma & \alpha - \delta \end{pmatrix} \in SL(2).$$

Notice that  $(\alpha, \gamma) \neq (0, 0)$ . We have to prove that there exists a unique  $\theta \in \mathbb{R}/2\pi$  such that  $s = r^{-1}g$  is symmetric with positive trace. By direct computation, one gets that  $s$  is symmetric if and only if  $\alpha \sin(\theta) = \gamma \cos(\theta)$ . For any  $(\alpha, \gamma) \in \mathbb{R}^2 \setminus (0, 0)$ , there exist two solutions of this equation  $\theta_1, \theta_2 \in \mathbb{R}/2\pi$  with  $\theta_2 = \theta_1 + \pi$ . Thus

$$\text{Tr} \left( \begin{pmatrix} \cos(\theta_1) & \sin(\theta_1) \\ -\sin(\theta_1) & \cos(\theta_1) \end{pmatrix} g \right) = -\text{Tr} \left( \begin{pmatrix} \cos(\theta_2) & \sin(\theta_2) \\ -\sin(\theta_2) & \cos(\theta_2) \end{pmatrix} g \right).$$

Observing that a symmetric matrix with determinant 1 has nonvanishing trace, either  $\theta_1$  or  $\theta_2$  provide  $\text{Tr}(s) > 0$ .  $\square$

Topologically,  $e^{\mathbf{K}} \simeq S^1$  and  $e^{\mathbf{P}} \simeq \mathbb{R}^2$ ; hence  $SL(2) \simeq S^1 \times \mathbb{R}^2$ . In the following, we represent  $SL(2)$  as the set  $\mathbb{R}^2 \times [0, 1]$  with the identification rule  $(a, b, 0) \sim (a, b, 1)$ . See Figure 6.

**3.3.3. Symmetries in the  $SL(2)$  problem.** We have the following symmetry properties:

(i) *cylindrical symmetry*:  $\text{Exp}(\theta, c, t) = e^{z_0 k} e^{x p_1 + y p_2}$ , where

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{pmatrix} \begin{pmatrix} x_0 \\ y_0 \end{pmatrix}$$

and  $(x_0, y_0, z_0)$  are defined by  $\text{Exp}(0, c, t) = e^{z_0 k} e^{x_0 p_1 + y_0 p_2}$ ;

(ii) *central symmetry*:  $\text{Exp}(\theta, -c, t) = e^{-z_0 k} e^{x p_1 + y p_2}$ , where

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \cos(2\theta) & \sin(2\theta) \\ \sin(2\theta) & -\cos(2\theta) \end{pmatrix} \begin{pmatrix} x_0 \\ y_0 \end{pmatrix}$$

and  $(x_0, y_0, z_0)$  are defined by  $\text{Exp}(\theta, c, t) = e^{z_0 k} e^{x_0 p_1 + y_0 p_2}$ .

**3.3.4. The conjugate locus.** With arguments similar to those of section 3.1.3, one checks that  $g = \text{Exp}(\theta, c, t)$  is a conjugate point if and only if

$$\begin{cases} \sinh(d) (2\sinh(d) - t\sqrt{1-c^2}\cosh(d)) = 0, & c \in (-1, 1), \\ \pm \frac{t^4}{12} = 0, & c = \pm 1, \\ \sin(d) (2\sin(d) - t\sqrt{c^2-1}\cos(d)) = 0, & c \notin [-1, 1] \end{cases}$$

 FIG. 7.  $\mathbf{k} \oplus \mathbf{p}$  problem on  $SU(2)$ : Section of the 2nd conjugate locus.

with  $d = \sqrt{1 - c^2} \frac{t}{2}$  when  $c \in (-1, 1)$  and  $d = \sqrt{c^2 - 1} \frac{t}{2}$  when  $c \notin [-1, 1]$ .

The first two equations have only the trivial solution  $t = 0$ . The third gives two series of conjugate times as follows:

(i) first series:  $t_{2n-1} = \frac{2n\pi}{\sqrt{c^2-1}}$ , to which correspond the conjugate loci  $C_{\text{Id}}^{2n-1} = e^{\mathbf{k}} \setminus \text{Id}$ ;

(ii) second series:  $t_{2n} = \frac{2x_n}{\sqrt{c^2-1}}$ , where  $\{x_1, x_2, \dots\}$  is the ordered set of the strictly positive solutions of  $x = \tan(x)$ , to which correspond the conjugate loci

$$C_{\text{Id}}^{2n} = \left\{ \begin{pmatrix} a_{11}^n(c, t) & a_{12}^n(c, t) \\ a_{21}^n(c, t) & a_{22}^n(c, t) \end{pmatrix} \middle| \begin{array}{l} c \in \mathbb{R}, \\ \theta \in \mathbb{R}/2\pi \end{array} \right\}$$

with

$$\begin{aligned} a_{11}^n(c, t) &= \cos(x_n) \cos(y_n) + \frac{\sin(x_n)}{\sqrt{c^2-1}} (\cos(\theta) + c \sin(y_n)), \\ a_{12}^n(c, t) &= \cos(x_n) \sin(y_n) + \frac{\sin(x_n)}{\sqrt{c^2-1}} (\sin(\theta) - c \cos(y_n)), \\ a_{21}^n(c, t) &= -\cos(x_n) \sin(y_n) + \frac{\sin(x_n)}{\sqrt{c^2-1}} (\sin(\theta) + c \cos(y_n)), \\ a_{22}^n(c, t) &= \cos(x_n) \cos(y_n) + \frac{\sin(x_n)}{\sqrt{c^2-1}} (-\cos(\theta) + c \sin(y_n)), \end{aligned}$$

where  $y_n = \frac{cx_n}{\sqrt{c^2-1}}$ .

*Remark 11.* Notice that not all geodesics have conjugate points. Indeed,  $\text{Exp}(\theta, c, \cdot)$  has a conjugate point if and only if  $c \in (-\infty, -1) \cup (1, +\infty)$ .

We present an image of the 2nd conjugate locus (Figure 7). For simplicity we present an image of its intersection with  $\{e^{\mathbf{k}} e^{ap_1} | a \in \mathbb{R}\}$ . The complete picture can be recovered using the cylindrical symmetry.

*Remark 12.* Notice that all even conjugate loci have self-intersection.

#### 4. A sub-Riemannian structure on lens spaces.

**4.1. Definition of  $L(p, q)$ .** Fix two coprime integers  $p, q \in \mathbb{Z}$ ,  $p, q \neq 0$ . The **lens space**  $L(p, q)$  is defined as the quotient of  $SU(2)$  with respect to the identification rule

$$\begin{pmatrix} \alpha_1 \\ \beta_1 \end{pmatrix} \sim \begin{pmatrix} \alpha_2 \\ \beta_2 \end{pmatrix} \text{ if } \exists \omega \in \mathbb{C} \text{ } p\text{th root of unity such that}$$

$$\begin{pmatrix} \alpha_2 \\ \beta_2 \end{pmatrix} = \begin{pmatrix} \omega & 0 \\ 0 & \omega^q \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \beta_1 \end{pmatrix}.$$

Lens spaces are three-dimensional compact manifolds, but, except for  $L(2, 1) \simeq SO(3)$ , they are neither Lie groups nor homogeneous spaces of  $SU(2)$ . The following topological equivalences hold:  $\forall p, q, k \in \mathbb{Z}$ ,  $p, q$  coprime,  $p, q \neq 0$ , we have  $L(p, q) \simeq L(p, -q) \simeq L(-p, q) \simeq L(p, q + kp)$ . Lens spaces have highly nontrivial topology; for details we refer the reader to [25].

The following theorem permits us to choose a representative of  $L(p, q)$  in  $SU(2)$ .

PROPOSITION 8. *Consider the set*

$$E_p = \left\{ \begin{pmatrix} \alpha \\ \beta \end{pmatrix} \in SU(2) \mid \operatorname{Re}(\alpha) > 0, \frac{\operatorname{Im}(\alpha)^2}{\sin\left(\frac{\pi}{p}\right)^2} + |\beta|^2 < 1 \right\} \subset SU(2)$$

and define  $\partial E_p^+ = \partial E_p \cap \{\operatorname{Im}(\alpha) \geq 0\}$ ,  $\partial E_p^- = \partial E_p \cap \{\operatorname{Im}(\alpha) \leq 0\}$ . Endow  $\overline{E_p}$  with the equivalence relation  $\div$  defined as follows:

1. The relation is reflexive;
2. moreover, given  $\begin{pmatrix} \alpha^+ \\ \beta^+ \end{pmatrix} \in \partial E_p^+$  and  $\begin{pmatrix} \alpha^- \\ \beta^- \end{pmatrix} \in \partial E_p^-$ , we have  $\begin{pmatrix} \alpha^+ \\ \beta^+ \end{pmatrix} \div \begin{pmatrix} \alpha^- \\ \beta^- \end{pmatrix}$  if
  - (i) either  $\operatorname{Im}(\alpha^+) = -\operatorname{Im}(\alpha^-) \neq 0$  and  $\beta^+ = e^{2\pi i \frac{q}{p}} \beta^-$ ; or
  - (ii)  $\operatorname{Im}(\alpha^+) = \operatorname{Im}(\alpha^-) = 0$  and  $\beta^+ = e^{2\pi i \frac{n}{p}} \beta^-$  for some  $n \in \{1, \dots, p\}$ .

The manifold  $\overline{E_p}/\div$  is diffeomorphic to  $L(p, q)$ .

*Proof.* Take  $\begin{pmatrix} \alpha \\ \beta \end{pmatrix} \in SU(2)$  and let us look for  $\omega$  pth root of unity such that  $\begin{pmatrix} \omega\alpha \\ \omega^q\beta \end{pmatrix} \in \overline{E_p}$ . This condition is equivalent to

$$(13) \quad \operatorname{Re}(\omega\alpha) \geq 0 \text{ and } \frac{\operatorname{Im}(\omega\alpha)^2}{\sin\left(\frac{\pi}{p}\right)^2} + |\omega^q\beta|^2 \leq 1.$$

Recalling that  $|\omega^q\beta|^2 = |\beta|^2 = 1 - |\alpha|^2$  and that  $\operatorname{Im}(\omega\alpha) = |\alpha| \sin(\arg(\omega\alpha))$  if  $\alpha \neq 0$ , we see that (13) is equivalent to

$$(14) \quad \arg(\omega\alpha) \in \left[-\frac{\pi}{p}, \frac{\pi}{p}\right] \quad \text{or} \quad \alpha = 0.$$

Thus,

(i) if  $\alpha \neq 0$ , there exists at least one solution  $\omega_1$  of  $\arg(\omega\alpha) \in \left[-\frac{\pi}{p}, \frac{\pi}{p}\right]$ . Moreover, we have two distinct solutions  $\omega_1, \omega_2$  if and only if  $\arg(\omega_1\alpha) = -\frac{\pi}{p}$  and  $\arg(\omega_2\alpha) = \frac{\pi}{p}$ . In this case,

$$\begin{pmatrix} \omega_1\alpha \\ \omega_1^q\beta \end{pmatrix} = \begin{pmatrix} |\alpha|e^{-i\frac{\pi}{p}} \\ \omega_1^q\beta \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} \omega_2\alpha \\ \omega_2^q\beta \end{pmatrix} = \begin{pmatrix} |\alpha|e^{i\frac{\pi}{p}} \\ \omega_2^q\beta \end{pmatrix};$$

observe that

$$\begin{pmatrix} \omega_1\alpha \\ \omega_1^q\beta \end{pmatrix} \div \begin{pmatrix} \omega_2\alpha \\ \omega_2^q\beta \end{pmatrix}.$$

(ii) if  $\alpha = 0$ , every  $\omega$  pth root of unity satisfies  $\begin{pmatrix} 0 \\ \omega^q\beta \end{pmatrix} \in \overline{E_p}$ ; observe that for all the pairs  $\omega_1, \omega_2$  we have

$$\begin{pmatrix} 0 \\ \omega_1^q\beta \end{pmatrix} \div \begin{pmatrix} 0 \\ \omega_2^q\beta \end{pmatrix}.$$

Hence  $\forall \begin{pmatrix} \alpha \\ \beta \end{pmatrix} \in SU(2)$  we have a unique

$$\left[ \begin{pmatrix} \omega\alpha \\ \omega^q\beta \end{pmatrix} \right]_{\div} \in \overline{E_p}/_{\div};$$

i.e., the function

$$\psi : \begin{array}{ccc} L(p, q) = SU(2)/\sim & \rightarrow & \overline{E_p}/_{\div}, \\ \left[ \begin{pmatrix} \alpha \\ \beta \end{pmatrix} \right] & \mapsto & \left[ \begin{pmatrix} \omega\alpha \\ \omega^q\beta \end{pmatrix} \right]_{\div} \end{array}$$

is bijective.  $\square$

*Remark 13.* A crucial observation for what follows is that the projection

$$\Pi : \begin{array}{ccc} SU(2) & \rightarrow & L(p, q), \\ g & \mapsto & [g] \end{array}$$

is a local diffeomorphism. Moreover,  $\Pi|_{E_p} : E_p \rightarrow L(p, q) \setminus [\partial E_p]$  is a diffeomorphism. In particular,  $E_p$  contains only one representative for each equivalence classes of  $L(p, q)$ ; i.e., if  $g, h \in E_p$  and  $[g] = [h]$ , then  $g = h$ .

*Remark 14.* Proposition 8 provides a picture of  $L(p, q)$ ; recall that  $SU(2)$  is drawn as two balls in  $\mathbb{R}^3$  (see section 3.1.2). Hence  $\overline{E_p} \subset SU(2)$  is drawn as a closed ellipsoid inside one of the two balls, via the map

$$\rho : \begin{array}{ccc} \overline{E_p} & \rightarrow & \overline{B_1(0)} \subset \mathbb{R}^3, \\ \begin{pmatrix} \alpha \\ \beta \end{pmatrix} & \mapsto & (\operatorname{Re}(\beta), \operatorname{Im}(\beta), \operatorname{Im}(\alpha)). \end{array}$$

The picture of  $E_p$  is

$$F_p = \left\{ (x_1, x_2, x_3) \in \overline{B_1(0)} \mid x_1^2 + x_2^2 + \frac{x_3^2}{\sin\left(\frac{\pi}{p}\right)^2} < 1 \right\},$$

and the one of  $\overline{E_p}$  is  $\overline{F_p}$ ; see Figure 8 (left). The identification  $\div$  induces the following identification on  $\overline{F_p}$ : given  $(x_1^+, x_2^+, x_3^+) \in \partial F_p^+ = \partial F_p \cap \{x_3 \geq 0\}$  and  $(x_1^-, x_2^-, x_3^-) \in \partial F_p^- = \partial F_p \cap \{x_3 \leq 0\}$ , they are identified when

$$x_3^+ = -x_3^- \text{ and } \begin{pmatrix} x_1^+ \\ x_2^+ \end{pmatrix} = \begin{pmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{pmatrix} \begin{pmatrix} x_1^- \\ x_2^- \end{pmatrix}$$

with  $\theta = \frac{2\pi q}{p}$ ; see Figure 8 (right).

*Remark 15.* Observe that the identification rule on  $\overline{F_p}$  gives a 1-to-1 identification between  $\partial F_p \cap \{x_3 > 0\}$  and  $\partial F_p \cap \{x_3 < 0\}$ , while there are, in general, more identified points on  $\{x_1^2 + x_2^2 = 1\} \cap \{x_3 = 0\}$ ; see Figure 9.

#### 4.2. Sub-Riemannian quotient structure on $L(p, q)$ .

**PROPOSITION 9.** *The sub-Riemannian structure on  $SU(2)$  given in section 3.1 induces a 2-dim sub-Riemannian structure on  $L(p, q) = SU(2)/\sim$  via the quotient map*

$$\Pi : \begin{array}{ccc} SU(2) & \rightarrow & L(p, q), \\ x & \mapsto & [x]; \end{array}$$

FIG. 8. Left:  $\overline{F}_4$ . Right: the representation of  $L(4,1)$ , with some examples of the identification rule.

FIG. 9.  $L(4,1)$ : some examples of the identification rule on  $\{x_1^2 + x_2^2 = 1\} \cap \{x_3 = 0\}$ .

i.e.,

(i) the map

$$\tilde{\Delta} : [g] \mapsto \Pi_*(\Delta(h)) \subset T_{[g]}L(p, q) \text{ with } h \in [g]$$

is a 2-dim smooth distribution on  $L(p, q)$  that is Lie bracket generating;

(ii)  $\tilde{\mathbf{g}}_{[g]}(v_*, w_*) = \langle v_*, w_* \rangle_{[g]} := \langle v, w \rangle_h$  with  $h \in [g]$ ,  $v, w \in T_h SU(2)$ ,  $\Pi_*(v) = v_*$ ,  $\Pi_*(w) = w_*$  is a smooth positive definite scalar product on  $\tilde{\Delta}$ .

*Proof.* The role of the maps  $\Pi$  and  $\Pi_{*|_g}$  is illustrated in Figure 10.

The map  $\Pi$  is a local diffeomorphism; thus  $\Pi_{*|_g} : T_g SU(2) \rightarrow T_{[g]}L(p, q)$  is a linear isomorphism, and hence  $\Pi_{*|_g}(\Delta(g))$  is a 2-dim subspace of  $T_{[g]}L(p, q)$ .

The following two statements are consequences of Lemma 10, presented below:

(i) the distribution  $\tilde{\Delta}([g])$  is well defined; i.e.,  $\forall h_1, h_2 \in [g]$  we have

$$\Pi_{*|_{h_1}}(\Delta(h_1)) = \Pi_{*|_{h_2}}(\Delta(h_2)).$$

(ii) The positive definite scalar product  $\langle v_*, w_* \rangle_{[g]}$  is well defined; i.e.,  $\forall h_1, h_2 \in [g]$ ,  $v_1, w_1 \in T_{h_1} SU(2)$ ,  $v_2, w_2 \in T_{h_2} SU(2)$  such that  $\Pi_{*|_{h_1}}(v_1) = \Pi_{*|_{h_2}}(v_2)$  and  $\Pi_{*|_{h_1}}(w_1) = \Pi_{*|_{h_2}}(w_2)$ , we have  $\langle v_1, w_1 \rangle_{h_1} = \langle v_2, w_2 \rangle_{h_2}$ .

LEMMA 10. Let  $h_1, h_2 \in [g]$  with  $h_2 = \begin{pmatrix} \omega & 0 \\ 0 & \omega^q \end{pmatrix} h_1$ . The map

$$\phi : \begin{pmatrix} \mathbf{p} \\ n_1 \\ m_1 \\ 0 \end{pmatrix} \mapsto \begin{pmatrix} \mathbf{p} \\ \operatorname{Re}(\omega^{q-1}) & -\operatorname{Im}(\omega^{q-1}) & 0 \\ \operatorname{Im}(\omega^{q-1}) & \operatorname{Re}(\omega^{q-1}) & 0 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} n_1 \\ m_1 \\ 0 \end{pmatrix}$$

$$\begin{array}{ccc}
 T_g SU(2) & \xrightarrow{\Pi_*|_g} & T_{[g]} L(p, q) \\
 \downarrow & & \downarrow \\
 SU(2) & \xrightarrow{\Pi} & L(p, q).
 \end{array}$$

FIG. 10. The role of the maps  $\Pi$  and  $\Pi_*$ .

is bijective. Moreover, it is an isometry with respect to the positive definite scalar product  $\langle \cdot, \cdot \rangle$  and satisfies,  $\forall \eta \in \mathfrak{p}$ ,

$$\frac{d}{dt}\Big|_{t=0} [h_1 e^{t\eta}] = \frac{d}{dt}\Big|_{t=0} [h_2 e^{t\phi(\eta)}].$$

*Proof.* Let  $h = \begin{pmatrix} a & \\ & b \end{pmatrix} \in SU(2)$  and  $\eta = (n, m, 0) \in \mathfrak{p}$ . We have

$$(15) \quad h e^{t\eta} = \begin{pmatrix} a \cos\left(\sqrt{n^2 + m^2} \frac{t}{2}\right) - b \sin\left(\sqrt{n^2 + m^2} \frac{t}{2}\right) \frac{n-im}{\sqrt{n^2+m^2}} \\ b \cos\left(\sqrt{n^2 + m^2} \frac{t}{2}\right) + a \sin\left(\sqrt{n^2 + m^2} \frac{t}{2}\right) \frac{n+im}{\sqrt{n^2+m^2}} \end{pmatrix}.$$

Take  $h_1, h_2 \in [g]$  with  $h_2 = \begin{pmatrix} \omega & 0 \\ 0 & \omega^q \end{pmatrix} h_1$  and  $\eta_1, \eta_2 \in \mathfrak{p}$  with coordinates  $\eta_1 = (n_1, m_1, 0)$  and  $\eta_2 = (n_2, m_2, 0)$ . Consider the trajectories

$$[h_1 e^{t\eta_1}] = \left[ \begin{pmatrix} a \cos\left(\sqrt{n_1^2 + m_1^2} \frac{t}{2}\right) - b \sin\left(\sqrt{n_1^2 + m_1^2} \frac{t}{2}\right) \frac{n_1-im_1}{\sqrt{n_1^2+m_1^2}} \\ b \cos\left(\sqrt{n_1^2 + m_1^2} \frac{t}{2}\right) + a \sin\left(\sqrt{n_1^2 + m_1^2} \frac{t}{2}\right) \frac{n_1+im_1}{\sqrt{n_1^2+m_1^2}} \end{pmatrix} \right]$$

and

$$\begin{aligned}
 [h_2 e^{t\eta_2}] &= \left[ \begin{pmatrix} \omega a \cos\left(\sqrt{n_2^2 + m_2^2} \frac{t}{2}\right) - \omega^q b \sin\left(\sqrt{n_2^2 + m_2^2} \frac{t}{2}\right) \frac{n_2-im_2}{\sqrt{n_2^2+m_2^2}} \\ \omega^q b \cos\left(\sqrt{n_2^2 + m_2^2} \frac{t}{2}\right) + \omega a \sin\left(\sqrt{n_2^2 + m_2^2} \frac{t}{2}\right) \frac{n_2+im_2}{\sqrt{n_2^2+m_2^2}} \end{pmatrix} \right] \\
 &= \left[ \begin{pmatrix} a \cos\left(\sqrt{n_2^2 + m_2^2} \frac{t}{2}\right) - \omega^{q-1} b \sin\left(\sqrt{n_2^2 + m_2^2} \frac{t}{2}\right) \frac{n_2-im_2}{\sqrt{n_2^2+m_2^2}} \\ b \cos\left(\sqrt{n_2^2 + m_2^2} \frac{t}{2}\right) + \omega^{1-q} a \sin\left(\sqrt{n_2^2 + m_2^2} \frac{t}{2}\right) \frac{n_2+im_2}{\sqrt{n_2^2+m_2^2}} \end{pmatrix} \right].
 \end{aligned}$$

Thus  $\frac{d}{dt}\Big|_{t=0} [h_1 e^{t\eta_1}] = \frac{d}{dt}\Big|_{t=0} [h_2 e^{t\eta_2}]$  in the case

$$\begin{cases} n_1^2 + m_1^2 = n_2^2 + m_2^2, \\ n_1 - im_1 = \omega^{q-1}(n_2 - im_2), \\ n_1 + im_1 = \omega^{1-q}(n_2 + im_2), \end{cases}$$

that is equivalent to  $\omega^{q-1}(n_1 + im_1) = n_2 + im_2$ . This equation is verified for  $\eta_2 = \phi(\eta_1)$ .  $\square$

Since  $\Pi$  is a local diffeomorphism,  $\forall g \in SU(2) \exists B(g)$  such that the map  $\Pi_{*|_{B(g)}} : T_{B(g)}SU(2) \rightarrow T_{B([g])}L(p, q)$  is a diffeomorphism, and thus  $\tilde{\Delta}$  is smooth and Lie bracket generating, and  $\langle v_*, w_* \rangle_{[g]}$  is smooth as a function of  $[g]$ .  $\square$

Proposition 9 implies that the sub-Riemannian structures on  $SU(2)$  and  $L(p, q)$  defined above are locally isometric via the map  $\Pi$ . As a consequence, the geodesics of  $(L(p, q), \tilde{\Delta}, \tilde{\mathbf{g}})$  are the projection of geodesics of  $(SU(2), \Delta, \mathbf{g})$ . The conjugate locus for  $L(p, q)$  can be obtained from that of  $SU(2)$  by the projection  $\Pi$ .

*Remark 16.* One can check that the sub-Riemannian structure induced by  $SU(2)$  on  $L(2, 1) \simeq SO(3)$  is equivalent to the  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian structure on  $SO(3)$  defined in section 3.2.

**5. Cut loci and distances.** In this section we prove the main theorems of the paper; i.e., we compute cut loci for  $SU(2)$ ,  $SO(3)$ , lens spaces, and  $SL(2)$ , and we prove the formula (3) for the sub-Riemannian distance on  $SU(2)$ .

Recall that our problems satisfy the following assumptions:

(i) Each point of  $M$  is reached by an optimal geodesic starting from  $\text{Id}$ ; see section 2.3;

(ii) we are in the three-dimensional contact case, and thus there are no abnormal minimizers. Hence Remark 4 applies.

**PROPOSITION 11.** *Let  $T(\theta, c)$  be the cut time for  $\text{Exp}(\theta, c, \cdot)$  (possibly  $+\infty$  if  $\text{Exp}(\theta, c, \cdot)$  is optimal on  $[0, +\infty)$ ). Define*

$$\mathcal{D} = \{(\theta, c, t) \in \Lambda_{\text{Id}} \times \mathbb{R}^+ \mid 0 < t < T(\theta, c)\}$$

*and  $M' = M \setminus (K_{\text{Id}} \cup \text{Id})$ . The function  $\text{Exp}|_{\mathcal{D}} : \mathcal{D} \rightarrow M'$  is a diffeomorphism from  $\mathcal{D}$  to  $M'$ .*

*Proof.* Let us first check that  $\text{Exp}(\mathcal{D}) \subset M'$ . By contradiction, let  $\text{Exp}(\theta, c, t) \in M \setminus M'$ ; thus  $t = 0$  or  $t = T(\theta, c)$  or  $\text{Exp}(\theta, c, \cdot)$  is not optimal in  $[0, t]$ , i.e.,  $t > T(\theta, c)$ . This is a contradiction. Let us verify that  $\text{Exp}|_{\mathcal{D}}$  is injective; by contradiction, let  $\text{Exp}(\theta_1, c_1, t_1) = \text{Exp}(\theta_2, c_2, t_2)$  with  $(\theta_1, c_1, t_1) \neq (\theta_2, c_2, t_2)$ . If  $t_1 \neq t_2$ , one of the two geodesics  $\text{Exp}(\theta_1, c_1, \cdot), \text{Exp}(\theta_2, c_2, \cdot)$  has already lost optimality, and thus  $t_i \geq T(\theta_i, c_i)$ ; hence  $(\theta_i, c_i, t_i) \notin \mathcal{D}$ , a contradiction. If  $t_1 = t_2$ , we have that  $\text{Exp}(\theta_1, c_1, t_1)$  is a cut point, and hence  $t_1 \geq T(\theta_1, c_1)$ , a contradiction. To verify that  $\text{Exp}|_{\mathcal{D}}$  is surjective, take  $g \in M'$  and observe that there is an optimal geodesic  $\text{Exp}(\theta, c, \cdot)$  reaching it at time  $t \leq T(\theta, c)$ . But  $t = T(\theta, c)$  implies  $g \in K_{\text{Id}}$ ; thus  $t < T(\theta, c)$ .

The smoothness of  $\text{Exp}|_{\mathcal{D}}$  and of its inverse follows from the facts that  $\text{Exp}$  is a local diffeomorphism outside the critical points (i.e., points where the differential of  $\text{Exp}$  is not of full rank) and that the critical points do not belong to  $\mathcal{D}$ . Indeed, by contradiction, let  $(\theta, c, t) \in \mathcal{D}$  be a critical point, and hence  $t$  is a conjugate time as follows: it is either the first conjugate time that coincides with the cut time (i.e.,  $t = T(\theta, c)$ ) or a greater conjugate time (i.e.,  $t > T(\theta, c)$ ). In both cases  $(\theta, c, t) \notin \mathcal{D}$ , a contradiction.  $\square$

### 5.1. The cut locus for $SU(2)$ .

**THEOREM 12.** *The cut locus for the  $\mathbf{k} \oplus \mathbf{p}$  problem on  $SU(2)$  is*

$$K_{\text{Id}} = e^{\mathbf{k}} \setminus \text{Id} = \{e^{c\mathbf{k}} \mid c \in (0, 4\pi)\}.$$

*Proof.* Let

$$g \in e^{\mathbf{k}} \setminus \text{Id} = \left\{ \begin{pmatrix} \alpha \\ 0 \end{pmatrix} \mid \alpha \in \mathbb{C}, |\alpha| = 1, \alpha \neq 1 \right\},$$

and let  $\text{Exp}(\theta, c, \cdot)$  be the minimizing geodesic steering  $\text{Id}$  to  $g$  in time  $T$ . As a consequence of the cylindrical symmetry, we have that  $\text{Exp}(\psi, c, T) = g \quad \forall \psi \in \mathbb{R}/2\pi$ ; thus  $(e^{\mathbf{k}} \backslash \text{Id}) \subset K_{\text{Id}}$ .

The core of the proof is to show that there are no cut points outside  $e^{\mathbf{k}}$ . Recall the expression of geodesics given in section 3.1.1. By contradiction, assume that  $g \in SU(2) \backslash e^{\mathbf{k}}$  is reached by two different optimal trajectories  $\text{Exp}(\theta, c, \cdot)$  and  $\text{Exp}(\psi, d, \cdot)$  at time  $T$ . Observe that  $\text{Exp}(\theta, c, \frac{2\pi}{\sqrt{1+c^2}})$  and  $\text{Exp}(\psi, d, \frac{2\pi}{\sqrt{1+d^2}}) \in e^{\mathbf{k}} \subset K_{\text{Id}}$ ; thus

$$(16) \quad 0 < T < \min \left\{ \frac{2\pi}{\sqrt{1+c^2}}, \frac{2\pi}{\sqrt{1+d^2}} \right\}.$$

Observe that  $\text{Exp}(\theta, c, T) = \text{Exp}(\psi, d, T)$  implies that  $|\beta|$  is equal in the two cases, i.e.,

$$(17) \quad \frac{\sin(\frac{\sqrt{1+c^2}T}{2})}{\sqrt{1+c^2}} = \frac{\sin(\frac{\sqrt{1+d^2}T}{2})}{\sqrt{1+d^2}}.$$

From this equation it follows that  $|c| = |d|$ . Indeed (17) is equivalent to

$$\frac{\sin(\frac{\sqrt{1+c^2}T}{2})}{\frac{\sqrt{1+c^2}T}{2}} = \frac{\sin(\frac{\sqrt{1+d^2}T}{2})}{\frac{\sqrt{1+d^2}T}{2}}.$$

From the facts that  $\frac{\sqrt{1+c^2}T}{2}, \frac{\sqrt{1+d^2}T}{2} \in (0, \pi)$  and that the function  $\frac{\sin p}{p}$  is injective for  $p \in (0, \pi)$ , it follows that  $\frac{\sqrt{1+c^2}T}{2} = \frac{\sqrt{1+d^2}T}{2}$ , and hence  $|c| = |d|$ .

Thus we consider the following two cases:

(i)  $c = d \in \mathbb{R}$ : the cylindrical symmetry implies that either  $\theta = \psi$  (so the two geodesics coincide) or  $g \in e^{\mathbf{k}}$ . This is a contradiction.

(ii)  $c = -d \in \mathbb{R} \setminus \{0\}$ : with no loss of generality we assume  $c > 0$ . Since by the central and cylindrical symmetries, we have

$$\text{Exp}(\psi, -c, t) = \left( e^{i(\psi+\theta-\arg(\beta))\beta} \bar{\alpha} \right), \quad \text{where} \quad \text{Exp}(\theta, c, t) = \begin{pmatrix} \alpha \\ \beta \end{pmatrix},$$

$\text{Exp}(\theta, c, t) = \text{Exp}(\psi, -c, t)$  implies  $\text{Im}(\alpha) = 0$ . Hence

$$(18) \quad c \cos\left(\frac{ct}{2}\right) \sin\left(\frac{\sqrt{1+c^2}t}{2}\right) = \sqrt{1+c^2} \sin\left(\frac{ct}{2}\right) \cos\left(\frac{\sqrt{1+c^2}t}{2}\right).$$

The terms  $c, \sin(\frac{\sqrt{1+c^2}t}{2}), \sqrt{1+c^2}, \sin(\frac{ct}{2})$  are nonzero because of (16) and  $c < \sqrt{1+c^2}$ . Thus  $\cos(\frac{ct}{2}) = 0$  if and only if  $\cos(\frac{\sqrt{1+c^2}t}{2}) = 0$ , which is impossible because  $0 < \frac{ct}{2} < \frac{\sqrt{1+c^2}t}{2} < \pi$ . Hence we rewrite (18) as

$$\frac{\tan\left(\frac{\sqrt{1+c^2}t}{2}\right)}{\frac{\sqrt{1+c^2}t}{2}} = \frac{\tan\left(\frac{ct}{2}\right)}{\frac{ct}{2}}$$

and state that  $(0, \tan(0)), (\frac{ct}{2}, \tan(\frac{ct}{2})), (\frac{\sqrt{1+c^2}t}{2}, \tan(\frac{\sqrt{1+c^2}t}{2}))$  are three distinct points aligned on the graph of the function  $\tan$  in  $[0, \pi)$ , which is impossible. This is a contradiction.  $\square$

The cut locus for the  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold  $SU(2)$  is given in Figure 11.

FIG. 11. The cut locus for the  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold  $SU(2)$ .

**5.1.1. The sub-Riemannian distance in  $SU(2)$ .** In this section we compute the sub-Riemannian distance on  $SU(2)$ , i.e., we prove Theorem 2.

Let

$$g = \begin{pmatrix} \alpha \\ 0 \end{pmatrix} = \begin{pmatrix} e^{i \arg(\alpha)} \\ 0 \end{pmatrix} \in e^{\mathbf{k}}.$$

$g$  is reached by a geodesic  $\text{Exp}(\theta, c, \cdot)$  at time  $\frac{2\pi}{\sqrt{1+c^2}}$  for some  $c \in \mathbb{R}$ . Observe that

$$(19) \quad \begin{aligned} \text{Exp}\left(\theta, c, \frac{2\pi}{\sqrt{1+c^2}}\right) &= \text{Exp}\left(\theta, \pm \sqrt{\frac{4\pi^2}{t^2} - 1}, t\right) \\ &= \begin{pmatrix} -\cos\left(\sqrt{\pi^2 - \frac{t^2}{4}}\right) \mp i \sin\left(\sqrt{\pi^2 - \frac{t^2}{4}}\right) \\ 0 \end{pmatrix} = \begin{pmatrix} e^{i\left(\pi \pm \sqrt{\pi^2 - \frac{t^2}{4}}\right)} \\ 0 \end{pmatrix}. \end{aligned}$$

Thus the distance  $d(g, \text{Id})$  is the smallest  $t > 0$  such that  $e^{i\left(\pi \pm \sqrt{\pi^2 - \frac{t^2}{4}}\right)} = e^{i \arg(\alpha)}$ , whose solution is  $t = 2\sqrt{\arg(\alpha)(2\pi - \arg(\alpha))}$ , where  $\arg(\alpha)$  is chosen in  $[0, 2\pi]$ .

Let  $g = \begin{pmatrix} \alpha \\ \beta \end{pmatrix} \in SU(2) \setminus e^{\mathbf{k}}$ . Applying Proposition 11, we have that  $\text{Exp}_{|\mathcal{D}}^{-1}(g)$  is well defined on  $\mathcal{D} = \left\{(\theta, c, t) \in \Lambda_{\text{Id}} \times \mathbb{R}^+ \mid 0 < t < \frac{2\pi}{\sqrt{1+c^2}}\right\}$ . Thus the sub-Riemannian distance of  $g$  from the origin is  $d(g, \text{Id}) = t$ , where  $t$  is the third component of  $\text{Exp}_{|\mathcal{D}}^{-1}(g)$ , i.e., the unique solution  $t$  of  $\text{Exp}(\theta, c, t) = g$  with  $(\theta, c, t) \in \mathcal{D}$ . Using the explicit form of  $\text{Exp}$  given in (3.1.1), one checks that the system

$$\begin{cases} \text{Exp}(\theta, c, t) = g, \\ (\theta, c, t) \in \mathcal{D} \end{cases}$$

is equivalent to

$$\begin{cases} -\frac{ct}{2} + \arctan\left(\frac{c}{\sqrt{1+c^2}} \tan\left(\frac{\sqrt{1+c^2}t}{2}\right)\right) = \arg(\alpha), \\ \frac{\sin\left(\frac{\sqrt{1+c^2}t}{2}\right)}{\sqrt{1+c^2}} = \sqrt{1-|\alpha|^2}, \\ \cos\left(\frac{ct}{2} + \theta\right) + i \sin\left(\frac{ct}{2} + \theta\right) = \arg(\beta). \end{cases}$$

The third equation has no role in the computation of distance as a consequence of the cylindrical symmetry.

*Remark 17.* The distance is a bounded function; this is due to its continuity and the compactness of  $SU(2)$ . The farthest point starting from  $\text{Id}$  is  $-\text{Id}$ , whose distance is  $2\pi$ .

Notice that  $\forall \alpha, \beta_1, \beta_2 \in \mathbb{C}, |\beta_1| = |\beta_2|$ , we have

$$d\left(\begin{pmatrix} \alpha \\ \beta_1 \end{pmatrix}, \text{Id}\right) = d\left(\begin{pmatrix} \alpha \\ \beta_2 \end{pmatrix}, \text{Id}\right) = d\left(\begin{pmatrix} \bar{\alpha} \\ \beta_1 \end{pmatrix}, \text{Id}\right).$$

This is due to the cylindrical and central symmetries.

**5.2. The cut locus for  $SO(3)$  and lens spaces.** In this section we compute the cut locus for lens spaces  $L(p, q)$ . As a particular case, we get the cut locus for  $SO(3) \simeq L(2, 1)$ .

**THEOREM 13.** *The cut locus for the sub-Riemannian problem on  $L(p, q)$  defined in section 9 is a stratification*

$$K_{[\text{Id}]} = K_{[\text{Id}]}^{\text{sym}} \cup K_{[\text{Id}]}^{\text{loc}}$$

with

$$K_{[\text{Id}]}^{\text{sym}} = [\partial E_p] = \left\{ \left[ \begin{pmatrix} \alpha \\ \beta \end{pmatrix} \right] \mid a, b \in \mathbb{C}, \text{Re}(\alpha) \geq 0, \frac{\text{Im}(\alpha)^2}{\sin\left(\frac{\pi}{p}\right)^2} + |\beta|^2 = 1 \right\},$$

$$K_{[\text{Id}]}^{\text{loc}} = [e^{\mathbf{k}}] \setminus [\text{Id}] = \left\{ \left[ \begin{pmatrix} \alpha \\ 0 \end{pmatrix} \right] \mid \alpha \in \mathbb{C}, |\alpha| = 1, \alpha^p \neq 1 \right\}.$$

*Proof.* Let us first prove the following lemma.

**LEMMA 14.** *A geodesic  $\gamma(\cdot)$  in  $L(p, q)$  steering  $[\text{Id}]$  to  $[g]$  in minimum time  $T$  admits a unique lift  $\gamma_0(\cdot)$  in  $SU(2)$  starting from  $\text{Id}$ .*

*Moreover,*  $\gamma_0(t) = \text{Exp}(\theta_0, c_0, t) \quad \forall t \in [0, T]$  *for some*  $\theta_0 \in \mathbb{R}/2\pi, c \in \mathbb{R}$ .

*Proof.* Take  $\gamma(\cdot)$  as in the hypotheses. Since  $L(p, q)$  and  $SU(2)$  are locally diffeomorphic via  $\Pi$ , there is a unique lift  $\gamma_0(\cdot)$  in  $SU(2)$  starting from  $\text{Id}$ ; i.e.,  $\gamma_0(0) = \text{Id}$  and  $[\gamma_0(t)] = \gamma(t) \quad \forall t \in [0, T]$ .

Let us prove that  $\gamma_0(\cdot)$  is an optimal trajectory reaching  $\gamma_0(T)$ . By contradiction, there exists a trajectory  $\gamma_1(\cdot)$  such that  $\gamma_1(t_1) = \gamma_0(T)$  with  $t_1 < T$ . Hence, its projection  $[\gamma_1(\cdot)]$  satisfies  $[\gamma_1(t_1)] = [g]$  with  $t_1 < T$ , a contradiction.

Since  $\gamma_0(\cdot)$  is an optimal trajectory, it is a geodesic of  $SU(2)$ , and there exist  $\theta \in \mathbb{R}/2\pi, c \in \mathbb{R}$  such that  $\gamma_0(t) = \text{Exp}(\theta_0, c_0, t) \quad \forall t \in [0, T]$ .  $\square$

Let us prove that  $K_{[\text{Id}]}^{\text{loc}} \subset K_{[\text{Id}]}$ . Consider  $[g] \in K_{[\text{Id}]}^{\text{loc}}$ , a geodesic steering  $[\text{Id}]$  to  $[g]$  in minimum time  $T$  with unique lift  $\text{Exp}(\theta_0, c_0, \cdot)$ . By the definition of  $K_{[\text{Id}]}^{\text{loc}}$ , we have  $\text{Exp}(\theta_0, c_0, T) \in e^{\mathbf{k}} \setminus \text{Id} \subset SU(2)$ ; i.e.,  $\text{Exp}(\theta_0, c_0, T)$  lies in the cut locus for the sub-Riemannian problem on  $SU(2)$ . Thus there exists another optimal geodesic  $\text{Exp}(\theta_1, c_1, \cdot)$  defined in  $[0, T]$  such that  $\text{Exp}(\theta_1, c_1, T) = \text{Exp}(\theta_0, c_0, T) \in [g]$ . Thus the geodesic  $[\text{Exp}(\theta_1, c_1, \cdot)]$  reaches  $[g]$  in minimum time. The geodesics in  $SU(2)$  are distinct in a neighborhood of  $\text{Id}$ , so their projections in a neighborhood of  $[\text{Id}]$  are distinct as well.

Let us now prove that  $K_{[\text{Id}]}^{\text{sym}} \subset K_{[\text{Id}]}$ . Consider  $[g] \in K_{[\text{Id}]}^{\text{sym}}$ , a geodesic steering  $[\text{Id}]$  to  $[g]$  in minimum time  $T$  with unique lift  $\text{Exp}(\theta_0, c_0, \cdot)$ ; call  $\text{Exp}(\theta_0, c_0, T) = \begin{pmatrix} \alpha \\ \beta \end{pmatrix} \in [g]$ . If  $\beta = 0$ , we have  $[g] \in K_{[\text{Id}]}^{\text{loc}}$  or  $[g] = [\text{Id}]$ , so assume  $\beta \neq 0$ . Due to the cylindrical and central symmetries, we have

$$\text{Exp}(\theta_0 + \psi, -c_0, T) = \begin{pmatrix} \bar{\alpha} \\ e^{2i(\theta_0 - \arg(\beta)) + i\psi} \beta \end{pmatrix}.$$

Consider  $\psi^+ \in \mathbb{R}/2\pi$  being a solution of  $e^{2i(\theta_0 - \arg(\beta)) + i\psi^+} = e^{2\pi i \frac{q}{p}}$  and  $\psi^- \in \mathbb{R}/2\pi$  being a solution of  $e^{2i(\theta_0 - \arg(\beta)) + i\psi^-} = e^{-2\pi i \frac{q}{p}}$ . If  $\text{Exp}(\theta_0, c_0, T) \in \partial E_p^+$ , we have  $[\text{Exp}(\theta_0 + \psi^+, -c_0, T)] = [\text{Exp}(\theta_0, c_0, T)] = [g]$ ; if  $\text{Exp}(\theta_0, c_0, T) \in \partial E_p^-$ , we have similarly  $[\text{Exp}(\theta_0 + \psi^-, -c_0, T)] = [\text{Exp}(\theta_0, c_0, T)] = [g]$ . If  $c_0 \neq 0$ , we have found two distinct trajectories reaching  $[g]$  in optimal time; if  $c_0 = 0$ , we have  $\text{Exp}(\theta_0, c_0, T) \in \partial E_p^+ \cap \partial E_p^-$ , and thus at least one of  $\psi^+$  and  $\psi^-$  is not null, so at least one of  $\text{Exp}(\theta_0 + \psi^+, 0, \cdot)$  and  $\text{Exp}(\theta_0 + \psi^-, 0, \cdot)$  is distinct from  $\text{Exp}(\theta_0, 0, \cdot)$  in a neighborhood of  $\text{Id}$ , as are their projections in a neighborhood of  $[\text{Id}]$ .

Finally, consider  $[g] \in L(p, q) \setminus (K_{[\text{Id}]}^{\text{loc}} \cup K_{[\text{Id}]}^{\text{sym}} \cup [\text{Id}])$  and assume by contradiction that there exist two distinct geodesics steering  $[\text{Id}]$  to  $[g]$  in minimum time  $T$  with distinct lifts  $\text{Exp}(\theta_0, c_0, \cdot)$ ,  $\text{Exp}(\theta_1, c_1, \cdot)$ . There are two possibilities as follows:

(i)  $\text{Exp}(\theta_0, c_0, T) = \text{Exp}(\theta_1, c_1, T)$ . In this case,  $\text{Exp}(\theta_0, c_0, T)$  lies in the cut locus for the sub-Riemannian problem on  $SU(2)$ , and hence  $[g] \in K_{[\text{Id}]}^{\text{loc}}$ , a contradiction.

(ii)  $\text{Exp}(\theta_0, c_0, T) \neq \text{Exp}(\theta_1, c_1, T)$ . Since by hypothesis  $[g] \notin K_{[\text{Id}]}^{\text{sym}}$ , we have  $\text{Exp}(\theta_0, c_0, T), \text{Exp}(\theta_1, c_1, T) \notin \partial E_p$ . Recall that, if  $[\text{Exp}(\theta_0, c_0, T)] = [\text{Exp}(\theta_1, c_1, T)]$  and  $\text{Exp}(\theta_0, c_0, T), \text{Exp}(\theta_1, c_1, T) \in E_p$ , then  $\text{Exp}(\theta_0, c_0, T) = \text{Exp}(\theta_1, c_1, T)$ , due to Remark 13. Thus we have that  $\text{Exp}(\theta_i, c_i, T) \in SU(2) \setminus \bar{E}_p$  for  $i = 0$  or  $i = 1$ . We assume without loss of generality that  $\text{Exp}(\theta_0, c_0, T) \in SU(2) \setminus \bar{E}_p$ ; thus the geodesic  $\text{Exp}(\theta_0, c_0, t)$  with  $t \in [0, T]$  steers  $\text{Id} \in E_p$  to  $\text{Exp}(\theta_0, c_0, T) \in SU(2) \setminus \bar{E}_p$ , and hence  $\exists \tilde{t} \in (0, T)$  such that  $\text{Exp}(\theta_0, c_0, \tilde{t}) \in \partial E_p$ . Then we have that  $\gamma_0(\tilde{t}) = [\text{Exp}(\theta_0, c_0, \tilde{t})] \in K_{[\text{Id}]}^{\text{sym}}$ , and thus  $\gamma_0(t)$  is no more optimal for  $t \in [0, T]$ , a contradiction.  $\square$

*Remark 18.* Notice that  $K_{[\text{Id}]}^{\text{loc}}$  is a manifold (a circle without a point), while  $K_{[\text{Id}]}^{\text{sym}}$  is not in general. Indeed, it is an orbifold. It can be seen as  $S^2 \subset \mathbb{R}^3$  with the following identification:  $(x_1^+, x_2^+, x_3^+) \in S^2 \cap \{x_3 \geq 0\}$  and  $(x_1^-, x_2^-, x_3^-) \in S^2 \cap \{x_3 \leq 0\}$  are identified when  $x_3^+ = -x_3^-$  and

$$\begin{pmatrix} x_1^+ \\ x_2^+ \end{pmatrix} = \begin{pmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{pmatrix} \begin{pmatrix} x_1^- \\ x_2^- \end{pmatrix}$$

with  $\theta = \frac{2\pi q}{p}$ . In the case  $SO(3) \simeq L(2, 1)$ , we have that  $K_{[\text{Id}]}^{\text{sym}} = \mathbb{RP}^2$  (see Figure 12 (left)), while in the other cases it is not locally Euclidean; in fact, take a neighborhood of a point  $P$  on the equator and observe that it is topologically equivalent to a set of  $p$  half-planes with a common line as the boundary.

Next we give an idea of the topology of the cut locus for  $L(4, 1)$ . Consider the space  $T_1$  made by the two intersecting strips  $\{(a, b, 0) \in \mathbb{R}^3 \mid a, b \in [-1, 1]\}$  and  $\{(a, 0, b) \in \mathbb{R}^3 \mid a, b \in [-1, 1]\}$  with the following identification:  $(-1, b, 0) \sim (1, 0, b)$  and  $(-1, 0, b) \sim (1, -b, 0)$ . The boundary of this set is topologically a circle  $S^1$ . Consider now a two-dimensional semisphere  $T_2$ . The cut locus  $K_{[\text{Id}]}^{\text{sym}}$  is topologically equivalent to the space given by gluing  $T_1$  and  $T_2$  along their boundaries  $S^1$ . The cut locus  $K_{[\text{Id}]}$  is given by gluing  $K_{[\text{Id}]}^{\text{sym}}$  with a circle  $S^1$  along a point on  $T_2$  and then removing

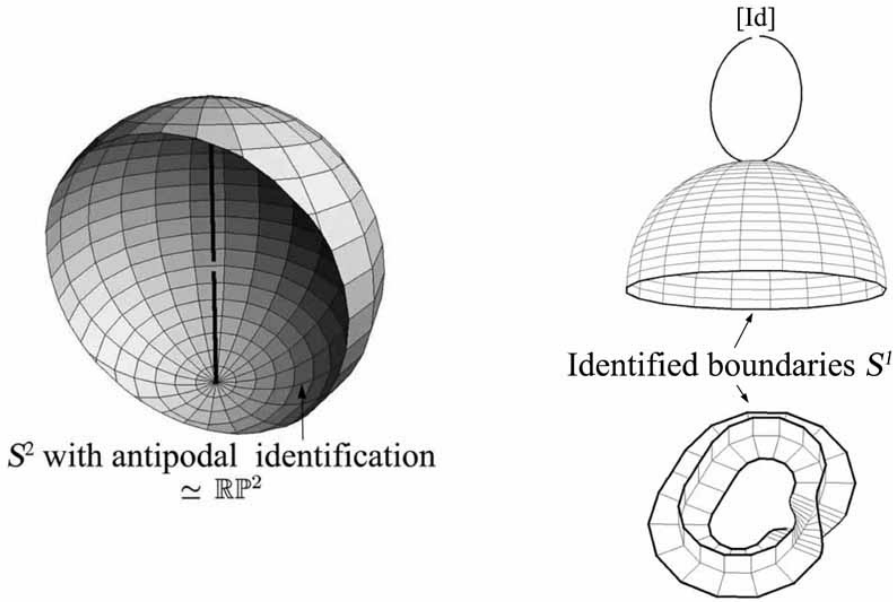

FIG. 12. Left: The cut locus for the sub-Riemannian problem on  $SO(3)$ . Right: The cut locus for the sub-Riemannian problem on  $L(4, 1)$ .

a point on  $S^1$  (the starting point). See a picture of it in Figure 12 (right).

### 5.3. The cut locus for $SL(2)$ .

THEOREM 15. The cut locus for the  $\mathbf{k} \oplus \mathbf{p}$  problem on  $SL(2)$  is a stratification

$$K_{\text{Id}} = K_{\text{Id}}^{\text{sym}} \cup K_{\text{Id}}^{\text{loc}}$$

with

$$K_{\text{Id}}^{\text{sym}} = e^{2\pi k} e^{\mathbf{p}} = \{g \in SL(2) \mid g = g^T, \text{Tr} g < 0\},$$

$$K_{\text{Id}}^{\text{loc}} = e^{\mathbf{k}} \setminus \text{Id} = \left\{ \begin{pmatrix} \cos(\alpha) & -\sin(\alpha) \\ \sin(\alpha) & \cos(\alpha) \end{pmatrix} \mid \alpha \in R/2\pi, \alpha \neq 0 \right\}.$$

*Proof.* Let us first prove that  $K_{\text{Id}}^{\text{loc}} \subset K_{\text{Id}}$ . Let  $g \in e^{\mathbf{k}} \setminus \text{Id}$ ; it is reached optimally by a geodesic  $\text{Exp}(\theta, c, \cdot)$  at time  $T$ . Due to the cylindrical symmetry, we have  $g = \text{Exp}(\psi, c, T) \forall \psi \in \mathbb{R}/2\pi$ ; thus  $g \in K_{\text{Id}}$ .

Let us now prove that  $K_{\text{Id}}^{\text{sym}} \subset K_{\text{Id}}$ . Let  $g = e^{2\pi k} e^{x_0 p_1 + y_0 p_2} \in e^{2\pi k} e^{\mathbf{p}}$ ; it is reached optimally by a geodesic  $\text{Exp}(\theta, c, \cdot)$  at time  $T$ . If  $x_0^2 + y_0^2 = 0$ , we have  $g = e^{2\pi k} \in K_{\text{Id}}^{\text{loc}}$ ; thus it is a cut point. If  $x_0^2 + y_0^2 \neq 0$ , due to the cylindrical and central symmetry, we have  $\text{Exp}(\theta + \psi, -c, T) = e^{-2\pi k} e^{x p_1 + y p_2}$  with

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \cos(2\theta + \psi) & \sin(2\theta + \psi) \\ \sin(2\theta + \psi) & -\cos(2\theta + \psi) \end{pmatrix} \begin{pmatrix} x_0 \\ y_0 \end{pmatrix}.$$

Choose  $\psi$  in such a way that  $\theta + \frac{\psi}{2}$  is the angle on the plane of the line passing through  $(0, 0)$  and  $(x_0, y_0)$ . In this way we have  $\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x_0 \\ y_0 \end{pmatrix}$ . Observing that  $e^{-2\pi k} = e^{2\pi k}$ , we finally have that  $g = \text{Exp}(\theta, c, T) = \text{Exp}(\theta + \psi, -c, T)$ . Observe that  $c \neq 0$  because  $\text{Exp}(\theta, 0, \cdot) \in e^{\mathbf{P}}$ ; thus the two geodesics  $\text{Exp}(\theta, c, \cdot)$ ,  $\text{Exp}(\theta + \psi, -c, \cdot)$  are distinct.

We now prove that there is no cut point outside  $K_{\text{Id}}^{\text{sym}} \cup K_{\text{Id}}^{\text{loc}}$ . By contradiction, let  $g \in SL(2) \setminus (K_{\text{Id}}^{\text{sym}} \cup K_{\text{Id}}^{\text{loc}} \cup \text{Id})$  be reached by two optimal trajectories  $\text{Exp}(\theta, c, \cdot)$  and  $\text{Exp}(\psi, d, \cdot)$  at time  $T$ . Writing

$$\text{Exp}(\theta, c, t) = \begin{pmatrix} g_{11}(\theta, c, t) & g_{12}(\theta, c, t) \\ g_{21}(\theta, c, t) & g_{22}(\theta, c, t) \end{pmatrix},$$

we have

$$(20) \quad r(c, t) := \sqrt{(g_{11} - g_{22})^2 + (g_{12} + g_{21})^2} = \begin{cases} \frac{\text{Sinh}(\frac{\sqrt{1-c^2}}{2} t)}{\frac{\sqrt{1-c^2}}{2}}, & c \in (-1, 1), \\ t, & c \in \{-1, 1\}, \\ \frac{\sin(\frac{\sqrt{c^2-1}}{2} t)}{\frac{\sqrt{c^2-1}}{2}}, & c \in (-\infty, -1) \cup (1, +\infty). \end{cases}$$

The identity  $\text{Exp}(\theta, c, T) = \text{Exp}(\psi, d, T)$  implies  $r(c, T) = r(d, T)$ , which implies  $c^2 = d^2$ . Indeed, observe that in the three cases described in (20) we have, respectively,  $r(c, t) > t$ ,  $r(c, t) = t$ ,  $r(c, t) < t$ ; thus  $c, d \in (-1, 1)$  or  $c, d \in \{-1, 1\}$  or  $c, d \in (-\infty, -1) \cup (1, +\infty)$ . In each of the three cases, the identity  $r(c, T) = r(d, T)$  implies  $c^2 = d^2$ . Indeed we have the following three cases.

*Case  $c, d \in (-1, 1)$ .* In this case the conclusion follows from the fact that  $\frac{\text{Sinh}(p)}{p}$  is injective for  $p \in (0, +\infty)$ .

*Case  $c, d \in \{-1, 1\}$ .* This case is straightforward.

*Case  $c, d \in (-\infty, -1) \cup (1, +\infty)$ .* Let us prove first that  $\frac{\sqrt{c^2-1}T}{2} \in (0, \pi)$ . By contradiction, assume  $\frac{\sqrt{c^2-1}T}{2} \geq \pi$ . There exists  $t \in (0, T]$  such that  $\frac{\sqrt{c^2-1}t}{2} = 0$ ; hence  $r(c, t) = 0$ , from which it follows that  $\text{Exp}(\theta, c, t) \in e^{\mathbf{K}}$ .

Hence either  $t < T$  (and  $\text{Exp}(\theta, c, \cdot)$  is not optimal on  $[0, T]$ , a contradiction) or  $t = T$  (and  $g \in K_{\text{Id}}^{\text{loc}} \cup \text{Id}$ , a contradiction). Similarly we prove that  $\frac{\sqrt{d^2-1}T}{2} \in (0, \pi)$ .

Now observe that  $r(c, T) = r(d, T)$  implies

$$\frac{\sin(\frac{\sqrt{c^2-1}T}{2})}{\frac{\sqrt{c^2-1}T}{2}} = \frac{\sin(\frac{\sqrt{d^2-1}T}{2})}{\frac{\sqrt{d^2-1}T}{2}}.$$

Recalling that  $\frac{\sin p}{p}$  is injective for  $p \in (0, \pi)$ , we have  $\frac{\sqrt{c^2-1}T}{2} = \frac{\sqrt{d^2-1}T}{2}$ ; hence  $c^2 = d^2$ .

We have the following two cases:

(i)  $c = d \in \mathbb{R}$ . The identity  $g_{11}(\theta, c, T) = g_{11}(\psi, c, T)$  implies either  $\theta = \psi$  (i.e., the geodesics coincide) or  $c \in (-\infty, -1) \cup (1, +\infty)$ , and thus  $\sin(\frac{\sqrt{c^2-1}T}{2}) = 0$ , i.e.,  $\text{exp}(\theta, c, T) \in e^{\mathbf{K}}$ ; hence either  $g = \text{Id}$  or  $g \in K_{\text{Id}}^{\text{loc}}$ , a contradiction.

(ii)  $c = -d \in \mathbb{R} \setminus \{0\}$ . Writing  $g = e^{zk}e^{x_0p_1+y_0p_2}$ , we have  $\text{Exp}(\psi, -c, T) = e^{-zk}e^{xp_1+yp_2}$ . The identity  $\text{Exp}(\theta, c, T) = \text{Exp}(\psi, -c, T)$  and the uniqueness of the

FIG. 13. The cut locus for the  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold  $SL(2)$ .

decomposition from section 3.3.2 imply  $e^{zk} = \pm \text{Id}$ . Thus  $g$  is symmetric, i.e.,  $g_{12}(\theta, c, T) = g_{21}(\theta, c, T)$ .

If  $c \in (-1, 1)$  this equation implies

$$\frac{\tan\left(c\frac{T}{2}\right)}{c\frac{T}{2}} = \frac{\text{Tanh}\left(\sqrt{1-c^2}\frac{T}{2}\right)}{\sqrt{1-c^2}\frac{T}{2}}.$$

Choosing  $c > 0$ , observe that the first positive solution  $T_1$  of the equation

$$\frac{\tan\left(c\frac{T_1}{2}\right)}{c\frac{T_1}{2}} = \frac{\text{Tanh}\left(\sqrt{1-c^2}\frac{T_1}{2}\right)}{\sqrt{1-c^2}\frac{T_1}{2}}$$

satisfies  $T_1 \in (\pi, 3\frac{\pi}{2})$ . The other cases,  $c \in \{-1, 1\}$  and  $c \in (-\infty, -1) \cup (1, +\infty)$ , are treated similarly and lead to  $T_1 \in (\pi, 3\frac{\pi}{2})$ .

Thus  $\cos\left(c\frac{T_1}{2}\right) < 0$ , and hence  $\text{Tr}(g) < 0$ . But  $\text{Exp}(\theta, c, T_1)$  symmetric and  $\text{Tr}(g) < 0$  implies  $\text{Exp}(\theta, c, T_1) \in K_{\text{Id}}^{\text{sym}}$ ; i.e.,  $T_1$  is a cut time. Thus either  $T = T_1$  (meaning that  $\text{Exp}(\theta, c, t) \in K_{\text{Id}}^{\text{sym}}$ ) or  $T > T_1$  and  $\text{Exp}(\theta, c, \cdot)$  is not optimal in  $[0, T]$ , a contradiction.  $\square$

We give a picture of the cut locus for the  $\mathbf{k} \oplus \mathbf{p}$  sub-Riemannian manifold  $SL(2)$  in Figure 13.

**Acknowledgments.** We are grateful to A. Agrachev for many illuminating discussions. We deeply thank G. Charlot for bringing to our attention some crucial properties of the cut locus, and we thank L. Paoluzzi for many explanations on lens spaces.

## ACCESSIBILITY AND CONTROLLABILITY IN THE PRESENCE OF FAST OSCILLATIONS\*

G. GRAMMEL†

**Abstract.** The accessibility properties of time-variant nonlinear control systems with fast time variables are investigated. It turns out that local accessibility can be carried from a time-invariant averaged system to the original system, provided the time variable is sufficiently fast, or equivalently, the singular perturbation parameter is sufficiently small. It is shown that the reachable sets of the averaged and the original systems contain common open sets. To this end, the singular perturbation parameter is considered as a homotopy parameter, and mapping degree methods are used. An application to controllability properties of time-variant nonlinear control systems with fast time variables is presented as well.

**Key words.** nonlinear control system, accessibility, fast oscillations, averaging

**AMS subject classifications.** 34C29, 93B03, 93B05

**DOI.** 10.1137/070706240

**1. Introduction.** We consider the singularly perturbed control system (SPCS)

$$(1) \quad \dot{z}(t) = f\left(z(t), \frac{t}{\epsilon}, u(t)\right),$$

where the parameter  $\epsilon > 0$  is small and hence reflects that the state  $z(t)$  moves slowly in comparison with the scaled time variable  $\frac{t}{\epsilon}$ . Obviously this system is time-variant and hence difficult to investigate with respect to any structural properties. As for exponential stability properties, it is common practice to construct an averaged system and to carry over information about the averaged system to the perturbed system, at least for small perturbation parameters. This method works perfectly for differential equations with slow and fast time variables whenever an averaged system can be constructed; see [11] and the references therein. It seems that much less attention has been paid to similar considerations with respect to controllability properties. In the present work we make use of local accessibility properties of the averaged control system (ACS) and show that these are transferred to the SPCS, at least for sufficiently small perturbation parameters  $\epsilon > 0$ . To this end it is shown that the reachable sets of the ACS and the SPCS have certain open sets in common for sufficiently small perturbation parameters. This is a well-known fact for regular perturbations; see [2], where a corresponding proof relies on an application of the implicit function theorem to a certain mapping obtained via geometric control theory. In the present work the method of proof is entirely different. Whereas we still make use of elementary geometric control theory, as presented in [10, 15], the transfer from the ACS to the SPCS relies on mapping degree arguments along with a particular approximation of a given trajectory to the ACS. For this purpose, the singular perturbation parameter is used to obtain a suitable homotopy. The result obtained on *robust local accessibility* is applied to show a transfer of controllability properties from the ACS to the SPCS.

†Center for Mathematics, Technical University of Munich, 3 Boltzmann Street, 85747 Garching, Germany (grammel@ma.tum.de).

The relation between averaging techniques and Lie brackets of vector fields has been the focus of a number of articles; see, e.g., [7, 8, 9] and the references therein. However, the main goal in these works is the construction of a meaningful limiting system, and the complications arise by an unbounded right-hand side of the differential equations involved. In the present paper we deal with a simpler situation. Since the fast oscillations are locally uniformly bounded, the construction of an ACS is straightforward and follows the pioneering work of Plotnikov [12], who, however, used a differential inclusion setting. The approximation results on nonlinear systems with two time scales, as presented in [1, 4, 13, 16], could be used just as well, if tailored in an appropriate way. It turns out that the Lie brackets for the ACS are averages of the corresponding Lie brackets for the SPCS.

The paper is organized as follows. The construction of the ACS is performed in section 2. The setting is fixed there as well. Section 3 contains the core of our presentation. Here it is shown that one can deduce local accessibility from the ACS to the SPCS. An application to a transfer of controllability properties is discussed in section 4.

## 2. Preliminaries. The setting is as follows.

*Assumption 2.1* (regularity). The state space of the singularly perturbed control system is the Euclidean space  $\mathbf{R}^n$ . The control range is a compact metric space  $\Omega$ . The controls are measurable functions  $u : \mathbf{R} \rightarrow \Omega$ , and the set of those controls is denoted by  $\mathcal{U}$ . For fixed  $\omega \in \Omega$  and  $s \in \mathbf{R}$ , the vector field  $\mathbf{R}^n \ni z \mapsto f(z, s, \omega) \in \mathbf{R}^n$  is of class  $C^\infty$ . The mapping  $\mathbf{R}^n \times \mathbf{R} \times \Omega \ni (z, s, \omega) \mapsto f(z, s, \omega) \in \mathbf{R}^n$  is continuous and uniformly Lipschitz continuous in the first argument; i.e., there is a constant  $L \geq 0$  such that one has

$$\|f(z_1, s, \omega) - f(z_2, s, \omega)\| \leq L\|z_1 - z_2\|$$

for all  $z_1, z_2 \in \mathbf{R}^n$ ,  $s \in \mathbf{R}$ , and  $\omega \in \Omega$ .

*Assumption 2.2* (periodicity). There is a time  $S > 0$ , the period, such that we have

$$f(z, s, \omega) = f(z, s + S, \omega)$$

for all  $(z, s, \omega) \in \mathbf{R}^n \times \mathbf{R} \times \Omega$ .

For  $\epsilon > 0$ ,  $z^0 \in \mathbf{R}^n$ ,  $t^0 \in \mathbf{R}$ , and  $u \in \mathcal{U}$ , let  $\mathbf{R} \ni t \mapsto z_\epsilon(t, z^0, t^0, u) \in \mathbf{R}^n$  be the unique trajectory to the SPCS (1) with initial condition  $z(t^0) = z^0$ . For  $t \geq t^0$ , the reachable set of the SPCS (1) is defined by

$$\mathcal{R}_\epsilon(t, z^0, t^0) := \bigcup_{u \in \mathcal{U}} \{z_\epsilon(t, z^0, t^0, u)\}.$$

Note that the reachable sets  $\mathcal{R}_\epsilon(t, z^0, t^0) \subset \mathbf{R}^n$  are bounded.

In what follows, we make use of the periodicity in order to construct an ACS reflecting the situation when the singular perturbation parameter tends to zero. An  $S$ -periodic control  $u \in \mathcal{U}$  generates an averaged vector field  $\omega_0^u$  on  $\mathbf{R}^n$  by

$$\omega_0^u(z) := \frac{1}{S} \int_0^S f(z, s, u(s)) ds.$$

Let  $\Omega_0 \subset C^\infty(\mathbf{R}^n; \mathbf{R}^n)$  be the collection of all averaged vector fields. In order to produce a control system with the averaged vector fields, we define a mapping  $f_0 :$

$\mathbf{R}^n \times \Omega_0 \rightarrow \mathbf{R}^n$  by

$$f_0(z, \omega_0) := \omega_0(z).$$

Then, the ACS on  $\mathbf{R}^n$  is given by

$$(2) \quad \dot{z}(t) = f_0(z(t), u_0(t)),$$

where  $u_0 : \mathbf{R} \rightarrow \Omega_0$  is measurable. Let  $\mathcal{U}_0$  be the set of measurable controls  $u_0 : \mathbf{R} \rightarrow \Omega_0$ .

For  $z^0 \in \mathbf{R}^n$ ,  $t^0 \in \mathbf{R}$ ,  $t \in \mathbf{R}$ , and  $u_0 \in \mathcal{U}_0$ , let  $\mathbf{R} \ni t \mapsto z_0(t, z^0, t^0, u_0) \in \mathbf{R}^n$  be the unique trajectory to the ACS (2) with initial condition  $z(t^0) = z^0$ . For  $t \geq t^0$ ,  $z^0 \in \mathbf{R}^n$ , the reachable set of the ACS (2) is defined by

$$\mathcal{R}_0(t, z^0, t^0) := \bigcup_{u_0 \in \mathcal{U}_0} \{z_0(t, z^0, t^0, u_0)\}.$$

The relation between the SPCS (1) and the ACS (2), in terms of reachable sets, is as follows.

**LEMMA 2.3.** *Let Assumptions 2.1 and 2.2 be satisfied. For any initial state  $z^0 \in \mathbf{R}^n$  and any time horizon  $T > 0$ , there is a constant  $K = K(z^0, T) \geq 0$  such that for all  $t^0 \in \mathbf{R}$ ,  $t \in [t^0, t^0 + T]$ , and all  $\epsilon > 0$ , the estimation*

$$d_H(\mathcal{R}_0(t, z^0, t^0), \mathcal{R}_\epsilon(t, z^0, t^0)) \leq K \epsilon$$

*holds true, where  $d_H(\cdot, \cdot)$  denotes the Hausdorff semimetric for bounded sets in  $\mathbf{R}^n$ .*

*Proof.* The proof follows from [5, Lemma 2.2 and its proof]. The result also can be deduced from [6, Theorem 2.3 and its proof].  $\square$

Note that in case of ordinary differential equations, i.e.,  $\Omega = \{\omega\}$  consists of one point only, the ACS (2) is reduced to

$$\dot{z}(t) = f_0(z(t)),$$

where the averaged vector field  $f_0 : \mathbf{R}^n \rightarrow \mathbf{R}^n$  is given by

$$f_0(z) := \frac{1}{S} \int_0^S f(z, s, \omega) ds.$$

In this case a proof of Lemma 2.3 can be found in [14].

**3. Accessibility via the averaged system.** In what follows we make use of local accessibility properties of the ACS.

**Assumption 3.1** (accessibility). The ACS (2) is locally accessible on  $\mathbf{R}^n$ ; i.e., for any  $z^0 \in \mathbf{R}^n$  and any  $T > 0$  the reachable set  $\mathcal{R}_0([0, T], z^0, 0)$  has interior points in  $\mathbf{R}^n$ .

Note that for any initial value  $z^0 \in \mathbf{R}^n$  and for any open neighborhood  $\mathcal{V} \subset \mathbf{R}^n$  about  $z^0 \in \mathbf{R}^n$ , there is a time  $T_{\mathcal{V}} > 0$  with

$$\mathcal{R}_0([0, T_{\mathcal{V}}], z^0, 0) \subset \mathcal{V}.$$

This property easily can be deduced from Assumptions 2.1 and 2.2 using Gronwall's lemma. Hence, the interior points of the reachable set  $\mathcal{R}_0([0, T], z^0, 0)$  are produced

locally about  $z^0 \in \mathbf{R}^n$ , and standard results on the relationship between local accessibility and Lie algebras generated by vector fields, such as Theorem 11 in [15], can be used.

The SPCS (1) is uniformly locally accessible on  $\mathbf{R}^n$  in the following sense.

**THEOREM 3.2.** *Let Assumptions 2.1, 2.2, and 3.1 be satisfied. For any initial value  $z^0 \in \mathbf{R}^n$ ,  $T > 0$ , there are  $\epsilon_0 > 0$ ,  $z^1 \in \mathbf{R}^n$ ,  $r > 0$  such that for any  $\epsilon \in [0, \epsilon_0]$  and any initial time  $t^0 \in \mathbf{R}$ , the inclusion*

$$B(r; z^1) \subset \mathcal{R}_\epsilon([t^0, t^0 + T], z^0, t^0)$$

is valid.

*Proof.* The proof is based on the homotopy invariance of the mapping degree. To this end we consider the perturbation parameter as a homotopy parameter.

*Step 1.* By the local accessibility of the ACS there is an open and dense set  $X^0 \subset \mathbf{R}^n$  such that for all  $z^0 \in X^0$  the Lie algebra generated by the vector fields  $\omega_0 \in \Omega_0$  has full rank  $n = \dim(\mathbf{R}^n)$ ; see, e.g., [15, Theorem 11, p. 177]. Let  $z^0 \in X^0$  (the case  $z^0 \notin X^0$  easily can be reduced to the case  $z^0 \in X^0$ ). Then (see, e.g., [15, Lemma 4.2.8, p. 152]), there are averaged vector fields  $\omega_0^1, \dots, \omega_0^n \in \Omega_0$  and times  $(t_1^0, \dots, t_n^0) \in (0, \frac{T}{n})^n$  such that the derivative of the mapping

$$\left(0, \frac{T}{n}\right)^n \ni (t_1, \dots, t_n) \mapsto (e^{\omega_0^n t_n} \circ \dots \circ e^{\omega_0^1 t_1})(z^0) \in \mathbf{R}^n$$

has full rank  $n = \dim(\mathbf{R}^n)$  at  $(t_1^0, \dots, t_n^0) \in (0, \frac{T}{n})^n$ . Here, the mapping  $\mathbf{R} \times \mathbf{R}^n \ni (t, z^0) \mapsto e^{t\omega} z^0 \in \mathbf{R}^n$  denotes the flow generated by the vector field  $\omega$  on  $\mathbf{R}^n$ . Let  $\mathcal{O} \subset (0, \frac{T}{n})^n$  be an open ball about  $(t_1^0, \dots, t_n^0) \in (0, \frac{T}{n})^n$  such that the mapping

$$H_0: \overline{\mathcal{O}} \rightarrow \mathbf{R}^n, \quad (t_1, \dots, t_n) \mapsto (e^{\omega_0^n t_n} \circ \dots \circ e^{\omega_0^1 t_1})(z^0)$$

is regular and injective. We set

$$z^1 := H_0(t_1^0, \dots, t_n^0).$$

Then we have

$$\deg(H_0, \mathcal{O}, z^1) \neq 0,$$

where  $\deg$  denotes the mapping degree of Brouwer. For an introduction to elementary properties of Brouwer's mapping degree, consult, for instance, [3]. It is convenient to describe the mapping  $H_0$  via a certain control function for the ACS (2). For  $(t_1, \dots, t_n) \in \overline{\mathcal{O}}$  we define

$$u_0^{(t_1, \dots, t_n)}(t) := \begin{cases} \omega_0^1 & \text{for } t \in (-\infty, t_1), \\ \omega_0^i & \text{for } t \in [t_1 + \dots + t_{i-1}, t_1 + \dots + t_i), \quad 2 \leq i \leq n-1, \\ \omega_0^n & \text{for } t \in [t_1 + \dots + t_{n-1}, \infty). \end{cases}$$

Then we have

$$H_0(t_1, \dots, t_n) = z_0(t_1 + \dots + t_n, z^0, 0, u_0^{(t_1, \dots, t_n)}).$$

*Step 2.* For  $\epsilon > 0$ ,  $t^0 \in \mathbf{R}$ , we define a control  $u_\epsilon^{(t_1, \dots, t_n)} \in \mathcal{U}$  for the SPCS (1) in the following way. We set

$$u_\epsilon^{(t_1, \dots, t_n)}(t) := \begin{cases} u_1(\frac{t}{\epsilon}) & \text{for } t \in (-\infty, t^0 + t_1), \\ u_i(\frac{t}{\epsilon}) & \text{for } t \in [t^0 + t_1 + \dots + t_{i-1}, t^0 + t_1 + \dots + t_i), \quad 2 \leq i \leq n-1, \\ u_n(\frac{t}{\epsilon}) & \text{for } t \in [t^0 + t_1 + \dots + t_{n-1}, \infty), \end{cases}$$

where, for  $i = 1, \dots, n$ ,  $u_i \in \mathcal{U}$  is an  $S$ -periodic control function generating  $\omega_0^i$ . We define a mapping

$$H_\epsilon : \overline{\mathcal{O}} \rightarrow \mathbf{R}^n, \quad (t_1, \dots, t_n) \mapsto z_\epsilon(t^0 + t_1 + \dots + t_n, z^0, t^0, u_\epsilon^{(t_1, \dots, t_n)}).$$

The continuity of  $H_\epsilon$  is obvious.

*Step 3.* Next we show that the mapping

$$[0, \infty) \times \overline{\mathcal{O}} \ni (\epsilon, t_1, \dots, t_n) \mapsto H_\epsilon(t_1, \dots, t_n) \in \mathbf{R}^n$$

is continuous as well. This is obviously the case at  $\epsilon > 0$  but has to be shown at  $\epsilon = 0$ . To this end we prove that there is a constant  $C = C(z^0, T) \geq 0$  with

$$(3) \quad \max_{t \in [0, T]} \|z_\epsilon(t^0 + t, z^0, t^0, u_\epsilon^{(t_1, \dots, t_n)}) - z_0(t, z^0, 0, u_0^{(t_1, \dots, t_n)})\| \leq C \epsilon$$

for all  $t^0 \in \mathbf{R}$ ,  $(t_1, \dots, t_n) \in \overline{\mathcal{O}}$  and sufficiently small  $\epsilon > 0$ . We set  $s_k := k\epsilon S$  for  $k = 0, 1, \dots, \lceil \frac{T}{\epsilon S} \rceil$  and use the abbreviations  $u_0 = u_0^{(t_1, \dots, t_n)}$ ,  $z_0(\cdot) := z_0(\cdot, z^0, 0, u_0)$ . Then we have

$$z_0(s_{k+1}) = z_0(s_k) + \int_{s_k}^{s_{k+1}} f_0(z_0(s), u_0(s)) ds.$$

We can also write

$$z_0(s_{k+1}) = z_0(s_k) + \int_{s_k}^{s_{k+1}} f_0(z_0(s_k), \omega_0^{i(k)}) ds + \epsilon S L E_{k,1} + E_{k,2},$$

where the errors  $E_{k,1} \in \mathbf{R}^n$  are caused by the fact that possibly  $z_0(s_k) \neq z_0(s)$  for some  $s \in (s_k, s_{k+1})$ . Note that we can estimate

$$\|E_{k,1}\| \leq \max_{s_k \leq s \leq s_{k+1}} \|z_0(s) - z_0(s_k)\| \leq \epsilon S P,$$

where  $P = P(T, z^0) \geq 0$  is an upper bound for the norm of the vector fields  $f$  (and hence for  $f_0$  as well) along the trajectories starting in  $z^0 \in \mathbf{R}^n$ . The errors  $E_{k,2} \in \mathbf{R}^n$  are of a different kind and appear because the discretization times  $s_k$  might not be the switching times of the control function  $u_0$ . Hence, the errors  $E_{k,2}$  appear for at most  $n = \dim(\mathbf{R}^n)$  different indices  $k$ . Alternatively, we can write

$$z_0(s_{k+1}) = z_0(s_k) + \int_{s_k}^{s_{k+1}} f\left(z_0(s_k), \frac{t^0 + s}{\epsilon}, u_\epsilon(t^0 + s)\right) ds + \epsilon S L E_{k,1} + E_{k,2},$$

where  $u_\epsilon = u_\epsilon^{(t_1, \dots, t_n)}$ . As for the corresponding trajectory of the SPCS (1), we use the abbreviations  $z_\epsilon(\cdot) = z_\epsilon(\cdot, z^0, t^0, u_\epsilon)$  and obtain

$$z_\epsilon(t^0 + s_{k+1}) = z_\epsilon(t^0 + s_k) + \int_{s_k}^{s_{k+1}} f\left(z_\epsilon(t^0 + s), \frac{t^0 + s}{\epsilon}, u_\epsilon(t^0 + s)\right) ds.$$

Replacing  $z_\epsilon(t^0 + s)$  by  $z_\epsilon(t^0 + s_k)$ , we possibly produce errors which are expressed by  $E_{k,3} \in \mathbf{R}^n$  in the following equality:

$$z_\epsilon(t^0 + s_{k+1}) = z_\epsilon(t^0 + s_k) + \int_{s_k}^{s_{k+1}} f\left(z_\epsilon(t^0 + s_k), \frac{t^0 + s}{\epsilon}, u_\epsilon(t^0 + s)\right) ds + \epsilon S L E_{k,3}.$$

Note that we can estimate

$$\|E_{k,3}\| \leq \max_{s_k \leq s \leq s_{k+1}} \|z_\epsilon(t^0 + s) - z_\epsilon(t^0 + s_k)\| \leq \epsilon SP.$$

Defining  $\Delta_k := \|z_\epsilon(t^0 + s_k) - z_0(s_k)\|$ , we obtain  $\Delta_0 = 0$  along with the recursive relation

$$\begin{aligned} \Delta_{k+1} &\leq \Delta_k + \int_{s_k}^{s_{k+1}} L\Delta_k ds + \epsilon SLE_{k,1} + E_{k,2} + \epsilon SLE_{k,3} \\ &\leq \Delta_k(1 + \epsilon SL) + \epsilon SLE_{k,1} + E_{k,2} + \epsilon SLE_{k,3}, \end{aligned}$$

where the number of indices  $k \in \{0, 1, \dots, [\frac{T}{\epsilon S}]\}$  with  $\|E_{k,2}\| > 0$  is not exceeding  $n = \dim(\mathbf{R}^n)$ . For those indices, we have the error estimations

$$\|E_{k,2}\| \leq 2\epsilon SP.$$

In the recursive relation above, the error  $\Delta_k$  is amplified by the factor  $1 + \epsilon SL \geq 1$  to obtain an estimation for  $\Delta_{k+1}$ . Hence, an early appearance of the errors  $E_{k,2} \geq 0$  has a large effect. In the worst case, we have

$$\|E_{k,2}\| = \begin{cases} 2\epsilon SP & \text{for } k = 0, 1, \dots, n-1, \\ 0 & \text{for } k = n, n+1, \dots, [\frac{n}{\epsilon S}]. \end{cases}$$

This yields the estimation

$$\Delta_k \leq (\epsilon SL\epsilon SP + 2\epsilon SP + \epsilon SL\epsilon SP) \sum_{l=0}^{k-1} (1 + \epsilon SL)^l \leq 2(\epsilon^2 S^2 LP + \epsilon SP)ne^{LT}$$

for  $k = 0, 1, \dots, n-1$ . For  $k = n-1, n, \dots, [\frac{T}{\epsilon S}]$ , we obtain the recursive relation

$$\Delta_{k+1} \leq \Delta_k(1 + \epsilon SL) + \epsilon SL\|E_{k,1}\| + \epsilon SL\|E_{k,3}\|,$$

which yields

$$\begin{aligned} \Delta_k &\leq \Delta_{n-1}(1 + \epsilon S)^{k-n+1} + 2\epsilon^2 S^2 PL \sum_{l=0}^{k-n} (1 + \epsilon SL)^l \\ &\leq 2(\epsilon^2 S^2 LP + \epsilon SP)ne^{2LT} + 2\epsilon SPL e^{LT}, \end{aligned}$$

from which (3) immediately follows. Now we take  $(t_1, \dots, t_n), (\hat{t}_1, \dots, \hat{t}_n) \in \overline{\mathcal{O}}$  and an  $\epsilon > 0$  sufficiently small. Then we can estimate

$$\begin{aligned} &\|H_\epsilon(t_1, \dots, t_n) - H_0(\hat{t}_1, \dots, \hat{t}_n)\| \\ &\leq \|H_\epsilon(t_1, \dots, t_n) - H_0(t_1, \dots, t_n)\| + \|H_0(t_1, \dots, t_n) - H_0(\hat{t}_1, \dots, \hat{t}_n)\| \\ &\leq C\epsilon + \|H_0(t_1, \dots, t_n) - H_0(\hat{t}_1, \dots, \hat{t}_n)\|, \end{aligned}$$

and the claim follows from the continuity of  $H_0$ .

*Step 4.* There is a ball  $B(r; z^1)$  about  $z^1 \in \mathbf{R}^n$  and an  $\epsilon_0 > 0$  such that

$$H_\epsilon(\partial\mathcal{O}) \cap B(r; z^1) = \emptyset$$

for all  $\epsilon \in [0, \epsilon_0]$ . By the homotopy invariance property of the mapping degree, we conclude that

$$\deg(H_\epsilon, \mathcal{O}, z) \neq 0$$

for all  $\epsilon \in [0, \epsilon_0]$  and all  $z \in B(r; z^1)$ , and the proof is finished.  $\square$

The Lie algebraic condition on local accessibility of the ACS is specified in the following remark.

*Remark 3.3.* Let  $\omega_0^1, \omega_0^2 \in \Omega_0$  be two averaged vector fields on  $\mathbf{R}^n$ ; i.e., there are  $u^1, u^2 \in \mathcal{U}$  such that we can write

$$\omega_0^i(z) = \frac{1}{S} \int_0^S f(z, s, u^i(s)) ds, \quad i = 1, 2,$$

for all  $z \in \mathbf{R}^n$ . A straightforward calculation shows that we can represent the Lie brackets of the averaged vector fields in the following way:

$$[\omega_0^1, \omega_0^2](z) = \frac{1}{S^2} \int_0^S \int_0^S [f(\cdot, s_1, u^1(s_1)), f(\cdot, s_2, u^2(s_2))](z) ds_1 ds_2$$

for all  $z \in \mathbf{R}^n$ . Similarly, higher order Lie brackets of the averaged vector fields are obtained by averaging higher order Lie brackets of the original vector fields.

**4. Controllability via the averaged system.** Theorem 3.2 has immediate applications to controllability properties of the singularly perturbed systems. Since complete controllability is an uncommon property of nonlinear control systems, the notion of a *control set* is presented in [2]. Roughly speaking a control set is a subset of the state space in which complete controllability holds. We give a similar notion of controllability for the time-variant singularly perturbed systems.

**DEFINITION 4.1.** Let  $M \subset \mathbf{R}^n$ . We say that the ACS (2) is controllable on  $M$  if

$$M \subset \mathcal{R}_0([0, \infty), z^0, 0)$$

for any initial state  $z^0 \in M$ . For a fixed  $\epsilon > 0$ , we say that the SPCS (1) is controllable on  $M$  if

$$M \subset \mathcal{R}_\epsilon([t^0, \infty), z^0, t^0)$$

for any pair of initial conditions  $(z^0, t^0) \in M \times \mathbf{R}$ .

**THEOREM 4.2.** Let Assumptions 2.1, 2.2, and 3.1 be satisfied. Let  $M \subset \mathbf{R}^n$  be compact with  $\text{int}M \neq \emptyset$ . If the ACS (2) is controllable on  $M$ , then there is an  $\epsilon_M > 0$  such that the SPCS (1) is controllable on  $M$  for all  $\epsilon \in (0, \epsilon_M]$ . In particular, there is a time  $T_M > 0$  such that

$$M \subset \mathcal{R}_\epsilon([t^0, t^0 + T_M], z^0, t^0)$$

for any pair of initial conditions  $(z^0, t^0) \in M \times \mathbf{R}$  and  $\epsilon \in (0, \epsilon_M]$ .

*Proof.* Let  $z^0 \in \text{int}M$ . There are  $\epsilon_0 > 0$ ,  $z^1 \in M$ ,  $r > 0$ ,  $T > 0$  such that for any  $\epsilon \in [0, \epsilon_0]$ , any initial time  $t^0 \in \mathbf{R}$ , and any initial state  $x^0 \in B(r; z^1)$ , we have the inclusion

$$z^0 \in \mathcal{R}_\epsilon([t^0, t^0 + T], x^0, t^0) \subset M.$$

This follows immediately from Theorem 3.2 via time reversal. Since the ACS (2) is controllable on  $M$ , for any  $z \in M$  there is an averaged control  $u_0 \in \mathcal{U}_0$  and a time  $T_z > 0$  with

$$z_0(t^0 + T_z, z, t^0, u_0) = z^1.$$

Additionally, by Lemma 2.3 there are  $\epsilon_z > 0$  and  $r_z > 0$  such that for any  $\epsilon \in [0, \epsilon_z]$ , any  $t^0 \in \mathbf{R}$ , and any  $x \in B(r_z; z)$ , we have

$$\mathcal{R}_\epsilon([t^0, t^0 + T_z], x, t^0) \cap B(r; z^1) \neq \emptyset.$$

By compactness of  $M$ , there are a time  $T_M^+ > 0$  and an  $\epsilon_M^+ > 0$  such that

$$z^0 \in \mathcal{R}_\epsilon([t^0, t^0 + T_M^+], z, t^0)$$

for all  $\epsilon \in (0, \epsilon_M^+]$ , all  $t^0 \in \mathbf{R}$ , and all  $z \in M$ . Note that the ACS (2) is controllable on  $M$  if we replace  $f$  by  $-f$ , i.e., after a time reversal. Hence, similar arguments show that there are a time  $T_M^- > 0$  and an  $\epsilon_M^- > 0$  such that

$$z \in \mathcal{R}_\epsilon([t^0, t^0 + T_M^-], z^0, t^0)$$

for all  $\epsilon \in (0, \epsilon_M^-]$  and all  $z \in M$ . Overall, we obtain the required result with

$$\epsilon_M := \min(\epsilon_M^+, \epsilon_M^-), \quad T_M := T_M^+ + T_M^-,$$

and the proof is finished.  $\square$

Clearly, the compactness of  $M$  is necessary in order to obtain a uniform maximal controllability time  $T_M \geq 0$  and a uniform bound  $\epsilon_M > 0$  for the singularly perturbed systems. Compactness does not mean an enormous restriction, since for noncompact  $M$  one still can consider compact subsets. A more serious restriction to the applicability of Theorem 4.2 is given by the presence of interior points in  $M$ . However, the following counterexample shows that it is indispensable for the transfer of controllability.

*Example 4.3.* Consider the SPCS in  $\mathbf{R}^2$  given by

$$\dot{z}_1(t) = z_1(t) \sin\left(\frac{t}{\epsilon}\right) - z_2(t) + z_1(t)u(t),$$

$$\dot{z}_2(t) = z_1(t) + z_2(t) \sin\left(\frac{t}{\epsilon}\right) + z_2(t)u(t),$$

where  $u(t) \in \Omega := \{0, 1\}$  for a.a.  $t \in \mathbf{R}$ . The ACS can be written as

$$\dot{z}_1(t) = -z_2(t) + z_1(t)w(t),$$

$$\dot{z}_2(t) = z_1(t) + z_2(t)w(t),$$

where  $w(t) \in [0, 1]$  for a.a.  $t \in \mathbf{R}$ . Clearly, the ACS is controllable on

$$M := S^1 = \{(z_1, z_2) \in \mathbf{R}^2 : z_1^2 + z_2^2 = 1\}.$$

Just take the constant control  $w \equiv 0$  in order to keep the radius  $r(t) = \sqrt{z_1(t)^2 + z_2(t)^2}$  constant. Using polar coordinates via the transformation

$$z_1(t) = r(t) \cos(\phi(t)), \quad z_2(t) = r(t) \sin(\phi(t)),$$

the SPCS becomes

$$\dot{r}(t) = r(t) \left( \sin \left( \frac{t}{\epsilon} \right) + u(t) \right), \quad \dot{\phi}(t) = 1.$$

The variation of constants yields the solution

$$r(t) = e^{\epsilon(1 - \cos(\frac{t}{\epsilon}))} e^{\int_0^t u(s) ds}$$

to the initial value  $r(0) = 1$ . Hence, for  $t > 0$ , we have  $r(t) = 1$  if and only if  $t \in \epsilon 2\pi\mathbb{N}$  and  $u(s) = 0$  for a.a.  $s \in [0, t]$ . Accordingly, for rational  $\epsilon > 0$ , the set of points in  $M = S^1$  that can be reached from an initial value  $(z_1^0, z_2^0) \in M$  is only finite. Clearly, the SPCS is not controllable on  $M = S^1$ . Notice that the ACS does not exactly meet Assumption 3.1, since it is not accessible at the origin. However, we can add additional controls locally about the origin in order to achieve local accessibility of the ACS without affecting the described behavior near the unit sphere  $S^1$ .

## ERGODIC CONTROL OF CONTINUOUS-TIME MARKOV CHAINS WITH PATHWISE CONSTRAINTS\*

TOMÁS PRIETO-RUMEAU<sup>†</sup> AND ONÉSIMO HERNÁNDEZ-LERMA<sup>‡</sup>

**Abstract.** This paper deals with unichain ergodic continuous-time controlled Markov chains (CMCs) with a denumerable state space and possibly unbounded reward rates as well as unbounded transition rates. The problem we are concerned with is to find control policies that maximize a sample-path average reward over the family of admissible policies for which a certain pathwise average cost is below a given value with probability one. To study this problem, first, we give conditions for the existence of sample-path average optimal policies. Then we analyze constrained average reward CMCs with “expected” constraints, and, finally, we apply these results to our original control problem with pathwise constraints. Examples on the control of a queueing system and an epidemic process illustrate the feasibility of our approach.

**Key words.** continuous-time controlled Markov chains, Markov decision processes, dynamic programming, ergodic control, constrained control problems

**DOI.** 10.1137/060668857

**1. Introduction.** This paper studies unichain ergodic continuous-time denumerable-state controlled Markov chains (CMCs), also known as Markov decision processes (MDPs). The corresponding transition and reward rates can both be unbounded. The problem we are concerned with is to maximize a long-run sample-path (or pathwise) average reward for the given CMC, subject to constraints on a given long-run pathwise average cost. (For expositional convenience we consider a single constraint, but it should be evident how to extend our results to any finite number of constraints.)

To analyze our problem we proceed in three steps. In the first one, we study *unconstrained* pathwise average reward CMCs. In the second step we give conditions for the existence of optimal policies for constrained CMCs with *expected constraints*; see (4.1). In the third and final step we extend the results in the former steps to our problem with *pathwise constraints* (also known in the literature as *hard constraints*); see (3.1). Our approach is illustrated with examples on the control of a queueing system and the control of an epidemic process.

As can be seen in recent papers, e.g., [3, 16, 19, 30] and their references, stochastic control problems with constraints form a very active area of research because they naturally arise in many important applications. However, almost all of the literature is concentrated on problems with *expected* constraints. In contrast, for problems with *pathwise* constraints, there is, to the best of our knowledge, just a handful of papers. For instance, Haviv [14] and Ross and Varadarajan [26, 27] study finite-state, finite-action, discrete-time Markov decision processes, mainly in the multichain case. The paper by Haviv is particularly interesting because it clearly shows, by means

of examples, that pathwise constraints are in general more “natural” than expected constraints—see also Ross and Varadarajan [26, Example 1]. We should also mention Wu, Arapostathis, and Shakkottai [28] who begin with a constrained queue in heavy traffic and end up with the ergodic control of a diffusion process with pathwise constraints—see [28, equations (6a), (6b)].

As can be seen in the related literature, there are several standard techniques for analyzing constrained control problems, such as convex analysis, Lagrange multipliers, linear programming, and dynamic programming. Our approach in this paper uses, mainly, a combination of the last three techniques.

The remainder of this paper is organized as follows. In section 2 we introduce the control model we will be dealing with. In section 3 we state our main results on CMCs with pathwise constraints (Theorem 3.3). The corresponding proofs are postponed to section 4. These proofs require several preliminary results which are of valuable interest by themselves. More precisely, we study the existence and characterization of (unconstrained) pathwise average optimal policies; see Theorem 4.3. Also, we consider problems with *expected* constraints which, as far as we know, have not been systematically studied for average reward CMCs; see Theorems 4.9 and 4.10. In section 5 we introduce the examples mentioned above, and we conclude in section 6 with some general remarks. Finally, in section 7 we give the proofs of two interesting results: one concerns the so-called Lyapunov conditions, and the other gives an easily verifiable condition for uniform exponential ergodicity of CMCs.

**2. Model definition and main assumptions.** We will deal with the control model

$$\{S, (A(i), i \in S), q_{ij}(a), r(i, a), u(i, a)\},$$

where

- $S$  is the state space, which we assume to be a denumerable set. Without loss of generality we will assume that  $S$  is the set of nonnegative integers, i.e.,  $S := \{0, 1, 2, \dots\}$ . (See the second example in section 5 for a bidimensional state space that can be suitably enumerated in the form  $0, 1, 2, \dots$ )
- for each  $i \in S$ ,  $A(i)$  is the set of admissible control actions in the state  $i$ , and it is assumed to be a Borel space, that is, a Borel subset of a complete and separable metric space. The action space  $A(i)$  is endowed with its Borel  $\sigma$ -algebra, denoted by  $\mathbb{B}(A(i))$ . We also define the set  $K := \{(i, a) : i \in S, a \in A(i)\}$ .
- for every  $i, j \in S$  and  $a \in A(i)$ ,  $q_{ij}(a)$  denotes the transition rate from  $i$  to  $j$  under the action  $a \in A(i)$ . The function  $a \mapsto q_{ij}(a)$  is measurable on  $\mathbb{B}(A(i))$  (measurability on the real numbers set  $\mathbb{R}$  is always with respect to the usual Borel  $\sigma$ -algebra) for each  $i, j \in S$ . By definition, the transition rates verify  $q_{ij}(a) \geq 0$  for every  $(i, a) \in K$  and  $j \in S$  such that  $i \neq j$ . We will also assume that they are *conservative*, i.e.,

$$(2.1) \quad \sum_{j \in S} q_{ij}(a) = 0 \quad \forall (i, a) \in K,$$

and *stable*, i.e.,

$$(2.2) \quad q(i) := \sup_{a \in A(i)} \{-q_{ii}(a)\} < \infty \quad \forall i \in S.$$

- the reward rate function  $r : K \rightarrow \mathbb{R}$  and the cost rate function  $u : K \rightarrow \mathbb{R}$  are measurable on  $A(i)$  for each fixed  $i \in S$ . We interpret  $r$  as a reward to be (somehow) maximized with the restriction that the cost  $u$  does not exceed (in a suitably defined sense) a given value.

This control model is the same as in, e.g., [9, 10, 12, 25], except that these references deal with *unconstrained* MDPs and so the control model does not include the cost rate  $u(i, a)$ .

**Control policies.** Let  $\Phi_m$  be the family of functions  $\varphi \equiv \{\varphi_t(B|i)\}$ , where  $t \geq 0$ ,  $i \in S$ , and  $B \in \mathbb{B}(A(i))$ , such that

- for each  $t \geq 0$  and  $i \in S$ ,  $B \mapsto \varphi_t(B|i)$  is a probability measure on  $(A(i), \mathbb{B}(A(i)))$ ;
- for each  $i \in S$  and  $B \in \mathbb{B}(A(i))$ , the function  $t \mapsto \varphi_t(B|i)$  is measurable on  $[0, \infty)$ .

We say that  $\varphi \in \Phi_m$  is a (*randomized*) *Markov policy*. Given  $\varphi \in \Phi_m$ , we will use the following notation:

$$(2.3) \quad q_{ij}(t, \varphi) := \int_{A(i)} q_{ij}(a) \varphi_t(da|i) \quad \forall i, j \in S, t \geq 0,$$

which is finite as a consequence of (2.1) and (2.2). We also define

$$(2.4) \quad r(t, i, \varphi) := \int_{A(i)} r(i, a) \varphi_t(da|i) \quad \text{and} \quad u(t, i, \varphi) := \int_{A(i)} u(i, a) \varphi_t(da|i)$$

for  $i, j \in S$  and  $t \geq 0$ . In what follows, we will impose conditions ensuring that the integrals in (2.4) are well defined and finite.

In the family of Markov policies, we will consider two especially relevant classes of policies: stationary policies and deterministic stationary policies.

Given a Markov policy  $\varphi \equiv \{\varphi_t(B|i)\}$ , we say that  $\varphi$  is *stationary* if it does not depend on  $t \geq 0$ , and we will write  $\varphi \equiv \{\varphi(B|i)\}$ . The set of stationary (randomized) policies is denoted by  $\Phi_s$ .

A stationary policy  $\varphi$  is *deterministic* if  $\varphi(\cdot|i)$  is a Dirac probability measure for each  $i \in S$ . The set of deterministic stationary policies can be identified with the class  $\mathbb{F}$  of functions  $f : S \rightarrow \cup_{i \in S} A(i)$  such that  $f(i) \in A(i)$  for every  $i \in S$ . Therefore, we have

$$\mathbb{F} \subseteq \Phi_s \subseteq \Phi_m.$$

When considering stationary policies  $\varphi \in \Phi_s$ , the expressions in (2.3) and (2.4) will be simply written as  $q_{ij}(\varphi)$ ,  $r(i, \varphi)$ , and  $u(i, \varphi)$ .

For each  $\varphi \in \Phi_m$  there exists a nonhomogeneous  $Q$ -process with transition rates given by  $q_{ij}(t, \varphi)$ ; for a proof, we refer to [29]. To ensure the regularity of the  $Q$ -process, we must impose further conditions on the control model.

**Assumptions.** We next state the assumptions on our control model. Our Assumptions A, B, and C below are mainly taken from [10, 25].

*Assumption A.* There exists a nondecreasing function  $w \geq 1$  on  $S$  such that

- $\lim_{i \rightarrow \infty} w(i) = \infty$ ;
- there exist constants  $b \geq c > 0$  and a finite set  $S_0 \subset S$  such that

$$\sum_{j \in S} q_{ij}(a) w(j) \leq -cw(i) + bI_{S_0}(i) \quad \forall (i, a) \in K,$$

where  $I$  denotes the indicator function;

- (c) there exists a constant  $M > 0$  such that  $|r(i, a)| \leq Mw(i)$  and  $|u(i, a)| \leq Mw(i)$  for every  $(i, a) \in K$ .

The function  $w$  in Assumption A is often referred to as a Lyapunov function or a moment-like function. Assumptions A(a) and A(b) ensure that, for each  $\varphi \in \Phi_m$ , there exists a Markov process  $\{x^\varphi(t)\}$ , with transition function  $p^\varphi(s, i, t, j)$ , for  $i, j \in S$  and  $t \geq s \geq 0$ , whose transition rates are given by  $q_{ij}(t, \varphi)$ . For a proof we refer to [9, Theorem 3.1].

Given an initial state  $i \in S$  at time  $s \geq 0$  and a Markov policy  $\varphi \in \Phi_m$ , we will denote by  $P_{s,i}^\varphi$  and  $E_{s,i}^\varphi$  the probability measure and the corresponding expectation operator defined by  $p^\varphi(s, i, t, j)$ . When  $s = 0$ ,  $P_{0,i}^\varphi$ ,  $E_{0,i}^\varphi$ , and  $p^\varphi(0, i, t, j)$  will be simply written as  $P_i^\varphi$ ,  $E_i^\varphi$ , and  $p^\varphi(i, t, j)$ , respectively.

DEFINITION 2.1. *Given  $\varphi \in \Phi_m$ ,  $i \in S$ , and  $T \geq 0$ , we define the total pathwise reward and the total expected reward on  $[0, T]$  as*

$$(2.5) \quad J_T^0(i, \varphi) := \int_0^T r(t, x(t), \varphi) dt \quad \text{and} \quad J_T(i, \varphi) := E_i^\varphi \left[ \int_0^T r(t, x(t), \varphi) dt \right],$$

*respectively. Replacing the reward rate  $r$  with the cost rate  $u$ , we obtain the definition of  $J_{u,T}^0(i, \varphi)$  and  $J_{u,T}(i, \varphi)$ .*

*The long-run pathwise average reward (or pathwise average reward, for short) and the long-run expected average reward (also referred to as gain or expected average reward) are given by*

$$J^0(i, \varphi) := \liminf_{T \rightarrow \infty} \frac{1}{T} J_T^0(i, \varphi) \quad \text{and} \quad J(i, \varphi) := \liminf_{T \rightarrow \infty} \frac{1}{T} J_T(i, \varphi),$$

*respectively. Similarly, the pathwise average cost and the expected average cost are, respectively, defined as*

$$J_u^0(i, \varphi) := \limsup_{T \rightarrow \infty} \frac{1}{T} J_{u,T}^0(i, \varphi) \quad \text{and} \quad J_u(i, \varphi) := \limsup_{T \rightarrow \infty} \frac{1}{T} J_{u,T}(i, \varphi).$$

These definitions follow a standard convention for CMCs: since  $r$  is a reward rate,  $J^0(i, \varphi)$  and  $J(i, \varphi)$  are defined as a “lim inf”; when  $u$  is a cost rate,  $J_u^0(i, \varphi)$  and  $J_u(i, \varphi)$  are defined as a “lim sup.”

We note that in (2.5) the Markov process is denoted by  $x(t)$  rather than  $x^\varphi(t)$ . This is because, for instance, in the notation  $J_T^0(i, \varphi)$  the initial state  $i$  and the policy  $\varphi$  completely determine the probability measure  $P_i^\varphi$ , and thus writing  $x^\varphi(t)$  is somewhat redundant.

Remark 2.2. Observe that, if  $\varphi \in \Phi_m$  is not randomized, then the random variables  $J^0(i, \varphi)$  and  $J_u^0(i, \varphi)$  denote the long-run average reward and cost of a given sample path of  $\{x^\varphi(t)\}_{t \geq 0}$ , while if  $\varphi \in \Phi_m$  is randomized, then the corresponding reward and cost are integrated with respect to  $\varphi_t(da|x(t))$  (recall (2.4)). The reason for this is that the transition rates themselves of the Markov process  $\{x^\varphi(t)\}$  are defined by integration with respect to  $\varphi_t(da|x(t))$ ; see (2.3). This is, however, the usual definition of the long-run pathwise average reward and cost for a randomized policy; see, e.g., [8].

The next lemma, which follows from [9, Theorem 3.1(a)], [10, Lemma 3.2(a)], and [15, Lemma 2.1], yields an estimate on the expected growth of  $w(x(t))$ .

LEMMA 2.3. *If Assumptions A(a) and A(b) hold, then*

$$(2.6) \quad E_i^\varphi w(x(t)) \leq e^{-ct}w(i) + \frac{b}{c}(1 - e^{-ct}) \quad \forall \varphi \in \Phi_m, i \in S, t \geq 0.$$

*Proof.* We give a sketch of the proof. The inequality

$$(2.7) \quad \sum_{j \in S} q_{ij}(a)w(j) \leq -cw(i) + bI_{S_0}(i) \quad \forall (i, a) \in K$$

in Assumption A(b) implies the inequality

$$(2.8) \quad \sum_{j \in S} q_{ij}(t, \varphi)w(j) \leq -cw(i) + b \quad \forall \varphi \in \Phi_m, i \in S, t \geq 0.$$

To see this, integrate (2.7) with respect to  $\varphi_t(da|i)$ . Then, the interchange of sum and integral is derived from the conservative and stability properties (2.1) and (2.2). Now, (2.8) is similar to the condition (a<sub>2</sub>) in [10, Lemma 3.2(a)]. Therefore, the result follows.  $\square$

Furthermore, if Assumption A(c) holds, then we derive from Lemma 2.3 that, for every  $\varphi \in \Phi_m$  and  $i \in S$ ,

$$(2.9) \quad |J(i, \varphi)| \leq bM/c \quad \text{and} \quad |J_u(i, \varphi)| \leq bM/c.$$

Our next assumption imposes the usual continuity-compactness conditions. The function  $w$  is taken from Assumption A.

*Assumption B.*

- (a) For each  $i \in S$ , the action space  $A(i)$  is compact.
- (b) For every  $i \in S$ ,  $q(i) \leq w(i)$ .
- (c) For each  $i, j \in S$ , the functions  $r(i, a)$ ,  $u(i, a)$ ,  $q_{ij}(a)$ , and  $\sum_{k \in S} q_{ik}(a)w(k)$  are continuous on  $A(i)$ .
- (d) There exist constants  $c' > 0$  and  $b' \geq 0$  such that

$$\sum_{j \in S} q_{ij}(a)w^2(j) \leq c'w^2(i) + b' \quad \forall (i, a) \in K.$$

Observe that the continuity of the  $q_{ij}(a)$ , together with Assumptions A(a) and B(d), implies that the series  $\sum_{k \in S} q_{ik}(a)w(k)$  is uniformly convergent on  $A(i)$  and, hence, continuous (cf. the last statement of Assumption B(c)).

Assumption B(b) is not strictly necessary. Indeed, it suffices that the function  $i \mapsto w(i)q(i)$  is bounded by a function  $w'$  satisfying a Lyapunov condition as the one stated in Assumption B(d). However, in practice,  $q(i)$  and  $w(i)$  are of the same order, and there is no loss of generality in assuming that  $q(i) \leq w(i)$ .

*Assumption C(a).* For each  $\varphi \in \Phi_s$ , the Markov process  $\{x^\varphi(t)\}_{t \geq 0}$  is irreducible.

By Assumptions A and C(a), for each  $\varphi \in \Phi_s$  the Markov process has a unique invariant probability measure, denoted by  $\mu_\varphi$ , and

$$\mu_\varphi(w) := \int_S w d\mu_\varphi$$

is finite; see [23, Theorem 4.2]. Moreover, by integration of (2.6) with respect to  $\mu_\varphi$ , we obtain  $\int_S w d\mu_\varphi \leq b/c$  for all  $\varphi \in \Phi_s$ . It follows also that  $J(i, \varphi)$  and  $J_u(i, \varphi)$  in

Definition 2.1 are constant if  $\varphi \in \Phi_s$  (i.e., they do not depend on the initial state of the system), and they verify

$$J(i, \varphi) = \lim_{T \rightarrow \infty} \frac{1}{T} J_T(i, \varphi) = \sum_{j \in S} r(j, \varphi) \mu_\varphi\{j\} =: g(\varphi)$$

and

$$(2.10) \quad J_u(i, \varphi) = \lim_{T \rightarrow \infty} \frac{1}{T} J_{u,T}(i, \varphi) = \sum_{j \in S} u(j, \varphi) \mu_\varphi\{j\} =: g_u(\varphi)$$

for all  $i \in S$ .

The following strong law of large numbers holds. Its proof is a direct consequence of the results in [2] and is therefore omitted. (Next, we will use the standard abbreviation “a.s.” for “almost surely.”)

**PROPOSITION 2.4.** *Suppose that Assumptions A and C(a) hold. For each  $\varphi \in \Phi_s$  and every initial state  $i \in S$ ,*

$$J^0(i, \varphi) = \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T r(x(t), \varphi) dt = g(\varphi) \quad P_i^\varphi\text{-a.s.}$$

and

$$J_u^0(i, \varphi) = \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T u(x(t), \varphi) dt = g_u(\varphi) \quad P_i^\varphi\text{-a.s.}$$

**3. Main results.** Now we are ready to define the ergodic control problem with pathwise constraints. Our goal is to maximize with probability one the long-run pathwise average reward  $J^0(i, \varphi)$  over the family of policies  $\varphi \in \Phi_m$  that satisfy the following constraint on the long-run pathwise average cost (which can be interpreted as a budgetary restriction):

$$J_u^0(i, \varphi) \leq \theta_0 \quad P_i^\varphi\text{-a.s.}$$

for  $i \in S$ , where  $\theta_0 \in \mathbb{R}$  is a given constant. In short (writing “s.t.” for “subject to”),

$$(3.1) \quad \max J^0(i, \varphi) \quad \text{s.t.} \quad \varphi \in \Phi_m \quad \text{and} \quad J_u^0(i, \varphi) \leq \theta_0 \quad \text{for } i \in S.$$

It is worth noting that if the stationary policy  $\varphi \in \Phi_s$  verifies  $g_u(\varphi) \leq \theta_0$ , then, as a consequence of Proposition 2.4,  $J_u^0(i, \varphi) \leq \theta_0$  with  $P_i^\varphi$ -probability one for every  $i \in S$ . Our definition of an optimal stationary policy for (3.1) is the following.

**DEFINITION 3.1.** *We say that a policy  $\varphi^* \in \Phi_s$  such that  $g_u(\varphi^*) \leq \theta_0$  is optimal for the pathwise constrained CMC (3.1), or pathwise constrained optimal, if for each  $\varphi \in \Phi_m$  and every  $i \in S$  such that  $J_u^0(i, \varphi) \leq \theta_0$   $P_i^\varphi$ -a.s., we have  $J^0(i, \varphi) \leq g(\varphi^*)$   $P_i^{\varphi^*}$ -a.s.*

If  $\varphi^* \in \Phi_s$  is a pathwise constrained optimal policy, then we define the optimal value of the constrained CMC (3.1) as  $V^* := g(\varphi^*)$ .

**Further assumptions.** Before stating our next assumption, we introduce some notation. We define the following norm on the space of functions  $v : S \rightarrow \mathbb{R}$ :

$$\|v\|_w := \sup_{i \in S} \frac{|v(i)|}{w(i)},$$

and we denote by  $\mathcal{B}_w(S)$  the Banach space of functions on  $S$  with finite  $w$ -norm.

Sufficient conditions for Assumption C(b) below are given in [10, 25]. More precisely, a monotonicity condition is proposed in [10], and a uniform integrability condition is given in [25]. Moreover, in Theorem 7.2 in the appendix we propose a new condition yielding Assumption C(b).

*Assumption C(b).* The control model is  $w$ -exponentially ergodic on  $\mathbb{F}$ ; that is, there exist constants  $\delta > 0$  and  $R > 0$  such that

$$\sup_{f \in \mathbb{F}} |E_i^f v(x(t)) - \mu_f(v)| \leq R e^{-\delta t} \|v\|_w w(i)$$

for every  $i \in S$ ,  $t \geq 0$ , and  $v \in \mathcal{B}_w(S)$ , where  $\mu_f(v) := \int_S v d\mu_f$ .

We state our last assumption.

*Assumption D.* There exist constants  $\tilde{b} \geq \tilde{c} > 0$  and a finite set  $\tilde{S}_0 \subset S$  such that

$$\sum_{j \in S} q_{ij}(a) w^2(j) \leq -\tilde{c} w^2(i) + \tilde{b} I_{\tilde{S}_0}(i) \quad \forall (i, a) \in K.$$

Obviously, Assumption D implies Assumption B(d). Theorem 7.1 in the appendix proves that Assumption D implies Assumption A(b). For future reference we note that, under Assumptions A(a) and D, a result similar to Lemma 2.3 holds. Namely,

$$(3.2) \quad E_i^\varphi w^2(x(t)) \leq e^{-\tilde{c}t} w^2(i) + \frac{\tilde{b}}{\tilde{c}} (1 - e^{-\tilde{c}t}) \quad \forall \varphi \in \Phi_m, i \in S, t \geq 0.$$

If in addition Assumption C(a) is satisfied, then, by integration of (3.2) with respect to  $\mu_\varphi$ ,

$$(3.3) \quad \int_S w^2 d\mu_\varphi \leq \tilde{b}/\tilde{c} \quad \forall \varphi \in \Phi_s.$$

Before stating our main theorem, we need to recall some results on *expected* average reward optimality taken from [10].

**Average reward optimality.** We say that a policy  $\varphi^* \in \Phi_m$  is *average reward optimal* or *gain optimal* for the reward rate function  $r$  if

$$J(i, \varphi^*) = \sup_{\varphi \in \Phi_m} J(i, \varphi) =: J^*(i) \quad \forall i \in S,$$

where the above supremum is finite as a consequence (2.9). Our next theorem characterizes the optimal value function  $J^*$  and the class of average reward optimal stationary policies; for a proof, see [10, Theorem 4.1].

**THEOREM 3.2.** *Suppose that Assumptions A, B, and C hold. Then*

- (i) *there exists a solution  $(g^*, h^*) \in \mathbb{R} \times \mathcal{B}_w(S)$  to the average reward optimality equation (AROE)*

$$(3.4) \quad g^* = \max_{a \in A(i)} \left\{ r(i, a) + \sum_{j \in S} q_{ij}(a) h^*(j) \right\} \quad \forall i \in S;$$

- (ii) *a deterministic stationary policy  $f^* \in \mathbb{F}$  is gain optimal if and only if  $f^*(i)$  attains the maximum in (3.4) for every  $i \in S$ . A stationary policy  $\varphi \in \Phi_s$  is gain optimal if and only if  $\varphi(\cdot|i)$  is supported on the set of maxima of (3.4) for each  $i \in S$ ;*

(iii) the constant  $g^*$  is the optimal gain, i.e.,  $J^*(i) = g^*$  for each  $i \in S$ .

The policies  $f \in \mathbb{F}$  attaining the maximum in the AROE (3.4) are usually referred to as *canonical*. The set of canonical policies is denoted by  $\mathbb{F}_{ca}$ . Since it is straightforward to see that  $\mathbb{F}_{ca}$  is nonempty, Theorem 3.2(ii) tacitly states the *existence of gain optimal policies in  $\mathbb{F}$* .

Obviously, a result similar to Theorem 3.2 holds when the reward rate function  $r$  is replaced with any reward rate function satisfying Assumptions A(c) and B(c).

**Pathwise constrained optimality.** Now we state our main results on the existence of pathwise constrained optimal policies and the characterization of the corresponding value function. (At this point, recall Definition 3.1.)

Under our standing assumptions (in particular, see (2.9) and Theorem 3.2) both

$$(3.5) \quad \theta_{\min} := \min_{\varphi \in \Phi_s} g_u(\varphi) \quad \text{and} \quad \theta_{\max} := \max_{\varphi \in \Phi_s} g_u(\varphi)$$

are finite. When dealing with the constrained problem (3.1), to avoid trivial situations we will assume that the constant  $\theta_0$  verifies

$$(3.6) \quad \theta_{\min} < \theta_0 < \theta_{\max}.$$

**THEOREM 3.3.** *Suppose that Assumptions A, B, C, and D hold, and consider the pathwise constrained CMC (3.1) with  $\theta_0 \in \mathbb{R}$  as in (3.6). Then*

- (i) *there exists a pathwise constrained optimal policy  $\varphi^* \in \Phi_s$ , that is,  $g(\varphi^*) = V^*$  and  $g_u(\varphi^*) \leq \theta_0$ ; in addition,  $\varphi^*$  is such that it randomizes in at most one state;*
- (ii) *there exist  $\lambda_0 \leq 0$  and  $h \in \mathcal{B}_w(S)$  such that*

$$V^* = \max_{a \in A(i)} \left\{ r(i, a) + \lambda_0(u(i, a) - \theta_0) + \sum_{j \in S} q_{ij}(a)h(j) \right\} \quad \forall i \in S;$$

- (iii) *for each  $\lambda \in (-\infty, 0]$ , let  $(g(\lambda), h_\lambda) \in \mathbb{R} \times \mathcal{B}_w(S)$  be a solution to the following AROE (such a solution indeed exists as a consequence of Theorem 3.2):*

$$g(\lambda) = \max_{a \in A(i)} \left\{ r(i, a) + \lambda(u(i, a) - \theta_0) + \sum_{j \in S} q_{ij}(a)h_\lambda(j) \right\} \quad \forall i \in S.$$

*Then  $V^* = \min_{\lambda \leq 0} g(\lambda)$ .*

For the proof of Theorem 3.3, see section 4 below.

**4. Proofs.** To prove the main result of this paper, Theorem 3.3, we need several preliminary results. These concern sample-path average optimality and CMCs with expected constraints.

**Sample-path average optimality.** In what follows, we will suppose that Assumptions A, B, C, and D are satisfied. Theorem 3.2 proves the existence of a gain (or *expected* average reward) optimal policy. Now we prove that there exist policies that are *pathwise* average reward optimal as in Definition 4.1 below.

Similar results for discrete-time Markov decision processes can be found in [18, Chapter 11]. Pathwise average optimality for continuous-time controlled Markov chains, under hypotheses similar to ours, has also been studied in [8]. For a discussion of the results in [8] and ours, see Remark 4.4 below.

DEFINITION 4.1. A policy  $\varphi^* \in \Phi_s$  is said to be sample-path average optimal if for every  $\varphi \in \Phi_m$  and  $i \in S$ ,  $J^0(i, \varphi) \leq g(\varphi^*)$   $P_i^\varphi$ -a.s.

In order to obtain a characterization of sample-path average optimal policies, we need a preliminary result that uses the notation (2.3). We also use  $\xrightarrow{p}$  to denote convergence in probability.

LEMMA 4.2. Suppose that Assumptions A(a), B(b), and D are verified. Given a Markov policy  $\varphi \in \Phi_m$ , an initial state  $i \in S$ , and an arbitrary  $h \in \mathcal{B}_w(S)$ , we have

$$\frac{1}{n} \int_0^n L^{\varphi, t} h(x(t)) dt \xrightarrow{p} 0 \quad \text{as } n \rightarrow \infty$$

with respect to  $P_i^\varphi$ , where  $(L^{\varphi, t} h)(i) := \sum_{j \in S} q_{ij}(t, \varphi) h(j)$  for  $i \in S$ .

*Proof.* By the theory of Markov processes we know that  $Z_t^\varphi := h(x(t)) - h(x(0)) - \int_0^t L^{\varphi, s} h(x(s)) ds$ , for  $t \geq 0$ , is a  $P_i^\varphi$ -martingale. Consider now the discrete-time martingale difference

$$Z_{n+1}^\varphi - Z_n^\varphi = h(x(n+1)) - h(x(n)) - \int_n^{n+1} L^{\varphi, s} h(x(s)) ds \quad \text{for } n \geq 0.$$

Observe that, by Assumptions A(b) (which is implied by Assumption D; see Theorem 7.1) and B(b),  $|(L^{\varphi, t} h)(i)| \leq \|h\|_w(2+b)w^2(i)$  and thus, using (3.2), we deduce that

$$\sup_{n \in \mathbb{N}} E_i^\varphi |Z_{n+1}^\varphi - Z_n^\varphi| < \infty.$$

As a consequence of [13, Theorem 2.18],  $Z_n^\varphi/n$  converges to 0 in probability. Moreover, it is easily proved that  $h(x(n))/n$  also converges in probability to 0. Hence, the result follows.  $\square$

The next result, together with Theorem 3.2, gives a characterization of sample-path average optimal stationary policies and the corresponding optimal value.

THEOREM 4.3. Suppose that Assumptions A, B, C, and D hold. A stationary policy is sample-path average optimal if and only if it is gain optimal.

*Proof.* As a consequence of Proposition 2.4, sample-path average optimal policies are necessarily gain optimal. Let us prove the converse result. Let  $(g^*, h^*) \in \mathbb{R} \times \mathcal{B}_w(S)$  be a solution of the AROE (3.4). We will show that, given a Markov policy  $\varphi \in \Phi_m$  and an initial state  $i \in S$ ,  $J^0(i, \varphi) \leq g^*$   $P_i^\varphi$ -a.s.

To this end, note that by the AROE, for every  $s \geq 0$ ,

$$r(s, x(s), \varphi) + L^{\varphi, s} h^*(x(s)) \leq g^*,$$

and thus

$$\frac{1}{t} \int_0^t r(s, x(s), \varphi) ds + \frac{1}{t} \int_0^t L^{\varphi, s} h^*(x(s)) ds \leq g^* \quad \forall t > 0.$$

By Lemma 4.2, there exists a sequence  $\{t_n\}_{n \geq 0}$  such that  $t_n \rightarrow \infty$  and

$$\frac{1}{t_n} \int_0^{t_n} L^{\varphi, s} h^*(x(s)) ds \xrightarrow{P_i^\varphi\text{-a.s.}} 0 \quad \text{as } n \rightarrow \infty.$$

Therefore, recalling Definition 2.1,

$$J^0(i, \varphi) \leq \liminf_{n \rightarrow \infty} \frac{1}{t_n} \int_0^{t_n} r(s, x(s), \varphi) ds \leq g^* \quad P_i^\varphi\text{-a.s.},$$

as we wanted to prove.  $\square$

*Remark 4.4.* As we have already mentioned, sample-path average optimality has been analyzed in [8]. In that paper, it is proved that canonical policies are sample-path average optimal under the “lim sup criterion” by imposing a Lyapunov condition on  $w^4$  (see [8, Assumption C(2)]), whereas our Theorem 4.3 shows that under a Lyapunov condition on  $w^2$  we reach sample-path average optimality for the “lim inf criterion.”

It is worth noting that, when dealing with stationary policies, the “lim inf” and the “lim sup” criteria are equivalent (see Proposition 2.4). When dealing with *nonstationary* policies, however, proving an inequality such as, e.g.,  $J^0(i, \varphi) \leq g^*$   $P_i^\varphi$ -a.s., is more difficult for the lim sup than for the lim inf criterion.

**CMCs with expected constraints.** As was remarked in section 1, there are several approaches to analyzing constrained CMCs. Here, we combine the Lagrange multipliers and the linear programming techniques with the dynamic programming equation approach. We assume that Assumptions A, B, C, and D hold.

We want to maximize, for every initial state  $i \in S$ ,  $J(i, \varphi)$  over the set of policies  $\varphi \in \Phi_m$  such that  $J_u(i, \varphi) \leq \theta_0$ , where  $\theta_0$  is as in (3.6). In short, we consider the following constrained problem:

$$(4.1) \quad \max J(i, \varphi) \quad \text{s.t.} \quad \varphi \in \Phi_m \quad \text{and} \quad J_u(i, \varphi) \leq \theta_0, \quad \text{for } i \in S.$$

**DEFINITION 4.5.** We say that a policy  $\varphi^* \in \Phi_m$  such that  $J_u(i, \varphi^*) \leq \theta_0$  for every  $i \in S$  is optimal for the constrained CMC (4.1) if, for each  $i \in S$  and every  $\varphi \in \Phi_m$  such that  $J_u(i, \varphi) \leq \theta_0$ , we have  $J(i, \varphi) \leq J(i, \varphi^*)$ .

We denote by  $V^*(i, \theta_0)$  the optimal value function of (4.1), i.e.,

$$V^*(i, \theta_0) := \sup_{\varphi \in \Phi_m} \{J(i, \varphi) : J_u(i, \varphi) \leq \theta_0\} \quad \text{for } i \in S.$$

Now we need to introduce some notation. We define the following norm on the space of functions  $v : S \rightarrow \mathbb{R}$ :

$$\|v\|_1 := \sup_{i \in S} |v(i)|,$$

and we denote by  $\mathcal{B}_1(S)$  the Banach space of functions on  $S$  with finite 1-norm. We also define  $\mathcal{C}_w(K)$  as the set of functions  $v : K \rightarrow \mathbb{R}$  such that  $i \mapsto \sup_{a \in A(i)} |v(i, a)|$  is in  $\mathcal{B}_w(S)$ , and, in addition,  $a \mapsto v(i, a)$  is continuous on  $A(i)$  for each  $i \in S$ . By Assumptions A(c) and B(c), the functions  $r$  and  $u$  are in  $\mathcal{C}_w(K)$ .

We denote by  $\mathcal{P}_w(S)$  the family of probability measures on  $S$  for which the integral of  $w$  is finite. In particular, for every  $\varphi \in \Phi_s$ ,  $\mu_\varphi$  is in  $\mathcal{P}_w(S)$ . Similarly, we denote by  $\mathcal{P}_w(K)$  the set of probability measures  $\mu$  on  $K$  such that  $\sum_{i \in S} w(i) \mu(\{i\} \times A(i)) < \infty$ . Finally, for each  $\varphi \in \Phi_s$ , we define  $\hat{\mu}_\varphi \in \mathcal{P}_w(K)$  as follows: for  $i \in S$  and measurable  $B \subseteq A(i)$ ,

$$\hat{\mu}_\varphi(\{i\} \times B) := \mu_\varphi\{i\} \varphi(B|i).$$

We consider the  $w$ -weak topology on  $\mathcal{P}_w(K)$ , i.e., the smallest topology for which

$$\hat{\mu} \mapsto \int_K v d\hat{\mu}$$

is continuous for every  $v \in \mathcal{C}_w(K)$ . The space  $\mathcal{P}_w(K)$  with the  $w$ -weak topology is a Borel space [5, Appendix A.5].

In what follows, we will analyze several properties of the set

$$\Gamma := \{\hat{\mu}_\varphi : \varphi \in \Phi_s\} \subseteq \mathcal{P}_w(K).$$

Lemma 4.6 below is a standard result (see, e.g., [20, section 3]). However, the denumerability of the state space  $S$  simplifies its proof and weakens its hypotheses. Actually, we use the well-known fact that if  $\mu_\varphi$  is an invariant probability measure for the Markov process with transition rates  $\{q_{ij}(\varphi)\}$ , then  $\sum_{i \in S} \mu_\varphi(i) q_{ij}(\varphi) = 0$  (see [1, Chapter 5]).

LEMMA 4.6. *Given  $\hat{\mu} \in \mathcal{P}_w(K)$ , a necessary and sufficient condition for  $\hat{\mu} \in \Gamma$  is that*

$$(4.2) \quad \int_K Lv \, d\hat{\mu} = 0 \quad \text{for every } v \in \mathcal{B}_1(S),$$

where  $(Lv)(i, a) := \sum_{j \in S} q_{ij}(a)v(j)$  for  $(i, a) \in K$ .

*Proof of the necessity.* Fix  $\hat{\mu} \in \Gamma$  and  $v \in \mathcal{B}_1(S)$ . Hence,  $\hat{\mu} = \hat{\mu}_\varphi$  for some  $\varphi \in \Phi_s$ . We have

$$\begin{aligned} \int_K Lv \, d\hat{\mu} &= \sum_{i \in S} \int_{A(i)} \left[ \sum_{j \in S} q_{ij}(a)v(j) \right] \varphi(da|i) \mu_\varphi\{i\} \\ &= \sum_{i \in S} \sum_{j \in S} q_{ij}(\varphi)v(j) \mu_\varphi\{i\} \\ (4.3) \quad &= \sum_{j \in S} v(j) \sum_{i \in S} \mu_\varphi\{i\} q_{ij}(\varphi) = 0, \end{aligned}$$

where the interchange of the sums in (4.3) follows from Assumptions A(b), B(b), and (3.3). This proves (4.2).

*Proof of the sufficiency.* Suppose that (4.2) holds for some  $\hat{\mu} \in \mathcal{P}_w(K)$ . Therefore, by a standard result on the disintegration of measures [17, Proposition D.8], there exists  $\varphi \in \Phi_s$  such that, for each  $i \in S$  and measurable  $B \subseteq A(i)$ ,

$$\hat{\mu}(\{i\} \times B) = \mu\{i\} \varphi(B|i),$$

where  $\mu \in \mathcal{P}_w(S)$  denotes the marginal of  $\hat{\mu}$  on  $S$ . Hence, as in the proof of the necessary condition, and letting  $v(\cdot) := I_{\{j\}}(\cdot)$ , we can show that  $\sum_{i \in S} \mu\{i\} q_{ij}(\varphi) = 0$  for every  $j \in S$ , and then  $\mu$  is necessarily the invariant probability measure of  $\{x^\varphi(t)\}_{t \geq 0}$ . Thus  $\hat{\mu} = \hat{\mu}_\varphi$ , as we wanted to prove.  $\square$

LEMMA 4.7. *The set  $\Gamma$  is convex and compact for the  $w$ -weak topology.*

*Proof.* It follows directly from Lemma 4.6 that any convex combination of measures in  $\Gamma$  lies in  $\Gamma$ .

For the compactness statement, we derive from Assumptions A(a) and B(a) that the sets  $\{(i, a) \in K : w^2(i) \leq nw(i)\}$  are compact in  $K$  for every  $n \geq 1$ . We also have, by (3.3),

$$\sup_{\hat{\mu} \in \Gamma} \int_K w^2 d\hat{\mu} = \sup_{\varphi \in \Phi_s} \int_S w^2 d\mu_\varphi < \infty.$$

Therefore, from [5, Corollary A.30(c)],  $\Gamma$  is compact.  $\square$

Observe that, when dealing with constrained CMCs, convexity is usually referred to the class of policies (see, e.g., [11, Lemma 3.3]). In this paper, however, we exploit convexity properties of the class of invariant state-action occupation measures, and thus our approach is quite different from that in [11].

Our next result is a direct consequence of the convexity property of  $\Gamma$  proved in Lemma 4.7, and it is stated without proof.

LEMMA 4.8. *The function  $\theta \mapsto V(\theta) := \sup\{\int_K r d\hat{\mu} : \hat{\mu} \in \Gamma, \int_K u d\hat{\mu} \leq \theta\}$  is concave and nondecreasing on  $[\theta_{\min}, \theta_{\max}]$ . (Recall the notation (3.5).)*

In particular, since  $V^*(i, \theta_0)$  is a supremum over  $\Phi_m$  (see Definition 4.5) and  $V(\theta_0)$  is a supremum over  $\Phi_s$ , we have

$$(4.4) \quad V(\theta_0) \leq V^*(i, \theta_0) \quad \forall i \in S.$$

A standard result for control problems with  $n$  constraints is that there exists an optimal randomized stationary policy that is a convex combination of at most  $n + 1$  deterministic stationary policies. (See, e.g., [7].) Part (iii) in the following theorem gives a more explicit characterization of this optimal policy. We use the notation introduced in Definition 4.5.

THEOREM 4.9. *Suppose that Assumptions A, B, C, and D hold, and consider the constrained CMC (4.1) with  $\theta_0$  as in (3.6). Then*

- (i) *the value function  $V^*(i, \theta_0)$  does not depend on  $i \in S$ , and  $V(\theta_0) \equiv V^*(i, \theta_0)$ ;*
- (ii) *there exist  $\lambda_0 \leq 0$  and  $h \in \mathcal{B}_w(S)$  such that*

$$V(\theta_0) = \max_{a \in A(i)} \left\{ r(i, a) + \lambda_0(u(i, a) - \theta_0) + \sum_{j \in S} q_{ij}(a)h(j) \right\} \quad \forall i \in S;$$

- (iii) *there exists an optimal randomized stationary policy which randomizes in at most one state.*

*Proof of (i).* By Lemma 4.8, the function  $V$ , defined on a closed bounded interval, is concave, and therefore its hypograph is a convex set. Notice that for every  $\hat{\mu} \in \Gamma$ , the point with coordinates  $(\int_K u d\hat{\mu}, \int_K r d\hat{\mu})$  belongs to the hypograph of  $V$ .

Let  $-\lambda_0$ , with  $\lambda_0 \leq 0$ , be a superdifferential (in analogy to a subdifferential) of  $V$  at  $\theta_0$ . The hypograph of  $V$  is contained in the half-space

$$\{(x, y) \in \mathbb{R}^2 : \lambda_0(x - \theta_0) + (y - V(\theta_0)) \leq 0\}.$$

In particular, for every  $\hat{\mu} \in \Gamma$ ,

$$\int_K (r + \lambda_0(u - \theta_0)) d\hat{\mu} \leq V(\theta_0),$$

and thus

$$(4.5) \quad \max_{\hat{\mu} \in \Gamma} \int_K (r + \lambda_0(u - \theta_0)) d\hat{\mu} \leq \max_{\hat{\mu} \in \Gamma} \left\{ \int_K r d\hat{\mu} : \int_K u d\hat{\mu} \leq \theta_0 \right\} = V(\theta_0).$$

Note that the two maxima above are attained because the functions  $\int_K r d\hat{\mu}$  and  $\int_K u d\hat{\mu}$  are continuous on  $\Gamma$ , by the definition of the  $w$ -weak topology, and because the sets  $\Gamma$  and  $\{\hat{\mu} \in \Gamma : \int_K u d\hat{\mu} \leq \theta_0\}$  are compact; recall Lemma 4.7.

Now, let us prove that (4.5) holds with equality. Let  $\hat{\mu}^* \in \Gamma$  attain the maximum in the right-hand equality of (4.5). Since  $\lambda_0 \leq 0$ ,

$$V(\theta_0) = \int_K r d\hat{\mu}^* \leq \int_K (r + \lambda_0(u - \theta_0)) d\hat{\mu}^* \leq \max_{\hat{\mu} \in \Gamma} \int_K (r + \lambda_0(u - \theta_0)) d\hat{\mu}.$$

Hence, we have shown that (4.5) holds with equality or, equivalently,

$$\max_{\varphi \in \Phi_s} \int_K (r + \lambda_0(u - \theta_0)) d\hat{\mu}_\varphi = \max_{\varphi \in \Phi_s} \left\{ \int_K r d\hat{\mu}_\varphi : \int_K u d\hat{\mu}_\varphi \leq \theta_0 \right\} = V(\theta_0).$$

The left-most term of this equality equals the optimal value of an expected average reward control problem with reward rate given by  $r + \lambda_0(u - \theta_0)$ . Therefore, by Theorem 3.2, there exists  $h \in \mathcal{B}_w(S)$  such that  $(V(\theta_0), h)$  is a solution of the corresponding AROE, i.e.,

$$(4.6) \quad V(\theta_0) = \max_{a \in A(i)} \left\{ r(i, a) + \lambda_0(u(i, a) - \theta_0) + \sum_{j \in S} q_{ij}(a) h(j) \right\} \\ = \sup_{\varphi \in \Phi_m} \left\{ \liminf_{T \rightarrow \infty} \frac{1}{T} E_i^\varphi \int_0^T [r(t, x(t), \varphi) + \lambda_0(u(t, x(t), \varphi) - \theta_0)] dt \right\}$$

for every  $i \in S$ .

Now, fix an initial state  $i \in S$  and an arbitrary policy  $\varphi \in \Phi_m$  such that  $J_u(i, \varphi) \leq \theta_0$ . We have

$$J(i, \varphi) \leq J(i, \varphi) + \liminf_{T \rightarrow \infty} \frac{1}{T} E_i^\varphi \int_0^T \lambda_0[u(t, x(t), \varphi) - \theta_0] dt \\ \leq \liminf_{T \rightarrow \infty} \frac{1}{T} E_i^\varphi \int_0^T [r(t, x(t), \varphi) + \lambda_0(u(t, x(t), \varphi) - \theta_0)] dt \\ \leq V(\theta_0),$$

and thus  $V^*(i, \theta_0) \leq V(\theta_0)$  for every  $i \in S$ , which together with (4.4) shows that  $V^*(i, \theta_0) = V(\theta_0)$  for every  $i \in S$ . This proves statement (i).

*Proof of (ii).* Statement (ii) follows now from (4.6).

*Proof of (iii).* We know from Theorem 7.2 that the control model is  $w$ -exponentially ergodic on  $\Phi_s$ , and it follows that for every  $\varphi \in \Phi_s$  the gain  $g(\varphi)$  verifies the corresponding Poisson equation (see [10, Lemma 5.1]). Then, by considering the topology of weak convergence on  $\Phi_s$  (see the proof of Theorem 7.2), one can extend the proof of Lemmas 5.3 and 5.4 in [24] and Lemma 5.16 in [12] and prove that the “gain function” (recall (2.10))

$$(4.7) \quad \varphi \mapsto g_u(\varphi)$$

is continuous on  $\Phi_s$ .

From the feasibility condition (3.6) and by the same argument as in the proof of [11, Theorem 2.1], we deduce that there exist two canonical policies (for the AROE (4.6))  $f_1^*$  and  $f_2^*$  in  $\mathbb{F}$ , which differ in at most one state  $i_0 \in S$ , and such that  $g_u(f_1^*) \leq \theta_0 \leq g_u(f_2^*)$ . Fix  $0 \leq \alpha \leq 1$ , and let  $\varphi_\alpha^* \in \Phi_s$  coincide with  $f_1^*$  and  $f_2^*$  in the states  $j \neq i_0$ , and let  $\varphi_\alpha^*(\cdot | i_0)$  randomize between  $f_1^*(i_0)$  and  $f_2^*(i_0)$  with probabilities  $\alpha$  and  $1 - \alpha$ , respectively.

We know that (see Theorem 3.2(ii)) for every  $\alpha \in [0, 1]$ , the policy  $\varphi_\alpha^*$  is expected average optimal for the reward rate  $r + \lambda_0(u - \theta_0)$ . By the continuity property of  $\alpha \mapsto g_u(\varphi_\alpha^*)$  (recall (4.7)), it follows that for some  $\alpha^* \in [0, 1]$ ,  $g_u(\varphi_{\alpha^*}^*) = \theta_0$ , and thus  $\varphi_{\alpha^*}^*$  is an optimal policy for the constrained CMC (4.1).  $\square$

Theorem 4.9 shows that the constrained control problem (4.1) is equivalent to a nonconstrained CMC depending on a constant  $\lambda_0 \leq 0$ . However, the constant  $\lambda_0$  is unknown. Moreover, its value is derived from the function  $V$ , which is precisely the function that we want to determine! To overcome this situation, we propose our next result, based on Ky-Fan's minimax theorem [6].

**THEOREM 4.10.** *Suppose that Assumptions A, B, C, and D are satisfied and consider the constrained CMC (4.1) with  $\theta_0$  as in (3.6).*

*For each  $\lambda \in (-\infty, 0]$ , let  $(g(\lambda), h_\lambda) \in \mathbb{R} \times \mathcal{B}_w(S)$  be a solution to the AROE*

$$g(\lambda) = \max_{a \in A(i)} \left\{ r(i, a) + \lambda(u(i, a) - \theta_0) + \sum_{j \in S} q_{ij}(a) h_\lambda(j) \right\} \quad \forall i \in S.$$

*Then  $V(\theta_0) = \min_{\lambda \leq 0} g(\lambda)$ .*

*Proof.* Consider the function  $H : \Gamma \times (-\infty, 0] \rightarrow \mathbb{R}$  defined by

$$H(\hat{\mu}, \lambda) := \int_K (r + \lambda(u - \theta_0)) d\hat{\mu}.$$

Obviously,  $H$  is concave (as it is linear) on  $\Gamma$  for fixed  $\lambda$ , and it is convex on  $(-\infty, 0]$  for every  $\hat{\mu}$ . Moreover,  $\Gamma$  is convex and compact (recall Lemma 4.7), and  $H$  is continuous on  $\Gamma$  for fixed  $\lambda$  (by the definition of the  $w$ -weak topology). It follows from [6, Theorem 8] that

$$\max_{\hat{\mu} \in \Gamma} \inf_{\lambda \leq 0} H(\hat{\mu}, \lambda) = \inf_{\lambda \leq 0} \max_{\hat{\mu} \in \Gamma} H(\hat{\mu}, \lambda).$$

Hence, on the one hand,  $\inf_{\lambda \leq 0} H(\hat{\mu}, \lambda)$  equals  $-\infty$  if  $\int_K u d\hat{\mu} > \theta_0$  and equals  $\int_K r d\hat{\mu}$  otherwise. Therefore, by Theorem 4.9,

$$V(\theta_0) = \max_{\hat{\mu} \in \Gamma} \inf_{\lambda \leq 0} H(\hat{\mu}, \lambda).$$

On the other hand, by arguments similar to those in Theorem 4.9,

$$\max_{\hat{\mu} \in \Gamma} H(\hat{\mu}, \lambda) = g(\lambda).$$

Therefore,  $V(\theta_0) = \inf_{\lambda \leq 0} g(\lambda)$ . As a consequence of Theorem 4.9, this infimum is attained at  $\lambda_0$ . This completes the proof.  $\square$

Theorem 4.10 shows that the constrained CMC can be solved by means of a parametric family of AROEs, which do not depend on unknown parameters, as it was the case for Theorem 4.9.

Finally, we give the proof of the main result in this paper.

*Proof of Theorem 3.3. Proof of (i).* By Theorem 4.9, we know that there exists an optimal stationary policy  $\varphi^* \in \Phi_s$  for the “expected” constrained problem (4.1), which randomizes in at most one state. Let us show that  $\varphi^*$  is also optimal for (3.1).

We know that

$$(4.8) \quad g(\varphi^*) = V(\theta_0) \quad \text{and} \quad g_u(\varphi^*) \leq \theta_0.$$

Let  $\lambda_0$  be as in Theorem 4.9. Fix an initial state  $i \in S$  and an arbitrary policy  $\varphi \in \Phi_m$ . We know from Theorems 4.3 and 4.9 that

$$\liminf_{T \rightarrow \infty} \frac{1}{T} \int_0^T [r(t, x(t), \varphi) + \lambda_0(u(t, x(t), \varphi) - \theta_0)] dt \leq V(\theta_0) \quad P_i^\varphi\text{-a.s.}$$

Therefore (recalling that  $\lambda_0 \leq 0$ ),

$$V(\theta_0) \geq J^0(i, \varphi) + \lambda_0(J_u^0(i, \varphi) - \theta_0) \quad P_i^\varphi\text{-a.s.}$$

Hence, if  $\varphi \in \Phi_m$  verifies  $J_u^0(i, \varphi) \leq \theta_0$   $P_i^\varphi$ -a.s., then  $J^0(i, \varphi) \leq V(\theta_0)$   $P_i^\varphi$ -a.s.

Therefore, by (4.8),  $g(\varphi^*) = V^* = V(\theta_0)$ , and thus  $\varphi^*$  is optimal for (3.1).

*Proof of (ii) and (iii).* Since  $V^* = V(\theta_0)$ , these results easily follow from Theorems 4.9 and 4.10. This completes the proof of Theorem 3.3.  $\square$

**5. Examples. A single-server controlled queueing system.** Consider a queueing system with state space  $S = \{0, 1, 2, \dots\}$ . The state variable is interpreted as the number of jobs (waiting or being served) in the system. For each  $i \in S$ , the action space  $A(i)$  is a compact metric space. Jobs arrive at a rate  $\lambda > 0$  and they are served at a rate  $\mu > 0$ . The decision-maker controls a service parameter  $h_1(i, a)$  (which allows either an increase or decrease in the service rate) and an arrival parameter  $h_2(i, a)$ , which is interpreted similarly. We suppose that the functions  $h_1$  and  $h_2$  are bounded and continuous on  $K$ . The transition rates of the system are given by

$$q_{01}(a) = -q_{00}(a) = h_2(0, a) \quad \forall a \in A(0),$$

assumed to be positive. In addition, for  $i \geq 1$ ,

$$q_{i,i-1}(a) = \mu i + h_1(i, a) \quad \text{and} \quad q_{i,i+1}(a) = \lambda i + h_2(i, a),$$

both assumed to be positive, and  $q_{ii}(a) = -q_{i,i-1}(a) - q_{i,i+1}(a)$  for every  $a \in A(i)$ .

The decision-maker obtains a reward with rate  $r(i, a) = pi$ , where  $p > 0$ , when there are  $i$  jobs in the system, and incurs a cost with rate  $c(i, a)$  depending on the control actions, where  $c(i, a)$  is assumed to be continuous on  $A(i)$  for each fixed  $i \in S$  and bounded on  $K$ .

This is the same controlled queueing system as in [10, section VI]. In that reference, the authors consider the net reward rate  $r - c$ . It seems plausible, however, that the controller may have an a priori estimate of the maximal cost per time unit that can be incurred when controlling the system. Therefore, the controller should maximize the long-run average reward with rate  $r$  subject to the restriction that the long-run average cost with rate  $c$  is less than or equal to, say,  $\theta_0$ , assumed to belong to the range of  $c$  (see (3.6)). Moreover, in this case, pathwise constraints are very realistic because, for instance, fitting a budget in terms of an “expected value” does not make much sense.

**PROPOSITION 5.1.** *Consider the controlled queueing system defined above, and suppose that  $\mu > \lambda$ . Then the controller has a pathwise constrained optimal policy.*

*Proof.* Let  $w(i) := C(i + 1)$ , where  $C \geq 1$ . Obviously, Assumptions A(a), B(a), B(c), and C(a) hold. Choosing  $C$  large enough, one can easily prove that Assumptions A(c) and B(b) are also satisfied. By Theorems 7.1 and 7.2, if we prove that Assumption D holds, that is, there exist constants  $\tilde{c} > 0$  and  $\tilde{b} \geq 0$ , and a finite set  $\tilde{S}_0 \subset S$  such that

$$(5.1) \quad \sum_{j \in S} q_{ij}(a) w^2(j) \leq -\tilde{c} w^2(i) + \tilde{b} I_{\tilde{S}_0}(i) \quad \forall (i, a) \in K,$$

then Assumptions A, B, and C will be satisfied.

To obtain (5.1) we first note that, by a simple calculation,

$$\sum_{j \in S} q_{ij}(a)w^2(j) \leq w^2(i)(-2(\mu - \lambda) + F(i)) \quad \forall (i, a) \in K,$$

where  $F$  is a positive function such that  $F(i) \rightarrow 0$  as  $i \rightarrow \infty$ . Therefore, letting  $\tilde{c} := \mu - \lambda$ , there exists some  $i^*$  such that

$$(5.2) \quad \sum_{j \in S} q_{ij}(a)w^2(j) \leq -\tilde{c}w^2(i) \quad \text{for } i > i^* \text{ and } (i, a) \in K.$$

Also, for large enough  $\tilde{b}$ ,

$$(5.3) \quad \sum_{j \in S} q_{ij}(a)w^2(j) \leq -\tilde{c}w^2(i) + \tilde{b} \quad \text{for } i \leq i^* \text{ and } (i, a) \in K.$$

We can now derive (5.1) from (5.2) and (5.3), with  $\tilde{S}_0 = \{0, 1, \dots, i^*\}$ . The stated result follows from Theorem 3.3.  $\square$

Observe that we have solved the control problem under hypotheses that are weaker than those in [10]. Indeed, we impose only the condition  $\mu > \lambda$ , whereas in [10] the authors require further assumptions (see Condition E<sub>4</sub> in [10, page 244]).

The reason for this is that, in [10], the authors derive  $w$ -exponential ergodicity from the monotonicity conditions in [10, Assumption C]. In particular, those assumptions require the set  $S_0$  in our Assumption A(b) to be necessarily  $S_0 = \{0\}$ . However, under our hypotheses, we derive  $w$ -exponential ergodicity from a Lyapunov condition on  $w^2$  (Theorem 7.2), and thus the set  $S_0$  in Assumption A(b) may be any petite set, in particular, any finite set, and thus Assumption A(b) becomes easier to verify. Similarly, the condition E<sub>1</sub>(b) in [8, page 43] is not needed. This shows that Assumption D appears to be of a great applicability in models of practical interest.

The following example consists of a bidimensional denumerable state space that can be enumerated in such a way that the Lyapunov condition in Assumption A is easily verified, in particular, the monotonicity requirement.

**A controlled epidemic process.** We analyze a birth and death epidemic process similar to the one described in [21]. We divide the population into three disjoint classes: the susceptibles (individuals who are not infected, but who are exposed to contagion), the infectives (who can transmit the infection to the susceptibles), and the immunized. For expositional clarity, we will focus on the dynamic evolution of the susceptibles and the infectives.

We assume that there are two sources of infection: either by propagation due to the presence of infectives or by an external source. To consider a more realistic model, we will suppose that the infectives and the susceptibles are subject to “natural” birth and death rates. We suppose that an infected person who recovers from the disease is immunized.

Finally, the controller wishes to minimize the average number of infectives, subject to a certain restriction on the expenses of a quarantine program (in order to avoid the propagation of the infection) and the level of medical treatment applied to the population.

We consider the state space  $S = \{0, 1, 2, \dots\} \times \{0, 1, 2, \dots\}$ , where  $(i, j) \in S$  denotes the number of infectives and susceptibles, respectively. When the population is at state  $(i, j)$ , the possible transitions are to the following states:

- $(i+1, j-1)$  (that is, a susceptible has been infected) with a rate  $\lambda_1(a_1)\sqrt{ij} + \lambda_2(a_2)j$ , where  $\sqrt{ij}$  corresponds to propagation of the infection (this expression was proposed in [22]), the control  $a_1 \in A_1$  stands for the level of the quarantine program, and where  $\lambda_2(a_2)j$  is the rate of infection from an external source (corrected according to the level  $a_2 \in A_2$  of the medical treatment);
- $(i, j+1)$  with a rate  $\lambda_S(i+j+1)$ , where  $\lambda_S > 0$  is the natural birth rate of a susceptible individual;
- $(i-1, j)$  with a rate  $\mu_I i + \mu(a_2)i$ , where  $\mu_I > 0$  is the natural death rate of an infected person, and where  $\mu(a_2)i$  is a recovery rate (depending on the level  $a_2$  of the medical treatment);
- $(i, j-1)$  with a rate  $\mu_S j$ , where  $\mu_S > 0$  is the natural death rate of the susceptibles;
- $(i+1, j)$  with a rate  $\lambda_I(i+j+1)$ , where  $\lambda_I > 0$  is the natural birth rate of an infective.

We suppose that the action space is  $A = A_1 \times A_2$ , where  $A_1$  and  $A_2$  are closed bounded intervals in  $[0, \infty)$ . We also suppose that the functions  $\lambda_1$ ,  $\lambda_2$ , and  $\mu$  are positive and continuous.

The reward rate to be maximized by the controller is  $r(i, j, a_1, a_2) = -i$ . The cost rate in the state  $(i, j) \in S$  is  $c_1(a_1)i + c_2(a_2)i + c_3(a_2)j$ . The first term corresponds to the quarantine program (applied to the infectives) and the other two to the medical treatment (applied to both the infectives and the susceptibles). Suppose that  $c_1$ ,  $c_2$ , and  $c_3$  are continuous.

We denote the state process under the policy  $\varphi \in \Phi_m$  by

$$\{x^\varphi(t)\}_{t \geq 0} \equiv \{(i^\varphi(t), j^\varphi(t))\}_{t \geq 0}.$$

The controller wishes to determine a policy  $\varphi \in \Phi_m$  that minimizes

$$\limsup_{T \rightarrow \infty} \frac{1}{T} \int_0^T i^\varphi(t) dt \quad \text{a.s.}$$

subject to the budgetary restriction

$$\begin{aligned} \limsup_{T \rightarrow \infty} \frac{1}{T} \int_0^T [(c_1(t, x^\varphi(t), \varphi) + c_2(t, x^\varphi(t), \varphi))i^\varphi(t) \\ + c_3(t, x^\varphi(t), \varphi)j^\varphi(t)] dt \leq \theta_0 \quad \text{a.s.}, \end{aligned}$$

for a given  $\theta_0$  that is assumed to be in the corresponding range (see (3.6)).

We choose a Lyapunov function of the form  $w(i, j) = C(i+j+1)$ , where  $C \geq 1$ . Observe that this function is nondecreasing on  $S$ , provided that the state space  $S$  is “enumerated” in the order

$$(0, 0), (1, 0), (0, 1), (2, 0), (1, 1), (0, 2), (3, 0), (2, 1), (1, 2), (0, 3), (4, 0), \dots$$

**PROPOSITION 5.2.** *Consider the controlled epidemic process described above, and suppose that*

$$(5.4) \quad \min\{\mu_I + \mu_S, \mu(a_2)\} > \lambda_I + \lambda_S \quad \forall a_2 \in A_2.$$

*Then there exists a stationary pathwise constrained optimal policy.*

*Proof.* As in the proof of Proposition 5.1, we can show that Assumptions A, B, C(a), and D hold, provided that the constant  $C$  (in the definition of  $w$ ) is large enough. The stated result follows from Theorem 3.3.

Note that the condition in the statement of this result depends neither on  $\lambda_1$  nor on  $\lambda_2$ . This is because the corresponding transition (from  $(i, j)$  to  $(i + 1, j - 1)$ ) does not modify the total size  $i + j$  of the population, and thus, in terms of stability, it does not affect the behavior of the dynamic system.  $\square$

Observe that, since the state space  $S$  is bidimensional, the total population can decrease along either  $i$  or  $j$ . Hence, the condition (5.4) involves the minimum of the two corresponding death rates.

Once again, we see that Theorem 7.2 allows us to show the existence of optimal policies for the corresponding control problem under fairly general assumptions. Indeed, the condition  $\mu > \lambda$  (Proposition 5.1) and  $\min\{\mu_I + \mu_S, \mu(a_2)\} > \lambda_I + \lambda_S$  for  $a_2 \in A_2$  (Proposition 5.2) are just the usual stability conditions for a noncontrolled dynamic system; that is, the service rate (respectively, the death rate) is greater than the arrival rate (respectively, the birth rate).

**6. Concluding remarks.** Our main motivation for this paper was to study average reward continuous-time CMCs with pathwise constraints, but, as shown in the previous sections, on our way to the final result (Theorem 3.3) we provided a detailed analysis of pathwise average optimality (Theorem 4.3) and constrained CMCs with *expected* constraints (Theorems 4.9 and 4.10). Furthermore, the examples in section 5 clearly show that our assumptions are verifiable with no special degree of difficulty.

An important open question is whether our approach here—for *denumerable-state* CMCs—can be systematically extended to more general Markov control problems, for instance, controlled diffusions [28].

**7. Appendix.** The next result is useful for the verification of the Lyapunov conditions. In particular, it shows that Assumption D implies Assumption A(b).

**THEOREM 7.1.** *Suppose that  $w : S \rightarrow [1, \infty)$  is a nondecreasing function such that  $\lim_{i \rightarrow \infty} w(i) = \infty$ , and fix an arbitrary  $0 < \alpha < 1$ . Suppose also that there exist constants  $b \geq c > 0$  and a finite set  $S_0 \subset S$  such that*

$$(7.1) \quad \sum_{j \in S} q_{ij}(a)w(j) \leq -cw(i) + bI_{S_0}(i) \quad \forall (i, a) \in K,$$

where the transition rates  $q_{ij}(a)$  verify the conditions (2.1) and (2.2). Then there exist constants  $\hat{b} \geq \hat{c} > 0$  such that

$$(7.2) \quad \sum_{j \in S} q_{ij}(a)w^\alpha(j) \leq -\hat{c}w^\alpha(i) + \hat{b}I_{S_0}(i) \quad \forall (i, a) \in K.$$

*Proof.* Fix  $i \in S$  and choose a constant  $C > c$ . Let  $x := C + q(i)$ . The inequality (7.1) can be rewritten as

$$\frac{1}{x} \left( \sum_{j \neq i} q_{ij}(a)w(j) + (x + q_{ii}(a))w(i) \right) \leq \frac{x - c}{x}w(i) + \frac{b}{x}I_{S_0}(i).$$

By Jensen's inequality, it follows that

$$\sum_{j \in S} q_{ij}(a)w^\alpha(j) + xw^\alpha(i) \leq x \left( (x - c)x^{-1}w(i) + bx^{-1}I_{S_0}(i) \right)^\alpha.$$

Using the inequality  $(y + z)^\alpha \leq y^\alpha + z^\alpha$ , we obtain

$$\sum_{j \in S} q_{ij}(a) w^\alpha(j) \leq [(x - c)^\alpha x^{1-\alpha} - x] w^\alpha(i) + b^\alpha x^{1-\alpha} I_{S_0}(i).$$

The concavity of the function  $y \mapsto y^\alpha$  implies that  $y^\alpha - z^\alpha \leq \alpha(y - z)z^{\alpha-1}$  whenever  $0 \leq y < z$ . Hence,

$$\sum_{j \in S} q_{ij}(a) w^\alpha(j) \leq -\alpha c w^\alpha(i) + b^\alpha x^{1-\alpha} I_{S_0}(i) \quad \forall (i, a) \in K.$$

Therefore, (7.2) holds with  $\hat{c} := \alpha c$  and  $\hat{b} := b^\alpha \max_{i \in S_0} \{(C + q(i))^{1-\alpha}\}$ . The fact that  $\hat{b} \geq \hat{c}$  follows from the inequality (2.6) when  $w$  is replaced with  $w^\alpha$ . This completes the proof.  $\square$

In our next result, we propose an alternative sufficient condition for uniform  $w$ -exponential ergodicity of CMCs (in particular, for Assumption C(b)).

**THEOREM 7.2.** *Suppose that Assumptions A(a), B(a), C(a), and D, as well as the continuity condition on  $a \mapsto q_{ij}(a)$  in Assumption B(c), are satisfied. Then the control model is  $w$ -exponentially ergodic on  $\Phi_s$ , that is, there exist constants  $\delta > 0$  and  $R > 0$  such that*

$$\sup_{\varphi \in \Phi_s} |E_i^\varphi v(x(t)) - \mu_\varphi(v)| \leq R e^{-\delta t} \|v\|_w w(i)$$

for every  $i \in S$ ,  $t \geq 0$ , and  $v \in \mathcal{B}_w(S)$ .

*Proof.* Fix an initial state  $i \in S$ , an integer  $k \geq 0$ , and  $t \geq 0$ . By (3.2),

$$\begin{aligned} w^2(i) + \tilde{b}/\tilde{c} &\geq \sup_{\varphi \in \Phi_s} \sum_{j \in S} p^\varphi(i, t, j) w^2(j) \geq \sup_{\varphi \in \Phi_s} \sum_{j \geq k} p^\varphi(i, t, j) w^2(j) \\ &\geq w(k) \cdot \sup_{\varphi \in \Phi_s} \sum_{j \geq k} p^\varphi(i, t, j) w(j). \end{aligned}$$

Therefore,  $\lim_{k \rightarrow \infty} \sup_{\varphi \in \Phi_s} \sum_{j \geq k} p^\varphi(i, t, j) w(j) = 0$ , which is precisely the uniform integrability condition in [25, Theorem 2.5] extended to the class of randomized stationary policies.

However, in the proof of [25, Theorem 2.5], the set  $S_0$  in Assumption A(b) is  $S_0 = \{0\}$ , and  $w$ -exponential ergodicity reduces to the class of deterministic stationary policies  $\mathbb{F}$ . This is not a real problem because the proof can be modified in order to account for the case of a finite set  $S_0$  and the class  $\Phi_s$ . Let us mention the main steps of this modified proof:

1. Observe that the corresponding discrete-time result (Key Theorem II in [4]) is stated for any finite so-called “taboo” set. In particular, choose  $S_0$  as the taboo set. The proof of Theorem 2.5 in [25] is the same, except for [25, Proposition 4.9]. However, using the same reasoning, one can prove a result similar to [25, Proposition 4.9], but now with a taboo set  $S_0$ .
2. In the set of stationary policies  $\Phi_s$  we consider the topology of the weak convergence, that is,  $\varphi_n \rightarrow \varphi$  when  $\varphi_n(\cdot|i)$  weakly converges to  $\varphi(\cdot|i)$  for every  $i \in S$ . With this topology,  $\Phi_s$  is compact and metrizable. The proof of Theorem 2.5 in [25] is now easily extended from  $\mathbb{F}$  to  $\Phi_s$ .

This completes the proof.  $\square$

Theorem 7.2 is of valuable interest by itself. In view of this theorem we now know that there exist (at least) *three* different sets of sufficient conditions for the  $w$ -exponential ergodicity in Assumption C(b), namely, monotonicity conditions [10], uniform integrability conditions [25], and a Lyapunov condition on  $w^2$  as in Assumption D (in fact, we can replace  $w^2$  with  $w^{1+\varepsilon}$  for some  $\varepsilon > 0$ ).

## CONTROLLABILITY OF THE KIRCHHOFF SYSTEM FOR BEAMS AS A LIMIT OF THE MINDLIN–TIMOSHENKO SYSTEM\*

F. D. ARARUNA<sup>†</sup> AND E. ZUAZUA<sup>‡</sup>

**Abstract.** We consider the dynamical one-dimensional Mindlin–Timoshenko system for beams. We analyze how its controllability properties depend on the modulus of elasticity in shear  $k$ . In particular we prove that the exact boundary controllability property of the Kirchhoff system may be obtained as a singular limit, as  $k \rightarrow \infty$ , of the partial controllability of projections over a sharp subspace of solutions generated by the eigenfunctions that converge, as  $k \rightarrow \infty$ , towards the spectrum of the Kirchhoff system.

**Key words.** vibrating beams, controllability, observability, Mindlin–Timoshenko, Kirchhoff, Ingham inequality, Fourier decomposition, singular limit

**1. Introduction.** The Mindlin–Timoshenko system of equations is a widely used and, physically, fairly complete mathematical model for describing the transverse vibrations of beams. For a beam of length  $L$  this one-dimensional system reads as follows:

$$(1.1) \quad \begin{cases} \frac{\rho h^3}{12} u'' - u_{xx} + k(u + v_x) = 0 & \text{in } Q, \\ \rho h v'' - k(u + v_x)_x = 0 & \text{in } Q, \end{cases}$$

where  $Q = (0, L) \times (0, T)$ ,  $(0, L)$  being the segment occupied by the beam with  $L > 0$  and  $T$  a given positive time. In this coupled system of two second order hyperbolic equations, the prime  $'$  stands for the partial derivative in time  $t$  and the subscript  $x$  for the space derivative. The unknown  $u = u(x, t)$  represents the angle of rotation and  $v = v(x, t)$  the vertical displacement at time  $t$  of the cross section located  $x$  units from the end-point  $x = 0$ . The constant  $h > 0$  represents the thickness of the beam that, for this model, is considered to be small and uniform, independent of  $x$ . The constant  $\rho$  is the mass density per unit volume of the beam, and the parameter  $k$  is the so-called modulus of elasticity in shear. It is given by the formula  $k = \widehat{k} E h / 2(1 + \mu)$ , where  $\widehat{k}$  is a shear correction coefficient,  $E$  is the Young's modulus, and  $\mu$  is the Poisson's ratio,  $0 < \mu < 1/2$ .

We impose the following boundary conditions on the left-hand side:

$$(1.2) \quad u(0, \cdot) = 0, \quad v_x(0, \cdot) = \Theta_k \quad \text{on } (0, T),$$

and on the right-hand side we impose

$$(1.3) \quad u(L, \cdot) = v_x(L, \cdot) = 0 \quad \text{on} \quad (0, T).$$

According to these conditions, the angle of rotation is kept fixed both at  $x = 0$  and  $x = L$ , and the boundary control  $\Theta_k$  is a lateral force applied on the vertical displacement at the extreme  $x = 0$ . In particular, no control is applied at  $x = L$ . To make the system complete, let us include the initial conditions

$$(1.4) \quad u(\cdot, 0) = u_0, \quad u'(\cdot, 0) = u_1, \quad v(\cdot, 0) = v_0, \quad v'(\cdot, 0) = v_1 \quad \text{in} \quad (0, L).$$

When assuming that the linear filament of the beam remains perpendicular to the deformed middle surface, the transverse shear effects are neglected and one obtains the so-called Kirchhoff system (see Lagnese and Lions [7])

$$(1.5) \quad \begin{cases} \rho h v'' - \frac{\rho h^3}{12} v''_{xx} + v_{xxxx} = 0 & \text{in } Q, \\ v_x(0, \cdot) = v_x(L, \cdot) = 0 & \text{on } (0, T), \\ v_{xxx}(0, \cdot) = \Xi, \quad v_{xxx}(L, \cdot) = 0 & \text{on } (0, T), \\ v(\cdot, 0) = v_0, \quad v'(\cdot, 0) = v_1 & \text{in } (0, L). \end{cases}$$

The control  $\Xi$  enters this system through the third derivative of the state at  $x = 0$ .

Note that neglecting the shear effects of the beam is formally equivalent to making the modulus  $k$  tend to infinity in (1.1), since  $k$  is inversely proportional to the shear angle.

The connections of these two systems and the singular perturbation problem of passing to the limit as  $k$  tends to infinity have been recently intensively investigated. We refer, for instance, to [11], [12], and [13], where these issues are addressed for a number of nonlinear models and under various boundary conditions.

This paper is devoted to the analysis of the controllability properties of these systems and the corresponding singular perturbation problem (as  $k \rightarrow \infty$ ). Our main goal is analyzing whether the exact controllability property of the Kirchhoff system (1.5) for beams may be obtained as a limit of those of the Mindlin–Timoshenko system (1.1)–(1.4) when the singular parameter  $k$  tends to infinity.

The problem of exact controllability for the Mindlin–Timoshenko system can be formulated as follows: given  $T > 0$ , large enough, and initial data  $\{u_0, u_1, v_0, v_1\}$ , to find a control  $\Theta_k$  such that the solution of system (1.1)–(1.4) satisfies the conditions

$$u(\cdot, T) = u'(\cdot, T) = v(\cdot, T) = v'(\cdot, T) = 0 \quad \text{in} \quad (0, L).$$

According to the Hilbert uniqueness method (HUM) introduced by Lions (see [8]), this property is equivalent to a suitable observability inequality for the adjoint system that, after reversing the sense of time, can be written as follows:

$$(1.6) \quad \begin{cases} \frac{\rho h^3}{12} \phi'' - \phi_{xx} + k(\phi + \psi_x) = f & \text{in } Q, \\ \rho h \psi'' - k(\phi + \psi_x)_x = g & \text{in } Q, \\ \phi(0, t) = \phi(L, t) = \psi_x(0, t) = \psi_x(L, t) = 0 & \text{on } (0, T), \\ \phi(x, 0) = \phi_0(x), \quad \phi'(x, 0) = \phi_1(x) & \text{in } (0, L), \\ \psi(x, 0) = \psi_0(x), \quad \psi'(x, 0) = \psi_1(x) & \text{in } (0, L). \end{cases}$$

To be more precise, in the observability problem,  $f$  and  $g$  vanish ( $f \equiv g \equiv 0$ ) so that the problem consists of estimating the energy of the initial data in terms of

boundary measurements. The general system (1.6) with nonvanishing right-hand side terms is useful when analyzing the well-posedness of the nonhomogeneous boundary value problem (1.1)–(1.4) by transposition.

We are mainly interested in the behavior of the controls  $\Theta_k$ , as  $k \rightarrow \infty$ , and whether in the limit as  $k \rightarrow \infty$  one obtains a control  $\Xi$  such that the solution of system (1.5) verifies

$$v(\cdot, T) = v'(\cdot, T) = 0 \quad \text{in} \quad (0, L).$$

This problem was treated initially in [7] with different boundary conditions. The goals in [7] were

- (i) to show that the control time  $T$  is independent of  $k$ , for any given initial state, and to find, for each  $k$ , a control  $\Theta_k$  driving the system (1.1)–(1.4) to rest at time  $T$ , and
- (ii) to study the behavior of  $\Theta_k$  as  $k \rightarrow \infty$ .

Combining the HUM and multiplier inequalities, the authors of [7] obtained a control time independent of  $k$ . But, to prove (ii), they imposed the physically unrealistic extra assumption that  $L < h$ . Moreover, in [7, Remarks 3.4 and 3.5, p. 109], it was conjectured that *as  $k \rightarrow \infty$ ,  $\Theta_k$  converges, in some appropriate sense, towards a control driving the system (1.5) to equilibrium in time  $T$ .*

In this paper we obtain the following main results:

- The controls  $\Theta_k$  of the Mindlin–Timoshenko system may diverge exponentially as  $k \rightarrow \infty$ .
- By analyzing the underlying spectrum, it is possible to decompose the adjoint system (1.6) into two subsystems. It is sufficient to obtain a uniform (with relation to  $k$ ) observability inequality for one of these subsystems.
- Accordingly, the exact controllability requirement on system (1.1)–(1.4) is relaxed to a partial controllability property over a suitable projection of solutions, and the controls  $\Theta_k$  remain bounded as  $k \rightarrow \infty$ .
- The partial controls  $\Theta_k$  obtained this way converge to an exact control for the limit system (1.5).

With these results, we conclude that the exact controllability property of the Kirchhoff system may be obtained as a limit of the partial controllability property of the Mindlin–Timoshenko system. This solves the problem proposed by Lagnese and Lions in [7] for the present boundary conditions. The uniform (with respect to the parameter  $k$ ) partial controllability result is taken over the subspace of the solutions generated by the eigenfunctions that, in the limit, cover the whole spectrum of the limit Kirchhoff model.

The rest of the paper is organized as follows. In section 2 we briefly mention some elementary properties (existence, uniqueness, and regularity) of solutions for system (1.6) and we rigorously study its limit behavior as  $k \rightarrow \infty$  towards the Kirchhoff system. In section 3 we analyze the properties of the spectrum of system (1.6), finding two families of eigenvalues. As  $k \rightarrow \infty$ , one of these families of eigenvalues tends to those of the limit Kirchhoff system, while the other one diverges, disappearing in the limit in the sense that, since they diverge, they do not lead to eigenvalues of the limit system. This fact occurs due to (and it is in agreement with) the asymptotic simplification that is produced when passing from a system of two equations and two dependent variables to a scalar equation with only one unknown variable. In section 4 we discuss some elementary properties of system (1.1)–(1.4) with nonhomogeneous boundary conditions, i.e., in the absence of controls. We also analyze the convergence,

as  $k \rightarrow \infty$ , towards the solution of the nonhomogeneous Kirchhoff system. Section 5 is devoted to the problem of observability for system (1.6). We show that the observability constant may blow up exponentially as  $k \rightarrow \infty$ . In section 6, applying the Ingham inequality in the Fourier decomposition of solutions, we get a uniform observability result filtering the eigenfunction components corresponding to eigenvalues that diverge as  $k \rightarrow \infty$ . Filtering corresponds, in other words, to projecting solutions over the subspace of eigencomponents that are well behaved. In section 7, combining the results of the previous section with the HUM, we derive the uniform partial controllability result. More precisely, we prove that the projection over the subspace of solutions of (1.1)–(1.4) generated by the eigenvalues convergent (as  $k \rightarrow \infty$ ) and their corresponding eigenfunctions is uniformly controllable with respect to  $k$ . In the limit we obtain the exact boundary controllability property of the Kirchhoff system (1.5). Therefore, we see that it suffices to consider only the solutions in a suitable subspace to ensure that the conjecture in [7] is true.

The analysis in this paper depends on the boundary conditions we have chosen that make possible the explicit computation of the spectrum. Similar results are expected for other boundary conditions, but a further analysis of this issue is needed.

The results in this paper are related to previous ones on the behavior of controls for systems of vibrations under singular perturbations. We refer to [2] and [3] for the problem of control and homogenization of the wave equation, and to [5] and [17] for the behavior of controls under numerical approximations. We also refer to [16] for a discussion and comparison of these two topics. Similar methods have also been used in [10] to analyze the partial controllability of a model for spherical shells.

**2. Asymptotic limit of the homogeneous system.** For the sake of completeness, in this section we study the asymptotic limit of the solutions of the homogeneous system (1.6) as  $k$  tends to infinity. Before, we mention some elementary properties of these solutions.

System (1.6) is well-posed in the energy space  $\mathcal{X} = H_0^1(0, L) \times L^2(0, L) \times H^1(0, L) \times L^2(0, L)$ . More precisely, for any  $\{\phi_0, \phi_1, \psi_0, \psi_1\} \in \mathcal{X}$  and  $\{f, g\} \in L^1(0, T; [L^2(0, L)]^2)$  there exists a unique solution in the class

$$(2.1) \quad \{\phi, \psi\} \in C^0([0, T]; H_0^1(0, L) \times H^1(0, L)) \cap C^1([0, T]; [L^2(0, L)]^2)$$

satisfying the inequality

$$(2.2) \quad \|\{\phi(t), \phi'(t), \psi(t), \psi'(t)\}\|_k \leq C_1 e^{C_2 T} \left( \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k + \|\{f, g\}\|_{L^1(0, T; [L^2(0, L)]^2)} \right)$$

for all  $t \in [0, T]$ , where the norm  $\|\cdot\|_k$  is defined by

$$\begin{aligned} \|\{u_1, u_2, v_1, v_2\}\|_k^2 &= \int_0^L |u_{1x}|^2 dx + \frac{\rho h^3}{12} \int_0^L |u_2|^2 dx + k \int_0^L |u_1 + v_{1x}|^2 dx \\ &\quad + \int_0^L |v_1|^2 dx + \rho h \int_0^L |v_2|^2 dx. \end{aligned}$$

On the other hand, the energy  $E_k(t)$  of the system

$$(2.3) \quad \begin{aligned} E_k(t) &= \frac{1}{2} \int_0^L \left\{ \frac{\rho h^3}{12} |\phi'(x, t)|^2 + \rho h |\psi'(x, t)|^2 + |\phi_x(x, t)|^2 \right. \\ &\quad \left. + k |\phi(x, t) + \psi_x(x, t)|^2 \right\} dx \end{aligned}$$

satisfies

$$(2.4) \quad \frac{dE_k}{dt}(t) = \int_0^L [f(x, t) \phi'(x, t) + g(x, t) \psi'(x, t)] dx.$$

In particular, when  $f \equiv g \equiv 0$ , the energy  $E_k$  is conserved along time.

Estimate (2.2) holds as a consequence of this energy identity and Gronwall's inequality because of the obvious relation between the energy  $E_k$  and the norm  $\|\cdot\|_k$ . The norm  $\|\cdot\|_k$  is equivalent to the square root of the sum  $E_k + \|v_1\|_{L^2(0,L)}^2$ . Note that the canonical norm in  $\mathcal{X}$  can be bounded above uniformly in terms of the norm  $\|\cdot\|_k$  for all  $k \geq 1$ ; i.e., there exists  $C > 0$  independent of  $k$  such that

$$(2.5) \quad \|\cdot\|_{\mathcal{X}} \leq C \|\cdot\|_k \quad \forall k \geq 1,$$

where  $\|\cdot\|_{\mathcal{X}}$  stands for the canonical norm in  $\mathcal{X}$ .

Let us note that the energy  $E_k$  does not define a norm in  $\mathcal{X}$ . Accordingly, it is natural to introduce the norm  $\|\cdot\|_k$  and the following decomposition of the energy space:  $\mathcal{X} = \mathcal{X}_0 \oplus \mathcal{X}_1$ , with

$$\mathcal{X}_0 = H_0^1(0, L) \times L^2(0, L) \times V \times H \quad \text{and} \quad \mathcal{X}_1 = \{ \{0, 0, c_1, c_2\} \in \mathcal{X}; c_i \in \mathbb{R}, i = 1, 2 \},$$

where

$$V = H^1(0, L) \cap H \quad \text{and} \quad H = \left\{ v \in L^2(0, L); \int_0^L v(x) dx = 0 \right\}.$$

In  $\mathcal{X}_0$  the energy defines a norm which is equivalent to  $\|\cdot\|_k$ . On the other hand, the spaces  $\mathcal{X}_0$  and  $\mathcal{X}_1$  are invariant under the flow generated by system (1.6) in the sense given in the following result.

**PROPOSITION 2.1.** *Given data  $\{\phi_0, \phi_1, \psi_0, \psi_1\}$  and  $\{0, f, 0, g\}$  belonging to  $\mathcal{X}_i$  and  $L^1(0, T; \mathcal{X}_i)$ , respectively, with  $i = 0, 1$ , the associated solution belongs to  $\mathcal{X}_i$  for all  $t \in [0, T]$ .*

*Proof.* First, we show that if  $\{\phi_0, \phi_1, \psi_0, \psi_1\} \in \mathcal{X}_0$  and  $\{0, f, 0, g\} \in L^1(0, T; \mathcal{X}_0)$ , then the corresponding solution belongs to  $\mathcal{X}_0$  for all  $t \in [0, T]$ . In fact, integrating  $(1.6)_2$  ( $(1.6)_2$  means the second equation in (1.6)) on  $]0, L[$  and using the conditions  $(1.6)_3$ , we have

$$\frac{d^2}{dt^2} \int_0^L \psi(x, t) dx = 0,$$

that is,

$$\int_0^L \psi(x, t) dx = \int_0^L \psi_0(x) dx + t \int_0^L \psi_1(x) dx = 0.$$

Now, if  $\{\phi_0, \phi_1, \psi_0, \psi_1\} \in \mathcal{X}_1$  and  $\{0, f, 0, g\} \in L^1(0, T; \mathcal{X}_1)$ , we have  $\phi_0 = \phi_1 = f = 0$ ,  $\psi_0 = c_1$ ,  $\psi_1 = c_2$ , and  $g = g(t) \in L^1(0, T)$ . In this way, we get, directly from the system (1.6), that  $\phi \equiv \psi_x \equiv 0$ . So  $\psi = \psi(t)$  and, by  $(1.6)_2$ , we obtain

$$\rho h \psi''(t) = g(t) \quad \forall t \in [0, T]$$

and, therefore,

$$\psi(t) = \int_0^t w(s) ds + c_2 t + c_1 \quad \forall t \in [0, T],$$

where  $w(\sigma) = (1/\rho h) \int_0^\sigma g(\xi) d\xi$ .  $\square$

We also have the following “hidden regularity” result.

PROPOSITION 2.2. *For any  $T > 0$ , there exists a constant  $C = C(T) > 0$ , independent of  $k$ , such that the solution  $\{\phi, \psi\}$  of (1.6) satisfies the inequality*

$$(2.6) \quad \|\{\phi_x(0, \cdot), \psi(0, \cdot)\}\|_{L^2(0,T) \times H^1(0,T)}^2 \leq C \left\{ \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k^2 + \|\{f, g\}\|_{L^1(0,T;[L^2(0,L)]^2)}^2 \right\}$$

for any  $\{\phi_0, \phi_1, \psi_0, \psi_1\} \in \mathcal{X}$  and  $\{f, g\} \in L^1(0, T; [L^2(0, L)]^2)$ .

*Proof.* It is enough to consider smooth solutions since a classical density argument allows us to extend the inequality (2.6) to finite-energy solutions. We use a multiplier method (see [8]). We multiply (1.6)<sub>1</sub> by  $(L - x)\phi_x$  and (1.6)<sub>2</sub> by  $(L - x)\psi_x$ , and after integrating by parts over  $Q$  we get

$$(2.7) \quad \begin{aligned} & \frac{L}{2} \int_0^T \left\{ \rho h |\psi'(0, t)|^2 + |\phi_x(0, t)|^2 \right\} dt = \frac{1}{2} \int_Q \left\{ \frac{\rho h^3}{12} |\phi'(x, t)|^2 + \rho h |\psi'(x, t)|^2 \right. \\ & \quad \left. + |\phi_x(x, t)|^2 + k |\phi(x, t) + \psi_x(x, t)|^2 \right\} dx dt - \int_Q \left\{ \frac{\rho h^3}{12} |\phi'(x, t)|^2 - |\phi_x(x, t)|^2 \right\} dx dt \\ & \quad - \left[ \frac{\rho h^3}{12} \int_0^L \phi'(x, t) (L - x) \phi_x(x, t) dx + \rho h \int_0^L \psi'(x, t) (L - x) \psi_x(x, t) dx \right] \Big|_0^T \\ & \quad + \int_Q f(x, t) (L - x) \phi_x(x, t) dx dt + \int_Q g(x, t) (L - x) \psi_x(x, t) dx dt. \end{aligned}$$

Using (2.2), from (2.7) we obtain the estimate

$$(2.8) \quad \|\{\phi_x(0, \cdot), \psi'(0, \cdot)\}\|_{[L^2(0,T)]^2}^2 \leq C \left\{ \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k^2 + \|\{f, g\}\|_{L^1(0,T;[L^2(0,L)]^2)}^2 \right\},$$

with  $C = C(T) > 0$  a constant independent of  $k$ .

On the other hand, by the trace theorem, there exists a constant  $C_\gamma > 0$ , independent of  $k$ , such that

$$\|\psi(0, \cdot)\|_{L^2(0,T)} \leq C_\gamma \|\psi(\cdot, t)\|_{H^1(Q)}.$$

Thus by (2.2) it follows that

$$(2.9) \quad \|\psi(0, \cdot)\|_{L^2(0,T)} \leq C \left( \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k + \|\{f, g\}\|_{L^1(0,T;[L^2(0,L)]^2)} \right),$$

where  $C = C(T) > 0$  is a constant independent of  $k$ .

Combining (2.8) and (2.9), we deduce the inequality (2.6), uniformly on  $k \geq 1$ .  $\square$

Concerning the asymptotic behavior of the solutions of the homogeneous Mindlin–Timoshenko system (1.6), as  $k$  tends to infinity, the following result holds.

THEOREM 2.1. *Let  $\{\phi_k, \psi_k\}$  be the unique solution of (1.6) with data  $\{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\} \in \mathcal{X}$  and  $\{f, g\} \in L^1(0, T; H_0^1(0, L) \times L^2(0, L))$ .*

(a) *Weak convergence. Assume that the initial data satisfy*

$$(2.10) \quad \|\{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\}\|_k^2 \leq C \quad \forall k \geq 1,$$

with  $C$  being a positive constant independent of  $k$  and

$$(2.11) \quad \{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\} \rightarrow \{\phi_0, \phi_1, \psi_0, \psi_1\} \text{ weakly in } \mathcal{X}.$$

Then, as  $k \rightarrow \infty$ , the following convergence property holds:

$$(2.12) \quad \{\phi_k, \phi'_k, \psi_k, \psi'_k\} \rightarrow \{-\psi_x, -\psi'_x, \psi, \psi'\} \text{ weakly* in } L^\infty(0, T; \mathcal{X}),$$

where  $\psi$  solves the homogeneous Kirchhoff system

$$(2.13) \quad \begin{cases} \rho h \psi'' - \frac{\rho h^3}{12} \psi''_{xx} + \psi_{xxxx} = f_x + g & \text{in } Q, \\ \psi_x(0, \cdot) = \psi_x(L, \cdot) = \psi_{xxx}(0, \cdot) = \psi_{xxx}(L, \cdot) = 0 & \text{on } (0, T), \\ \psi(\cdot, 0) = \psi_0, \quad \left[ \psi(\cdot, 0) - \frac{h^2}{12} \psi_{xx}(\cdot, 0) \right]' = \psi_1 + \frac{h^2}{12} \phi_{1x} & \text{in } (0, L). \end{cases}$$

(b) Strong convergence. If the initial data satisfy the additional conditions

$$(2.14) \quad \phi_0 + \psi_{0x} = 0, \quad \lim_{k \rightarrow \infty} E_k(0) = \mathcal{E}(0),$$

where  $\mathcal{E}(t)$  is the energy of (2.13) given by

$$(2.15) \quad \mathcal{E}(t) = \frac{1}{2} \int_0^L \left\{ \rho h |\psi'(x, t)|^2 + \frac{\rho h^3}{12} |\psi'_x(x, t)|^2 + |\psi_{xx}(x, t)|^2 \right\} dx,$$

then, for  $1 < p < \infty$ , the following strong convergence holds as  $k \rightarrow \infty$ :

$$(2.16) \quad \{\phi_k, \phi'_k, \psi_k, \psi'_k\} \rightarrow \{-\psi_x, -\psi'_x, \psi, \psi'\} \text{ strongly in } L^p(0, T; \mathcal{X}).$$

*Remark 2.1.*

- The existence and uniqueness of weak solutions of the limit system (2.13) can be obtained by classical methods. More precisely, when  $\{\psi_0, \psi_1, f_x + g\} \in W \times H^1(0, L) \times L^1(0, T; L^2(0, L))$ , where  $W = \{v \in H^2(0, L); v_x(0) = v_x(L) = 0\}$ , there exists a unique finite energy solution  $\psi$  in the class

$$\psi \in C^0([0, T]; W) \cap C^1([0, T]; H^1(0, L))$$

satisfying the variational formulation of (2.13)

$$\rho h \frac{d}{dt} (\psi'(t), w) + \frac{\rho h^3}{12} \frac{d}{dt} (\psi'_x(t), w_x) + (\psi_{xx}(t), w_{xx}) = (f_x(t) + g(t), w)$$

for all  $w \in W$ , the boundary conditions (2.13)<sub>2</sub>, and the initial conditions (2.13)<sub>3</sub>. Here  $(\cdot, \cdot)$  represents the inner product in  $L^2(0, L)$ . Furthermore the energy  $\mathcal{E}(t)$  in (2.15) satisfies

$$\mathcal{E}'(t) = \int_0^L [f_x(x, t) + g(x, t)] \psi'(x, t) dx.$$

If  $f_x + g \equiv 0$ , the energy is conserved.

- Note, however, that, in order to identify fully the initial data of the solutions of the limit system (2.13) and, more precisely, to determine the initial data of  $\psi'$ , an elliptic equation has to be solved. Namely, the initial datum for the velocity  $\psi'$  in (2.13)<sub>3</sub> is determined by solving the elliptic equation

$$(2.17) \quad \psi'(\cdot, 0) \in H^1(0, L) : \quad \rho h \psi'(0) - \frac{\rho h^3}{12} \psi'_{xx}(0) = \rho h \psi_1 + \frac{\rho h^3}{12} \phi_{1x},$$

as the proof of the theorem will show.

To be more precise, this elliptic equation can be written in the variational form

$$(2.18) \quad -\frac{\rho h^3}{12} (\psi'_x(0), w_x) - \rho h (\psi'(0), w) = \frac{\rho h^3}{12} (\phi_1, w_x) - \rho h (\psi_1, w) \quad \forall w \in H^1(0, L)$$

in which the term  $\phi_{1x}$ , which is an element of  $(H^1(0, L))'$ , is not the derivative of  $\phi_1$  in the sense of transposition but rather the linear mapping so that, when acting on any element  $w$  of  $H^1(0, L)$ , yields the value  $-(\phi_1, w_x)$ . The same can be said about  $\psi'_{xx}(0)$ , which represents the element of  $(H^1(0, L))'$  yielding  $-(\psi'_x(0), w_x)$ .

- Similar results hold when the right-hand side terms  $\{f_k, g_k\}$  depend on  $k$  and converge in a suitable sense. But we shall not discuss this issue since it is not needed for the purpose of this paper.

*Proof of Theorem 2.1.* We will prove the theorem in two steps.

*Step 1. Weak convergence.* Considering  $\{f, g\} \in L^2(0, T; H_0^1(0, L) \times L^2(0, L))$  and the sequence of initial data  $\{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\} \in \mathcal{X}$  satisfying (2.10), the right-hand side of (2.2) and the energies  $E_k$  are uniformly bounded on  $k$ . Consequently

$$\left| \begin{array}{l} (\{\phi_k, \phi'_k, \psi_k, \psi'_k\}) \text{ is bounded in } L^\infty(0, T; \mathcal{X}), \\ (\sqrt{k}[\phi_k + \psi_{kx}]) \text{ is bounded in } L^\infty(0, T; L^2(0, L)). \end{array} \right|$$

This immediately yields a uniform bound for  $\phi$ ,  $\phi'$ , and  $\psi'$  in the corresponding spaces. We also get a uniform bound on  $\psi$  in  $L^2(0, L)$ . The uniform bound on  $\psi$  in  $H^1(0, L)$  can be easily obtained from the bound in  $L^2(0, L)$  and in  $\|\cdot\|_k$  and the fact that

$$(2.19) \quad \begin{aligned} \|\psi_x\|_{L^2(0, L)} &\leq \|\phi + \psi_x\|_{L^2(0, L)} + \|\phi\|_{L^2(0, L)} \leq k \|\phi + \psi_x\|_{L^2(0, L)} + \|\phi\|_{L^2(0, L)} \\ &\leq C \|\{\phi, \phi', \psi, \psi'\}\|_k. \end{aligned}$$

Extracting subsequences, which we still denote by  $(\{\phi_k, \psi_k\})$ , we get

$$(2.20) \quad \{\phi_k, \phi'_k, \psi_k, \psi'_k\} \rightarrow \{\phi, \phi', \psi, \psi'\} \text{ weakly } * \text{ in } L^\infty(0, T; \mathcal{X})$$

with

$$(2.21) \quad \phi + \psi_x = 0.$$

For test functions  $\{z, w\} \in H_0^1(0, L) \times H^1(0, L)$  satisfying

$$(2.22) \quad z + w_x = 0,$$

the variational formulation of (1.6) reduces to

$$(2.23) \quad \frac{\rho h^3}{12} \frac{d}{dt} (\phi'_k(t), z) + \rho h \frac{d}{dt} (\psi'_k(t), w) + (\phi_{kx}(t), z_x) = (f(t), z) + (g(t), w).$$

Using the convergences (2.20) in (2.23) and applying identities (2.21) and (2.22), the limit weak formulation can be written in terms of  $\psi$  as follows:

$$(2.24) \quad \rho h \frac{d}{dt} (\psi'(t), w) + \frac{\rho h^3}{12} \frac{d}{dt} (\psi'_x(t), w_x) + (\psi_{xx}(t), w_{xx}) = (f_x(t) + g(t), w) \quad \forall w \in W.$$

This identity is a weak form of (2.13)<sub>1</sub>. The two boundary conditions

$$\psi_x(0, t) = \psi_x(L, t) = 0 \quad \text{on} \quad (0, T)$$

are deduced from the facts that  $\psi_x = -\phi$  and that  $\phi$  satisfies the Dirichlet boundary conditions. The other two in (2.13), namely,

$$\psi_{xxx}(0, t) = \psi_{xxx}(L, t) = 0 \quad \text{on} \quad (0, T),$$

are implicit in the weak form of the equation since the test function  $w$  does not vanish on the boundary.

To conclude our result, it remains to identify the initial data of the limit system. In view of the convergences (2.20), and classical compactness arguments,  $\psi_k \rightarrow \psi$  in  $C^0([0, T]; L^2(0, L))$ . Then  $\psi_k(\cdot, 0) \rightarrow \psi(\cdot, 0)$  in  $L^2(0, L)$ , which, combined with (2.11), guarantees that  $\psi(\cdot, 0) = \psi_0$ . In order to identify  $\psi'(\cdot, 0)$ , we multiply both sides of (2.23) by the function  $\theta_\delta \in H^1(0, T)$  defined by

$$\theta_\delta(t) = \begin{cases} -\frac{t}{\delta} + 1 & \text{if } 0 \leq t \leq \delta, \\ 0 & \text{if } \delta < t \leq T \end{cases}$$

and we integrate by parts to obtain

$$\begin{aligned} & -\frac{\rho h^3}{12} (\phi'_k(0), z) + \frac{\rho h^3}{12\delta} \int_0^\delta (\phi'_k(t), z) dt - \rho h (\psi'_k(0), w) + \frac{\rho h}{\delta} \int_0^\delta (\psi'_k(t), w) dt \\ & + \int_0^\delta (\phi_{kx}(t), z_x) \theta_\delta(t) dt = -\frac{\rho h^3}{12} (\phi_{1k}, z) - \rho h (\psi_{1k}, w) + \frac{\rho h^3}{12\delta} \int_0^\delta (\phi'_k(t), z) dt \\ & + \frac{\rho h}{\delta} \int_0^\delta (\psi'_k(t), w) dt + \int_0^\delta (\phi_{kx}(t), z_x) \theta_\delta(t) dt = \int_0^\delta (f(t), z) \theta_\delta(t) dt \\ & + \int_0^\delta (g(t), w) \theta_\delta(t) dt. \end{aligned}$$

Passing to the limit in the last equality as  $k \rightarrow \infty$  and using (2.21) and (2.22), we get

$$\begin{aligned} & \frac{\rho h^3}{12} (\phi_1, w_x) - \rho h (\psi_1, w) + \frac{\rho h^3}{12\delta} \int_0^\delta (\psi'_x(t), w_x) dt + \frac{\rho h}{\delta} \int_0^\delta (\psi'(t), w) dt \\ & + \int_0^\delta (\psi_{xx}(t), w_{xx}) \theta_\delta(t) dt = \int_0^\delta (f_x(t), w) \theta_\delta(t) dt + \int_0^\delta (g(t), w) \theta_\delta(t) dt. \end{aligned}$$

On the other hand, multiplying in (2.24) by  $\theta_\delta$  and integrating in time, we obtain an expression that, compared with the previous one, yields the identity (2.18). This completes the proof of part (a) of the theorem.

*Step 2. Strong convergence.* We know by (2.4) that the energy  $E_k(t)$  associated with  $\{\phi_k, \psi_k\}$  of (1.6) satisfies

$$(2.25) \quad E_k(t) = E_k(0) + \int_0^t \int_0^L [f(x, s) \phi'_k(x, s) + g(x, s) \psi'_k(x, s)] dx ds.$$

On the other hand, in view of Remark 2.1 and (2.21), it follows that the energy of system (2.13) satisfies

$$\mathcal{E}(t) = \mathcal{E}(0) + \int_0^t \int_0^L [-f(x, s) \psi'_x(x, s) + g(x, s) \psi'(x, s)] dx dt.$$

Therefore, combining (2.14), (2.20), (2.21), and (2.25), we get

$$(2.26) \quad \lim_{k \rightarrow \infty} E_k(t) = \mathcal{E}(t).$$

As a consequence of (2.26), we have the norm convergence which, together with the weak convergence result (2.12), yields the strong convergence one, (b), of the theorem.

Let us develop this last argument in more detail. In view of the weak convergence of solutions and the structure of the energy  $E_k$ , it follows that

$$\liminf_{k \rightarrow \infty} \int_0^T E_k(t) dt \geq \frac{1}{2} \int_0^T \int_0^L \left[ \frac{\rho h^3}{12} |\psi'_x|^2 + \rho h |\psi'|^2 + |\psi_{xx}|^2 \right] dx dt = \int_0^T \mathcal{E}(t) dt.$$

This fact, together with (2.20), (2.21), and (2.26), implies

$$\begin{aligned} \lim_{k \rightarrow \infty} \int_0^T \int_0^L |\phi'_k|^2 dx dt &= \int_0^T \int_0^L |\psi'_x|^2 dx dt, \\ \lim_{k \rightarrow \infty} \int_0^T \int_0^L |\psi'_k|^2 dx dt &= \int_0^T \int_0^L |\psi'|^2 dx dt, \\ \lim_{k \rightarrow \infty} \int_0^T \int_0^L |\phi_{kx}|^2 dx dt &= \int_0^T \int_0^L |\psi_{xx}|^2 dx dt, \end{aligned}$$

and

$$(2.27) \quad \lim_{k \rightarrow \infty} k \int_0^T \int_0^L |\phi_k + \psi_{kx}|^2 dx dt \rightarrow 0.$$

This, combined with the weak convergence, implies the strong convergence of  $\{\phi'_k, \psi'_k, \phi_{kx}\}$  to  $\{-\psi'_x, \psi', -\psi_{xx}\}$  in  $[L^2(Q)]^3$ . The strong convergence of  $\psi_k$  in  $L^2(0, T; H^1(0, L))$  is then a consequence of (2.27) and the fact that  $\phi_k$  strongly converges to  $-\psi_x$  in  $L^2(Q)$ .

Strong convergence in  $L^2(0, T; \mathcal{X})$ , together with the uniform boundedness in  $L^\infty(0, T; \mathcal{X})$ , implies strong convergence in  $L^p(0, T; \mathcal{X})$  for all  $1 < p < \infty$ .  $\square$

**3. Spectral analysis.** This section is devoted to analyzing the asymptotic behavior, as  $k$  tends to infinity, of the spectrum of the Mindlin–Timoshenko system. With this goal in mind, we write system (1.6) (with  $f = g = 0$ ) in the following abstract form:

$$\Phi' = -i\mathcal{A}\Phi,$$

where  $\Phi = [\phi, \phi', \psi, \psi']^T$  and the operator  $\mathcal{A} : D(\mathcal{A}) \subset \mathcal{X} \rightarrow \mathcal{X}$  is given by

$$\mathcal{A} = i \begin{bmatrix} 0 & 1 & 0 & 0 \\ \frac{12}{\rho h^3} \left( \frac{\partial^2}{\partial x^2} - k \right) & 0 & -\frac{12k}{\rho h^3} \frac{\partial}{\partial x} & 0 \\ 0 & 0 & 0 & 1 \\ \frac{k}{\rho h} \frac{\partial}{\partial x} & 0 & \frac{k}{\rho h} \frac{\partial^2}{\partial x^2} & 0 \end{bmatrix}$$

with domain

$$D(\mathcal{A}) = [H_0^1(0, L) \cap H^2(0, L)] \times H_0^1(0, L) \times W \times H^1(0, L).$$

The eigenvalue problem for the operator  $\mathcal{A}$  reads

$$(3.1) \quad \mathcal{A}\Phi = \lambda\Phi.$$

Let us compute the eigenvalues and the corresponding eigenfunctions. In view of the various equations involved in (3.1) and the boundary conditions satisfied by the components  $\phi$  and  $\psi$ , the solutions  $\Phi = [\phi, \phi', \psi, \psi']^T$  associated with the eigenfunctions are such that

$$\{\phi(x, t), \psi(x, t)\} = e^{-i\lambda t} \{\sin(m\pi x/L), c \cos(m\pi x/L)\},$$

where the constant  $c$  is to be determined in terms of  $m$  and  $\lambda$ . In particular, computing the components  $\phi$  and  $\psi$  suffices to identify the 4-component vector.

From (3.1) we have

$$(3.2) \quad \begin{cases} \lambda^2 \frac{\rho h^3}{12} \phi - \phi_{xx} + k(\phi + \psi_x) = 0, \\ \lambda^2 \rho h \psi - k(\phi + \psi_x)_x = 0. \end{cases}$$

Taking the derivative of (3.2)<sub>1</sub> with respect to  $x$  and substituting in (3.2)<sub>2</sub>, we get

$$(3.3) \quad \psi = \frac{1}{\lambda^2 \rho h} \left( \phi_{xxx} - \frac{\lambda^2 \rho h^3}{12} \phi_x \right).$$

Now, doing the same in (3.3) and substituting in (3.2)<sub>1</sub>, it follows that

$$\phi_{xxxx} - \left( \frac{\rho h \lambda^2}{k} + \frac{\lambda^2 \rho h^3}{12} \right) \phi_{xx} + \left( \frac{\lambda^4 \rho^2 h^4}{12k} + \lambda^2 \rho h \right) \phi = 0.$$

Since  $\phi(x, t) = e^{-i\lambda t} \sin(m\pi x/L)$ , we obtain, for  $\lambda$ , the fourth degree equation

$$(3.4) \quad \lambda^4 - \left( \frac{12\pi^2 m^2}{\rho h^3 L^2} + \frac{\pi^2 k m^2}{\rho h L^2} + \frac{12k}{\rho h^3} \right) \lambda^2 + \frac{12\pi^4 k m^4}{\rho^2 h^4 L^4} = 0,$$

while  $c$  satisfies

$$(3.5) \quad c = \frac{\pi^3 m^3}{\lambda^2 \rho h L^3} - \frac{h^2 m \pi}{12L}.$$

Solving (3.4), we find the eigenvalues

$$\begin{aligned} \tilde{\lambda}_{k,m}^{\pm} = \pm & \left[ \frac{6\pi^2 m^2}{\rho h^3 L^2} + \frac{\pi^2 k m^2}{2\rho h L^2} + \frac{6k}{\rho h^3} \right. \\ & \left. + \frac{1}{2} \sqrt{\frac{144k^2}{\rho^2 h^6} + \frac{288\pi^2 k m^2}{\rho^2 h^6 L^2} + \frac{24\pi^2 k^2 m^2}{\rho^2 h^4 L^2} + \left( \frac{12\pi^2 m^2}{\rho h^3 L^2} - \frac{\pi^2 k m^2}{\rho h L^2} \right)^2} \right]^{\frac{1}{2}} \end{aligned}$$

and

$$\lambda_{k,m}^{\pm} = \pm \left[ \frac{6\pi^2 m^2}{\rho h^3 L^2} + \frac{\pi^2 k m^2}{2\rho h L^2} + \frac{6k}{\rho h^3} - \frac{1}{2} \sqrt{\frac{144k^2}{\rho^2 h^6} + \frac{288\pi^2 k m^2}{\rho^2 h^6 L^2} + \frac{24\pi^2 k^2 m^2}{\rho^2 h^4 L^2} + \left( \frac{12\pi^2 m^2}{\rho h^3 L^2} - \frac{\pi^2 k m^2}{\rho h L^2} \right)^2} \right]^{\frac{1}{2}}.$$

We denote by  $c_m$  and  $\tilde{c}_m$  the corresponding values of  $c$  according to the definition (3.5).

For  $m$  fixed, we see easily that, as  $k$  tends to infinity,

$$(3.6) \quad \tilde{\lambda}_{k,m}^{\pm} \rightarrow \pm\infty.$$

This corresponds to that half of the spectrum that disappears when letting  $k$  tend to infinity, in the sense that, since  $\tilde{\lambda}_{k,m}^{\pm}$  diverge as  $k \rightarrow \infty$ , do not lead to any eigenvalue of the limit system.

The following result describes the asymptotic behavior of the other family of eigenvalues.

PROPOSITION 3.1. *For fixed  $m \in \mathbb{N}$ , as  $k \rightarrow \infty$ ,*

$$(3.7) \quad \lambda_{k,m}^{\pm} \rightarrow \lambda_m^{\pm} = \pm \sqrt{\frac{12\pi^4 m^4}{12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2}}.$$

*These are the eigenvalues of the limit Kirchhoff system (2.13) (with  $f_x + g = 0$ ) for which the corresponding eigenfunctions are  $\cos(m\pi x/L)$ .*

*Proof.* It is sufficient to prove convergence for the  $+$  sign. To simplify the notation we denote by  $\lambda_{k,m}$  the eigenvalues  $\lambda_{k,m}^+$ . We have to observe that

$$(3.8) \quad \left| \lambda_{k,m} - \sqrt{\frac{12\pi^4 m^4}{12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2}} \right| = \left| \frac{\lambda_{k,m}^2 - \frac{12\pi^4 m^4}{12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2}}{\lambda_{k,m} + \sqrt{\frac{12\pi^4 m^4}{12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2}}} \right| \\ = \left| \frac{(12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2) \lambda_{k,m}^2 - 12\pi^4 m^4}{(12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2) \lambda_{k,m} + \sqrt{(12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2) (12\pi^4 m^4)}} \right|.$$

Let us now analyze separately the numerator and denominator of this expression.

Using the algebraic identity  $a - b = (a^2 - b^2) / (a + b)$ , we get

$$(3.9) \quad |\lambda_{k,m}|^2 = \frac{12\pi^4 k m^4}{\rho^2 h^4 L^4} \left[ \frac{6\pi^2 m^2}{\rho h^3 L^2} + \frac{\pi^2 k m^2}{2\rho h L^2} + \frac{6k}{\rho h^3} \right. \\ \left. + \frac{1}{2} \sqrt{\frac{144k^2}{\rho^2 h^6} + \frac{288\pi^2 k m^2}{\rho^2 h^6 L^2} + \frac{24\pi^2 k^2 m^2}{\rho^2 h^4 L^2} + \frac{144\pi^4 m^4}{\rho^2 h^6 L^4} - \frac{24\pi^4 k m^4}{\rho^2 h^4 L^4} + \frac{\pi^4 k^2 m^4}{\rho^2 h^2 L^4}} \right]^{-1}.$$

Then the numerator  $\mathcal{N}$  on the right-hand side of (3.8) can be rewritten as

$$\mathcal{N} = \left| -12\pi^4 m^4 + (12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2) \frac{12\pi^4 k m^4}{\rho^2 h^4 L^4} \left[ \frac{6\pi^2 m^2}{\rho h^3 L^2} + \frac{\pi^2 k m^2}{2\rho h L^2} + \frac{6k}{\rho h^3} \right. \right. \\ \left. \left. + \frac{1}{2} \sqrt{\frac{144k^2}{\rho^2 h^6} + \frac{288\pi^2 k m^2}{\rho^2 h^6 L^2} + \frac{24\pi^2 k^2 m^2}{\rho^2 h^4 L^2} + \frac{144\pi^4 m^4}{\rho^2 h^6 L^4} - \frac{24\pi^4 k m^4}{\rho^2 h^4 L^4} + \frac{\pi^4 k^2 m^4}{\rho^2 h^2 L^4}} \right]^{-1} \right|,$$

that is,

$$\mathcal{N} = \left| -12\pi^4 m^4 + \frac{(12L^2 + \pi^2 h^2 m^2) 12\pi^4 m^4}{\frac{6\pi^2 m^2}{k} + \frac{\pi^2 h^2 m^2}{2} + 6L^2 + \frac{\rho h^3 L^2}{2} \sqrt{r}} \right|,$$

where

$$r = \frac{144}{\rho^2 h^6} + \frac{288\pi^2 m^2}{\rho^2 h^6 L^2 k} + \frac{24\pi^2 m^2}{\rho^2 h^4 L^2} + \frac{144\pi^4 m^4}{\rho^2 h^6 L^4 k^2} - \frac{24\pi^4 m^4}{\rho^2 h^4 L^4 k} + \frac{\pi^4 m^4}{\rho^2 h^2 L^4}.$$

Thus, we have the following estimate:

$$\begin{aligned} \mathcal{N} &= \left| \frac{72\pi^4 L^2 m^4 + 6\pi^6 h^2 m^6 - \frac{72\pi^6 m^6}{k} - 6\pi^4 \rho h^3 L^2 m^4 \sqrt{r}}{\frac{6\pi^2 m^2}{k} + \frac{\pi^2 h^2 m^2}{2} + 6L^2 + \frac{\rho h^3 L^2}{2} \sqrt{r}} \right| \\ &\leq \left| \left( \frac{144\pi^2 L^2 m^2}{h^2} + 12\pi^4 m^4 - \frac{144\pi^4 m^4}{h^2 k} \right) - 12\pi^2 \rho h L^2 m^2 \sqrt{r} \right| \\ (3.10) \quad &= \left| \frac{\left( \frac{144\pi^2 L^2 m^2}{h^2} + 12\pi^4 m^4 - \frac{144\pi^4 m^4}{h^2 k} \right)^2 - (12\pi^2 \rho h L^2 m^2)^2 r}{\frac{144\pi^2 L^2 m^2}{h^2} + 12\pi^4 m^4 - \frac{144\pi^4 m^4}{h^2 k} + 12\pi^2 \rho h L^2 m^2 \sqrt{r}} \right| \\ &= \left| \frac{4(12)^3 \pi^4 L^2 m^4}{12h^2 L^2 k + \pi^2 h^4 m^2 k - 12\pi^2 h^2 m^2 + \rho h^5 L^2 k \sqrt{r}} \right|. \end{aligned}$$

Dividing the numerator of the last fraction of (3.10) by the second term of its denominator, it follows that

$$(3.11) \quad \mathcal{N} \leq \frac{4(12)^3 \pi^2 L^2 m^2}{h^4 k}.$$

On the other hand, the denominator  $\mathbf{D}$  of the last term of (3.8) is bounded below by

$$(3.12) \quad \mathbf{D} \geq 12\sqrt{\rho h \pi^2 L^2 m^2}.$$

From (3.8), (3.11), and (3.12) we obtain that

$$(3.13) \quad \left| \lambda_{k,m} - \sqrt{\frac{12\pi^4 m^4}{12\rho h L^4 + \pi^2 \rho h^3 L^2 m^2}} \right| \leq \frac{c}{k},$$

where  $c = 4(12)^2/h^4\sqrt{\rho h}$ . The estimate (3.13) immediately implies the statement (3.7) of the proposition.  $\square$

*Remark 3.1.* As we mentioned above, the eigenvalues  $\tilde{\lambda}_{k,m}^\pm$  tend to  $\pm\infty$ . In other words, they disappear as  $k$  tends to infinity. This fact is intimately related to the asymptotic simplification that the system undergoes when passing from a system of two equations and two dependent variables to a scalar equation with only one dependent variable. Obviously, for a complete description of the space of solutions of (2.13), the eigenpairs  $(\lambda_m^\pm, \cos(m\pi x/L))$  obtained in the limit as  $k$  tends to infinity suffice.

**4. Asymptotic limit of the controlled system.** Our interest now is to study the asymptotic behavior of the solutions  $\{u_k, v_k\}$  of the system (1.1)–(1.4) when  $k$  tends to infinity. They are defined by transposition (see [9]) as follows. First, we consider the solution of the adjoint system

$$(4.1) \quad \begin{cases} \frac{\rho h^3}{12} \phi'' - \phi_{xx} + k(\phi + \psi_x) = f & \text{in } Q, \\ \rho h \psi'' - k(\phi + \psi_x)_x = g & \text{in } Q, \\ \phi(0, \cdot) = \phi(L, \cdot) = \psi_x(0, \cdot) = \psi_x(L, \cdot) = 0 & \text{on } (0, T), \\ \phi(\cdot, T) = \phi'(\cdot, T) = \psi(\cdot, T) = \psi'(\cdot, T) = 0 & \text{in } (0, L). \end{cases}$$

As indicated in the introduction, although, normally, the adjoint system is taken to be homogeneous (i.e.,  $f \equiv g \equiv 0$ ), we consider the case where  $f$  and  $g$  are arbitrary since this is useful to define the solution of (1.1)–(1.4) by transposition.

This system may be reduced to (1.6) by the change of variables  $t \rightarrow T - t$ . Then, when  $\{f, g\} \in L^1(0, T; H_0^1(0, L) \times L^2(0, L))$ , it admits a unique solution in the class (2.1) satisfying (2.2) and the hidden regularity property (2.6). Moreover, the conditions of Theorem 2.1 on the initial data and right-hand side terms are satisfied for (4.1). Therefore, in the limit as  $k \rightarrow \infty$ ,

$$(4.2) \quad \phi + \psi_x = 0.$$

Multiplying both sides of (1.1)<sub>1</sub> by  $\phi$  and of (1.1)<sub>2</sub> by  $\psi$  and integrating, formally, by parts in  $Q$ , we obtain the identity

$$(4.3) \quad \begin{aligned} & \int_Q [f(x, t)u(x, t) + g(x, t)v(x, t)] dx dt = \frac{\rho h^3}{12} \int_0^L \phi(x, 0)u_1(x) dx \\ & - \frac{\rho h^3}{12} \int_0^L \phi'(x, 0)u_0(x) dx + \rho h \int_0^L [\psi(x, 0)v_1(x) - \psi'(x, 0)v_0(x)] dx \\ & - k \int_0^T \Theta_k \psi(0, t) dt. \end{aligned}$$

In view of (2.1) and (2.6), the right-hand side of (4.3) makes sense, provided

$$(4.4) \quad \{u_0, u_1, v_0, v_1\} \in \mathcal{X}' = L^2(0, L) \times H^{-1}(0, L) \times L^2(0, L) \times [H^1(0, L)]'$$

and

$$(4.5) \quad \Theta_k \in [H^1(0, T)]'.$$

Assuming that  $\Theta_k$  is of the form

$$(4.6) \quad \Theta_k = \Theta'_{1k}/k \text{ with } \Theta_{1k} \in L^2(0, T) \text{ of compact support in } (0, T),$$

the identity (4.3) may be rewritten as

$$(4.7) \quad \int_Q [f(x, t) u(x, t) + g(x, t) v(x, t)] dx dt = \frac{\rho h^3}{12} [\langle u_1, \phi(\cdot, 0) \rangle_0 - (u_0, \phi'(\cdot, 0))] + \rho h [\langle v_1, \psi(\cdot, 0) \rangle_1 - (v_0, \psi'(\cdot, 0))] + \int_0^T \Theta_{1k} \psi'(0, t) dt,$$

where  $\langle \cdot, \cdot \rangle_0$  (resp.,  $\langle \cdot, \cdot \rangle_1$ ) represents the duality between  $H^{-1}(0, L)$  (resp.,  $(H^1(0, L))'$ ) and  $H_0^1(0, L)$  (resp.,  $H^1(0, L)$ ).

Note that in (4.6) the prime ' stands for the classical derivative in the sense of distributions.

We adopt (4.7) as a definition of the solution of (1.1)–(1.4) in the sense of transposition. Arguing as in [8] and in view of the hidden regularity properties in Proposition 2.2, we deduce that system (1.1)–(1.4) has a unique solution in the class

$$\{u, v\} \in C^0([0, T]; [L^2(0, L)]^2).$$

Moreover, there exists a constant  $C > 0$ , independent of  $k$ , such that

$$(4.8) \quad \|\{u, v\}\|_{L^\infty(0, T; [L^2(0, L)]^2)} \leq C \left( \|\{u_0, u_1, v_0, v_1\}\|_{\mathcal{X}'} + \|\Theta_{1k}\|_{L^2(0, T)} \right).$$

Similarly one can show that

$$(4.9) \quad \{u, v\} \in C^1([0, T]; H^{-1}(0, L) \times [H^1(0, L)]')$$

and show an estimate of the form

$$(4.10) \quad \|\{u, v\}\|_{W^{1, \infty}(0, T; H^{-1}(0, L) \times [H^1(0, L)]')} \leq C \left( \|\{u_0, u_1, v_0, v_1\}\|_{\mathcal{X}'} + \|\Theta_{1k}\|_{L^2(0, T)} \right).$$

The solution by transposition of the system (1.5) can be defined in a similar way. Indeed, multiplying system (1.5) by the weak solution  $\psi$  of the backward problem (that can be transformed into (2.13) by time-reversal)

$$(4.11) \quad \begin{cases} \rho h \psi'' - \frac{\rho h^3}{12} \psi_{xx}'' + \psi_{xxxx} = f_x + g & \text{in } Q, \\ \psi_x(0, \cdot) = \psi_x(L, \cdot) = \psi_{xxx}(0, \cdot) = \psi_{xxx}(L, \cdot) = 0 & \text{on } (0, T), \\ \psi(\cdot, T) = \psi'(\cdot, T) = 0 & \text{in } (0, L) \end{cases}$$

and after integrating by parts in  $Q$ , we get

$$(4.12) \quad \int_Q [g(x, t) + f_x(x, t)] v(x, t) dx dt = \frac{\rho h^3}{12} [\langle v_{1x}, \psi_x(\cdot, 0) \rangle_0 - (v_{0x}, \psi'_x(\cdot, 0))] + \rho h [(v_1, \psi(\cdot, 0)) - (v_0, \psi'(\cdot, 0))] + \int_0^T \Xi \psi(0, t) dt.$$

We adopt identity (4.12) as a definition of the solution of (1.5) in the sense of transposition. In this sense, when  $\{v_0, v_1\} \in H^1(0, L) \times L^2(0, L)$ , system (1.5) possesses a unique solution in the class  $v \in C^0([0, T]; H^1(0, L)) \cap C^1([0, T]; L^2(0, L))$ .

The following result describes the asymptotic behavior as  $k \rightarrow \infty$ .

THEOREM 4.1. Consider initial data  $\{u_0, u_1, v_0, v_1\} \in \mathcal{X}'$  independent of  $k$  such that

$$(4.13) \quad u_0 + v_{0x} = 0, \quad u_1 + v_{1x} = 0,$$

and  $\Theta_k$  satisfying (4.6) and

$$(4.14) \quad \Theta_{1k} \rightarrow \Theta_1 \text{ weakly in } L^2(0, T), \quad \Theta_1 \text{ being of compact support in } (0, T).$$

Let  $\{u_k, v_k\}$  be the solution of (1.1)–(1.4). Then, as  $k \rightarrow \infty$ , the convergence

$$(4.15) \quad \{u_k, v_k\} \rightarrow \{-v_x, v\} \text{ weakly* in } L^\infty(0, T; L^2(0, L) \times L^2(0, L))$$

holds, where  $v$  is the solution of system (1.5) with  $\Xi = -\Theta'_1$ .

Remark 4.1. As we shall see in the application to controllability, the controls for both the Midlin–Timoshenko and Kirchhoff systems can be taken to be of compact support in  $(0, T)$ .

Proof of Theorem 4.1. For data  $\{u_0, u_1, v_0, v_1, \Theta_k\}$  in the conditions of Theorem 4.1, we consider, for each  $k > 0$ ,  $\{u_k, v_k\}$  the unique solution of (1.1) – (1.4) in the sense of transposition.

Using (2.1), (2.2), (2.6), and (4.14), it follows, by (4.7), that

$$\{u_k, v_k\} \text{ is bounded in } L^\infty(0, T; L^2(0, L) \times L^2(0, L)).$$

Then we can extract a subsequence, that we still denote in the same form, such that

$$(4.16) \quad \{u_k, v_k\} \rightarrow \{u, v\} \text{ weakly* in } L^\infty(0, T; L^2(0, L) \times L^2(0, L)).$$

Applying (4.2), (4.14), and (4.16) in (4.7), we obtain, in the limit,

$$(4.17) \quad \int_Q [f(x, t) u(x, t) + g(x, t) v(x, t)] dx dt = \frac{\rho h^3}{12} [-\langle u_1, \psi_x(\cdot, 0) \rangle_0 + (u_0, \psi'_x(\cdot, 0))] \\ + \rho h [\langle v_1, \psi(\cdot, 0) \rangle_1 - (v_0, \psi'(\cdot, 0))] + \int_0^T \Theta_1 \psi'(0, t) dt,$$

where  $\psi$  is the weak solution of system (4.11). Note that here we have used the fact that the weak convergence property in Theorem 2.1 is also true for the solutions of the adjoint system evaluated at time  $t = 0$ . This result has not been explicitly stated in Theorem 2.1 but can be derived in view of the properties stated there and standard arguments.

On the other hand, from (1.1)<sub>1</sub> we have that

$$u_k + v_{kx} = -\frac{1}{k} \left( \frac{\rho h^3}{12} u''_k - u_{kxx} \right).$$

Then, in the limit as  $k \rightarrow \infty$  (convergence takes place in a very weak topology),

$$u + v_x = 0.$$

In this way, using the last equation, and the compatibility conditions on the initial data (4.13), identity (4.17) can be written as in (4.12) with  $\Xi = -\Theta'_1$ . Thus,  $v$  is the unique solution, by transposition, of system (1.5).  $\square$

**5. Nonuniform observability.** In this section we consider the adjoint system (1.6) in the particular case where  $f \equiv g \equiv 0$ . More precisely, assume that  $\{\phi, \psi\}$  solves

$$(5.1) \quad \begin{cases} \frac{\rho h^3}{12} \phi'' - \phi_{xx} + k(\phi + \psi_x) = 0 & \text{in } Q, \\ \rho h \psi'' - k(\phi + \psi_x)_x = 0 & \text{in } Q, \\ \phi(0, t) = \phi(L, t) = \psi_x(0, t) = \psi_x(L, t) = 0 & \text{on } (0, T), \\ \phi(x, 0) = \phi_0(x), \quad \phi'(x, 0) = \phi_1(x) & \text{in } (0, L), \\ \psi(x, 0) = \psi_0(x), \quad \psi'(x, 0) = \psi_1(x) & \text{in } (0, L). \end{cases}$$

We have the following observability result.

**THEOREM 5.1.** *For  $T > 2\alpha L$ , with*

$$\alpha = \max \left\{ \sqrt{\frac{\rho h^3}{12}}, \sqrt{\frac{\rho h}{k}} \right\}, \quad k \geq 1, \quad \text{and } h \leq \min \left\{ \sqrt[3]{\frac{3}{\rho}}, \frac{1}{4\rho} \right\},$$

*there exists a constant  $C_k^* > 0$  such that, for any solution of (5.1),*

$$(5.2) \quad \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k^2 \leq C_k^* \int_0^T \left\{ |\phi_x(0, t)|^2 + |\psi(0, t)|^2 + \rho h |\psi'(0, t)|^2 \right\} dt.$$

*More precisely,*

$$C_k^* = AC_k,$$

*where  $A = A(T, L, \rho, h)$  is a positive constant and*

$$(5.3) \quad C_k = \frac{L}{2(T - 2\alpha L)} \exp \left( \sqrt{k}L + \frac{2\sqrt{3}L}{h} + L^3 + 3L \right).$$

*Remark 5.1.*

- The observability time in Theorem 5.1 is optimal and uniform in the sense that, for  $k$  large enough, or more precisely, for  $k \geq 12/h^2$ , we can take  $T > 2L\sqrt{\rho h^3/12}$  independent of  $k$ . However, the observability constant  $C_k^*$  diverges exponentially as  $k \rightarrow \infty$ . Therefore it is not of use for getting uniform controllability results as  $k$  tends to infinity.
- The hypotheses of Theorem 5.1 on  $h$  and  $k$  are natural since, as it was said in the introduction, the Mindlin–Timoshenko model was deduced for thin beams (which makes the smallness assumption on  $h$  natural) and also because we are interested in the singular limit  $k \rightarrow \infty$ .

*Proof of Theorem 5.1.*

*Step 1.* First, we consider  $\{\phi_0, \phi_1, \psi_0, \psi_1\} \in \mathcal{X}_0$ . In this case the energy defines a norm equivalent to the usual one  $\|\cdot\|_k$ . We will prove that

$$(5.4) \quad E_k(0) \leq C_k \int_0^T \left\{ |\phi_x(0, t)|^2 + |\psi(0, t)|^2 + \rho h |\psi'(0, t)|^2 \right\} dt.$$

For this, we use a genuinely one-dimensional method which consists roughly of viewing (5.1)<sub>1</sub> and (5.1)<sub>2</sub> as evolution equations with respect to  $x$ , while  $t$  plays the role of the space variable. This argument was used in [15] when studying the controllability of the semilinear wave equation in one space dimension.

Let us define the functional

$$(5.5) \quad F_k(x) = \frac{1}{2} \int_{\alpha x}^{T-\alpha x} \left\{ \frac{\rho h^3}{12} |\phi'(x, t)|^2 + \rho h |\psi'(x, t)|^2 + |\phi_x(x, t)|^2 + k |\phi(x, t) + \psi_x(x, t)|^2 + |\psi(x, t)|^2 \right\} dt.$$

Note that

$$(5.6) \quad F_k(0) = \frac{1}{2} \int_0^T \left\{ |\phi_x(0, t)|^2 + |\psi(0, t)|^2 + \rho h |\psi'(0, t)|^2 \right\} dt.$$

The derivative of the functional  $F_k$  is

$$(5.7) \quad F'_k(x) = \int_{\alpha x}^{T-\alpha x} \left\{ \frac{\rho h^3}{12} \phi'(x, t) \phi'_x(x, t) + \rho h \psi'(x, t) \psi'_x(x, t) + \phi_x(x, t) \phi_{xx}(x, t) + k (\phi(x, t) + \psi_x(x, t)) (\phi(x, t) + \psi_x(x, t))_x + \psi(x, t) \psi_x(x, t) \right\} dt - \frac{1}{2} \sum_{t=T-\alpha x, \alpha x} \left\{ \frac{\rho h^3}{12} |\phi'(x, t)|^2 + \rho h |\psi'(x, t)|^2 + |\phi_x(x, t)|^2 + k |\phi(x, t) + \psi_x(x, t)|^2 + |\psi(x, t)|^2 \right\}.$$

Integrating by parts and using (5.1)<sub>1</sub>, we get

$$(5.8) \quad \begin{aligned} & \int_{\alpha x}^{T-\alpha x} \frac{\rho h^3}{12} \phi'(x, t) \phi'_x(x, t) dt = - \int_{\alpha x}^{T-\alpha x} \frac{\rho h^3}{12} \phi''(x, t) \phi_x(x, t) dt \\ & + \left[ \frac{\rho h^3}{12} \phi'(x, t) \phi_x(x, t) \right]_{\alpha x}^{T-\alpha x} = - \int_{\alpha x}^{T-\alpha x} \phi_{xx}(x, t) \phi_x(x, t) dt \\ & + \int_{\alpha x}^{T-\alpha x} k (\phi(x, t) + \psi_x(x, t)) \phi_x(x, t) dt + \left[ \frac{\rho h^3}{12} \phi'(x, t) \phi_x(x, t) \right]_{\alpha x}^{T-\alpha x}. \end{aligned}$$

Since  $h \leq (3/\rho)^{\frac{1}{3}}$ , we have

$$(5.9) \quad \begin{aligned} & \left[ \frac{\rho h^3}{12} \phi'(x, t) \phi_x(x, t) \right]_{\alpha x}^{T-\alpha x} \leq \frac{1}{4} \sum_{t=T-\alpha x, \alpha x} \left\{ \left( \frac{\rho h^3}{6} \right)^2 |\phi'(x, t)|^2 + |\phi_x(x, t)|^2 \right\} \\ & \leq \frac{1}{4} \sum_{t=T-\alpha x, \alpha x} \left\{ \frac{\rho h^3}{12} |\phi'(x, t)|^2 + \rho h |\psi'(x, t)|^2 + |\phi_x(x, t)|^2 + k |\phi(x, t) + \psi_x(x, t)|^2 + |\psi(x, t)|^2 \right\}. \end{aligned}$$

Using (5.1)<sub>2</sub> and integrating by parts, it follows that

$$(5.10) \quad \begin{aligned} & \int_{\alpha x}^{T-\alpha x} k (\phi(x, t) + \psi_x(x, t)) (\phi(x, t) + \psi_x(x, t))_x dt \\ & = \int_{\alpha x}^{T-\alpha x} \rho h \psi''(x, t) [\phi(x, t) + \psi_x(x, t)] dt = - \int_{\alpha x}^{T-\alpha x} \rho h \phi'(x, t) \psi'(x, t) dt \\ & - \int_{\alpha x}^{T-\alpha x} \rho h \psi'(x, t) \psi'_x(x, t) dt + \{\rho h \psi'(x, t) [\phi(x, t) + \psi_x(x, t)]\}_{\alpha x}^{T-\alpha x}. \end{aligned}$$

We also get

$$\begin{aligned}
 (5.11) \quad & \{\rho h \psi'(x, t) [\phi(x, t) + \psi_x(x, t)]\}_{|\alpha x}^{T-\alpha x} \leq \frac{1}{4} \sum_{t=T-\alpha x, \alpha x}^{T-\alpha x} \{(2\rho h)^2 |\psi'(x, t)|^2 \\
 & + |\phi(x, t) + \psi_x(x, t)|^2\} \leq \frac{1}{4} \sum_{t=T-\alpha x, \alpha x} \left\{ \frac{\rho h^3}{12} |\phi'(x, t)|^2 + \rho h |\psi'(x, t)|^2 \right. \\
 & \left. + |\phi_x(x, t)|^2 + k |\phi(x, t) + \psi_x(x, t)|^2 + |\psi(x, t)|^2 \right\}
 \end{aligned}$$

because  $h \leq 1/4\rho$  and  $k \geq 1$ .

Thus, substituting (5.8)–(5.11) in (5.7), we deduce

$$\begin{aligned}
 (5.12) \quad F'_k(x) & \leq \int_{\alpha x}^{T-\alpha x} k (\phi(x, t) + \psi_x(x, t)) \phi_x(x, t) dt + \int_{\alpha x}^{T-\alpha x} \psi(x, t) \psi_x(x, t) dt \\
 & - \int_{\alpha x}^{T-\alpha x} \rho h \phi'(x, t) \psi'(x, t) dt \leq \left( \sqrt{k} + \frac{2\sqrt{3}}{h} + L^2 + 3 \right) L F_k(x)
 \end{aligned}$$

and, therefore,

$$(5.13) \quad F_k(x) \leq \exp \left( \sqrt{k}L + \frac{2\sqrt{3}L}{h} + L^3 + 3L \right) F_k(0).$$

Integrating (5.13) in  $(0, L)$ , we have

$$(5.14) \quad \int_0^L F_k(x) dx \leq L \exp \left( \sqrt{k}L + \frac{2\sqrt{3}L}{h} + L^3 + 3L \right) F_k(0).$$

Since  $T > 2\alpha L$ , we obtain, by conservation of energy and (5.14),

$$\begin{aligned}
 (5.15) \quad (T - 2\alpha L) E_k(0) & = \int_{\alpha L}^{T-\alpha L} E_k(0) dt = \int_{\alpha L}^{T-\alpha L} E_k(t) dt \leq \int_0^L F_k(x) dx \\
 & \leq L \exp \left( \sqrt{k}L + \frac{2\sqrt{3}L}{h} + L^3 + 3L \right) F_k(0),
 \end{aligned}$$

which implies (5.4).

*Step 2.* We consider now  $\{\phi_0, \phi_1, \psi_0, \psi_1\} \in \mathcal{X}$  and decompose it in the following way:

$$\{\phi_0, \phi_1, \psi_0, \psi_1\} = \{\phi_0, \phi_1, \psi_0 - c_1, \psi_1 - c_2\} + \{0, 0, c_1, c_2\},$$

where  $c_1 = (1/L) \int_0^L \psi_0(x) dx$  and  $c_2 = (1/L) \int_0^L \psi_1(x) dx$ . In this way, according to inequality (5.4), for the initial data  $\{\tilde{\phi}_0, \tilde{\phi}_1, \tilde{\psi}_0, \tilde{\psi}_1\} = \{\phi_0, \phi_1, \psi_0 - c_1, \psi_1 - c_2\} \in \mathcal{X}_0$ , the corresponding solution  $\{\tilde{\phi}, \tilde{\psi}\}$  of (5.1) satisfies

$$\left\| \{\tilde{\phi}_0, \tilde{\phi}_1, \tilde{\psi}_0, \tilde{\psi}_1\} \right\|_k^2 \leq C_{1k} \int_0^T \left\{ \left| \tilde{\phi}_x(0, t) \right|^2 + \left| \tilde{\psi}(0, t) \right|^2 + \rho h \left| \tilde{\psi}'(0, t) \right|^2 \right\} dt,$$

with  $C_{1k} = 2(1 + L + L^2) C_k$  and  $C_k$  as in (5.3).

Taking into account that  $\tilde{\psi} = \psi - c_2 t - c_1$ , it follows that  $\{\phi, \psi\}$  verifies

$$\begin{aligned}
 \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k^2 &\leq 2\|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k^2 + 2\|\{0, 0, c_1, c_2\}\|_k^2 \\
 &\leq 2C_{1k} \int_0^T \left\{ |\phi_x(0, t)|^2 + |(\psi - c_2 t - c_1)(0, t)|^2 + \rho h |(\psi' - c_2)(0, t)|^2 \right\} dt \\
 (5.16) \quad &+ 2L \left[ (c_1)^2 + (c_2)^2 \right] \leq 4C_{1k} \int_0^T \left\{ |\phi_x(0, t)|^2 + |\psi(0, t)|^2 + \rho h |\psi'(0, t)|^2 \right\} dt \\
 &+ 2L \left[ (1 + 4TC_{1k})(c_1)^2 + \left( 1 + 2\rho h TC_{1k} + \frac{4T^3}{3} C_{1k} \right) (c_2)^2 \right].
 \end{aligned}$$

We now need to estimate the last term of (5.16). Integrating (5.1)<sub>2</sub> from 0 to  $L$  and using the initial and boundary conditions of system (5.1), we have

$$\int_0^L \psi'(x, t) dx = c_2 L \quad \text{and} \quad \int_0^L \psi(x, t) dx = (c_1 + tc_2)L.$$

Hence

$$(c_2)^2 \leq \frac{1}{L} \int_0^L |\psi'(x, t)|^2 dx \leq \frac{2}{\rho h L} E_k(t)$$

and

$$\begin{aligned}
 (c_1)^2 &\leq \frac{2}{L} \int_0^L |\psi(x, t)|^2 dx + 2T^2 (c_2)^2 \\
 (5.17) \quad &\leq \frac{4}{L} \max \left\{ \frac{T^2}{\rho h}, 1 \right\} \left[ E_k(t) + \frac{1}{2} \int_0^L |\psi(x, t)|^2 dx \right].
 \end{aligned}$$

Combining these estimates, we see that the observability inequality in the theorem follows easily.  $\square$

In the following section we show how the uniform (with respect to  $k$ ) observability inequality can be proved in a subspace of solutions that, as  $k \rightarrow \infty$ , covers the whole energy space for the limit system.

**6. Uniform observability.** To prove the uniform observability of filtered solutions of the Mindlin–Timoshenko system (5.1), we need the following refined version of the classical Ingham inequality on the theory of nonharmonic Fourier series (see Haraux [4] and Micu and Zuazua [14]).

**THEOREM 6.1** (see [4], [14]). *Let  $f = f(t)$  be of the form  $f(t) = \sum_{n \in \mathbb{Z}} a_n e^{i\lambda_n t}$ , where  $(\lambda_n)_n$  is a sequence of real numbers such that there exist  $N \in \mathbb{N}$ ,  $\gamma > 0$ , and  $\gamma_\infty > 0$  such that*

$$(6.1) \quad \lambda_{n+1} - \lambda_n \geq \gamma_\infty > 0 \quad \text{if} \quad |n| > N,$$

$$(6.2) \quad \lambda_{n+1} - \lambda_n \geq \gamma > 0 \quad \forall n \in \mathbb{Z}.$$

*Let  $T > 0$  be such that  $T > 2\pi/\gamma_\infty$ . Then, there exist two positive constants  $C^{(1)}$  and  $C^{(2)}$  such that*

$$(6.3) \quad C^{(1)} \sum_{n \in \mathbb{Z}} |a_n|^2 \leq \int_0^T |f(t)|^2 dt \leq C^{(2)} \sum_{n \in \mathbb{Z}} |a_n|^2$$

for all  $(a_n)_n \in l^2$ . More precisely,  $C^{(1)} = C^{(1)}(2N+1)$  and  $C^{(2)} = C^{(2)}(2N+1)$ , where  $C^{(i)}(j)$ ,  $i = 1, 2$ , are given by the following recurrent formulas:

$$\begin{cases} C^{(1)}(j+1) = \left[ \left( \frac{2C^{(2)}(j)}{|J|} + 1 \right) \frac{4}{C^{(1)}(j)(|J|\gamma_\infty - 2\pi)^2 \gamma^2} + \frac{2}{|J|} \right]^{-1}, \\ C^{(2)}(j+1) = 2[|J|(j+1) + C^{(2)}(0)], \quad j = 0, 1, \dots, \end{cases}$$

and  $C^{(1)}(0)$ ,  $C^{(2)}(0)$  are such that (6.3) holds in the particular case in which  $\gamma_\infty = \gamma > 0$ .

*Remark 6.1.* The particular case when  $\gamma_\infty = \gamma$  corresponds to the classical result by Ingham [6] which shows the existence of positive constants  $C^{(1)}$  and  $C^{(2)}$  such that (6.3) holds when  $T > 2\pi/\gamma$ . Theorem 6.1 allows us to deduce that, for general sequences  $(\lambda_n)_n$ , inequality (6.3) holds when  $T$  is smaller, because the asymptotic gap  $\gamma_\infty$  is in general larger than  $\gamma$ .

To apply Theorem 6.1 and deduce the uniform observability of system (5.1), we need precise estimates on the gap of the spectrum of (5.1). For this, we will look for solutions of this system in separated variables.

According to the asymptotic properties of the two families of eigenvalues  $(\lambda_{k,m})_{m \in \mathbb{N}}$  and  $(\tilde{\lambda}_{k,m})_{m \in \mathbb{N}}$  of (5.1) given by Proposition 3.1 and by (3.6), respectively, we consider only the family  $(\lambda_{k,m})_{m \in \mathbb{N}}$ , because it is precisely this one and its corresponding eigenfunctions that generate the solutions that converge to the solutions of the limit Kirchhoff system, while the other one disappears, as  $k$  tends to infinity, in the sense that it does not lead to the eigenvalues of the limit system.

Let us now consider the class of solutions of (5.1) generated by the eigenfunctions associated with the eigenvalues  $\lambda_{k,m}$ :

$$W_\lambda = \left\{ \{\phi, \psi\} \text{ solution of (5.1) such that} \right. \\ \left. \{\phi, \psi\} = \sum_{m \in \mathbb{N}} \left( a_{k,m}^+ e^{-i\lambda_{k,m}^+ t} + a_{k,m}^- e^{-i\lambda_{k,m}^- t} \right) \left\{ \sin\left(\frac{m\pi x}{L}\right), c_m \cos\left(\frac{m\pi x}{L}\right) \right\} \right\}$$

with  $c_m$  being as in (3.5) and  $a_{k,m}^\pm = (a_{k,m}^0 - ia_{k,m}^1/\lambda_{k,m}^\pm)/2$ , where  $a_{k,m}^0$  and  $a_{k,m}^1$  are the Fourier coefficients of the initial data  $\{\phi_0, \phi_1\}$  on the basis of sinusoidal eigenfunctions,

$$\{\phi_0, \phi_1\} = \left\{ \sum_{m \in \mathbb{N}} a_{k,m}^0 \sin\left(\frac{m\pi x}{L}\right), \sum_{m \in \mathbb{N}} a_{k,m}^1 \sin\left(\frac{m\pi x}{L}\right) \right\}.$$

Obviously, this is a strict subspace of the whole space of solutions. Indeed, in this subspace we have excluded all the eigencomponents associated with the eigenvalues  $\tilde{\lambda}_{k,m}^\pm$ . In this subspace there is a one-to-one correspondence between the initial data  $\{\phi_0, \phi_1\}$  of  $\phi$  and the initial data  $\{\psi_0, \psi_1\}$  of  $\psi$ . More precisely, the Fourier coefficients of the latter are related to the previous ones by the relations

$$(6.4) \quad b_{k,m}^0 = c_m a_{k,m}^0, \quad b_{k,m}^1 = c_m a_{k,m}^1.$$

Let us analyze the gap between consecutive eigenvalues  $\lambda_{k,m}^\pm$ . For this, we address the following result.

PROPOSITION 6.1. *Given*

$$0 < \epsilon < \pi^2 \sqrt{12/(12\rho hL^2 + \pi^2\rho h^3)}/L$$

and

$$k \geq 8(12)^3 L/\epsilon \pi \sqrt{6\rho h^3}$$

we have

$$(6.5) \quad \left| \lambda_{k,m+1}^\pm - \lambda_{k,m}^\pm \right| \geq \gamma_\infty > 0 \quad \text{with} \quad \gamma_\infty = \frac{\pi}{L} \sqrt{\frac{12}{\rho h^3}} - \epsilon \quad \forall m \geq m_0,$$

where

$$(6.6) \quad m_0 = \frac{2}{h} \sqrt[4]{\frac{9L^2}{\epsilon^2(12\rho hL^2 + \pi^2\rho h^3)}}.$$

On the other hand,

$$(6.7) \quad \left| \lambda_{k,m+1}^\pm - \lambda_{k,m}^\pm \right| \geq \gamma > 0 \quad \text{with} \quad \gamma = \frac{\pi^2}{L} \sqrt{\frac{12}{12\rho hL^2 + \pi^2\rho h^3}} - \epsilon \quad \forall m \geq 1.$$

*Proof.* To simplify the notation, we denote by  $\lambda_{km}$  both  $\lambda_{k,m}^+$  and  $\lambda_{k,m}^-$ . In view of (3.13) we get

$$\begin{aligned} |\lambda_{k,m+1} - \lambda_{k,m}| &\geq \frac{(m+1)\pi^2}{L} \sqrt{\frac{12}{\frac{12\rho hL^2}{(m+1)^2} + \pi^2\rho h^3}} - \frac{m\pi^2}{L} \sqrt{\frac{12}{\frac{12\rho hL^2}{m^2} + \pi^2\rho h^3}} - \frac{2c}{k} \\ &\geq \frac{\pi^2}{L} \sqrt{\frac{12}{\frac{12\rho hL^2}{m^2} + \pi^2\rho h^3}} - \frac{2c}{k} \geq \frac{\pi}{L} \sqrt{\frac{12}{\rho h^3}} - \left( \frac{24\sqrt{3}L}{h^2m\sqrt{12\rho hL^2 + \pi^2\rho h^3m^2}} + \frac{2c}{k} \right), \end{aligned}$$

with  $c$  being as (3.13), that is,  $c = 4(12)^2/h^4\sqrt{\rho h}$ . It is easy to see that when  $m \geq m_0$ , with  $m_0$  as in (6.6), and  $k \geq 4c/\epsilon$ , then

$$\frac{24\sqrt{3}L}{h^2m\sqrt{12\rho hL^2 + \pi^2\rho h^3m^2}} + \frac{2c}{k} \leq \epsilon.$$

This implies the asymptotic gap condition (6.5).

Let us analyze now the behavior of the gap for all  $m \geq 1$ . Proceeding as before we have

$$|\lambda_{k,m+1} - \lambda_{k,m}| \geq \frac{\pi^2}{L} \sqrt{\frac{12}{\frac{12\rho hL^2}{m^2} + \pi^2\rho h^3}} - \frac{2c}{k} \geq \frac{\pi^2}{L} \sqrt{\frac{12}{12\rho hL^2 + \pi^2\rho h^3}} - \frac{2c}{k}$$

for all  $m \geq 1$ . In this way we obtain the gap (6.7), and this concludes the proof of the proposition.  $\square$

In view of the gap conditions (6.5) and (6.7) we have all the ingredients we need to prove the following result.

THEOREM 6.2. *Let  $T > 2L\sqrt{\rho h^3/12}$ . Then there exist positive constants  $c = c(T)$  and  $C = C(T)$  such that*

$$(6.8) \quad c \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k^2 \leq \int_0^T |\psi'(0, t)|^2 dt \leq C \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k^2$$

for all solutions  $\{\phi, \psi\}$  of (5.1) in the class  $W_\lambda$  with initial data  $\{\phi_0, \phi_1, \psi_0, \psi_1\}$  satisfying the condition

$$(6.9) \quad \phi_0 + \psi_{0x} = 0.$$

*Proof.* We consider  $\{\phi, \psi\} \in W_\lambda$  as the solution of (5.1) with initial data  $\{\phi_0, \phi_1, \psi_0, \psi_1\}$  satisfying (6.9). Thus

$$(6.10) \quad \psi'(0, t) = -i \sum_{m \in \mathbb{N}} c_m \left( a_{k,m}^+ \lambda_{k,m}^+ e^{-i\lambda_{k,m}^+ t} + a_{k,m}^- \lambda_{k,m}^- e^{-i\lambda_{k,m}^- t} \right).$$

Let  $T > 2L\sqrt{\rho h^3/12}$ . Applying Theorem 6.1 to the series (6.10) and using the gap conditions, we deduce the existence of positive constants  $C^{(1)} = C^{(1)}(T, \gamma)$  and  $C^{(2)} = C^{(2)}(T, \gamma)$  such that

$$(6.11) \quad \begin{aligned} & C^{(1)} \sum_{m \in \mathbb{N}} c_m^2 \left[ \left( a_{k,m}^+ \lambda_{k,m}^+ \right)^2 + \left( a_{k,m}^- \lambda_{k,m}^- \right)^2 \right] \\ & \leq \int_0^T |\psi'(0, t)|^2 dt \leq C^{(2)} \sum_{m \in \mathbb{N}} c_m^2 \left[ \left( a_{k,m}^+ \lambda_{k,m}^+ \right)^2 + \left( a_{k,m}^- \lambda_{k,m}^- \right)^2 \right]. \end{aligned}$$

Since the initial data  $\{\phi_0, \phi_1, \psi_0, \psi_1\}$  satisfy (6.9), it is easy to see that, for the family of solutions under consideration, the following equivalence holds true:

$$(6.12) \quad \sum_{m \in \mathbb{N}} c_m^2 \left[ \left( a_{k,m}^+ \lambda_{k,m}^+ \right)^2 + \left( a_{k,m}^- \lambda_{k,m}^- \right)^2 \right] \sim \|\{\phi_0, \phi_1, \psi_0, \psi_1\}\|_k^2$$

uniformly on  $k$  for all data  $\{\phi_0, \phi_1, \psi_0, \psi_1\}$  whose solution  $\{\phi, \psi\} \in W_\lambda$ . Combining (6.11) and (6.12) we complete the proof of the theorem.  $\square$

*Remark 6.2.* Let us compare the observability inequalities in (6.8) with Theorem 5.1 as follows:

- In Theorem 5.1, the observed quantity in the right-hand side term of (5.2) depends on both  $\phi$  and  $\psi$ . This would imply a controllability result for system (1.1)–(1.4), but with an extra control entering on  $u$  at  $x = 0$ . In (6.8) the observed quantity depends only on  $\psi$  (more precisely on  $\psi'(0, t)$ ) and this corresponds to using one simple control in (1.1)–(1.4).
- The time of controllability in (6.8) is smaller and the observability constant remains bounded as  $k \rightarrow \infty$ .
- We obtained inequalities (6.8) only for the solutions in the subspace  $W_\lambda$ , since the other family of eigenvalues  $(\tilde{\lambda}_{k,m})_{m \in \mathbb{N}}$  diverges (as  $k \rightarrow \infty$ ) and, consequently, the subspace they generate does not contribute to our main goal, which is to show the controllability of the Kirchhoff system as a limit of the Mindlin–Timoshenko one, as we shall see in the following section.

*Remark 6.3.* Let us finally mention a variant of the observability result in (6.8) that will be used in what follows. Consider a function  $\beta : (0, T) \rightarrow [0, 1]$  in the class  $C^\infty$  such that

$$(6.13) \quad \beta(t) = \begin{cases} 1 & \text{if } t \in (2\epsilon, T - 2\epsilon), \\ 0 & \text{if } t \in (0, \epsilon) \cup (T - \epsilon, T) \end{cases}$$

with  $\epsilon > 0$  sufficiently small such that  $T - 2\epsilon > 2L\sqrt{\rho h^3/12}$ . In view of the time invariance of system (5.1), we deduce

$$(6.14) \quad c \|\{\phi(\cdot, \epsilon), \phi'(\cdot, \epsilon), \psi(\cdot, \epsilon), \psi'(\cdot, \epsilon)\}\|_k^2 \leq \int_0^T \beta(t) |\psi'(0, t)|^2 dt$$

for all solutions  $\{\phi, \psi\}$  of (5.1) in the class  $W_\lambda$ .

**7. Uniform controllability in optimal time.** Due to the results of uniform observability obtained in the previous section, we can apply the HUM to obtain a uniform (with respect to  $k$ ) controllability result for suitable projections of solutions of the Mindlin–Timoshenko system. To be more precise, since only the eigenvalues of the family  $(\lambda_{k,m})_{m \in \mathbb{N}}$  tend to eigenvalues of the limit Kirchhoff system, it is sufficient to obtain the control result on the projections  $\Pi_\lambda$  over the eigencomponents entering in the subspace  $W_\lambda^0$  of  $W_\lambda$  as follows:

$W_\lambda^0 = \{\{\phi, \psi\} \in W_\lambda \text{ such that the initial data } \{\phi_0, \phi_1, \psi_0, \psi_1\} \text{ satisfy (6.9)}\}.$

The partial controllability condition we shall achieve at the final time  $t = T$  reads

$$(7.1) \quad \Pi_\lambda \{u_k(\cdot, T), u'_k(\cdot, T), v_k(\cdot, T), v'_k(\cdot, T)\} = 0.$$

This means that

$$(7.2) \quad \begin{aligned} \frac{\rho h^3}{12} \langle u'_k(\cdot, T), \sin(m\pi x/L) \rangle_0 + \rho h \langle v'_k(\cdot, T), c_m \cos(m\pi x/L) \rangle_1 &= 0, \\ \frac{\rho h^3}{12} (u_k(\cdot, T), \sin(m\pi x/L)) + \rho h (v_k(\cdot, T), c_m \cos(m\pi x/L)) &= 0 \quad \forall m \in \mathbb{N}. \end{aligned}$$

Furthermore, we also describe the asymptotic behavior of the controls, as  $k \rightarrow \infty$ . As we shall see, they converge to exact controls for the limit system. The following holds.

**THEOREM 7.1.** *Let  $T > 2L\sqrt{\rho h^3/12}$ . Then, for all initial data  $\{u_0, u_1, v_0, v_1\} \in \mathcal{X}'$  satisfying the compatibility condition (4.13), there exists a control  $\Theta_k \in H^{-1}(0, T)$ , with*

$$k\Theta_k = \Theta'_{1k} : \Theta_{1k} \in L^2(0, T) \text{ of compact support in } (0, T),$$

such that the solution  $\{u_k, v_k\}$  of (1.1)–(1.4) satisfies (7.1).

Moreover, the function  $\Theta_{1k}$  may be written in the form  $\Theta_{1k} = -\rho h \beta(\cdot) \widehat{\psi}'_k(0, \cdot)$ , where  $\{\widehat{\phi}_k, \widehat{\psi}_k\} \in W_\lambda^0$  is the solution of system (5.1) with initial data  $\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\}$  minimizing the functional

$$(7.3) \quad \begin{aligned} J_k \{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\} &= \frac{\rho h}{2} \int_0^T \beta(t) |\psi'_k(0, t)|^2 dt - \frac{\rho h^3}{12} \langle u_1, \phi_{0k} \rangle_0 \\ &\quad + \frac{\rho h^3}{12} (u_0, \phi_{1k}) - \rho h [\langle v_1, \psi_{0k} \rangle_1 - (v_0, \psi_{1k})] \end{aligned}$$

over  $W_\lambda^0$ , where  $\{\phi_k, \psi_k\} \in W_\lambda^0$  is the solution of (5.1) with initial data  $\{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\}$ . Furthermore, as  $k \rightarrow \infty$ ,

$$\Theta_{1k} \rightarrow \Theta_1 \text{ strongly in } L^2(0, T)$$

with  $\Theta_1$  of compact support in  $(0, T)$ . The limit control  $\Xi = -\Theta_1' \in H^{-1}(0, T)$  is an exact control driving system (1.5) to equilibrium in time  $T$ . Moreover, the function  $\Theta_1$  may be written in the form  $\Theta_1 = -\rho h \beta(\cdot) \hat{\psi}'(0, \cdot)$ , where  $\hat{\psi}$  is the solution of the adjoint system

$$(7.4) \quad \begin{cases} \rho h \psi'' - \frac{\rho h^3}{12} \psi_{xx}'' + \psi_{xxxx} = 0 & \text{in } Q, \\ \psi_x(0, \cdot) = \psi_x(L, \cdot) = \psi_{xxx}(0, \cdot) = \psi_{xxx}(L, \cdot) = 0 & \text{on } (0, T), \\ \psi(\cdot, 0) = \psi_0, \quad \psi'(\cdot, 0) = \psi_1 & \text{in } (0, L), \end{cases}$$

with initial data  $\{\hat{\psi}_0, \hat{\psi}_1\} \in W \times H^1(0, L)$  minimizing the functional

$$(7.5) \quad J\{\psi_0, \psi_1\} = \frac{\rho h}{2} \int_0^T \beta(t) |\psi'(0, t)|^2 dt - \frac{\rho h^3}{12} [\langle v_{1x}, \psi_{0x} \rangle_0 - \langle v_{0x}, \psi_{1x} \rangle] - \rho h [\langle v_1, \psi_0 \rangle - \langle v_0, \psi_1 \rangle],$$

where  $\psi$  is the solution of (7.4) with initial data  $\{\psi_0, \psi_1\}$ .

*Remark 7.1.* In the hypotheses of Theorem 7.1, there are many possible controls  $\Theta_k \in H^{-1}(0, T)$  and  $\Xi \in H^{-1}(0, T)$  fulfilling the controllability requirements. The construction we develop below, presented in the statement of the theorem, provides controls of the form  $\Theta_k = \mu_k'$  and  $\Xi = \mu'$ , with  $\mu_k, \mu \in L^2(0, T)$  having compact support in time and a minimal  $L_\beta^2$ -norm. The weight function  $\beta$  is chosen as in (6.13).

*Proof of Theorem 7.1.* We proceed in several steps.

*Step 1. Existence of the control.* Consider  $\{\phi_k, \psi_k\} \in W_\lambda^0$  the unique solution of the adjoint system (5.1) with initial data  $\{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\}$ . Multiplying (1.1)<sub>1</sub> and (1.1)<sub>2</sub> by  $\phi_k$  and  $\psi_k$ , respectively, and integrating by parts in  $Q$ , we get

$$\begin{aligned} & \frac{\rho h^3}{12} \{ [\langle u_k'(\cdot, T), \phi_k(\cdot, T) \rangle_0 - \langle u_k(\cdot, T), \phi_k'(\cdot, T) \rangle] - [\langle u_1, \phi_{0k} \rangle_0 - \langle u_0, \phi_{1k} \rangle] \} \\ & + \rho h \{ [\langle v_k'(\cdot, T), \psi_k(\cdot, T) \rangle_1 - \langle v_k(\cdot, T), \psi_k'(\cdot, T) \rangle] - [\langle v_1, \psi_{0k} \rangle_1 - \langle v_0, \psi_{1k} \rangle] \} \\ & - \int_0^T \Theta_{1k} \psi_k'(0, t) dt = 0. \end{aligned}$$

Thus to prove (7.1) in the sense of (7.2) it is sufficient to prove the existence of  $\Theta_{1k} \in L^2(0, T)$  such that

$$(7.6) \quad -\frac{\rho h^3}{12} [\langle u_1, \phi_{0k} \rangle_0 - \langle u_0, \phi_{1k} \rangle] - \rho h [\langle v_1, \psi_{0k} \rangle_1 - \langle v_0, \psi_{1k} \rangle] - \int_0^T \Theta_{1k} \psi_k'(0, t) dt = 0$$

for all data  $\{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\}$  whose solution  $\{\phi_k, \psi_k\} \in W_\lambda^0$ .

In view of the structure of  $\beta$  and due to (6.8), the quadratic functional  $J_k$  defined in (7.3) is continuous, strictly convex, and coercive. So, there exists a unique

minimizer  $\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\}$ , whose solution  $\{\widehat{\phi}_k, \widehat{\psi}_k\} \in W_\lambda^0$  can be characterized by the formula

$$(7.7) \quad \begin{aligned} & -\frac{\rho h^3}{12} [\langle u_1, \phi_{0k} \rangle_0 - \langle u_0, \phi_{1k} \rangle] - \rho h [\langle v_1, \psi_{0k} \rangle_1 - \langle v_0, \psi_{1k} \rangle] \\ & + \rho h \int_0^T \beta(t) \widehat{\psi}'_k(0, t) \psi'_k(0, t) dt = 0 \end{aligned}$$

for all data  $\{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\}$  whose solution  $\{\phi_k, \psi_k\} \in W_\lambda^0$ .

According to (7.7), the function  $\Theta_{1k} = -\rho h \beta(\cdot) \widehat{\psi}'_k(0, \cdot) \in L^2(0, T)$ , where  $\{\widehat{\phi}_k, \widehat{\psi}_k\} \in W_\lambda^0$  solves (5.1) with the minimizer  $\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\}$  as data, verifies (7.6). Therefore

$$(7.8) \quad \Theta_k = -\frac{\rho h}{k} \left[ \beta(\cdot) \widehat{\psi}'_k(0, \cdot) \right]' \in H^{-1}(0, T)$$

is the control we were looking for.

*Step 2. Uniform bound of the control.* Let us observe that, since  $\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\}$  is the minimizer of  $J_k$ , we have

$$J_k \left\{ \widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k} \right\} \leq J_k \{0, 0, 0, 0\} = 0.$$

Consequently

$$(7.9) \quad \int_0^T |\Theta_{1k}(t)|^2 dt \leq C \|\{u_0, u_1, v_0, v_1\}\|_{\mathcal{X}'} \left\| \left\{ \widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k} \right\} \right\|_k.$$

In view of the first inequality of (6.8), we can estimate the last term in (7.9) by

$$(7.10) \quad C \|\{u_0, u_1, v_0, v_1\}\|_{\mathcal{X}'} \left( \int_0^T \rho h \beta(t) \left| \widehat{\psi}'_k(0, t) \right|^2 dt \right)^{\frac{1}{2}}.$$

Combining (7.9) and (7.10), we obtain

$$(7.11) \quad \|\Theta_{1k}\|_{L^2(0, T)} \leq C \|\{u_0, u_1, v_0, v_1\}\|_{\mathcal{X}'}.$$

*Step 3. Convergence of controls.* Thanks to (7.11) there exists a subsequence of  $(\Theta_{1k})$  (still denoted by the index  $k$  to simplify the notation) such that

$$(7.12) \quad \Theta_{1k} \rightharpoonup \Theta_1 \text{ weakly in } L^2(0, T).$$

We now consider  $\{u_k, v_k\}$  as the solution of (1.1)–(1.4) with  $\Theta_k$  given in (7.8). Thus, we are in the conditions of Theorem 4.1 and we can assert that the convergence (4.15) holds.

It remains to prove that  $\Xi = -\Theta'_1$  is the control such that the solution  $v$  of (1.5) satisfies

$$(7.13) \quad v(\cdot, T) = v'(\cdot, T) = 0 \quad \text{in } (0, L),$$

with

$$(7.14) \quad \Theta_1 = -\rho h \beta(\cdot) \widehat{\psi}'(0, \cdot),$$

where  $\widehat{\psi}$  is the solution of (7.4) with initial data  $\{\widehat{\psi}_0, \widehat{\psi}_1\} \in W \times H^1(0, L)$  minimizing the functional (7.5). For this, it is sufficient to prove that

$$(7.15) \quad \begin{aligned} & -\frac{\rho h^3}{12} [\langle v_{1x}, \psi_{0x} \rangle_0 - (v_{0x}, \psi_{1x})] - \rho h [(v_1, \psi_0) - (v_0, \psi_1)] \\ & + \rho h \int_0^T \beta(t) \widehat{\psi}'(0, t) \psi'(0, t) dt = 0 \quad \forall \{\psi_0, \psi_1\} \in W \times H^1(0, L), \end{aligned}$$

where  $\psi$  is the solution of (7.4) with initial data  $\{\psi_0, \psi_1\}$ .

We know that, for  $\Theta_{1k} = -\rho h \beta(\cdot) \widehat{\psi}'_k(0, \cdot)$ , where  $\{\widehat{\phi}_k, \widehat{\psi}_k\} \in W_\lambda^0$  is the solution of (5.1) with the minimizer  $\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\}$  as data, the solution of system (1.1)–(1.4) satisfies (7.1). Hence, we get

$$(7.16) \quad -\frac{\rho h^3}{12} [\langle u_1, \phi_{0k} \rangle_0 - (u_0, \phi_{1k})] - \rho h [\langle v_1, \psi_{0k} \rangle_1 - (v_0, \psi_{1k})] - \int_0^T \Theta_{1k} \psi'_k(0, t) dt = 0$$

for all data  $\{\phi_{0k}, \phi_{1k}, \psi_{0k}, \psi_{1k}\}$  whose solution  $\{\phi_k, \psi_k\} \in W_\lambda^0$ .

Combining the first inequalities in (6.8) and (7.11) we deduce that the sequence  $(\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\})$  is uniformly bounded in  $\mathcal{X}$ . So, extracting a subsequence, that we still denote by  $(\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\})$ , we get

$$\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\} \rightarrow \{\bar{\phi}_0, \bar{\phi}_1, \bar{\psi}_0, \bar{\psi}_1\} \text{ weakly in } \mathcal{X},$$

and, by (2.2) (in this case  $f = g = 0$ ), we can pass to the limit as  $k \rightarrow \infty$  on the corresponding solutions and see that the limit  $\bar{\psi}$  is the weak solution of (7.4) with initial data  $\{\bar{\psi}_0, \bar{\psi}_1\}$ .

Multiplying (5.1)<sub>1</sub> and (5.1)<sub>2</sub> by  $(-\eta \sigma_{xx})$  and  $\eta \sigma_x$ , respectively, where  $\eta$  belongs to  $C_0^1(2\epsilon, T - 2\epsilon)$  and  $\sigma(x) = (L - x)e^{(x-L)^3 x^3}$ , and integrating in  $(0, L) \times (2\epsilon, T - 2\epsilon)$ , with  $\epsilon > 0$  small enough, we get the following identity for the solution  $\{\widehat{\phi}_k, \widehat{\psi}_k\}$ :

$$(7.17) \quad \begin{aligned} & \frac{\rho h^3}{12} \int_{2\epsilon}^{T-2\epsilon} \int_0^L \widehat{\phi}'_k(x, t) \eta'(t) \sigma_{xx}(x) dx dt - \int_{2\epsilon}^{T-2\epsilon} \int_0^L \widehat{\phi}_{kx}(x, t) \eta(t) \sigma_{xxx}(x) \\ & + \rho h \int_{2\epsilon}^{T-2\epsilon} \int_0^L \widehat{\psi}'_{xk}(x, t) \eta'(t) \sigma(x) dx dt + \rho h L \int_{2\epsilon}^{T-2\epsilon} \beta(t) \widehat{\psi}'_k(0, t) \eta'(t) dt = 0, \end{aligned}$$

with  $\beta$  being the function in (6.13).

Passing to the limit in (7.17) we deduce that  $\bar{\psi}$  satisfies

$$(7.18) \quad \begin{aligned} & -\frac{\rho h^3}{12} \int_{2\epsilon}^{T-2\epsilon} \int_0^L \bar{\psi}'_x(x, t) \eta'(t) \sigma_{xx}(x) dx dt - L \int_{2\epsilon}^{T-2\epsilon} \Theta_1 \eta'(t) dt \\ & + \int_{2\epsilon}^{T-2\epsilon} \int_0^L \bar{\psi}_{xx}(x, t) \eta(t) \sigma_{xxx}(x) + \rho h \int_{2\epsilon}^{T-2\epsilon} \int_0^L \bar{\psi}'_x(x, t) \eta'(t) \sigma(x) dx dt = 0. \end{aligned}$$

On the other hand, multiplying (7.4)<sub>1</sub> by  $\eta \sigma_x$ , we have the following identity for the limit solution  $\bar{\psi}$ :

$$(7.19) \quad \begin{aligned} & \rho h \int_{2\epsilon}^{T-2\epsilon} \int_0^L \overline{\psi}'_x(x, t) \eta'(t) \sigma(x) dx dt + \rho h L \int_{2\epsilon}^{T-2\epsilon} \beta(t) \overline{\psi}'(0, t) \eta'(t) dt \\ & - \frac{\rho h^3}{12} \int_{2\epsilon}^{T-2\epsilon} \int_0^L \overline{\psi}'_x(x, t) \eta'(t) \sigma_{xx}(x) dx dt + \int_{2\epsilon}^{T-2\epsilon} \int_0^L \overline{\psi}_{xx}(x, t) \eta(t) \sigma_{xxx}(x) dx dt = 0. \end{aligned}$$

Combining (7.18) and (7.19) we finally deduce

$$(7.20) \quad \int_{2\epsilon}^{T-2\epsilon} \left[ \Theta_1 + \rho h \beta(t) \overline{\psi}'(0, t) \right] \eta'(t) dt = 0 \quad \forall \eta \in C_0^1(2\epsilon, T-2\epsilon)$$

and then

$$(7.21) \quad \Theta_1 = -\rho h \beta(\cdot) \overline{\psi}'(0, \cdot),$$

where  $\overline{\psi}$  is the solution of the adjoint system (7.4).

To show that (7.15) is satisfied it is sufficient to pass to the limit in (7.16) using as test functions the solutions of the corresponding adjoint systems in separated variables. In this way, one rigorously reproduces at the variational level the proof that, heuristically, would consist of passing to the limit in (7.2) and, using the fact that  $u = -v_x$  in the limit, of deducing

$$(7.22) \quad -\frac{\rho h^3}{12} [\langle v_{1x}, \psi_{0x} \rangle_0 - \langle v_{0x}, \psi_{1x} \rangle] - \rho h [\langle v_1, \psi_0 \rangle - \langle v_0, \psi_1 \rangle] - \int_0^T \Theta_1 \psi'(0, t) dt = 0$$

and, consequently,

$$(v(\cdot, T), \cos(m\pi x/L)) = (v'(\cdot, T), \cos(m\pi x/L)) = 0 \quad \forall m \in \mathbb{N}.$$

To conclude the proof of the theorem, it remains to prove that the function  $\Theta_1$  can be identified as in (7.14). In fact, it follows from (7.15), (7.21), and (7.22) that

$$\int_0^T \beta(t) \left[ \widehat{\psi}'(0, t) - \overline{\psi}'(0, t) \right] \psi'(0, t) dt = 0$$

for all solutions  $\psi$  of the adjoint problem (7.4).

Taking  $\psi = \widehat{\psi} - \overline{\psi}$ , it follows that

$$\int_0^T \beta(t) \left[ \widehat{\psi}'(0, t) - \overline{\psi}'(0, t) \right]^2 dt = 0$$

and, therefore, we obtain (7.14). Considering (7.15) and (7.16) with data  $\{\widehat{\psi}_0, \widehat{\psi}_1\}$  and  $\{\widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k}\}$ , respectively, we get

$$\begin{aligned} & -\frac{\rho h^3}{12} \left[ \langle u_1, \widehat{\phi}_{0k} \rangle_0 - \langle u_0, \widehat{\phi}_{1k} \rangle \right] - \rho h \left[ \langle v_1, \widehat{\psi}_{0k} \rangle_1 - \langle v_0, \widehat{\psi}_{1k} \rangle \right] \\ & + \rho h \int_0^T \beta(t) \left| \widehat{\psi}'_k(0, t) \right|^2 dt = 0 \end{aligned}$$

and

$$\begin{aligned} & -\frac{\rho h^3}{12} \left[ \langle v_{1x}, \widehat{\psi}_{0x} \rangle_0 - \langle v_{0x}, \widehat{\psi}_{1x} \rangle \right] - \rho h \left[ \langle v_1, \widehat{\psi}_0 \rangle - \langle v_0, \widehat{\psi}_1 \rangle \right] \\ & + \rho h \int_0^T \beta(t) \left| \widehat{\psi}'(0, t) \right|^2 dt = 0. \end{aligned}$$

It follows from the last two equations that

$$\int_0^T \beta(t) \left| \widehat{\psi}'_k(0, t) \right|^2 dt \rightarrow \int_0^T \beta(t) \left| \widehat{\psi}'(0, t) \right|^2 dt$$

which, together with the weak convergence (7.12), yields

$$\Theta_{1k} \rightarrow \Theta_1 \text{ strongly in } L^2(0, T)$$

and

$$\lim_{k \rightarrow \infty} J_k \left\{ \widehat{\phi}_{0k}, \widehat{\phi}_{1k}, \widehat{\psi}_{0k}, \widehat{\psi}_{1k} \right\} = J \left\{ \widehat{\psi}_0, \widehat{\psi}_1 \right\},$$

proving the theorem.  $\square$

*Remark 7.2.* According to Theorem 7.1 we can recover the exact controllability property of the Kirchhoff system as a limit of the partial controllability properties of the Mindlin–Timoshenko one.

*Remark 7.3.* Let us observe also that these results are obtained for the optimal control time  $T > 2L\sqrt{\rho h^3/12}$  which is the best possible one for both Mindlin–Timoshenko and Kirchhoff systems.

## AN INTRINSIC BEHAVIORAL APPROACH TO THE GAP METRIC\*

WENMING BIAN<sup>†</sup>, MARK FRENCH<sup>†</sup>, AND HARISH K. PILLAI<sup>‡</sup>

**Abstract.** An intrinsic trajectory level approach without any recourse to an algebraic structure of a representation is utilized to develop a behavioral approach to robust stability. In particular it is shown how the controllable behavior can be constructed at the trajectory level via Zorn's lemma, and this is utilized to study the controllable-autonomous decomposition. Stability concepts are defined, and the relation between this framework and the well-known difficulties of classical input-output approaches to systems over the doubly infinite time axis are discussed. The gap distance is generalized to the behavioral setting via a trajectory level definition; and a basic robust stability theorem is established for linear shift invariant behaviors. The robust stability theorem is shown to provide an explicit robustness interpretation to the behavioral  $\mathcal{H}^\infty$  synthesis of Willems and Trentelmann.

**Key words.** linear shift invariant behaviors, maximal controllable subbehavior, gap metric, robust stability

**1. Introduction.** We begin by observing that the graph topology with its various metrizations plays a fundamental role in the theory of robust stability for classical linear time invariant systems [1, 4, 19]. The contribution of this paper is to develop the basic theory of robust stability involving the gap distance directly from a behavioral perspective, observing that recent approaches to generalizations of the gap metric [4] have been purely trajectory based and hence are easily amenable to such an approach. There has been previous interest in developing behavioral notions of the gap metric; see, e.g., [11] for an example.

From a behavioral point of view [9, 14, 15, 16], the approach is especially fundamental. Much has been made of the intrinsic nature of behavioral definitions and the need for “representation-free” approaches. In this note, we do not have recourse to representations at all; indeed all proofs are at the intrinsic trajectory level and are not restricted, for example, to differential systems. This gives this paper a different “flavor” to much of the recent behavioral literature which is predominately of an algebraic nature. We illustrate our results by considering a system with a pair of (in general) noncommensurate delays: such a system class falls out of the scope of the existing algebraic techniques of the existing behavioral theory for delay systems where, to achieve an algebraic structure, delays are assumed to be commensurate [5].

There are two interrelated reasons for this approach. The first is mathematical: only a limited set-theoretic/analytic structure is required to obtain the required results; hence it is inappropriate to utilize any further structures (e.g., of an algebraic type); this in turn yields greater generality. The second is of applied consequence: a powerful robust stability result should impose as little structure as possible on the

structure of the perturbations permitted: the perturbed systems may not be representable by differential systems; and they may, for example, arise as a delay or distributed system or even defy direct representation. A set-theoretic treatment of the perturbed system is therefore the appropriate treatment.

Our basic robust stability theorem provides a self-contained basis for the robustness interpretation of the behavioral  $\mathcal{H}^\infty$  results in [17, 12]. The composition of the set-theoretic/analytic treatment in this paper of the resulting perturbed systems is thus set against the controller synthesis for the nominal system, which appropriately is in the context of systems with greater structure (i.e., differential systems).

In relation to the classical approaches, we remark that the standard  $\mathcal{H}^2$  gap is a metric on transfer functions and does not directly apply to systems which either have nonzero initial conditions or which are not minimal (i.e., have uncontrollable modes). The  $\nu$ -gap [13] metric also induces the graph topology on transfer functions and can handle nonzero initial conditions at zero by its definition on the doubly infinite time axis. However, the  $\nu$ -gap is also directly applicable only to controllable systems. By defining systems to be limits of Cauchy sequences in the graph topology [13], the standard gap approaches can also be extended to nonminimal cases; a contribution of this paper from a classical perspective is to provide an alternate and slightly more general approach to these cases. The trajectory formulation considered is also directly applicable to infinite-dimensional systems both in the context of the nominal and perturbed plant and controller: for example delay-differential systems are directly handled, compared to the less direct classical techniques (e.g., the Cauchy sequence approach). We observe also that within the classical framework there has been a move towards representation-free approaches to the gap, e.g., especially for approaches to nonlinear systems [4]. The behavioral approach considered here is one natural extension of this viewpoint.

We emphasize that the main contribution is not in the minor increase in scope of the resulting theorem (as discussed above); rather the contribution is in an alternative and direct derivation of the results within a behavioral framework. Furthermore, we argue that the behavioral approach taken overcomes the well-known difficulties [3] of input-output systems theories on the doubly infinite time axis.

The paper is structured as follows. In section 3 we introduce and review fundamental definitions in the behavioral setting and develop an intrinsic set-theoretic approach to the controllable part of a behavior. Section 4 discusses the controllable-autonomous decomposition, again from a purely trajectory level viewpoint. Section 5 introduces stability definitions and the notion of a closed loop interconnection and considers the concept of stabilizability. From this intrinsic trajectory level framework, two independent issues are discussed. Namely, in section 6 we consider the Georgiou–Smith double time axis “paradox” and show that the Georgiou–Smith example can be satisfactorily treated within the framework considered. Second, in section 7, we utilize the developed framework to develop a fundamental robust stability result. Section 8 shows how this result provides an appropriate interpretation of the robustness guarantee achieved by the behavioral  $\mathcal{H}_\infty$  synthesis of Willems and Trentelmann, and section 9 concludes with an example.

**2. An intrinsic approach to controllable subbehaviors.** Let  $\mathcal{T}$  denote the time set, taken throughout to be either  $\mathbb{Z}$  or  $\mathbb{R}$ , and let  $\mathcal{T}_+ = \mathbb{N}$  if  $\mathcal{T} = \mathbb{Z}$  and  $\mathcal{T}_+ = \mathbb{R}_+$  if  $\mathcal{T} = \mathbb{R}$ . An interval, say  $[a, b]$ , is understood as  $[a, b] = \{t \in \mathcal{T}, a \leq t \leq b\}$ . For  $n \geq 1$ , let  $\text{map}(\mathcal{T}, \mathbb{R}^n)$  be the set of all maps from  $\mathcal{T}$  to  $\mathbb{R}^n$ . An  $n$ -valued behavior  $\mathfrak{B}$  is a subset of  $\text{map}(\mathcal{T}, \mathbb{R}^n)$ , i.e.,  $\mathfrak{B} \subset \text{map}(\mathcal{T}, \mathbb{R}^n)$ . The shift operator  $\sigma_t$ ,  $t \in \mathcal{T}$ , is

defined:  $\sigma_t w(\cdot) = w(\cdot + t)$ .

DEFINITION 2.1. *Let  $\mathfrak{B}$  be a behavior. Then*

1.  *$\mathfrak{B}$  is said to be linear if  $\mathfrak{B}$  is a vector space;*
2.  *$\mathfrak{B}$  is said to be shift invariant (time invariant) if  $w \in \mathfrak{B}$  implies  $\sigma_t w \in \mathfrak{B}$  for all  $t \in \mathcal{T}$ .*

Smooth differential behaviors are linear, shift invariant, continuous-time behaviors which can be expressed as the kernel of a differential operator, i.e., those for which there exists a polynomial valued matrix  $R$  such that

$$(2.1) \quad \mathfrak{B} = \left\{ w \in C^\infty \mid R \left( \frac{d}{dt} \right) w = 0 \right\}.$$

Equivalently in the discrete-time setting, the operator is that of unit shifts:

$$(2.2) \quad \mathfrak{B} = \{ w \in \text{map}(\mathbb{Z}, \mathbb{R}^n) \mid R(\sigma_1) w = 0 \},$$

and such behaviors are called difference behaviors.

Observe that in this note we will be interested in nondifferential/difference behaviors, for example, systems incorporating a time delay.

DEFINITION 2.2. *A behavior  $\mathfrak{B}$  is said to have memory  $l \geq 0$  if for any  $w_1, w_2 \in \mathfrak{B}$  with  $w_1|_{[a, a+l]} = w_2|_{[a, a+l]}$  and  $a \in \mathcal{T}$  the trajectory*

$$w_3(t) = \begin{cases} w_1(t) & \text{if } t \leq a, \\ w_2(t) & \text{if } t \geq a \end{cases}$$

*also lies in  $\mathfrak{B}$ .*

Clearly, a shift invariant behavior  $\mathfrak{B}$  has memory  $l \geq 0$  if and only if for any  $w_1, w_2 \in \mathfrak{B}$  with  $w_1|_{[0, l]} = w_2|_{[0, l]}$  the trajectory

$$(2.3) \quad w_3(t) = \begin{cases} w_1(t) & \text{if } t \leq 0, \\ w_2(t) & \text{if } t \geq 0 \end{cases}$$

*also lies in  $\mathfrak{B}$ .*

If a behavior has memory  $0 \leq l < \infty$ , it is said to have finite memory; if  $l = 0$ , then it is memoryless. Note that a nonmemoryless continuous-time differential behavior has finite memory, and  $l > 0$  can be taken to be arbitrarily small; a discrete time behavior also has finite memory, and here  $l \geq 0$  depends on the system order. The minimal memory  $l_0 \geq 0$  of a behavior  $\mathfrak{B}$  is the largest number such that  $\mathfrak{B}$  has memory  $l$  for all  $l > l_0$ . Note that the minimum is not necessarily attained.

The standard definition of autonomy is that behavior  $\mathfrak{B}$  is said to be autonomous if, for any  $w_1, w_2 \in \mathfrak{B}$ ,  $w_1|_{(-\infty, 0]} = w_2|_{(-\infty, 0]}$  implies  $w_1 = w_2$ . Note that as far as differential systems are concerned, autonomous behaviors have finite memory. We therefore relax the definition for autonomy as follows.

DEFINITION 2.3. *A behavior  $\mathfrak{B}$  is said to be autonomous if there exists  $0 \leq l_0 < \infty$  such that, for any  $w_1, w_2 \in \mathfrak{B}$  and any interval  $V$  of length greater than  $l_0$ ,  $w_1|_V = w_2|_V$  implies  $w_1 = w_2$ .*

Nonautonomy of a behavior is thus just the existence of a trajectory in the behavior whose support has a complement containing an interval of length greater than  $l_0$ , e.g., a compactly supported trajectory.

It should be observed that it is possible that if  $\mathfrak{B}$  has minimal memory  $l_0$ , then, e.g., an autonomous subbehavior can have a minimal memory (i)  $l = 0$ , (ii)  $0 < l < l_0$ , or (iii)  $l = l_0$ ; for example, consider the following:

$$(2.4) \quad \dot{y}(t) = ay(t - 2\tau) + by(t - \tau) + cy(t) + du(t - 2\tau);$$

then  $l_0 = 2\tau$  and the autonomous behavior  $\mathfrak{B}_{u=0}$  corresponds to (i) if  $a = b = 0$ , (ii) if  $a = c = 0, b \neq 0$ , and (iii) if  $b = c = 0, a \neq 0$ .

The behavioral notion of controllability is defined in [9] for differential behaviors. However, this definition is restrictive since it assumes shift invariance of the behavior concerned. We therefore give a modified definition for behavioral controllability that is applicable to more general behaviors but coincides with the notion of controllability in [9] for the case of shift invariant behaviors.

**DEFINITION 2.4.** *A behavior  $\mathfrak{B}$  is said to be controllable if, given  $w_1, w_2 \in \mathfrak{B}$  and  $s \in \mathcal{T}$ , there exist  $w_3 \in \mathfrak{B}$  and  $\tau \in \mathcal{T}_+$  such that*

$$(2.5) \quad w_3(t) = \begin{cases} w_1(t) & \text{if } t \leq s, \\ w_2(t) & \text{if } t \geq s + \tau. \end{cases}$$

This definition requires that the concatenating function  $w_3$  lies in  $\mathfrak{B}$ . This can be hard to guarantee in certain cases, including generalizations to multidimensional systems. Therefore we next introduce the notion of  $\mathfrak{B}$ -controllability.

**DEFINITION 2.5.** *Given a behavior  $\mathfrak{B}$ , a subbehavior  $\mathfrak{B}^* \subset \mathfrak{B}$  is said to be  $\mathfrak{B}$ -controllable if for all  $w_1, w_2 \in \mathfrak{B}^*$  and  $s \in \mathcal{T}$  there exist  $w_3 \in \mathfrak{B}$  and  $\tau \in \mathcal{T}_+$  such that*

$$(2.6) \quad w_3(t) = \begin{cases} w_1(t) & \text{if } t \leq s, \\ w_2(t) & \text{if } t \geq s + \tau. \end{cases}$$

We remark that if  $\mathfrak{B}, \mathfrak{B}^*$  are both shift invariant behaviors and  $\mathfrak{B}^* \subset \mathfrak{B}$ , then  $\mathfrak{B}^*$  is  $\mathfrak{B}$ -controllable if and only if, given any  $w_1, w_2 \in \mathfrak{B}^*$ , there exist  $w_3 \in \mathfrak{B}$  and  $\tau \in \mathcal{T}_+$  such that

$$(2.7) \quad w_3(t) = \begin{cases} w_1(t) & \text{if } t \leq 0, \\ w_2(t) & \text{if } t \geq \tau. \end{cases}$$

If  $\mathfrak{B}^* = \mathfrak{B}$ , then the  $\mathfrak{B}$ -controllability of  $\mathfrak{B}^*$  is the same as the controllability defined by Definition 2.4. So controllability in the sense of Definition 2.4 implies  $\mathfrak{B}$ -controllability. But the following example shows that the converse does not hold.

*Example.* Let  $\mathfrak{B} = C^\infty(\mathbb{R}, \mathbb{R})$  and  $\mathfrak{B}^*$  be the set of all constant functions. Then both  $\mathfrak{B}$  and  $\mathfrak{B}^*$  are linear shift invariant behaviors with finite memory and  $\mathfrak{B}^* \subset \mathfrak{B}$ . It is straightforward to check that  $\mathfrak{B}^*$  is  $\mathfrak{B}$ -controllable. However, it is neither  $\mathfrak{B}^*$ -controllable nor controllable in the sense of Definition 2.4. Similarly, let  $\mathfrak{B} = C^0(\mathbb{R}, \mathbb{R})$ . Then the subbehavior  $\mathfrak{B}^* = \text{span}\{e^t\}$  is  $\mathfrak{B}$ -controllable, but it is not  $\mathfrak{B}^*$ -controllable.

We now consider the properties of  $\mathfrak{B}$ -controllable behaviors.

**LEMMA 2.6.** *Suppose  $\mathfrak{B}$  is a behavior. Then there exists at least one maximal  $\mathfrak{B}$ -controllable subbehavior.*

*Proof.* First, any behavior has at least one  $\mathfrak{B}$ -controllable subbehavior, i.e.,  $\{0\}$ . Second, set inclusion defines a partial order on the set of all  $\mathfrak{B}$ -controllable subbehaviors. Any chain of  $\mathfrak{B}$ -controllable subbehaviors,

$$(2.8) \quad \mathfrak{B}_\alpha \subset \mathfrak{B}_\beta \subset \cdots \subset \mathfrak{B}_\gamma \subset \cdots,$$

where  $\alpha, \beta, \gamma \cdots \in \Gamma$  and  $\Gamma$  is the index set, has an upper bound:

$$(2.9) \quad \mathfrak{B}_\alpha \subset \bigcup_{\beta \in \Gamma} \mathfrak{B}_\beta = \mathfrak{B}^*.$$

$\mathfrak{B}^* \subset \mathfrak{B}$  is  $\mathfrak{B}$ -controllable since, given any  $w_1, w_2 \in \mathfrak{B}^*$ , we have  $w_1 \in B_\alpha$ ,  $w_2 \in \mathfrak{B}_\beta$  for some  $\alpha, \beta \in \Gamma$ , hence  $w_1, w_2 \in \mathfrak{B}_\gamma$ ,  $\gamma = \max\{\alpha, \beta\}$ , and by the  $\mathfrak{B}$ -controllability of  $\mathfrak{B}_\gamma$  it follows that there exists  $w_3 \in \mathfrak{B}$  satisfying (2.6) as required. Zorn's lemma then gives the existence of a maximal  $\mathfrak{B}$ -controllable subbehavior as required.  $\square$

Note that this set-theoretic construction is extremely general: we do not require any linearity, memory, or differential/difference structure on  $\mathfrak{B}$ . In general, maximal  $\mathfrak{B}$ -controllable subbehaviors are not unique. However, if the behavior  $\mathfrak{B}$  is linear, then there exists a unique maximal  $\mathfrak{B}$ -controllable linear subbehavior.

**THEOREM 2.7.** *Suppose  $\mathfrak{B}$  is a linear behavior. Then there exists a unique maximal linear  $\mathfrak{B}$ -controllable subbehavior.*

*Proof.* We consider the set of all linear  $\mathfrak{B}$ -controllable subbehaviors. With the relation induced by subset inclusion, this set is partially ordered and a maximal subbehavior  $\mathfrak{B}_{\text{cont}}$  exists which is also linear.

To show the uniqueness, let  $\mathfrak{B}_1$  be another linear maximal  $\mathfrak{B}$ -controllable subbehavior, and let  $\mathfrak{B}_2$  denote the linear span of  $\mathfrak{B}_{\text{cont}}$  and  $\mathfrak{B}_1$ :  $\mathfrak{B}_2 = \mathfrak{B}_{\text{cont}} + \mathfrak{B}_1$ . Let  $w_1, w_2 \in \mathfrak{B}_2$ . Without loss of generality, we may suppose that  $w_i = \alpha_i x_i + \beta_i y_i$  with  $\alpha_i, \beta_i \in \mathbb{R}$ ,  $x_i \in \mathfrak{B}_{\text{cont}}$ ,  $y_i \in \mathfrak{B}_1$ , and  $i = 1, 2$ . Since  $0 \in \mathfrak{B}_{\text{cont}} \cap \mathfrak{B}_1$  and by the definition of  $\mathfrak{B}$ -controllability, we have the following: for all  $s \in \mathcal{T}$ , there exist  $\tau_1, \tau_2 > 0$  and  $z_1, v_1 \in \mathfrak{B}$  such that  $z_1|_{(-\infty, s]} = x_1|_{(-\infty, s]}$ ,  $z_1|_{[s+\tau_1, \infty)} = 0|_{[s+\tau_1, \infty)}$ ,  $v_1|_{(-\infty, s]} = y_1|_{(-\infty, s]}$ ,  $v_1|_{[s+\tau_2, \infty)} = 0|_{[s+\tau_2, \infty)}$ . Let  $\tau_3 = \max\{\tau_1, \tau_2\}$  and  $w_3 = \alpha_1 z_1 + \beta_1 v_1 \in \mathfrak{B}$ . Then we have  $w_3|_{(-\infty, s]} = \alpha_1 x_1|_{(-\infty, s]} + \beta_1 y_1|_{(-\infty, s]} = w_1|_{(-\infty, s]}$  and  $w_3|_{[s+\tau_3, \infty)} = 0|_{[s+\tau_3, \infty)}$ . This shows that  $w_1$  is switched to 0 in  $\mathfrak{B}$ . Similarly we can prove that there exist  $\tau_4 > 0, w_4 \in \mathfrak{B}$  such that  $w_4|_{(-\infty, s]} = 0|_{(-\infty, s]}$  and  $w_4|_{[s+\tau_4, \infty)} = w_2|_{[s+\tau_4, \infty)}$ . Write  $\tau_5 = \max\{\tau_3, \tau_4\}$ ,  $w_5 = w_3 + w_4$ . Then we see that  $w_5 \in \mathfrak{B}$ ,  $w_5|_{(-\infty, s]} = w_1|_{(-\infty, s]}$  and  $w_5|_{[s+\tau_5, \infty)} = w_2|_{[s+\tau_5, \infty)}$ . This shows that  $\mathfrak{B}_2$  is  $\mathfrak{B}$ -controllable. The maximality of  $\mathfrak{B}_{\text{cont}}$  along with  $\mathfrak{B}_{\text{cont}} \subset \mathfrak{B}_2$  implies that the two behaviors are the same. Hence  $\mathfrak{B}_{\text{cont}}$  is unique.  $\square$

In the rest of this paper, for a linear behavior  $\mathfrak{B}$ , we always use  $\mathfrak{B}_{\text{cont}}$  to denote its unique maximal  $\mathfrak{B}$ -controllable subbehavior.

The above proof also shows that the sum of any two linear  $\mathfrak{B}$ -controllable subbehaviors is  $\mathfrak{B}$ -controllable and, therefore, so is the sum of all linear  $\mathfrak{B}$ -controllable subbehaviors. Hence

$$\mathfrak{B}_{\text{cont}} = \text{span}\{B \subset \mathfrak{B} : B \text{ is linear and } \mathfrak{B}\text{-controllable}\}.$$

Next we show that shift invariance is preserved for the unique maximal  $\mathfrak{B}$ -controllable subbehaviors. In particular, in the shift invariant linear setting,  $\mathfrak{B}_{\text{cont}}$  is linear and shift invariant.

**LEMMA 2.8.** *Suppose  $\mathfrak{B}$  is shift invariant and has a unique maximal  $\mathfrak{B}$ -controllable subbehavior  $\mathfrak{B}^*$ . Then  $\mathfrak{B}^*$  is shift invariant.*

*Proof.* Let  $r, s \in \mathcal{T}$ ,  $\sigma_r w_1, \sigma_r w_2 \in \sigma_r \mathfrak{B}^*$  with  $w_1, w_2 \in \mathfrak{B}^*$ . Then there exist  $w_3 \in \mathfrak{B}$  and  $\tau > 0$  such that  $w_3(t) = w_1(t)$  for  $t \leq s + r$  and  $w_3(t) = w_2(t)$  for  $t \geq s + r + \tau$ . Hence

$$\sigma_r w_3(t) = \begin{cases} \sigma_r w_1(t) & \text{if } t \leq s, \\ \sigma_r w_2(t) & \text{if } t \geq s + \tau. \end{cases}$$

Since  $\sigma_r w_3 \in \sigma_r \mathfrak{B} = \mathfrak{B}$ , we see that  $\sigma_r \mathfrak{B}^*$  is  $\mathfrak{B}$ -controllable and hence  $\sigma_r \mathfrak{B}^* \subset \mathfrak{B}^*$  as  $\mathfrak{B}^*$  is the unique maximal  $\mathfrak{B}$ -controllable subbehavior.  $\square$

**COROLLARY 2.9.** *Suppose  $\mathfrak{B}$  is linear and shift invariant. Then  $\mathfrak{B}_{\text{cont}}$  is linear and shift invariant.*

We conclude this section by showing that  $\mathfrak{B}$ -controllable linear subbehaviors inherit memory properties from the original behavior  $\mathfrak{B}$ .

**LEMMA 2.10.** *Let  $\mathfrak{B}$  be a linear shift invariant behavior with finite memory  $l \geq 0$ . Then  $\mathfrak{B}_{\text{cont}}$  has memory  $l \geq 0$ .*

*Proof.* First, we need a new notion: a subbehavior  $\mathfrak{B}^*$  is 0- $\mathfrak{B}$ -controllable if it is shift invariant and, given any  $w_1, w_2 \in \mathfrak{B}^*$ , there exist  $w_3 \in \mathfrak{B}$  and  $\tau \in \mathcal{T}_+$  satisfying (2.7). Using the same procedure as used in Theorem 2.7, we can see that a maximal linear 0- $\mathfrak{B}$ -controllable subbehavior of  $\mathfrak{B}$  exists, denoted by  $\mathfrak{B}_{\text{cont}}^0$ , which is shift invariant. By the remark following Definition 2.5,  $\mathfrak{B}_{\text{cont}} = \mathfrak{B}_{\text{cont}}^0$ .

Now let  $w_1, w_2 \in \mathfrak{B}_{\text{cont}}$  with  $w_1|_{[0,l]} = w_2|_{[0,l]}$ . Then

$$w_3(t) = \begin{cases} w_1(t) & \text{if } t < 0 \\ w_2(t) & \text{if } t \geq 0 \end{cases} \in \mathfrak{B}.$$

Since  $\mathfrak{B}_{\text{cont}}$  is  $\mathfrak{B}$ -controllable, for any  $w \in \mathfrak{B}_{\text{cont}}$ , there exist  $\tau_1 > 0$  and  $v_1 \in \mathfrak{B}$  such that  $v_1|_{(-\infty,0]} = w|_{(-\infty,0]}$  and  $v_1|_{[\tau_1,\infty)} = w|_{[\tau_1,\infty)}$ ; that is,  $w_3$  can be switched to  $w$ . Similarly, there exist  $\tau_2 > 0$  and  $v_2 \in \mathfrak{B}$  such that  $v_2|_{(-\infty,0]} = w|_{(-\infty,0]}$  and  $v_2|_{[\tau_2,\infty)} = w_2|_{[\tau_2,\infty)} = w_3|_{[\tau_2,\infty)}$ ; that is,  $w$  can be switched to  $w_3$ . Hence  $\text{span}\{w_3\} + \mathfrak{B}_{\text{cont}}^0$  is 0- $\mathfrak{B}$ -controllable. By its maximality  $w_3 \in \mathfrak{B}_{\text{cont}}^0$  and therefore  $w_3 \in \mathfrak{B}_{\text{cont}}$  as shown above. This completes the proof.  $\square$

We remark that all results in this section remain valid if the  $\mathfrak{B}$ -controllability is replaced by the controllability defined in Definition 2.4.

Given a linear differential behavior  $\mathfrak{B}$ , a unique maximal controllable (as per Definition 2.4) subbehavior exists, denoted by  $\mathfrak{B}_c$ . Since this controllable subbehavior is  $\mathfrak{B}$ -controllable,  $\mathfrak{B}_c \subset \mathfrak{B}_{\text{cont}}$ . The next lemma shows that for certain behaviors (that can be represented as kernels of certain classes of operator) the two notions of controllability (Definitions 2.4 and 2.5) coincide. In particular, for differential/difference behaviors,  $\mathfrak{B}_{\text{cont}}$  equals  $\mathfrak{B}_c$ .

We introduce the following notation. Let  $R : \text{dom}(R) \rightarrow \text{im}(R) \subset \text{map}(\mathcal{T}, \mathbb{R}^{n_2})$  be an operator, where  $\text{dom}(R) \subset \text{map}(\mathcal{T}, \mathbb{R}^{n_1})$  is the domain of  $R$  and  $\text{im}(R) \subset \text{map}(\mathcal{T}, \mathbb{R}^{n_2})$  denotes the image of  $R$ .

**DEFINITION 2.11.** *Let  $R : \text{dom}(R) \rightarrow \text{im}(R) \subset \text{map}(\mathcal{T}, \mathbb{R}^{n_2})$  be an operator, where  $\text{dom}(R) \subset \text{map}(\mathcal{T}, \mathbb{R}^{n_1})$ .  $R$  is said to have local action if there exists  $k_2 \geq k_1 > 0$  such that, for all  $t \in \mathcal{T}$ ,  $w_1, w_2 \in \text{dom}(R)$  with  $w_1|_{[t-k_2, t+k_2]} = w_2|_{[t-k_2, t+k_2]}$  implies  $(Rw_1)|_{[t-k_1, t+k_1]} = (Rw_2)|_{[t-k_1, t+k_1]}$ .*

Differential operators, (backward) difference operators, and delay-differential operators all have local action property. For differential operators, the constants  $k_1, k_2$  can be as small as possible. For difference/delay operators,  $k_2 - k_1$  should be greater than or equal to the maximum of differences/delays involved.

**LEMMA 2.12.** *Let  $\mathfrak{B}$  be a linear behavior and  $\mathfrak{B}_c$  be the maximal controllable subbehavior of  $\mathfrak{B}$  (as per Definition 2.4). Let  $R : \text{dom}(R) \rightarrow \text{map}(\mathcal{T}, \mathbb{R}^{n_1})$ ,  $R_c : \mathfrak{B} \rightarrow \text{map}(\mathcal{T}, \mathbb{R}^{n_2})$  and  $S : \text{im}(R_c) \rightarrow \text{map}(\mathcal{T}, \mathbb{R}^{n_1})$  be linear operators, where  $\mathfrak{B} \subset \text{dom}(R) \subset \text{map}(\mathcal{T}, \mathbb{R}^n)$ . Suppose*

- (i)  $R = SR_c$ ;
- (ii)  $\mathfrak{B} = \{w \in \text{dom}(R), Rw = 0\}$  and  $\mathfrak{B}_c = \{w \in \mathfrak{B} : R_c w = 0\}$ ;
- (iii) the behavior  $\mathfrak{B}_S = \{w \in \text{im}(R_c) : Sw = 0\}$  is autonomous; and

(iv)  $R_c$  has local action.

Then  $\mathfrak{B}_{\text{cont}} = \mathfrak{B}_c$ .

*Proof.* Let

$$\mathfrak{B}_1 = \left\{ w \in \mathfrak{B} : \begin{array}{l} \text{for any } s \in \mathcal{T}, \text{ there exist } \tau_1, \tau_2 \geq 0, v_1, v_2 \in \mathfrak{B} \text{ such that} \\ v_1|_{(-\infty, s]} = w|_{(-\infty, s]} \text{ and } v_1|_{[s+\tau_1, \infty)} = 0|_{[s+\tau_1, \infty)}, \\ v_2|_{(-\infty, s]} = 0|_{(-\infty, s]} \text{ and } v_2|_{[s+\tau_2, \infty)} = w|_{[s+\tau_2, \infty)}. \end{array} \right\}.$$

We claim that  $\mathfrak{B}_{\text{cont}} = \mathfrak{B}_1$  and  $\mathfrak{B}_1 = \mathfrak{B}_c$ , so  $\mathfrak{B}_{\text{cont}} = \mathfrak{B}_c$ .

We first prove  $\mathfrak{B}_{\text{cont}} = \mathfrak{B}_1$ . Since  $0 \in \mathfrak{B}_{\text{cont}}$ , any  $w \in \mathfrak{B}_{\text{cont}}$  can be patched to 0 in  $\mathfrak{B}$  and vice versa. This shows that  $\mathfrak{B}_{\text{cont}} \subset \mathfrak{B}_1$ . To show the reverse inclusion, let  $w_1, w_2 \in \mathfrak{B}_1$ . Then for any  $s \in \mathcal{T}$  there exist  $\tau_i \geq 0$  and  $u_i, v_i \in \mathfrak{B}$  ( $i = 1, 2$ ) such that

$$\begin{aligned} u_i|_{(-\infty, s]} &= w_i|_{(-\infty, s]}, & u_i|_{[s+\tau_i, \infty)} &= 0|_{[s+\tau_i, \infty)}, \\ v_i|_{(-\infty, s]} &= 0|_{(-\infty, s]} & \text{and } v_i|_{[s+\tau_i, \infty)} &= w_i|_{[s+\tau_i, \infty)}. \end{aligned}$$

From this it follows that  $u_1 + v_2$  patches  $w_1$  to  $w_2$  and  $u_2 + v_1$  patches  $w_2$  to  $w_1$ . So  $\text{span}\{w_1, w_2\}$  is  $\mathfrak{B}$ -controllable and therefore  $w_1, w_2 \in \mathfrak{B}_{\text{cont}}$ , which proves that  $\mathfrak{B}_1 \subset \mathfrak{B}_{\text{cont}}$ .

We now prove  $\mathfrak{B}_1 = \mathfrak{B}_c$ . Since  $\mathfrak{B}_c \subset \mathfrak{B}_{\text{cont}} = \mathfrak{B}_1$ , we need only prove  $\mathfrak{B}_1 \subset \mathfrak{B}_c$ . Suppose it is not the case. Then there exists  $w \in \mathfrak{B}_1 \setminus \mathfrak{B}_c$  such that  $R_c w \neq 0$ ; that is, there exists  $t_0 \in \mathcal{T}$  with  $R_c w(t_0) \neq 0$ . Since  $R_c$  has local action, there exists  $k_2 > k_1 > 0$  such that for all  $t \in \mathcal{T}$

$$w_1, w_2 \in \mathfrak{B} \quad \text{with } w_1|_{[t-k_2, t+k_2]} = w_2|_{[t-k_2, t+k_2]}$$

implies

$$(R_c w_1)|_{[t-k_1, t+k_1]} = (R_c w_2)|_{[t-k_1, t+k_1]}.$$

Let  $s \in \mathcal{T}$  such that  $s > t_0 + k_2$ . By the definition of  $\mathfrak{B}_1$ , there exist  $\tau > 0$  and  $w_s \in \mathfrak{B}$  such that

$$w_s|_{(-\infty, s]} = w|_{(-\infty, s]} \quad \text{and} \quad w_s|_{[s+\tau, \infty)} = 0|_{[s+\tau, \infty)}.$$

Let  $v_s = R_c w_s$ . Since  $w_s \in \mathfrak{B} = \{w : R_c w = 0\}$ , by assumption (i),  $Sv_s = SR_c w_s = R_c w_s = 0$  and therefore  $v_s \in \mathfrak{B}_S$ . Since  $R_c$  has local action and  $w_s|_{[s+\tau, \infty)} = 0|_{[s+\tau, \infty)}$ , there exist  $a, b \geq s + \tau, a < b$  such that  $v_s|_{[a, b]} = R_c w_s|_{[a, b]} = R_c 0|_{[a, b]} = 0|_{[a, b]}$ . By the autonomy of  $\mathfrak{B}_S$  (choosing  $a, b$  such that  $b - a > \text{minimum memory of } \mathfrak{B}_S$ ),  $v_s \equiv 0$ , i.e.,  $R_c w_s = 0$ . Since  $w_s|_{(-\infty, s]} = w|_{(-\infty, s]}$  and  $t_0 < s - k_2$ , we see that  $w_s|_{[t_0-k_2, t_0+k_2]} = w|_{[t_0-k_2, t_0+k_2]}$ . Therefore, by the local action assumption on  $R_c$ ,  $(R_c w)(t_0) = (R_c w_s)(t_0) = 0$ . This is a contradiction and completes the proof.  $\square$

We may now apply this lemma to linear differential, delay-differential, and difference behaviors, that is, behaviors defined by systems of differential/delay-differential/difference equations. As shown in [5, 9], those behaviors are kernels of linear operators governed by matrices of polynomials.

**THEOREM 2.13.** *For a differential/delay-differential/difference behavior  $\mathfrak{B}$ , its maximal  $\mathfrak{B}$ -controllable subbehavior  $\mathfrak{B}_{\text{cont}}$  is the same as its maximal controllable subbehavior  $\mathfrak{B}_c$ .*

*Proof.* We first suppose that  $\mathfrak{B}$  is a differential behavior. Both  $\mathfrak{B}$  and  $\mathfrak{B}_c$  have the representations

$$\mathfrak{B} = \left\{ w \in \mathfrak{C}^\infty : R \left( \frac{d}{dt} \right) w = 0 \right\}, \quad \mathfrak{B}_c = \left\{ w \in \mathfrak{B} : R_c \left( \frac{d}{dt} \right) w = 0 \right\},$$

where  $R(\xi), R_c(\xi)$  are  $m \times n$  matrices of polynomials of  $\xi$ . Since  $\mathfrak{B}_c \subset \mathfrak{B}$ , there exists a nonsingular polynomial matrix  $S$  such that  $R = SR_c$ . Moreover, the kernel of  $S$  is an autonomous behavior. So all assumptions of Lemma 2.12 hold and  $\mathfrak{B}_{\text{cont}} = \mathfrak{B}_c$ .

If  $\mathfrak{B}$  is a delay-differential behavior, as shown in [5], the proof is almost the same except that the matrix operators are  $R(\frac{d}{dt}, \sigma), R_c(\frac{d}{dt}, \sigma)$  with  $\sigma$  the delay operation. Where no differentiation operators are present, we obtain the proof for the difference behavior case.  $\square$

Earlier, we have shown that

$$\mathfrak{B}_{\text{cont}} = \Sigma \{ B \subset \mathfrak{B} : B \text{ is linear and } \mathfrak{B}\text{-controllable} \}.$$

Since  $\mathfrak{B}_c = \mathfrak{B}_{\text{cont}}$  for a differential/difference behavior  $\mathfrak{B}$ , this gives us a direct set-theoretic construction of  $\mathfrak{B}_c$ . To the best of the authors' knowledge, this direct set-theoretic construction of  $\mathfrak{B}_c$  does not appear in the literature. Within the behavioral literature, the controllable subbehavior is typically constructed algebraically given the equations governing the behavior, and it is shown via the duality between the behavior and the algebraic structure that the controllable subbehavior is the "largest" such subset. It is noteworthy to observe that in some settings (e.g., both one-dimensional (1D) and  $n$ -dimensional ( $n$ D) differential systems), the existence of the corresponding maximal algebraic object appears constructively; see [9, 8].

**3. The autonomous-controllable decomposition.** For 1D differential/difference behaviors  $\mathfrak{B}$  it is well known that  $\mathfrak{B}$  can be split into a direct sum of the controllable and an autonomous part:

$$\mathfrak{B} = \mathfrak{B}_c \oplus \mathfrak{B}_a,$$

where  $\mathfrak{B}_c \subset \mathfrak{B}$  is the maximal controllable subbehavior of  $\mathfrak{B}$  as per Definition 2.4 and  $\mathfrak{B}_a$  is an autonomous subbehavior. Because of Theorem 2.13, we in fact have

$$(3.1) \quad \mathfrak{B} = \mathfrak{B}_{\text{cont}} \oplus \mathfrak{B}_a.$$

This direct sum decomposition is a special feature which holds only for certain classes of systems (such as the differential case [9]). For example, in the  $n$ D differential/difference setting, it is known that this sum is not direct for  $n > 1$  (see [18]), and in the context of delay differential systems it is known only that the sum is direct for commensurate delays [5]. However, since an additive decomposition is critical to what follows, we do not restrict our attention to direct sums but treat it as an important special case.

Therefore this section examines both direct and nondirect sum decompositions at the trajectory level and examines the relationship between autonomy of any direct summand to the  $\mathfrak{B}$ -controllable part and the corresponding lack of controllability of this part. We wish to show that, under certain conditions,  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} \oplus \mathfrak{B}^*$  or  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} + \mathfrak{B}^*$  implies that  $\mathfrak{B}^*$  is autonomous. Behaviors with such decomposition will be studied later on for stability and robustness. We have already established a connection between  $\mathfrak{B}_{\text{cont}}$  and  $\mathfrak{B}_c$  (the maximal controllable subbehavior of  $\mathfrak{B}$  as

per Definition 2.4). Note that in this paper we are considering only behaviors defined over the time set  $\mathcal{T}$  which is either  $\mathbb{Z}$  or  $\mathbb{R}$ .

We begin the study of these decompositions first by considering linear, shift invariant, autonomous behaviors.

LEMMA 3.1. *Let  $\mathfrak{B}$  be linear, shift invariant, autonomous behavior. Let  $\mathfrak{B}_{\text{cont}}$  be the maximal linear  $\mathfrak{B}$ -controllable subbehavior of  $\mathfrak{B}$ . Then  $\mathfrak{B}_{\text{cont}} = \{0\}$ .*

*Proof.* First, it is obvious that  $0 \in \mathfrak{B}_{\text{cont}}$ . Suppose there exists  $w \neq 0, w \in \mathfrak{B}_{\text{cont}}$ . By  $\mathfrak{B}$ -controllability, there exist trajectories  $w_1, w_2 \in \mathfrak{B}$  and  $\tau_1, \tau_2 > 0$  such that  $w_1|_{(-\infty, 0]} = 0, w_1|_{(\tau_1, \infty)} = w|_{(\tau_1, \infty)}$  and  $w_2|_{(-\infty, 0]} = w|_{(-\infty, 0]}, w_2|_{(\tau_2, \infty)} = 0$ . By shift invariance,  $\sigma_{-\tau_2-l_0} w_1 \in \mathfrak{B}$ , where  $l_0$  is the minimum finite memory. Since  $\sigma_{-\tau_2-l_0} w_1|_{[\tau_2, \tau_2+l_0]} = 0 = w_2|_{[\tau_2, \tau_2+l_0]}$ , it follows from the autonomous assumption that  $\sigma_{-\tau_2-l_0} w_1(t) = w_2(t)$  for all  $t \in \mathcal{T}$ . This tells us that  $w_2(t) = 0$  for all  $t \in \mathcal{T}$  and therefore  $w_1 = \sigma_{\tau_2+l_0} w_2 = 0$ . So  $w \equiv 0$ , which is a contradiction.  $\square$

Note that the above lemma is only in one direction.

For any  $V \subset \mathcal{T}$ , let  $P_V$  denote the natural projection (restriction) of signals defined on  $\mathcal{T}$  onto signals defined on  $V$ . As shorthand we write  $P_+$  for  $P_{\mathcal{T}_+}$  and  $P_-$  for  $P_{\mathcal{T} \setminus \mathcal{T}_+}$ .

LEMMA 3.2. (1)  $P_V(\mathfrak{B}_1 + \mathfrak{B}_2) = P_V\mathfrak{B}_1 + P_V\mathfrak{B}_2$  for any two behaviors  $\mathfrak{B}_1, \mathfrak{B}_2$ .

(2) If  $\mathfrak{B}$  is a linear, shift invariant behavior with finite memory  $l > 0$  and  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} \oplus \mathfrak{B}^*$ , then  $P_V\mathfrak{B} = P_V\mathfrak{B}_{\text{cont}} \oplus P_V\mathfrak{B}^*$  for all intervals  $V$  of length greater than  $l$ .

*Proof.* Claim (1) is rather obvious. To establish claim (2), we need only prove that the sum  $P_V\mathfrak{B}_{\text{cont}} \oplus P_V\mathfrak{B}^*$  is direct. Let  $w_1 \in \mathfrak{B}^*, w_2 \in \mathfrak{B}_{\text{cont}}$  such that  $w_1|_V = w_2|_V$ , i.e.,  $w_1|_V = w_2|_V \in P_V\mathfrak{B}_{\text{cont}} \cap P_V\mathfrak{B}^*$ . Consider any  $w_3 \in \mathfrak{B}_{\text{cont}}$ . By the memory property  $w_1$  can be patched to  $w_2$  and conversely, and by  $\mathfrak{B}$ -controllability  $w_2$  can be patched to  $w_3$  and conversely. This tells that  $w_1$  can be patched to  $w_3$  in  $\mathfrak{B}$  and conversely. Hence  $\mathfrak{B}' := \mathfrak{B}_{\text{cont}} + \text{span}(w_1)$  is  $\mathfrak{B}$ -controllable. Since  $\mathfrak{B}_{\text{cont}}$  is the unique maximal  $\mathfrak{B}$ -controllable subbehavior of  $\mathfrak{B}$ , it must contain  $\mathfrak{B}'$ . Hence  $w_1 \in \mathfrak{B}_{\text{cont}}$ . By the direct sum property it follows that  $w_1 = 0$ , and hence  $w_1|_V = w_2|_V = 0$ .  $\square$

PROPOSITION 3.3. *Let  $\mathfrak{B}$  be a linear, shift invariant behavior with finite memory. Then the following are equivalent:*

1.  $\mathfrak{B}_{\text{cont}}$  splits  $\mathfrak{B}$ ; i.e.,  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} \oplus \mathfrak{B}^*$  for some subbehavior  $\mathfrak{B}^* \subset \mathfrak{B}$ .
2. There exists a behavior  $\mathfrak{B}^*$  for which  $(\mathfrak{B}^*)_{\text{cont}} = \{0\}$  (where  $(\mathfrak{B}^*)_{\text{cont}}$  is the maximal linear  $\mathfrak{B}$ -controllable subbehavior of  $\mathfrak{B}^*$ ) and  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} \oplus \mathfrak{B}^*$ .

*Proof.* That 2 implies 1 is obvious. It remains to show that 1 implies 2.

Since  $\mathfrak{B}_{\text{cont}}$  splits  $\mathfrak{B}$ , there exists  $\mathfrak{B}^*$  such that  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} \oplus \mathfrak{B}^*$ . Then  $(\mathfrak{B}^*)_{\text{cont}} \subset \mathfrak{B}_{\text{cont}} \cap \mathfrak{B}^* = \{0\}$ .  $\square$

Note that if one considers the maximal  $\mathfrak{B}^*$ -controllable subbehavior of  $\mathfrak{B}^*$ , instead of  $(\mathfrak{B}^*)_{\text{cont}}$ , then the conclusion of Proposition 3.3 continues to hold. At this juncture, we would like to comment that since Lemma 3.1 is only in one direction, we cannot conclude that  $\mathfrak{B}^*$  in Proposition 3.3 is autonomous. We further observe that if  $\mathfrak{B}_c$  (the controllable part of a behavior  $\mathfrak{B}$  as per Definition 2.4) has finite codimension (as in the differential [10] and commensurate delay [5] settings), then it is known that  $\mathfrak{B}_c$  splits  $\mathfrak{B}$ . In these cases, we know that the summand  $\mathfrak{B}^*$  is autonomous (by the traditional definition).

Unfortunately the autonomy of  $\mathfrak{B}^*$  in the present situation remains a problem. So we introduce the following definition for the rest of this paper.

DEFINITION 3.4. *A behavior  $\mathfrak{B}$  is said to have a controllable-autonomous decomposition if there exists an autonomous subbehavior of  $\mathfrak{B}$ , denoted by  $\mathfrak{B}_{\text{aut}}$ , such*

that

$$\mathfrak{B} = \mathfrak{B}_{\text{cont}} + \mathfrak{B}_{\text{aut}}.$$

**4. Stability.** Stability is determined by the signal spaces involved. We will consider the spaces  $L^p(\mathcal{T}, \mathbb{R}^n)$  with  $0 \leq p \leq \infty$ . In the case when  $\mathcal{T} = \mathbb{R}$ , it is the standard  $L^p$  spaces such as  $L^2(\mathbb{R}, \mathbb{R}^n)$  and  $L^\infty(\mathbb{R}, \mathbb{R}^n)$  for continuous-time signals. In the case when  $\mathcal{T} = \mathbb{Z}$ , it becomes the standard  $l^p$  spaces used for discrete signals.

Given a general normed signal space (say)  $Y$  of signals from  $\mathcal{T}$  or  $\mathcal{T}_+$  to  $\mathbb{R}^n$ , the corresponding extended space  $Y_e$  is defined as

$$Y_e = \{y : \mathcal{I} \rightarrow \mathbb{R}^n : T_\tau y \in Y \text{ for all } \tau \in \mathcal{I}_+\},$$

where  $\mathcal{I} = \mathcal{T}$  or  $\mathcal{T}_+$  subject to on which set the space  $Y$  is defined, and  $T_\tau$  is the truncation operator, that is,  $(T_\tau y)(t) = y(t)$  for  $t \leq \tau$  and 0 for  $t > \tau$ .

In this section, the behaviors considered will be restricted to be within the extended signal spaces  $L_e^p := L_e^p(\mathcal{T}, \mathbb{R}^n)$ ,  $1 \leq p \leq \infty$ , i.e.,  $L^p$  behaviors or subsets of  $L_e^p$ .

As shorthand we write  $X = L^p(\mathcal{T}_+) =: L^p(\mathcal{T}_+, \mathbb{R}^n)$ ,  $1 \leq p \leq \infty$ . So  $X_e = L_e^p(\mathcal{T}_+)$ . We remark that when the results do not need a normed structure on the signal spaces, our discussions and definitions also remain valid for  $C^\infty$  behaviors (with  $X = C^\infty(\mathcal{T}_+)$ ).

We generalize the standard behavioral definition of stability for autonomous systems as follows.

**DEFINITION 4.1.** *An autonomous system  $\mathfrak{B}_{\text{aut}}$  is said to be  $X$ -stable if, for any  $w \in \mathfrak{B}_{\text{aut}}$ ,  $w|_{[0, \infty)} \in X$ .*

This notion of stability can be equivalently expressed as the statement that  $\mathfrak{B}_{\text{aut}}$  is stable if and only if  $P_+ \mathfrak{B}_{\text{aut}} \subset X$ . For nonautonomous systems, we adopt the following stability concept for behaviors with input-output partition (see [9]), which captures the notion of “whatever the past, given a bounded future input, the future output is bounded.”

**DEFINITION 4.2.** *A behavior  $\mathfrak{B}$  with input-output partition  $u|y$  is  $X$ -stable if for all  $(u, y) \in \mathfrak{B}$  with  $u|_{\mathcal{T}_+} \in X$  we have  $y|_{\mathcal{T}_+} \in X$ .*

When  $X$  is given, throughout the paper we refer to the notion of “ $X$ -stability” simply as “stability.”

Associated with any behavior are the stable subbehaviors which correspond to the behavior taking zero values up to time  $t = 0$ .

**DEFINITION 4.3.** *The graph  $\mathcal{G}_{\mathfrak{B}}$  of a behavior  $\mathfrak{B}$  is defined to be*

$$(4.1) \quad \mathcal{G}_{\mathfrak{B}} := \{w \in X \mid \text{there exists } v \in \mathfrak{B} \text{ such that } v|_{\mathcal{T}_-} = 0, v|_{\mathcal{T}_+} = w|_{\mathcal{T}_+}\}.$$

The extended graph  $\mathcal{Z}_{\mathfrak{B}}$  of  $\mathfrak{B}$  is defined to be

$$\mathcal{Z}_{\mathfrak{B}} := \{w \in X_e \mid \text{there exists } v \in \mathfrak{B} \text{ such that } v|_{\mathcal{T}_-} = 0, v|_{\mathcal{T}_+} = w|_{\mathcal{T}_+}\}.$$

Note that when  $\mathcal{T} = \mathbb{R}$ ,  $X = L^2(\mathbb{R}_+)$ ,  $\mathcal{G}_{\mathfrak{B}}$  corresponds to the classical  $\mathcal{H}^2$  graph [13].

**LEMMA 4.4.** *Let  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} \oplus \mathfrak{B}_{\text{aut}}$  be a linear, shift invariant behavior with finite memory. Then  $\mathcal{Z}_{\mathfrak{B}_{\text{cont}}} = \mathcal{Z}_{\mathfrak{B}}$  and  $\mathcal{G}_{\mathfrak{B}_{\text{cont}}} = \mathcal{G}_{\mathfrak{B}}$ .*

*Proof.* Since  $\mathfrak{B}_{\text{cont}} \subset \mathfrak{B}$  it follows that  $\mathcal{Z}_{\mathfrak{B}_{\text{cont}}} \subset \mathcal{Z}_{\mathfrak{B}}$  and  $\mathcal{G}_{\mathfrak{B}_{\text{cont}}} \subset \mathcal{G}_{\mathfrak{B}}$ . Conversely, let  $w \in \mathcal{Z}_{\mathfrak{B}}$ . By the direct sum, there exist  $w_1 \in \mathfrak{B}_{\text{cont}}$ ,  $w_2 \in \mathfrak{B}_{\text{aut}}$  such that

$w = w_1 + w_2$ . By definition of  $\mathcal{Z}_{\mathfrak{B}}$ , it follows that  $(w_1 + w_2)|_{\mathcal{T}_-} = 0$ , so by Lemma 3.2(2),  $w_1|_{\mathcal{T}_-} = w_2|_{\mathcal{T}_-} = 0$ . By the autonomy of  $\mathfrak{B}_{\text{aut}}$ , it follows that  $w_2 = 0$ . Hence  $\mathcal{Z}_{\mathfrak{B}} \subset \mathcal{Z}_{\mathfrak{B}_{\text{cont}}}$  and  $\mathcal{G}_{\mathfrak{B}} \subset \mathcal{G}_{\mathfrak{B}_{\text{cont}}}$ .  $\square$

We now introduce a notion of uniform stability, which captures the property that in addition to stability there is a uniform gain between future inputs and outputs when the past is zero. We will discuss the relation between this notion of stability and dissipativity descriptions of stability in section 7.

DEFINITION 4.5. *A linear behavior with input-output partition  $u|y$  is uniformly stable if*

1.  $\mathfrak{B}$  is stable;
2. *there exists a bounded operator  $\Psi: X \rightarrow X$  such that for all  $(u, y) \in \mathfrak{B}$  such that  $u|_{\mathcal{T}_+} \in X$ ,  $(u, y)|_{\mathcal{T}_-} = 0$  it follows that  $y = \Psi(u)$ .*

Note that the existence of a single stable autonomous subbehavior  $\mathfrak{B}_{\text{aut}}$  such that  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} \oplus \mathfrak{B}_{\text{aut}}$  does *not* imply stability. For an example, consider  $\dot{x} = x + u$ ,  $\dot{z} = -z$ ,  $y = x + z$ . Then the subbehavior generated by  $\dot{z} = -z$ ,  $u = x = 0$ ,  $y = z$  is stable and has the direct sum property, and yet the behavior is not stable. However, in the context of differential systems, this property characterizes *stabilizability* (see [9] for the case of  $X = C_0(\mathbb{R}_+)$ ).

DEFINITION 4.6. *A behavior  $\mathfrak{B}$  is said to be stabilizable if for all  $w_1 \in \mathfrak{B}$  there exists  $w_2 \in \mathfrak{B}$  such that  $w_1|_{(-\infty, 0]} = w_2|_{(-\infty, 0]}$  and  $w_2|_{[0, \infty)} \in X$ .*

A useful sufficient condition for stabilizability is as follows.

LEMMA 4.7. *Let  $\mathfrak{B}$  be a linear shift invariant behavior with finite memory. If  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} + \mathfrak{B}_{\text{aut}}$  and  $\mathfrak{B}_{\text{aut}}$  is stable, then  $\mathfrak{B}$  is stabilizable.*

*Proof.* Suppose there exists a stable autonomous subbehavior  $\mathfrak{B}_{\text{aut}}$  such that  $\mathfrak{B} = \mathfrak{B}_{\text{cont}} + \mathfrak{B}_{\text{aut}}$ . Then, given any  $w \in \mathfrak{B}$ , there exist  $w_1 \in \mathfrak{B}_{\text{cont}}$ ,  $w_2 \in \mathfrak{B}_{\text{aut}}$  such that  $w = w_1 + w_2$ . By controllability and shift invariance of  $\mathfrak{B}_{\text{cont}}$ ,  $w_1$  can be patched with  $0 \in \mathfrak{B}_{\text{cont}}$  so that there exists  $w'_1 \in X$  such that  $w_1|_{(-\infty, 0]} = w'_1|_{(-\infty, 0]}$ . By the stability of  $\mathfrak{B}_{\text{aut}}$ ,  $w_2 \in X$ . Hence  $w' = w'_1 + w_2 \in X$  and  $w|_{(-\infty, 0]} = w'|_{(-\infty, 0]}$ , and thus  $\mathfrak{B}$  is stabilizable as required.  $\square$

It is natural to ask whether the converse holds, that is, whether stabilizability of  $\mathfrak{B}$  implies stability of  $\mathfrak{B}_{\text{aut}}$ . For differential systems, Theorem 5.2.30 in [9] establishes the equivalence. For delay-differential systems with commensurate delays, the equivalence has been conjectured in [5, p. 117]. It is thus useful to define the weaker notion of “soundly stabilizable” and to formally note the equivalence of “soundly stabilizable” and “stabilizable” for differential systems as follows.

DEFINITION 4.8. *A behavior  $\mathfrak{B}$  is said to be soundly stabilizable if there exists a stable  $\mathfrak{B}_{\text{aut}}$  such that  $\mathfrak{B} = \mathfrak{B}_{\text{aut}} + \mathfrak{B}_{\text{cont}}$ .*

PROPOSITION 4.9. *For a differential behavior  $\mathfrak{B}$ ,  $\mathfrak{B}$  is stabilizable if and only if it is soundly stabilizable.*

*Proof.* See Theorem 5.2.30 in [9].  $\square$

We are primarily interested in the standard feedback interconnections shown in Figures 1 and 2.

DEFINITION 4.10. *Given a plant behavior  $\mathfrak{B}^P$ , a controller behavior  $\mathfrak{B}^C$ , and interconnection behavior  $\mathfrak{B}^I$ ,*

$$(4.2) \quad \mathfrak{B}^I = \{(w_0, w_1, w_2)^T \in X_e \mid w_0 = w_1 + w_2\},$$

*we define the closed-loop behavior  $\mathfrak{B}^{P \wedge C}$  as follows:*

$$\mathfrak{B}^{P \wedge C} = \{(w_0, w_1, w_2)^T \in \mathfrak{B}^I \mid w_1 \in \mathfrak{B}^P, w_2 \in \mathfrak{B}^C\}.$$

FIG. 1. The closed loop.

FIG. 2. The interconnected behaviors:  $w_i = (u_i, y_i)^T$ ,  $i = 0, 1, 2$ .

To ensure uniqueness of solutions of the closed loop (modulo the autonomous part of the behavior) we adopt the following definition.

DEFINITION 4.11. Given a plant behavior  $\mathfrak{B}^P$ , a controller behavior  $\mathfrak{B}^C$ , and interconnection behavior  $\mathfrak{B}^I$  (4.2), the behavior  $\mathfrak{B}^{P \wedge I C}$  is said to be well-posed if

$$(4.3) \quad X_e = \mathcal{Z}_{\mathfrak{B}^P} \oplus \mathcal{Z}_{\mathfrak{B}^C}.$$

This captures the idea that for the interconnection of behaviors with a zero past, “ $w_0$  is an input, and for any input  $w_0$ , there exist unique internal signals  $w_1, w_2$ .”

By (4.3), any  $w_0 \in X_e$  has a unique decomposition  $w_0 = w_1 + w_2$  with  $w_1 \in \mathcal{Z}_{\mathfrak{B}^P}$  and  $w_2 \in \mathcal{Z}_{\mathfrak{B}^C}$ . Hence two projection operators can be defined as below:

$$(4.4) \quad \begin{aligned} \Pi_{P//C}: X_e &\rightarrow \mathcal{Z}_{\mathfrak{B}^P}, w_0 \mapsto w_1, \\ \Pi_{C//P}: X_e &\rightarrow \mathcal{Z}_{\mathfrak{B}^C}, w_0 \mapsto w_2. \end{aligned}$$

Due to the interconnection behavior, we have

$$(4.5) \quad \Pi_{P//C} + \Pi_{C//P} = I.$$

DEFINITION 4.12. A controller behavior  $\mathfrak{B}^C$  is said to be a stabilizing controller for a plant behavior  $\mathfrak{B}^P$  if  $\mathfrak{B}^{P \wedge I C}$  is stable.

**5. Double axis time theories.** In [3] it is shown that classical notions of stability and causality lead to problematic inconsistencies when input-output systems defined over a doubly infinite time axis are considered. In particular a causal and stable system  $P_h$  was considered, defined by the following convolution:

$$(5.1) \quad P_h: u \mapsto y \quad : \quad y(t) = \int_{-\infty}^{\infty} h(t - \tau)u(\tau) d\tau = (h * u)(t),$$

where  $h(t) = \exp(t)$  for  $t \geq 0$  and 0 otherwise. The interconnection of  $P_h$  with a controller  $C$  implementing negative unity feedback with gain greater than one as in

Figure 1 was considered. It was shown [3] that if such a closed loop is considered to be well-posed and stable (in the sense that the (single valued) map  $\Pi: L^2(\mathbb{R}_+) \rightarrow L^2(\mathbb{R}_+)$  defined by  $\begin{pmatrix} u_0 \\ y_0 \end{pmatrix} \mapsto \begin{pmatrix} u_1 \\ y_1 \end{pmatrix}$  exists (and necessarily has finite induced norm)), then necessarily the classical  $L^2(\mathbb{R})$  graph of  $P_h$  is closed. It was further shown in [3] that the trajectories

$$(5.2) \quad \tilde{u}(t) = \begin{cases} \exp(-t), & t \geq 0, \\ 0, & t < 0, \end{cases} \quad \tilde{y}(t) = \begin{cases} -\frac{1}{2} \exp(-t), & t \geq 0, \\ -\frac{1}{2} \exp(t), & t < 0, \end{cases}$$

can be obtained as the limit of a sequence of trajectories lying in the  $L^2(\mathbb{R})$  graph of  $P_h$ , which is a contradiction since this solution does not satisfy the relation (5.1). Furthermore, it can be shown [3] that if  $w_0 = (\tilde{u}, \tilde{y})^T$  acts as the disturbance to the closed loop  $[P_h, C]$ , where  $C$  is negative unity feedback in Figure 1, then there is no solution  $w_1 = (u_1, y_1)^T$ .

We view the above observations as indicating an inadequacy of (5.1) as a complete physical model. By linearity the input-output model (5.1) enforces that  $u = 0$  implies  $y = 0$ , and hence there is no nontrivial autonomous subbehavior. By the natural inclusion of such autonomous subbehaviors, and with the corresponding relaxations of the notions of causality, well-posedness, and stability, the example can be reconsidered as follows.

Let  $\mathfrak{B}^{P_h}$  denote the smallest differential behavior containing all trajectories  $(u, y)$  satisfying (5.1). It can be observed that  $\mathfrak{B}^{P_h}$  can be expressed by the following (minimal) kernel representation:

$$\mathfrak{B}^{P_h} = \{w \in L^1_{\text{loc}}(\mathbb{R}) \mid [-1 \ s - 1] w = 0\},$$

where  $s = \frac{d}{dt}$ , where solutions are interpreted in the weak sense in  $L^1_{\text{loc}}(\mathbb{R})^1$  (rather than  $L^1_e(\mathbb{R})$ ) to avoid any possible implicit imposition of a time direction. The behavior  $\mathfrak{B}^{P_h}$  can be explicitly expressed as

$$\mathfrak{B}^{P_h} = \left\{ \begin{pmatrix} u \\ y \end{pmatrix} \in L^1_{\text{loc}}(\mathbb{R}) \mid \begin{array}{l} y(t) = y_0 \exp(t) + \int_{-\infty}^t \exp(t - \tau) u(\tau) d\tau, \\ y_0 \in \mathbb{R}, u \in L^1_{\text{loc}}(\mathbb{R}). \end{array} \right\}.$$

In terms of the definitions given in this paper, this behavior is indeed stabilizable, and negative unity feedback with a gain greater than one provides a well-posed stabilizing interconnection: if  $\mathfrak{B}^C = \{w \in L^2_e(\mathbb{R}_+) \mid w = (u, y)^T, u(t) = -ky(t)\}$ , then  $\mathcal{B}^{P_h \wedge_I C}$  is (uniformly) stable for  $k > 1$ . It is important to observe that

$$\begin{pmatrix} \tilde{u} \\ \tilde{y} \end{pmatrix} = \begin{pmatrix} \tilde{u} \\ -\frac{1}{2} \exp(t) + \int_{-\infty}^t \exp(t - \tau) \tilde{u}(\tau) d\tau \end{pmatrix} \in \mathcal{B}^{P_h} \cap L^2(\mathbb{R}),$$

since  $(\tilde{u}, \tilde{y})^T$  can be explained by the sum of the unforced solution  $(0, \exp(\cdot))^T$  and the forced solution  $(\tilde{u}, \int_{-\infty}^t \exp(t - \tau) \tilde{u}(\tau) d\tau)^T$ .

It is important to observe that the approach developed in this paper provides an alternative approach to addressing the classical problems of a doubly infinite time axis. The approach taken here is perhaps halfway between a double and a half line time axis, in that signals are defined over the whole of  $\mathbb{R}$ , but stability notions are related to boundedness of signals when restricted to  $\mathbb{R}_+$ . Only in the case of uniform

<sup>1</sup>  $f \in L^1_{\text{loc}}(\mathbb{R})$  if, for all compact  $\Omega \subset \mathbb{R}$ ,  $f|_{\Omega} \in L^1(\Omega)$ .

stability do we consider an induced norm and a zero past. The notion of well-posedness again restricts our attention to the subbehavior with a zero past and importantly does not impose uniqueness of solutions:  $(w_0, w_1, w_2), (w_0, v_1, v_2) \in \mathfrak{B}^{P_h \wedge C}$  does not imply  $(w_1, w_2) = (v_1, v_2)$  in general.

The approach considered in [7] identifies the operator  $P_h$  defined by (5.1) with its  $L^2(\mathbb{R})$  closure  $\bar{P}_h$ . In this case, the closure exists and is the (stable) anticausal operator  $\bar{P}_h = P_g: L^2(\mathbb{R}) \rightarrow L^2(\mathbb{R})$ , where

$$(5.3) \quad P_g: u \mapsto y \quad : \quad y(t) = \int_{-\infty}^{\infty} g(t - \tau)u(\tau) \, d\tau = (g * u)(t),$$

where  $g(t) = -\exp(t)$  for  $t \leq 0$  and zero otherwise. In [3], the identification of these two input-output systems is interpreted as “more or less amount[ing] to abandoning any notion of causality,” and it was stated that “this is not a natural option, however, if the direction of time is well-defined.” It has the additional problem that  $\bar{P}_h$  is stable, whose response on the bounded input  $u(t) = 1$  if  $0 \leq t \leq 1$ ,  $u(t) = 0$  otherwise is the following bounded output signal:

$$y(t) = \begin{cases} 0 & \text{if } t > 1, \\ 1 - \exp(1 - t) & \text{if } 0 \leq t \leq 1, \\ \exp(t) - \exp(1 + t) & \text{if } t < 0. \end{cases}$$

We view this as problematic, since  $P_h$  itself is defined as an operator  $L^2(\mathbb{R}) \rightarrow L^2_{\text{loc}}(\mathbb{R})$ , with the following unbounded output response to the above input:

$$y(t) = \begin{cases} \exp(t) - \exp(1 + t) & \text{if } t > 1, \\ 1 - \exp(t) & \text{if } 0 \leq t \leq 1, \\ 0 & \text{if } t < 0. \end{cases}$$

These problems are avoided only in the case whereby the input-output operator has causal closure. In the discrete setting, the class of such transfer functions has been precisely characterized in [6] as the class of all Smirnoff functions, a class which includes all causal stable operators and excludes all causal unstable operators (as in the example considered), thus indicating the intrinsic difficulties with the input-output theory over  $\mathbb{R}$ .

In common with these other approaches to resolving the so-called Georgiou–Smith paradox, the procedure of identifying the convolution system (5.1) with the smallest differential behavior containing the same input-output pairs also identifies the same behavior  $\mathcal{B}^P = \mathcal{B}^{P_h} = \mathcal{B}^{P_g}$  to the anticausal input-output system (5.3), as it is easily verified that  $\mathfrak{B}^P$  contains all trajectories  $(u, y) \in L^1_{\text{loc}}$  satisfying (5.3).<sup>2</sup> However, the consideration of  $\mathcal{B}^P$  permits us to maintain a sensible notion of causality as follows.

**DEFINITION 5.1.** *A behavior  $\mathfrak{B}$  with input-output partition  $(u, y)$  is said to be causal if*

$$T_\tau u_1 = T_\tau u_2 \quad \implies \quad T_\tau \mathfrak{B}_{u_1} = T_\tau \mathfrak{B}_{u_2},$$

where  $\mathfrak{B}_u = \{w \in \mathfrak{B} \mid \exists y \text{ such that } w = (u, y) \in \mathfrak{B}\}$ .

<sup>2</sup>Importantly, however,  $\mathcal{B}^P$  also includes unbounded trajectories such as  $(0, \exp(\cdot))^T$  which are neither of the form  $(u, P_h u)^T$  nor  $(u, P_g u)^T$ .

This can be interpreted as stating that the set of all past trajectories which can be generated from a particular past input cannot be affected by changing the future input, and it represents a generalization of the notion of a causal operator (where the nonuniqueness of the output given the input is suitably accounted for). We can now observe that  $\mathfrak{B}^P$  indeed preserves causality, and we have thus arrived at a position whereby we can consider a suitable treatment of the system (5.1) in which the physical object under study can be thought of as causal and stabilizable. We find the explanation of trajectories of the system as a combination of an autonomous unforced subbehavior and a causal input to be more in line with physical thinking than the interpretation of the trajectories arising from a noncausal input to a single valued operator.

### 6. A behavioral generalization of the gap metric and robust stability.

In this section we will be concerned with deriving the behavioral version of the central robust stability theorem for linear time invariant systems. Our concern, for now, is with behaviors whose underlying signal space is equipped with a norm  $\|\cdot\|$ ; that is,  $X$  is a vector space and all behaviors  $\mathfrak{B}$  are such that  $P_+\mathfrak{B} \subset X_e$ . Furthermore, we assume that  $(X, \|\cdot\|)$  has the property that  $\|T_\tau x\| \leq a$  with  $a > 0$  for all  $\tau \geq 0$  implies  $x \in X$ . The classical Lebesgue and Sobolev signal spaces, e.g.,  $X = L^p$ ,  $l^p$ ,  $W^{p,m}$   $1 \leq m, p \leq \infty$ , satisfy this condition.

DEFINITION 6.1. *A mapping  $\Psi : \text{dom}(\Psi) \subset X_e \rightarrow X_e$  is said to be causal if  $T_\tau \Psi w = T_\tau \Psi T_\tau w$  for all  $w \in \text{dom}(\Psi)$  and  $\tau > 0$  and with  $T_\tau w \in \text{dom}(\Psi)$ . Its induced norm, denoted by  $\|\Psi\|$ , is defined as*

$$\|\Psi\| = \sup \left\{ \frac{\|T_\tau \Psi w\|}{\|T_\tau w\|} : w \in \text{dom}(\Psi), \tau > 0, T_\tau w \neq 0 \text{ and } T_\tau w \in \text{dom}(\Psi) \right\}.$$

Observe that  $\|\Pi_{P//C}\| \geq 1$  since, for any  $w_0 \in \mathcal{G}_{\mathfrak{B}^P}$ ,  $\Pi_{P//C} w_0 = w_0$ . Motivated by [4] and the considerations in section 4 we define the following notion of a gap distance between behaviors.

DEFINITION 6.2. *Given two behaviors  $\mathfrak{B}^1, \mathfrak{B}^2$  define a gap functional:*

$$(6.1) \quad \vec{\delta}(\mathfrak{B}^1, \mathfrak{B}^2) = \begin{cases} \inf_{\Phi \in \mathcal{O}} \|(I - \Phi)|_{\mathcal{G}_{\mathfrak{B}^1}}\| & \text{if } \mathfrak{B}^2 \text{ is soundly stabilizable,} \\ 1 & \text{if not,} \end{cases}$$

$$(6.2) \quad \delta(\mathfrak{B}^1, \mathfrak{B}^2) = \max \left\{ \vec{\delta}(\mathfrak{B}^1, \mathfrak{B}^2), \vec{\delta}(\mathfrak{B}^2, \mathfrak{B}^1) \right\},$$

where

$$\mathcal{O} = \{\Phi : \text{dom}(\Phi) \subset \mathcal{G}_{\mathfrak{B}^1} \rightarrow \mathcal{G}_{\mathfrak{B}^2} \mid \Phi \text{ bijective, causal, } \Phi(0) = 0\}.$$

In the case of differential systems, the above definition of the gap can be related to the classical definitions as follows. Let  $P_1(s)$ ,  $P_2(s)$  denote transfer functions corresponding to  $\mathfrak{B}_{\text{cont}}^{P_1}$ ,  $\mathfrak{B}_{\text{cont}}^{P_2}$  respectively, and let  $(N_i, D_i) \in \mathcal{RH}_\infty$  form normalized coprime factorizations of  $P_i$ ,  $i = 1, 2$ . It follows that the classical graphs for  $P_1(s)$  and  $P_2(s)$  correspond (in the frequency domain) to the time domain graphs  $\mathcal{G}_{\mathfrak{B}_{\text{cont}}^{P_1}}$ ,  $\mathcal{G}_{\mathfrak{B}_{\text{cont}}^{P_2}}$ . In the case where  $X = L^2$ , it has been shown in [4] and the references therein that

$$(6.3) \quad \inf_{\Phi \in \mathcal{O}} \|(I - \Phi)|_{\mathcal{G}_{P_1(s)}}\| = \vec{\delta}_0(P_1(s), P_2(s)),$$

where the classical gap  $\vec{\delta}_0$  can be expressed in a number of equivalent manners. Here we adopt an expression [13] which shows that the gap corresponds to the size of smallest stable coprime factor perturbation between the two plants:

$$\vec{\delta}_0(P_1(s), P_2(s)) = \inf \left\{ \left\| \begin{pmatrix} \Delta_N \\ \Delta_D \end{pmatrix} \right\|_{\mathcal{H}^\infty} \mid \begin{pmatrix} \Delta_N \\ \Delta_D \end{pmatrix} \in \mathcal{RH}^\infty, P_2 = (N_1 + \Delta_N)(D_1 + \Delta_D)^{-1} \right\}.$$

In the context of differential systems, Lemma 4.4 shows that  $\mathcal{G}_{\mathfrak{B}_{\text{cont}}^1} = \mathcal{G}_{\mathfrak{B}^1}$  and  $\mathcal{G}_{\mathfrak{B}_{\text{cont}}^2} = \mathcal{G}_{\mathfrak{B}^2}$ , and Proposition 4.9 shows the equivalence between the concepts of sound stabilizability and stabilizability. Therefore it can be easily shown that the gap functional is determined as follows:

$$(6.4) \quad \vec{\delta}(\mathfrak{B}^1, \mathfrak{B}^2) = \begin{cases} \vec{\delta}_0(P_1(s), P_2(s)) & \text{if } \mathfrak{B}^2 \text{ is stabilizable,} \\ 1 & \text{if not.} \end{cases}$$

We also remark, for completeness, that the directed gap can be computed via a standard  $\mathcal{H}^\infty$  optimization [2]:

$$\vec{\delta}_0(P_1, P_2) = \inf_{Q \in \mathcal{H}^\infty} \left\| \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} - \begin{pmatrix} D_2 \\ N_2 \end{pmatrix} Q \right\|.$$

Observe that Definition 6.2 is a “real” behavioral definition: everything is defined in terms of trajectories, and all subbehaviors involved can be expressed in set-theoretic terms from the original behavior  $\mathfrak{B}$ . From a behavioral perspective, it should also be noted that the definition does not require a distinguished input-output partition. It is natural to wish to substitute the condition of stabilizability for that of sound stabilizability in the definition of the gap functional, but as we have discussed previously the equivalence of these concepts is known only in the case of differential systems (see Proposition 4.9).

The central reason for consideration of gap distances in systems theory is to obtain robust stability results (see Theorem 6.6 below). In particular we want  $\delta$  to capture the idea that any sensible stabilizing controller for  $\mathfrak{B}^P$  will also stabilize  $\mathfrak{B}^{P_1}$ , provided  $\delta(\mathfrak{B}^P, \mathfrak{B}^{P_1})$  is small. By definition, the distance between  $\mathfrak{B}$  and  $\mathfrak{B}_{\text{cont}}$  is zero if  $\mathfrak{B}$  is soundly stabilizable—this is reasonable since *any* stabilizing controller for  $\mathfrak{B}$  will automatically stabilize  $\mathfrak{B}_{\text{cont}}$  since  $\mathfrak{B}_{\text{cont}} \subset \mathfrak{B}$ . Consequently,  $\delta$  is necessarily at most a pseudometric; indeed the distance between two stabilizable differential systems with the same transfer function will be 0 (since the graphs of the behaviors are identical, the minimizing  $\Phi$  in the definition of the gap distance can be taken to be the identity, and hence the gap distance is zero).

For the controllable-autonomous decomposition of the interconnected behavior, we have the following lemma.

LEMMA 6.3. *Suppose  $\mathfrak{B}^P, B^C$  are linear behaviors with controllable-autonomous decompositions  $\mathfrak{B}^P = \mathfrak{B}_{\text{cont}}^P + \mathfrak{B}_{\text{aut}}^P$ ,  $\mathfrak{B}^C = \mathfrak{B}_{\text{cont}}^C + \mathfrak{B}_{\text{aut}}^C$ . Then  $\mathfrak{B}^{P \wedge I C}$  has the following controllable-autonomous decomposition:  $\mathfrak{B}^{P \wedge I C} = \mathfrak{B}_{\text{cont}}^{P \wedge I C} + \mathfrak{B}_{\text{aut}}^{P \wedge I C}$  and*

$$(6.5) \quad \begin{aligned} \mathfrak{B}_{\text{cont}}^{P \wedge I C} &= \{(w_1 + w_2, w_1, w_2) \mid w_1 \in \mathfrak{B}_{\text{cont}}^P, w_2 \in \mathfrak{B}_{\text{cont}}^C\}, \\ \mathfrak{B}_{\text{aut}}^{P \wedge I C} &= \{(w_1 + w_2, w_1, w_2) \mid w_1 \in \mathfrak{B}_{\text{aut}}^P, w_2 \in \mathfrak{B}_{\text{aut}}^C\}. \end{aligned}$$

*If, in addition,  $\mathfrak{B}^P = \mathfrak{B}_{\text{cont}}^P \oplus \mathfrak{B}_{\text{aut}}^P$ ,  $\mathfrak{B}^C = \mathfrak{B}_{\text{cont}}^C \oplus \mathfrak{B}_{\text{aut}}^C$ , then  $\mathfrak{B}^{P \wedge I C} = \mathfrak{B}_{\text{cont}}^{P \wedge I C} \oplus \mathfrak{B}_{\text{aut}}^{P \wedge I C}$ .*

*Proof.* It is straightforward to verify that  $\mathfrak{B}_{\text{cont}}^{P \wedge I C}$  is the maximal controllable behavior and that  $\mathfrak{B}_{\text{aut}}^{P \wedge I C}$  is autonomous. Let  $w \in \mathfrak{B}^{P \wedge I C}$ . Then  $w = (v_1 + v_2, v_1, v_2)$ , and by the decompositions of  $\mathfrak{B}^P$ ,  $\mathfrak{B}^C$ , there exist elements  $x_1 \in \mathfrak{B}_{\text{cont}}^P$ ,  $x_2 \in \mathfrak{B}_{\text{aut}}^P$  and  $y_1 \in \mathfrak{B}_{\text{cont}}^C$ ,  $y_2 \in \mathfrak{B}_{\text{aut}}^C$  such that  $v_1 = x_1 + x_2$ ,  $v_2 = y_1 + y_2$ . Consequently, there exists a decomposition of  $w = z_1 + z_2$ , where  $z_1 \in (\mathfrak{B}_{\text{cont}}^P + \mathfrak{B}_{\text{cont}}^C) \times \mathfrak{B}_{\text{cont}}^P \times \mathfrak{B}_{\text{cont}}^C$  and  $z_2 \in (\mathfrak{B}_{\text{aut}}^P + \mathfrak{B}_{\text{aut}}^C) \times \mathfrak{B}_{\text{aut}}^P \times \mathfrak{B}_{\text{aut}}^C$ , namely  $z_1 = (x_1 + y_1, x_1, y_1)$ ,  $z_2 = (x_2 + y_2, x_2, y_2)$ .

When  $\mathfrak{B}^P = \mathfrak{B}_{\text{cont}}^P \oplus \mathfrak{B}_{\text{aut}}^P$ ,  $\mathfrak{B}^C = \mathfrak{B}_{\text{cont}}^C \oplus \mathfrak{B}_{\text{aut}}^C$ , the existence for each of  $x_1, x_2, y_1, y_2$  and  $z_1, z_2$  is unique. Hence  $\mathfrak{B}^{P \wedge I C} = \mathfrak{B}_{\text{cont}}^{P \wedge I C} \oplus \mathfrak{B}_{\text{aut}}^{P \wedge I C}$ .  $\square$

The following key results relate a condition of stability of a particular half-line projection to stability of the entire system behavior.

LEMMA 6.4. *Let  $\mathfrak{B}^{P \wedge I C}$  be well-posed, and let*

$$\hat{\mathfrak{B}} = \left\{ w = (w_0, w_1, w_2) \in \mathfrak{B}_{\text{cont}}^{P \wedge I C} : w_0|_{[0, \infty)} = 0 \right\}.$$

*Suppose  $X = \mathcal{G}_{\mathfrak{B}^P} \oplus \mathcal{G}_{\mathfrak{B}^C}$ . Then, for any  $(w_0, w_1, w_2) \in \hat{\mathfrak{B}}$ ,  $w_1|_{[0, \infty)}, w_2|_{[0, \infty)} \in X$ .*

*Proof.* Let  $w = (w_0, w_1, w_2) \in \hat{\mathfrak{B}}$ . By controllability, there exist  $\tau \geq 0$ ,  $\bar{w} = (\bar{w}_0, \bar{w}_1, \bar{w}_2) \in \mathfrak{B}^{P \wedge I C}$  such that  $\bar{w}|_{(-\infty, -\tau]} = 0$  and  $\bar{w}|_{[0, \infty)} = w|_{[0, \infty)}$ . Therefore  $\sigma_\tau \bar{w}_1 \in \mathcal{Z}_{\mathfrak{B}^P}$ ,  $\sigma_\tau \bar{w}_2 \in \mathcal{Z}_{\mathfrak{B}^C}$ , and  $\bar{w}_0|_{\mathbb{R} \setminus (-\tau, 0]} = 0$ , and hence  $\bar{w}_0|_{[0, \infty)}, \sigma_\tau \bar{w}_0|_{[0, \infty)} \in X$ . Since  $X = \mathcal{G}_{\mathfrak{B}^P} \oplus \mathcal{G}_{\mathfrak{B}^C}$ ,  $\sigma_\tau \bar{w}_0|_{[0, \infty)} = z_1 + z_2$  for some  $z_1 \in \mathcal{G}_{\mathfrak{B}^P}$ ,  $z_2 \in \mathcal{G}_{\mathfrak{B}^C}$ . By the well-posedness assumption, it follows that  $z_1 = \sigma_\tau \bar{w}_1$ ,  $z_2 = \sigma_\tau \bar{w}_2$ . Since  $\bar{w}|_{[0, \infty)} = w|_{[0, \infty)}$  and  $z_1, z_2 \in X$ , we see that  $w_1|_{[0, \infty)}, w_2|_{[0, \infty)} \in X$ .  $\square$

PROPOSITION 6.5. *Let  $\mathfrak{B}^P, \mathfrak{B}^C$  be linear, shift invariant behaviors with finite memory and  $\mathfrak{B}^P = \mathfrak{B}_{\text{cont}}^P \oplus \mathfrak{B}_{\text{aut}}^P$ ,  $\mathfrak{B}^C = \mathfrak{B}_{\text{cont}}^C \oplus \mathfrak{B}_{\text{aut}}^C$ . Suppose  $\mathfrak{B}^P$  and  $\mathfrak{B}^C$  are soundly stabilizable and  $\mathfrak{B}^{P \wedge I C}$  is well-posed. Suppose further that  $X = \mathcal{G}_{\mathfrak{B}^P} \oplus \mathcal{G}_{\mathfrak{B}^C}$ . Then  $\mathfrak{B}^{P \wedge I C}$  is stable.*

*Proof.* Suppose  $w \in \mathfrak{B}^{P \wedge I C}$ , and  $w = (w_0, w_1, w_2)$ . We have to show that if  $w_0|_{[0, \infty)} \in X$ , then  $w_1|_{[0, \infty)}, w_2|_{[0, \infty)} \in X$ . Let  $w_0 \in X$ . Since  $\mathfrak{B}^{P \wedge I C} = \mathfrak{B}_{\text{cont}}^{P \wedge I C} + \mathfrak{B}_{\text{aut}}^{P \wedge I C}$ , it follows that  $w = x + y$ , where  $x = (x_0, x_1, x_2) \in \mathfrak{B}_{\text{cont}}^{P \wedge I C}$  and  $y = (y_0, y_1, y_2) \in \mathfrak{B}_{\text{aut}}^{P \wedge I C}$ . By stability of  $\mathfrak{B}_{\text{aut}}^P, \mathfrak{B}_{\text{aut}}^C$  we know that  $x_0|_{[0, \infty)} = w_0 - y_0|_{[0, \infty)} \in X$ .

Let

$$\tilde{x}_0 = \begin{cases} 0, & t \leq 0, \\ x_0, & t > 0. \end{cases}$$

Then  $\tilde{x}_0|_{[0, \infty)} \in X$ . Since  $X = \mathcal{G}_{\mathfrak{B}^P} \oplus \mathcal{G}_{\mathfrak{B}^C}$ , we see that

$$(6.6) \quad \tilde{x}_0|_{[0, \infty)} = \tilde{x}_1|_{[0, \infty)} + \tilde{x}_2|_{[0, \infty)} \quad \text{for some } \tilde{x}_1 \in \mathcal{G}_{\mathfrak{B}^P}, \tilde{x}_2 \in \mathcal{G}_{\mathfrak{B}^C}.$$

Consider  $v = (v_0, v_1, v_2) := (x_0 - \tilde{x}_0, x_1 - \tilde{x}_1, x_2 - \tilde{x}_2)$ . Since  $x_1, \tilde{x}_1 \in \mathfrak{B}_{\text{cont}}^P$ ,  $x_2, \tilde{x}_2 \in \mathfrak{B}_{\text{cont}}^C$ , we see that  $x_1 - \tilde{x}_1 \in \mathfrak{B}_{\text{cont}}^P$ ,  $x_2 - \tilde{x}_2 \in \mathfrak{B}_{\text{cont}}^C$ , and hence  $v \in \mathfrak{B}_{\text{cont}}^{P \wedge I C}$ . Since  $v_0|_{[0, \infty)} = 0, v \in \hat{\mathfrak{B}}$ . By the above lemma,  $v_1|_{[0, \infty)}, v_2|_{[0, \infty)} \in X$ . Since  $\tilde{x}_1, \tilde{x}_2 \in X$ , we see that  $x_1|_{[0, \infty)}, x_2|_{[0, \infty)} \in X$ . By the stability assumption of  $\mathfrak{B}_{\text{aut}}^P$  and  $\mathfrak{B}_{\text{aut}}^C$ , it follows that  $w_1|_{[0, \infty)}, w_2|_{[0, \infty)} \in X$ . This completes the proof.  $\square$

We can now give the proof of the main robust stability result. Before giving the proof we remark that the result follows straightforwardly from Proposition 6.5 once it has been shown that  $X = \mathcal{G}_{\mathfrak{B}_{\text{cont}}^P} \oplus \mathcal{G}_{\mathfrak{B}_{\text{cont}}^C}$  and that this classical condition is obtained directly using the technique of [1]: we have included this part of the proof from [1] for completeness.

THEOREM 6.6. *Suppose  $\mathfrak{B}^P, \mathfrak{B}^{P_1}, \mathfrak{B}^C$  are linear, shift invariant behaviors with finite memory. If*

1.  $\mathfrak{B}^P, \mathfrak{B}^C$  are soundly stabilizable,
2.  $\mathfrak{B}^{P \wedge I^C}$  is well-posed, causal, and uniformly stable,
3.  $\mathfrak{B}^{P_1 \wedge I^C}$  is well-posed, causal, and
4.  $\tilde{\delta}(\mathfrak{B}^P, \mathfrak{B}^{P_1}) \|\Pi_{P//C}\| < 1$ ,

then  $\mathfrak{B}^{P_1 \wedge I^C}$  is uniformly stable.

*Proof.* Condition 6.6 implies that there exists a stable  $\mathfrak{B}_{\text{aut}}^{P_1}$  such that  $\mathfrak{B}^{P_1} = \mathfrak{B}_{\text{cont}}^{P_1} + \mathfrak{B}_{\text{aut}}^{P_1}$  by definition of the gap and since  $\|\Pi_{P//C}\| \geq 1$ .

By condition 6.6, there exists a surjective mapping  $\Phi : D \subset \mathcal{G}_{\mathfrak{B}^P} \rightarrow \mathcal{G}_{\mathfrak{B}^{P_1}}$  such that

$$\|\Phi - I\| \|\Pi_{P//C}\| < 1.$$

Let  $(w_0, w_1, w_2) \in \mathfrak{B}^{P_1 \wedge I^C}$  with  $(w_0, w_1, w_2)|_{\mathcal{T}_-} = 0, (w_0, w_1, w_2)|_{\mathcal{T}_+} \in X$ . By definition of the extended graph,  $w_1 \in \mathcal{Z}_{\mathfrak{B}^{P_1}}, w_2 \in \mathcal{Z}_{\mathfrak{B}^C}$ .

For any  $\tau > 0$ , by sound stabilizability and Lemma 4.7, there exist  $\bar{w}_1 \in \mathfrak{B}^{P_1}, \bar{w}_2 \in \mathfrak{B}^C$  such that  $\bar{w}_i|_{\mathcal{T}_-} = \sigma_\tau w_i|_{\mathcal{T}_-}, \bar{w}_i|_{\mathcal{T}_+} \in X$  for  $i = 1, 2$ . This shows that  $w_i|_{(-\infty, \tau]} = w_i^\tau|_{(-\infty, \tau]}$ , where  $w_i^\tau = \sigma_{-\tau} \bar{w}_i$ , and  $w_i^\tau|_{\mathcal{T}_-} = 0, w_i^\tau|_{\mathcal{T}_+} \in X$ . By shift invariance,  $w_1^\tau|_{\mathcal{T}_+} \in \mathcal{G}_{\mathfrak{B}^{P_1}}, w_2^\tau|_{\mathcal{T}_+} \in \mathcal{G}_{\mathfrak{B}^C}$  and  $T_\tau w_i = T_\tau w_i^\tau$ .

Since  $\Phi$  is surjective from  $\mathcal{G}_{\mathfrak{B}^P}$  to  $\mathcal{G}_{\mathfrak{B}^{P_1}}$ , there exist  $w_3^\tau \in \mathcal{G}_{\mathfrak{B}^P}$  and  $w_1^\tau|_{\mathcal{T}_+} = \Phi w_3^\tau$ . Write  $x_\tau = w_3^\tau + w_2^\tau|_{\mathcal{T}_+}$ . Then by condition 6.6,  $\Pi_{P//C} x_\tau = w_3^\tau \in X, \Pi_{C//P} x_\tau = w_2^\tau|_{\mathcal{T}_+} \in X$  and

$$\begin{aligned} T_\tau(w_0|_{\mathcal{T}_+}) &= T_\tau(w_1|_{\mathcal{T}_+}) + T_\tau(w_2|_{\mathcal{T}_+}) = T_\tau(w_1^\tau|_{\mathcal{T}_+}) + T_\tau(w_2^\tau|_{\mathcal{T}_+}) = T_\tau \Phi w_3^\tau + T_\tau(w_2^\tau|_{\mathcal{T}_+}) \\ &= T_\tau \Phi \Pi_{P//C} x_\tau + T_\tau \Pi_{C//P} x_\tau = T_\tau \Phi \Pi_{P//C} T_\tau x_\tau + T_\tau \Pi_{C//P} T_\tau x_\tau \\ (6.7) \quad &= T_\tau(\Phi - I) \Pi_{P//C} T_\tau x_\tau + T_\tau x_\tau \end{aligned}$$

and

$$(6.8) \quad T_\tau \Pi_{P_1//C}(w_0|_{\mathcal{T}_+}) = T_\tau(w_1|_{\mathcal{T}_+}) = T_\tau \Phi w_3^\tau = T_\tau \Phi \Pi_{P//C} x_\tau = T_\tau \Phi \Pi_{P//C} T_\tau x_\tau.$$

By (6.7), we have

$$\|T_\tau x_\tau\| \leq \|T_\tau(w_0|_{\mathcal{T}_+})\| + \|T_\tau(\Phi - I) \Pi_{P//C} T_\tau x_\tau\| \leq \|w_0|_{\mathcal{T}_+}\| + \|\Phi - I\| \|\Pi_{P//C}\| \|T_\tau x_\tau\|,$$

which gives

$$\|T_\tau x_\tau\| \leq \frac{\|w_0|_{\mathcal{T}_+}\|}{1 - \|\Phi - I\| \|\Pi_{P//C}\|}.$$

By (6.8), we have

$$\begin{aligned} \|T_\tau \Pi_{P_1//C}(w_0|_{\mathcal{T}_+})\| &\leq \|T_\tau(\Phi - I) \Pi_{P//C} T_\tau x_\tau\| + \|T_\tau \Phi \Pi_{P//C} T_\tau x_\tau\| \\ &\leq (1 + \|\Phi - I\|) \|\Pi_{P//C}\| \frac{\|w_0|_{\mathcal{T}_+}\|}{1 - \|\Phi - I\| \|\Pi_{P//C}\|}. \end{aligned}$$

Hence  $w_1 = \Pi_{P_1//C}(w_0|_{\mathcal{T}_+}) \in X$  and, therefore, by (4.5),  $w_2 = \Pi_{C//P_1}(w_0) \in X$ .

So, for any  $w_0$  with  $w_0|_{\mathcal{T}_+} \in X, w_0|_{\mathcal{T}_-} = 0$ , we have shown that there exist  $w_1 \in \mathcal{G}_{\mathfrak{B}^{P_1}}, w_2 \in \mathcal{G}_{\mathfrak{B}^C}$  such that  $w_0|_{\mathcal{T}_+} = w_1 + w_2$ , i.e.,  $X = \mathcal{G}_{\mathfrak{B}^{P_1}} + \mathcal{G}_{\mathfrak{B}^C}$ . By the well-posedness assumption, the sum is direct. Applying Proposition 6.5, we see that  $\mathfrak{B}^{P_1 \wedge I^C}$  is stable. The above proof shows that both  $\Pi_{P_1//C}$  and  $\Pi_{C//P_1}$  are bounded. Hence  $\mathfrak{B}^{P_1 \wedge I^C}$  is uniformly stable.  $\square$

Due to Proposition 4.9, we have the following corollary.

**COROLLARY 6.7.** *Suppose  $\mathfrak{B}^P, \mathfrak{B}^{P_1}, B^C$  are linear, shift invariant differential behaviors with finite memory. If  $\mathfrak{B}^P, \mathfrak{B}^C$  are stabilizable,  $\mathfrak{B}^{P \wedge I^C}$  is uniformly stable, and  $\mathfrak{B}^{P_1 \wedge I^C}$  is well-posed, causal, and  $\tilde{\delta}(\mathfrak{B}^P, \mathfrak{B}^{P_1}) \|\Pi_{P//C}\| < 1$ , then  $\mathfrak{B}^{P_1 \wedge I^C}$  is uniformly stable.*

### 7. Relation to the behavioral $\mathcal{H}^\infty$ synthesis of Trentelman and Willems.

Within the context of  $L^2$  signal spaces, classical  $\mathcal{H}^\infty$  synthesis [20] provides constructions for controllers  $C$  which achieve  $\|\Pi_{P//C}\| \leq 1$ , i.e., solve the normalized version of the inequality required in our robustness theorems. The classical gap robustness results then provide an explicit description of plant uncertainties tolerated in the closed loop. In direct counterpart, and in the interests of a self-contained behavioral theory, it is relevant to relate the results of this paper to the behavioral approach to  $\mathcal{H}^\infty$  synthesis found in [12, 17], for then our basic robust stability theorem completes a “behavioral robust control theory” by providing an explicit robustness interpretation of the behavioral  $\mathcal{H}^\infty$  synthesis results.

Therefore we explicitly describe the relationship between the problem formulation of [12, 17] and this paper. We first consider Proposition 1 of [12]. By choosing the exogenous variable  $d$  to be  $w_0$  and the endogenous “to be controlled” variable  $f$  to be  $w_1$ , we have

$$\mathcal{K} = \{(w_0, w_1) \in C^\infty \mid \exists w_2 \in C^\infty \text{ such that } (w_0, w_1, w_2) \in \mathfrak{B}^{P \wedge_I C}\},$$

and  $G_{w_0 \rightarrow w_1}$  is the transfer function corresponding to  $\Pi_{P//C}$ . Proposition 1 asserts that if  $\mathfrak{B}^P$ ,  $\mathfrak{B}^C$  are smooth differential behaviors and  $\mathfrak{B}^{P \wedge_I C}$  is controllable, then the following are equivalent:

1. in  $\mathcal{K}$ ,  $w_0$  is the input,  $w_1$  is the output, and  $\|G_{w_0 \rightarrow w_1}\|_{\mathcal{H}_\infty} \leq 1$ ;
2.  $\mathcal{K}$  is  $\Sigma$ -dissipative on  $\mathbb{R}_-$ , and  $m(\mathcal{K}) = \sigma_+(\Sigma)$ ;
3.  $\|w_1\|_{\mathcal{L}^2(\mathbb{R}, \mathbb{R}^f)} \leq \|w_0\|_{\mathcal{L}^2(\mathbb{R}, \mathbb{R}^d)}$ ,  $w_0$  is free in  $\mathcal{K}$ , and  $(0, w_1) \in \mathcal{K}$  implies that  $\lim_{t \rightarrow \infty} w_1(t) = 0$ .

Here  $\Sigma = \text{diag}(I_d, -I_f)$ ,  $\sigma_+(\Sigma)$  is the number of positive eigenvalues of  $\Sigma$ , and  $m(\mathcal{K})$  is the number of “free” input variables: in the context of this paper the free variables enter additively in both the input and output channels, and hence  $m(\mathcal{K}) = \dim(\mathcal{U} \times \mathcal{Y})$ . We refer the reader to [12, 17] for the definition of  $\Sigma$ -dissipativity on  $\mathbb{R}_-$ .

We now relate the above stability concepts to the notion of uniform stability, within an  $L^2$  context, as considered in this paper. Consider the following condition:

4.  $\mathfrak{B}^{P \wedge_I C}$  is uniformly stable, and  $\|\Pi_{P//C}\|_{L^2(\mathbb{R}_+)} \leq 1$ .

Then we have the following proposition.

**PROPOSITION 7.1.** *Let  $X = L^2(\mathbb{R}_+)$ . Suppose  $\mathfrak{B}^P$ ,  $\mathfrak{B}^C$  are differential behaviors and  $\mathfrak{B}^{P \wedge_I C}$  is controllable. Then 1, 2, 3, and 4 are equivalent.*

*Proof.* Proposition 1 of [12] establishes the equivalence between 1, 2, and 3. It is well known that  $\|\Pi_{P//C}\|_{L^2(\mathbb{R}_+)} = \|G_{w_0 \rightarrow w_1}\|_{\mathcal{H}_\infty}$ . Hence 4 implies 1. On the other hand, suppose 1 holds. Consider  $(w_0, w_1, w_2) \in \mathfrak{B}^{P \wedge_I C}$ , and suppose  $w_0|_{\mathbb{R}_+} \in X$ . Let  $w_0 = x_0 + y_0$ , where  $x_0|_{\mathbb{R}_+} = 0$ ,  $y_0|_{\mathbb{R}_-} = 0$ . Then there exist  $x_1, x_2, y_1, y_2$  such that  $(x_0, x_1, x_2) \in \widehat{\mathfrak{B}^{P \wedge_I C}} \subset \mathfrak{B}^{P \wedge_I C}$ ,  $(y_0, y_1, y_2) \in \mathfrak{B}^{P \wedge_I C}$ , and  $x_1 + y_1 = w_1$ ,  $x_2 + y_2 = w_2$ . By Lemma 6.4, and since  $x_0|_{\mathbb{R}_+} = 0 \in X$ , it follows that  $x_1|_{\mathbb{R}_+}, x_2|_{\mathbb{R}_+} \in X$ . Since  $G_{w_0 \rightarrow w_1} \in \mathcal{H}_\infty$  and  $y_0|_{\mathbb{R}_+} \in X$  it follows that  $y_1|_{\mathbb{R}_+}, y_2|_{\mathbb{R}_+} \in X$ . Hence  $w_1|_{\mathbb{R}_+}, w_2|_{\mathbb{R}_+} \in X$ , and consequently  $\mathfrak{B}^{P \wedge_I C}$  is stable. The inequality in 1 implies the inequality in 4, and hence 1 implies 4 as required.  $\square$

Within the context of disturbance attenuation for linear controllable differential systems in an  $L^2$  setting, the results of [12, 17] establish conditions under which there exists a controllable differentiable behavior  $\mathfrak{B}^C$  which renders  $\Sigma$ -dissipativity on  $\mathbb{R}_-$  of the closed-loop interconnection  $\mathfrak{B}^{P \wedge_I C}$ . Here  $\mathfrak{B}^P$  is also required to be a controllable differential behavior. Since the resulting interconnection  $\mathfrak{B}^{P \wedge_I C}$  is controllable, and by the above, it follows that this synthesis yields the uniform stability condition 4

above, and, in turn, the robust stability theorem (Theorem 6.6) provides an explicit description of a set of plants for which stability can be guaranteed.

It is worth noting that it is observed in [17] that the synthesis can be extended in an ad hoc manner from the controllable case to the general case by introducing appropriate stabilizability assumptions in the analysis. Theorem 6.6 can be utilized to achieve these observations directly. Given a (soundly) stabilizable plant behavior  $\mathfrak{B}^P$ , follow the  $\mathcal{H}^\infty$  synthesis to derive a controller  $\mathfrak{B}^C$  (which is controllable) for the controllable plant subbehavior  $\mathfrak{B}_{\text{cont}}^P$ . Then, since  $\vec{\delta}(\mathfrak{B}_{\text{cont}}^P, \mathfrak{B}^P) = 0$ , Theorem 6.6 can be applied to establish the required uniform stability for the interconnection of the derived controller behavior  $\mathfrak{B}^C$  and the original plant  $\mathfrak{B}^P$ .

**8. An illustrative example.** We consider an example in an  $L^\infty$  setting. Let the behaviors for the nominal system  $P$ , the perturbed system  $P_1$ , and the controller  $C$  be given by

$$\mathfrak{B}^P = \left\{ \begin{pmatrix} u_1 \\ v_1 \\ x \end{pmatrix} \left| \begin{array}{l} u_1, v_1, x \in L_e^\infty(\mathbb{R}, \mathbb{R}), \dot{x} = au_1 + bv_1 \end{array} \right. \right\},$$

$$\mathfrak{B}^{P_1} = \left\{ \begin{pmatrix} u_1 \\ v_1 \\ x \end{pmatrix} \left| \begin{array}{l} u_1, v_1, x \in L_e^\infty(\mathbb{R}, \mathbb{R}), \dot{x} = a\sigma_{\tau_1}u_1 + b\sigma_{\tau_2}v_1 \end{array} \right. \right\},$$

and

$$\mathfrak{B}^C = \left\{ \begin{pmatrix} cy \\ dy \\ y \end{pmatrix} \left| \begin{array}{l} y \in L_e^\infty(\mathbb{R}, \mathbb{R}), \end{array} \right. \right\},$$

where  $a, b, c, d \in \mathbb{R}$  such that  $ac + bd = -1$ .  $\mathfrak{B}^P, \mathfrak{B}^{P_1}$ , and  $\mathfrak{B}^C$  are all linear, shift invariant behaviors with finite memory. Moreover, they are all controllable so that  $\mathfrak{B}^P = \mathfrak{B}_{\text{cont}}^P + \{0\}$ ,  $\mathfrak{B}^{P_1} = \mathfrak{B}_{\text{cont}}^{P_1} + \{0\}$ , and  $\mathfrak{B}^C = \mathfrak{B}_{\text{cont}}^C + \{0\}$ . We also have

$$\begin{aligned} \mathcal{G}_{\mathfrak{B}^P} &= \left\{ \begin{pmatrix} u_1 \\ v_1 \\ x \end{pmatrix} \left| \begin{array}{l} u_1, v_1, x \in L^\infty(\mathbb{R}, \mathbb{R}), \dot{x} = au_1 + bv_1, \\ u_1|_{\mathbb{R}_-} = v_1|_{\mathbb{R}_-} = x|_{\mathbb{R}_-} = 0, \end{array} \right. \right\}, \\ \mathcal{G}_{\mathfrak{B}^{P_1}} &= \left\{ \begin{pmatrix} u_1 \\ v_1 \\ x \end{pmatrix} \left| \begin{array}{l} u_1, v_1, x \in L^\infty(\mathbb{R}, \mathbb{R}), \dot{x} = a\sigma_{\tau_1}u_1 + b\sigma_{\tau_2}v_1, \\ u_1|_{\mathbb{R}_-} = v_1|_{\mathbb{R}_-} = x|_{\mathbb{R}_-} = 0, \end{array} \right. \right\}, \\ \mathcal{Z}_{\mathfrak{B}^P} &= \left\{ \begin{pmatrix} u_1 \\ v_1 \\ x \end{pmatrix} \left| \begin{array}{l} u_1, v_1, x \in L_e^\infty(\mathbb{R}, \mathbb{R}), \dot{x} = au_1 + bv_1, \\ u_1|_{\mathbb{R}_-} = v_1|_{\mathbb{R}_-} = x|_{\mathbb{R}_-} = 0, \end{array} \right. \right\}, \\ \mathcal{Z}_{\mathfrak{B}^{P_1}} &= \left\{ \begin{pmatrix} u_1 \\ v_1 \\ x \end{pmatrix} \left| \begin{array}{l} u_1, v_1, x \in L_e^\infty(\mathbb{R}, \mathbb{R}), \dot{x} = a\sigma_{\tau_1}u_1 + b\sigma_{\tau_2}v_1, \\ u_1|_{\mathbb{R}_-} = v_1|_{\mathbb{R}_-} = x|_{\mathbb{R}_-} = 0. \end{array} \right. \right\}. \end{aligned}$$

The parallel projection  $\Pi_{P//C}$  operator is given by

$$\Pi_{P//C} \begin{pmatrix} u_0 \\ v_0 \\ y_0 \end{pmatrix} = \begin{pmatrix} u_0 - cy_0 + cx \\ v_0 - dy_0 + dx \\ x \end{pmatrix} \quad \text{for any } u_0, v_0, y_0 \in L_e^\infty(\mathbb{R}_+, \mathbb{R}),$$

where  $x$  is the unique solution to the equation

$$\dot{x} = -x + au_0 + bv_0 + y_0, x(0) = 0.$$

After straightforward calculation, we see that  $\|T_\tau x\| \leq \|T_\tau(au_0 + bv_0 + y_0)\|$  for any  $\tau > 0$  and

$$\|\Pi_{P/JC}\| \leq 1 + |c| + |d|(1 + |a| + |b|).$$

This shows that  $\mathfrak{B}^{P \wedge I^C}$  is uniformly stable.

To estimate the gap between  $\mathfrak{B}^P$  and  $\mathfrak{B}^{P_1}$ , we let

$$\Phi \begin{pmatrix} u \\ v \\ x \end{pmatrix} = \begin{pmatrix} u \\ v \\ y \end{pmatrix} \quad \text{for any } \begin{pmatrix} u \\ v \\ x \end{pmatrix} \in \mathfrak{B}^P,$$

where

$$\begin{pmatrix} u \\ v \\ y \end{pmatrix} \in \mathfrak{B}^{P_1}.$$

Then

$$\begin{aligned} |x(t) - y(t)| &= \left| \int_0^t (au(s) + bv(s))ds - \int_0^t (au(s - \tau_1) + bv(t - \tau_2))ds \right| \\ &\leq |a| \left| \int_{t-\tau}^t u(s)ds \right| + |b| \left| \int_{t-\tau}^t v(s)ds \right| \\ &\leq \tau_1 |a| \|u\| + \tau_2 |b| \|v\| \end{aligned}$$

and so

$$\begin{aligned} \|(I - \Phi)|_{\mathcal{G}_{\mathfrak{B}^P}}\| &= \sup \left\{ \frac{\|T_\tau(x - y)\|}{\|T_\tau(u, v, x)^\top\|} \mid \tau > 0, \begin{pmatrix} u \\ v \\ x \end{pmatrix} \in \mathcal{G}_{\mathfrak{B}^P}, \begin{pmatrix} u \\ v \\ x \end{pmatrix} \neq 0 \right\} \\ &\leq \tau_1 |a| + \tau_2 |b|. \end{aligned}$$

Hence,  $\vec{\delta}(\mathfrak{B}^P, \mathfrak{B}^{P_1}) \leq |a|\tau_1 + |b|\tau_2$  and, by Theorem 6.6,  $\mathfrak{B}^{P_1 \wedge I^C}$  is uniformly stable, provided

$$(\tau_1 |a| + \tau_2 |b|)[1 + |c| + |d|(1 + |a| + |b|)] < 1.$$

By definition of uniform stability, this means that

(i) for any  $u_1, v_1, x, y \in L_e^\infty(\mathbb{R}, \mathbb{R})$  with  $\dot{x} = a\sigma_{\tau_1}u_1 + b\sigma_{\tau_2}v_1$  on  $\mathbb{R}$  and  $(u_1 + cy)|_{\mathbb{R}_+}, (v_1 + dy)|_{\mathbb{R}_+}, (x + y)|_{\mathbb{R}_+} \in L^\infty(\mathbb{R}_+, \mathbb{R})$ , we have  $u_1|_{\mathbb{R}_+}, v_1|_{\mathbb{R}_+}, x|_{\mathbb{R}_+}, y|_{\mathbb{R}_+} \in L^\infty(\mathbb{R}_+, \mathbb{R})$ ;

(ii) the mappings which map  $(u_0, v_0, x_0)|_{\mathbb{R}_+}$  to  $(u_1, v_1, x_1)$  and  $(cy, dy, y)$ , respectively, are both bounded, where  $u_1 + cy = u_0, v_1 + dy = v_0, x_1 + y = x_0, (cy, dy, y)|_{\mathbb{R}_-} = 0, (u_1, v_1, x_1)|_{\mathbb{R}_-} = 0$ , and

$$\dot{x}_1 = a\sigma_{\tau_1}u_1 + b\sigma_{\tau_2}v_1.$$

We remark, as in the introduction, that such a system lies outside the scope of the existing algebraic behavioral theory for delay systems where delays  $\tau_1, \tau_2$  would additionally be required to be commensurate [5].

**Acknowledgments.** The authors would like to thank the reviewers and the associate editor for comments which have greatly improved the manuscript and led to the development of the discussion in section 5.

## ALGEBRAIC STRUCTURES IN NONLINEAR SYSTEMS OVER RINGS OBTAINED BY IMMERSION\*

TOSHIYUKI OHTSUKA<sup>†</sup>

**Abstract.** An immersion of a system is a mapping of the initial state exactly preserving the input-output map. As has already been shown, a system is immersible into a rational-in-the-state representation (RSR) and a polynomial-in-the-state representation (PSR) if and only if the field generated by the observation space is finitely generated, which is true in most practical systems. In this paper, some algebraic structures and their geometric counterparts associated with an RSR and a PSR obtained via an immersion are discussed. First, RSRs and PSRs are viewed as systems over rings in a unified framework, and the notions of an invariant ideal and an invariant variety, which are related to a differential algebraic equation, are introduced. Then, it is shown that an RSR and a PSR have invariant ideals and invariant varieties associated with an immersion. In particular, an invariant variety of an RSR or a PSR is the Zariski closure of the image of the immersion, i.e., the smallest variety containing the image of the immersion. The degrees of freedom in RSRs and PSRs obtained via immersion are also investigated and are characterized in terms of invariant ideals.

**1. Introduction.** An immersion [9, 15, 18, 22] of a system is a mapping of the initial state from the original state space to another state space, so as to preserve the input-output map exactly, and it is usually a mapping to a higher-dimensional space. The model structure of the given system can be simplified while preserving the input-output map with an immersion. Immersions into linear [1, 5, 12, 15], bilinear [16], quasi-state-affine [2], and rational and polynomial [22] systems have been discussed in the literature.

Immersion was used in [1, 2, 12, 15] to design an observer for a nonlinear system that is immersible into a linear system or other particular forms. Similarly, immersion into a polynomial system is potentially applicable to observer design for a broad class of nonlinear systems if the general methodology of observer design is established for polynomial systems. Often in system analysis and control design we assume polynomial systems [4, 14, 20, 23, 26, 27]. These techniques may be applicable to a wider class of nonlinear systems through the use of immersion. In contrast to the polynomial approximation of a nonlinear system, immersion does not raise problems due to approximation errors and can preserve the input-output map over an unbounded region in the state space, which is useful when applying theoretical results, at the expense of an increase in the dimension.

Although only a restricted class of nonlinear systems is immersible into linear or bilinear systems, most practical systems are immersible into rational systems and polynomial systems, as shown in [22]. More precisely, a nonlinear system is immersible

into a rational-in-the-state representation (RSR), a polynomial-in-the-state representation (PSR), and a quadratic-in-the-state representation (QSR) if and only if a field generated by the observation space is finitely generated over the field of real numbers. Moreover, it is sufficient for immersibility into these representations that all functions in the given system are differentially algebraic functions, which most practical systems consist of. Therefore, an RSR, a PSR, or a QSR can be used as a general model structure for a wide class of nonlinear systems.

In contrast to previous work on immersion, this paper focuses on structures in systems obtained via immersion, rather than immersibility conditions. Although RSRs and PSRs are general forms of nonlinear systems on their own, they have particular structures of rational functions and polynomials, respectively. Therefore, some properties of the original system or the immersion may be reflected in additional algebraic structures in the RSRs and PSRs. Moreover, those algebraic structures may have some geometric interpretations. In fact, it is shown in this paper that the algebraic structures of RSRs and PSRs can be characterized in terms of rings, and their geometric counterparts are expressed naturally in terms of affine varieties rather than a manifold in differential geometry. These algebraic and geometric structures can be found in rational or polynomial systems aside from immersion-related problems.

This paper is organized as follows. In section 2, definitions of immersions and immersibility conditions are briefly reviewed, and an algebraic characterization is given for the minimal dimension of RSRs. In section 3, we show that RSRs and PSRs can be viewed as systems over rings in a unified framework and introduce the notions of an invariant ideal and an invariant variety. Then, we show the existence of an invariant ideal and an invariant variety in a system over a ring obtained by immersion. The notions of an invariant ideal and an invariant variety can be used as fundamental tools in analysis and the control of systems over rings in general. As a further application of algebraic tools, we characterize the degrees of freedom in systems over a ring in section 4, which again highlights the importance of invariant ideals in the analysis of nonlinear systems over rings. Finally, concluding remarks are given in section 5.

## 2. System immersion.

**2.1. Immersion and invariant immersion.** We treat an input-affine nonlinear system,

$$\Sigma \begin{cases} \dot{x} = g_0(x) + \sum_{i=1}^m g_i(x)u_i, \\ y = h(x), \end{cases}$$

where  $x(t) \in U \subset \mathbf{R}^n$  denotes the state vector,  $U$  an open set,  $u(t) = [u_1(t), \dots, u_m(t)]^T \in \mathbf{R}^m$  the input vector, and  $y(t) \in \mathbf{R}^p$  the output vector. The system is denoted by  $\Sigma(g_0, g_1, \dots, g_m, h)$  (by  $\Sigma$  for short hereafter). System  $\Sigma$  is said to be analytic on  $U$  if  $g_i : U \rightarrow \mathbf{R}^n$  ( $i \in I_{0,m}$ ) and  $h : U \rightarrow \mathbf{R}^p$  are analytic functions on  $U$ . Sets of indices are denoted as  $I_{i_1, i_2} = \{i \in \mathbf{Z} : i_1 \leq i \leq i_2\}$  and  $I_{i_1, \infty} = \{i \in \mathbf{Z} : i \geq i_1\}$ . The admissible set  $\Omega$  of the input function  $u : [0, \infty) \rightarrow \mathbf{R}^m$  is a set of bounded piecewise continuous functions with a common upper bound. We assume  $|u_i(t)| \leq 1$  ( $t \geq 0, i \in I_{1,m}$ ) without loss of generality. The trajectory of the state equation of system  $\Sigma$  starting from an initial state in  $U$  at  $t = 0$  and driven by an input function  $u$  is denoted by  $\Phi_t^{\Sigma, u} : U \rightarrow U$ . That is, for a given initial state  $x_0 \in U$  and an input function  $u \in \Omega$ , the solution of the state equation is given by  $x(t) = \Phi_t^{\Sigma, u}(x_0)$ . A set

of all possible Lie derivatives of the output map,  $\mathcal{L}_\Sigma$ , and the observation space  $\mathcal{O}_\Sigma$  are defined, respectively, by

$$\mathcal{L}_\Sigma = \{L_{g_{i_1}} \dots L_{g_{i_k}} h_j : j \in I_{1,p}, (i_1, \dots, i_k) \in I_{0,m}^k, k \in I_{0,\infty}\},$$

$$\mathcal{O}_\Sigma = \text{span}_{\mathbf{R}} \mathcal{L}_\Sigma,$$

where  $h = [h_1, \dots, h_p]^T$  and  $L_{g_i} h_j = (\partial h_j / \partial x) g_i$ . The observability codistribution at  $x_0 \in U$  is a vector space over  $\mathbf{R}$  given by

$$d\mathcal{O}_\Sigma(x_0) = \text{span}_{\mathbf{R}} \left\{ \frac{\partial \eta}{\partial x}(x_0) : \eta \in \mathcal{O}_\Sigma \right\}.$$

First, we define an immersion of a system [9, 15, 18].

**DEFINITION 2.1.** *An analytic system  $\Sigma(g_0, \dots, g_m, h)$  defined on an open set  $U \subset \mathbf{R}^n$  is said to be immersible on an open set  $U' \subset U$  into another  $\tilde{n}$ -dimensional system  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$  if there exists an analytic mapping  $\alpha : U' \rightarrow \mathbf{R}^{\tilde{n}}$  such that  $\tilde{\Sigma}$  is analytic on an open set containing  $\alpha(U')$ , and for every  $x_0 \in U'$  and for every  $u \in \Omega$ ,*

$$h \circ \Phi_t^{\Sigma, u}(x_0) = \tilde{h} \circ \Phi_t^{\tilde{\Sigma}, u}(\alpha(x_0))$$

*holds for every sufficiently small  $t > 0$ . Such a mapping  $\alpha$  is called an immersion of  $\Sigma$  on  $U'$  into  $\tilde{\Sigma}$ . We omit  $U'$  when it is obvious in the context or  $U' = U$ .*

The following proposition [22] is useful for checking whether or not a given mapping  $\alpha$  is an immersion.

**PROPOSITION 2.2.** *Let  $U \subset \mathbf{R}^n$  be an open set, let  $\alpha : U \rightarrow \mathbf{R}^{\tilde{n}}$  be an analytic mapping, let  $\Sigma(g_0, \dots, g_m, h)$  be an analytic system on  $U$ , and let  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$  be an analytic system on an open set containing  $\alpha(U)$ . The mapping  $\alpha$  is an immersion of  $\Sigma$  into  $\tilde{\Sigma}$  if and only if the following holds for all  $x_0 \in U$ :*

$$L_{g_{i_1}} \dots L_{g_{i_k}} h(x_0) = L_{\tilde{g}_{i_1}} \dots L_{\tilde{g}_{i_k}} \tilde{h}(\alpha(x_0)),$$

$$(i_1, \dots, i_k) \in I_{0,m}^k, k \in I_{0,\infty}.$$

Next, we define a particular form of an immersion [22].

**DEFINITION 2.3.** *An analytic system  $\Sigma(g_0, \dots, g_m, h)$  defined on an open set  $U \subset \mathbf{R}^n$  is said to be invariantly immersible on an open set  $U' \subset U$  into another  $\tilde{n}$ -dimensional system  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$  if there exists an analytic mapping  $\alpha : U' \rightarrow \mathbf{R}^{\tilde{n}}$  such that  $\tilde{\Sigma}$  is analytic on an open set containing  $\alpha(U')$ , and, for all  $x \in U'$ ,*

$$L_{g_i} \alpha(x) = \tilde{g}_i(\alpha(x)), \quad i \in I_{0,m},$$

$$h(x) = \tilde{h}(\alpha(x))$$

*hold. Such a mapping  $\alpha$  is called an invariant immersion of  $\Sigma$  on  $U'$  into  $\tilde{\Sigma}$ .*

Often, the invariant immersion is simply called an *immersion* in the literature. However, we distinguish invariant immersions from immersions in this work because the former not only preserves the input-output map but also has additional geometric properties. That is, for every state trajectory  $x(t) \in U'$  of the original system  $\Sigma$ ,  $\alpha(x(t)) \in \alpha(U')$  is a state trajectory of  $\tilde{\Sigma}$ .

**2.2. Immersibility conditions.** Rational and polynomial structures with respect to the state are discussed in this paper, for which the notions of fields and rings are suitable. Let  $C^\omega(U)$  be the ring of all real-valued analytic functions on an open set  $U \subset \mathbf{R}^n$ . For a subset  $A \subset C^\omega(U)$ ,  $\mathbf{R}[A]$  denotes the ring generated by  $A$  over  $\mathbf{R}$ . If  $U$  is a domain (connected open set),  $\mathbf{R}[A]$  is an integral domain and its fraction field  $\mathbf{R}(A)$  is well defined and called the field generated by  $A$  over  $\mathbf{R}$ . If  $A = \{\alpha_1, \dots, \alpha_\nu\}$  and  $\alpha = [\alpha_1, \dots, \alpha_\nu]^T$ ,  $\mathbf{R}[A]$  and  $\mathbf{R}(A)$  are also denoted by  $\mathbf{R}[\alpha]$  and  $\mathbf{R}(\alpha)$ , respectively. For a state vector  $\tilde{x} \in \mathbf{R}^{\tilde{n}}$ , its elements  $\tilde{x}_1, \dots, \tilde{x}_{\tilde{n}}$  can be regarded as analytic functions on  $\mathbf{R}^{\tilde{n}}$ , and  $\mathbf{R}[\tilde{x}]$  and  $\mathbf{R}(\tilde{x})$  denote a polynomial ring and a rational function field, respectively. We denote the subset of  $\mathbf{R}[\tilde{x}]$  with the total degree less than or equal to  $\ell$  as  $\mathbf{R}[\tilde{x}]_{\leq \ell}$ . Then, an RSR, a PSR, and a QSR are formally defined as follows [22].

**DEFINITION 2.4.** Consider a system  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$  with a state vector  $\tilde{x} \in \mathbf{R}^{\tilde{n}}$ . System  $\tilde{\Sigma}$  is said to be an RSR if  $\tilde{g}_i(\tilde{x}) \in \mathbf{R}(\tilde{x})^{\tilde{n}}$  ( $i \in I_{0,m}$ ) and  $\tilde{h}(\tilde{x}) \in \mathbf{R}(\tilde{x})^p$ . System  $\tilde{\Sigma}$  is said to be a PSR if  $\tilde{g}_i(\tilde{x}) \in \mathbf{R}[\tilde{x}]^{\tilde{n}}$  ( $i \in I_{0,m}$ ) and  $\tilde{h}(\tilde{x}) \in \mathbf{R}[\tilde{x}]^p$ . In particular, a PSR  $\tilde{\Sigma}$  is said to be a QSR if  $\tilde{g}_i(\tilde{x}) \in \mathbf{R}[\tilde{x}]_{\leq 2}^{\tilde{n}}$  ( $i \in I_{0,m}$ ) and  $\tilde{h}(\tilde{x}) \in \mathbf{R}[\tilde{x}]_{\leq 1}^p$ .

It has already been proved that immersibilities are equivalent between an RSR, a PSR, and a QSR [22].

**PROPOSITION 2.5.** For an analytic system  $\Sigma$  defined on an open set  $U$ , the following three claims are equivalent:

- (i) System  $\Sigma$  is immersible (resp., invariantly immersible) on  $U$  into an RSR.
- (ii) System  $\Sigma$  is immersible (resp., invariantly immersible) on  $U$  into a PSR.
- (iii) System  $\Sigma$  is immersible (resp., invariantly immersible) on  $U$  into a QSR.

Since it suffices to consider an RSR consisting of rational functions, immersibility and invariant immersibility are well characterized in terms of fields [22].

**PROPOSITION 2.6.** For an analytic system  $\Sigma$  defined on a domain  $U$ , the following three claims are equivalent:

- (i) On an open and dense subset of  $U$ , system  $\Sigma$  is invariantly immersible into an RSR with an analytic mapping defined on  $U$ .
- (ii) On an open and dense subset of  $U$ , system  $\Sigma$  is immersible into an RSR with an analytic mapping defined on  $U$ .
- (iii) The field  $\mathbf{R}(\mathcal{O}_\Sigma)$  is finitely generated over  $\mathbf{R}$ .

Moreover, if (iii) holds, every set of analytic generators of  $\mathbf{R}(\mathcal{O}_\Sigma)$  gives an invariant immersion in (i).

Many types of nonlinear systems satisfy condition (iii) in Proposition 2.6 and are (invariantly) immersible into an RSR, a PSR, and a QSR. Moreover, as shown in [22], it is sufficient for invariant immersibility into an RSR that all functions in a given system are differentially algebraic functions, which most practical systems consist of.

In advance of ring-theoretic discussions in subsequent sections, we give a field-theoretic characterization for the minimal dimension of RSRs obtained by immersion.

**THEOREM 2.7.** Suppose condition (iii) in Proposition 2.6 holds, and let  $\rho$  be the degree of transcendency of  $\mathbf{R}(\mathcal{O}_\Sigma)$  over  $\mathbf{R}$ . If  $\mathbf{R}(\mathcal{O}_\Sigma)$  is a purely transcendental extension of  $\mathbf{R}$ , the minimal dimension of RSRs into which  $\Sigma$  is invariantly immersible on an appropriate open subset of  $U$  is  $\rho$ . Otherwise, the minimal dimension of the RSRs is  $\rho + 1$ .

*Proof.* Note that  $\mathbf{R}(\mathcal{O}_\Sigma)$  has at least  $\rho$  generators, which are algebraically independent of each other. If  $\mathbf{R}(\mathcal{O}_\Sigma)$  is a purely transcendental extension of  $\mathbf{R}$ , there exists a transcendence basis  $\{\alpha_1, \dots, \alpha_\rho\} \subset \mathbf{R}(\mathcal{O}_\Sigma)$  such that  $\mathbf{R}(\mathcal{O}_\Sigma) = \mathbf{R}(\alpha_1, \dots, \alpha_\rho)$ . Since

every element in  $\mathcal{O}_\Sigma \subset C^\omega(U)$  is analytic, it is nonzero on an open and dense subset of  $U$ . Therefore, the mapping  $\alpha = [\alpha_1, \dots, \alpha_\rho]^T$ , consisting of elements in  $\mathbf{R}(\mathcal{O}_\Sigma)$ , is analytic on an open and dense subset of  $U$ . Then, there exists an open set  $U'' \subset U$  such that  $\Sigma$  is invariantly immersible on  $U''$  into an RSR with  $\alpha$ .

If  $\mathbf{R}(\mathcal{O}_\Sigma)$  is not a purely transcendental extension of  $\mathbf{R}$ ,  $\mathbf{R}(\mathcal{O}_\Sigma) \neq \mathbf{R}(\alpha_1, \dots, \alpha_\rho)$  for any transcendence basis  $\{\alpha_1, \dots, \alpha_\rho\} \subset \mathbf{R}(\mathcal{O}_\Sigma)$ . However, since  $\mathbf{R}(\mathcal{O}_\Sigma)$  is finitely generated over  $\mathbf{R}$ , there exist a finite number of elements  $\beta_1, \dots, \beta_\mu \in \mathbf{R}(\mathcal{O}_\Sigma)$  ( $\mu \geq 1$ ) such that  $\mathbf{R}(\mathcal{O}_\Sigma) = \mathbf{R}(\alpha_1, \dots, \alpha_\rho, \beta_1, \dots, \beta_\mu)$ , where  $\mathbf{R}(\alpha_1, \dots, \alpha_\rho, \beta_1, \dots, \beta_\mu)$  is a finite algebraic extension of  $\mathbf{R}(\alpha_1, \dots, \alpha_\rho)$  [19, Theorem 3.1.3]. Moreover, since the characteristic of  $\mathbf{R}(\alpha_1, \dots, \alpha_\rho)$  is zero, its finite extension is always a simple extension [19, Theorem 2.5.2]. That is, there exists a primitive element  $\gamma \in \mathbf{R}(\mathcal{O}_\Sigma)$  such that  $\mathbf{R}(\alpha_1, \dots, \alpha_\rho, \beta_1, \dots, \beta_\mu) = \mathbf{R}(\alpha_1, \dots, \alpha_\rho, \gamma)$ , which implies  $\mathbf{R}(\mathcal{O}_\Sigma) = \mathbf{R}(\alpha_1, \dots, \alpha_\rho, \gamma)$ . The mapping  $\alpha' = [\alpha_1, \dots, \alpha_\rho, \gamma]^T$  is analytic on an open and dense subset of  $U$ , and there exists an open set  $U'' \subset U$  such that  $\Sigma$  is invariantly immersible on  $U''$  into a RSR with  $\alpha'$ .  $\square$

### 3. Algebraic structures after immersion.

**3.1. Ideals associated with an immersion.** Suppose, for a given system  $\Sigma(g_0, \dots, g_m, h)$  on a domain  $U \subset \mathbf{R}^n$ , we have  $\mathbf{R}(\mathcal{O}_\Sigma) = \mathbf{R}(\alpha)$  with an analytic mapping  $\alpha : U \rightarrow \mathbf{R}^{\tilde{n}}$ . Then, Proposition 2.6 implies that  $\Sigma$  is invariantly immersible into an RSR  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$  with  $\alpha$  on an open and dense subset  $U' \subset U$ . Let the state vector of  $\tilde{\Sigma}$  be  $\tilde{x} \in \mathbf{R}^{\tilde{n}}$ . Since all functions in  $\tilde{\Sigma}$  are rational functions of  $\tilde{x}$ , we have  $\mathcal{O}_{\tilde{\Sigma}} \subset \mathbf{R}(\tilde{x})$ . Moreover, since  $\tilde{\Sigma}$  is defined on an open set containing  $\alpha(U')$ , denominators of the rational functions in  $\tilde{\Sigma}$  do not vanish identically on  $\alpha(U)$ , which implies a particular algebraic structure in  $\tilde{\Sigma}$ , as discussed below. A basic tool for analyzing an algebraic structure in a system after immersion is a relation ideal of a mapping [7, 19].

DEFINITION 3.1. Given a subset  $S \subset \mathbf{R}^{\tilde{n}}$ , denote by

$$\mathcal{I}(S) = \{\tilde{f} \in \mathbf{R}[\tilde{x}] : \tilde{f}(\tilde{x}) = 0 \text{ for all } \tilde{x} \in S\}$$

the ideal of polynomials vanishing on  $S$ . When  $S$  is an image of a mapping  $\alpha : U \rightarrow \mathbf{R}^{\tilde{n}}$ ,  $\mathcal{I}(\alpha(U))$  is called the relation ideal of  $\alpha$ .

Let  $P = \mathcal{I}(\alpha(U))$  be the relation ideal of the immersion of  $\Sigma$  into the RSR  $\tilde{\Sigma}$ , and let  $\alpha^* : \mathbf{R}[\tilde{x}] \rightarrow \mathbf{R}[\alpha]$  be a *substitution mapping* (or a pull back) defined by  $\alpha^*(f) = f(\alpha)$  for  $f \in \mathbf{R}[\tilde{x}]$ . Then,  $\alpha^*$  is a surjective ring homomorphism such that  $\text{Ker } \alpha^* = P$ , which induces a ring isomorphism  $\mathbf{R}[\alpha] \cong \mathbf{R}[\tilde{x}]/P$ . Since  $\mathbf{R}[\alpha]$  is an integral domain,  $P$  is a prime ideal.

As mentioned previously, every denominator of functions in the RSR  $\tilde{\Sigma}$  is not identically zero on  $\alpha(U)$  or, equivalently, does not belong to the prime ideal  $P$ . Therefore, every element of  $\tilde{g}_0, \dots, \tilde{g}_m$  and  $\tilde{h}$  belongs to not only the rational function field  $\mathbf{R}(\tilde{x})$  but also the *localization* of  $\mathbf{R}[\tilde{x}]$  at  $P$ , which is given by

$$\mathbf{R}[\tilde{x}]_P = \{f/g \in \mathbf{R}(\tilde{x}) : f, g \in \mathbf{R}[\tilde{x}], \text{ and } g \notin P\}.$$

Note that  $\mathbf{R}[\tilde{x}]_P$  is a *local ring* with the unique maximal ideal

$$P\mathbf{R}[\tilde{x}]_P = \{f/g \in \mathbf{R}(\tilde{x}) : f, g \in \mathbf{R}[\tilde{x}], g \notin P, \text{ and } f \in P\}.$$

It should also be noted that an element of  $\mathbf{R}[\tilde{x}]_P$  does not necessarily define a rational function on the whole of  $\alpha(U)$  because its denominator can vanish at some points.

However, there exists an open and dense subset  $U' \subset U$  such that an element of  $\mathbf{R}[\tilde{x}]_P$  is analytic on an open set containing  $\alpha(U')$ .

We can naturally extend the substitution mapping  $\alpha^* : \mathbf{R}[\tilde{x}] \rightarrow \mathbf{R}[\alpha]$  to a mapping  $\alpha^* : \mathbf{R}[\tilde{x}]_P \rightarrow \mathbf{R}(\alpha)$ , which is also a surjective ring homomorphism with  $\text{Ker } \alpha^* = PR[\tilde{x}]_P$  and induces a ring isomorphism  $\mathbf{R}(\alpha) \cong \mathbf{R}[\tilde{x}]_P / PR[\tilde{x}]_P$ . We use the same symbol to denote the substitution mappings for  $\mathbf{R}[\tilde{x}]$  and  $\mathbf{R}[\tilde{x}]_P$  because their domains are obvious from the context.

An immediate application of the maximal ideal  $PR[\tilde{x}]_P$  is the test of the observability rank condition for the system after immersion.

**THEOREM 3.2.** *Let  $\alpha$  be an invariant immersion of system  $\Sigma$  defined on a domain  $U \subset \mathbf{R}^n$  into an RSR  $\tilde{\Sigma}$  with the state vector  $\tilde{x} \in \mathbf{R}^{\tilde{n}}$  such that  $\mathbf{R}(\mathcal{O}_\Sigma) = \mathbf{R}(\alpha)$ , and let  $P \subset \mathbf{R}[\tilde{x}]$  be the relation ideal of  $\alpha$ . Then, there exist  $r_1, \dots, r_{\tilde{n}} \in PR[\tilde{x}]_P$  such that  $\tilde{x}_i + r_i \in \mathbf{R}(\mathcal{O}_{\tilde{\Sigma}})$  ( $i \in I_{1,\tilde{n}}$ ). Moreover, the observability rank condition  $\dim d\mathcal{O}_{\tilde{\Sigma}}(\tilde{x}) = \tilde{n}$  holds if*

$$\det \left( I_{\tilde{n}} + \frac{\partial r}{\partial \tilde{x}}(\tilde{x}) \right) \neq 0,$$

where  $r = [r_1, \dots, r_{\tilde{n}}]^T$  and  $I_{\tilde{n}}$  denotes the  $\tilde{n} \times \tilde{n}$  identity matrix.

*Proof.* Since every  $\alpha_i$  belongs to  $\mathbf{R}(\mathcal{O}_\Sigma)$ , there exist a finite number of elements  $H_1, \dots, H_\mu \in \mathcal{O}_\Sigma$  and rational functions  $\phi_i(X_1, \dots, X_\mu)$  ( $i \in I_{0,\tilde{n}}$ ) such that

$$\alpha_i = \phi_i(H_1, \dots, H_\mu).$$

Then, by Proposition 2.2, there also exist a finite number of elements  $\tilde{H}_1, \dots, \tilde{H}_\mu \in \mathcal{O}_{\tilde{\Sigma}}$  such that  $H_i = \tilde{H}_i \circ \alpha$ , and, consequently,  $\tilde{\alpha}_i = \phi_i(\tilde{H}_1, \dots, \tilde{H}_\mu) \in \mathbf{R}(\mathcal{O}_{\tilde{\Sigma}})$  also satisfy  $\alpha_i = \tilde{\alpha}_i \circ \alpha$ . Therefore,  $\tilde{\alpha}_i$  belongs to  $\mathbf{R}[\tilde{x}]_P$  and  $\alpha^*(\tilde{\alpha}_i) = \alpha_i$ . Since  $\tilde{x}_i \in \mathbf{R}[\tilde{x}]_P$  also satisfies  $\alpha^*(\tilde{x}_i) = \alpha_i$ , and  $\alpha^* : \mathbf{R}[\tilde{x}]_P \rightarrow \mathbf{R}(\alpha)$  is a ring homomorphism, we have  $\alpha^*(\tilde{\alpha}_i - \tilde{x}_i) = 0$ , which implies  $r_i = \tilde{\alpha}_i - \tilde{x}_i \in \text{Ker } \alpha^* = PR[\tilde{x}]_P$ .

Let  $\phi = [\phi_1, \dots, \phi_{\tilde{n}}]^T$ ,  $\tilde{H} = [\tilde{H}_1, \dots, \tilde{H}_\mu]^T$ , and  $X = [X_1, \dots, X_\mu]^T$ . From the definition of  $\tilde{\alpha}_i$ , we have  $\tilde{x} + r = \phi(\tilde{H})$ . By taking partial differentiation with respect to  $\tilde{x}$ , we have

$$I_{\tilde{n}} + \frac{\partial r}{\partial \tilde{x}}(\tilde{x}) = \frac{\partial \phi}{\partial X}(\tilde{H}) \frac{\partial \tilde{H}}{\partial \tilde{x}}(\tilde{x}).$$

If the determinant of the left-hand side is nonzero, the rank of  $\partial \tilde{H}(\tilde{x}) / \partial \tilde{x}$  on the right-hand side must be  $\tilde{n}$ , which implies  $\dim d\mathcal{O}_{\tilde{\Sigma}}(\tilde{x}) = \tilde{n}$ .  $\square$

It should be noted that Theorem 3.2 is applicable not only to RSRs but also to PSRs because PSRs are also RSRs.

**3.2. Nonlinear systems over rings.** Now, we can characterize some algebraic structures of RSRs and PSRs after immersion in terms of such a subring of the rational function field  $\mathbf{R}(\tilde{x})$  as  $\mathbf{R}[\tilde{x}]$  and  $\mathbf{R}[\tilde{x}]_P$  rather than  $\mathbf{R}(\tilde{x})$  itself. To this end, we prepare some ring-theoretic notions of nonlinear system theory in place of the usual differential geometric settings.

Let  $R$  be a partial differential subring of  $\mathbf{R}(\tilde{x})$ , such as  $\mathbf{R}[\tilde{x}]$  and  $\mathbf{R}[\tilde{x}]_P$ , satisfying  $(\partial / \partial \tilde{x}_i)R \subset R$  for all  $i \in I_{1,\tilde{n}}$ . Then, a PSR or an RSR  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$  is regarded as a *system over a ring* such that  $\tilde{g}_0, \dots, \tilde{g}_m \in R^{\tilde{n}}$  and  $\tilde{h} \in R^p$  for an appropriate ring  $R$ . Note that the state  $\tilde{x}$  belongs to Euclidean space as usual in the present notion of a system over a ring, which is different from *linear systems over rings* [6, 13]. It

should also be noted that we consider a partial differential ring, while the conventional differential algebraic system theory [8, 10, 24] is based on ordinary differential fields with the single derivation operator  $d/dt$ .

The vector fields  $\tilde{g}_0, \dots, \tilde{g}_m$  can be viewed as elements of a free  $R$ -module  $R^{\tilde{n}}$  rather than sections of a tangent bundle. Moreover, the Lie derivative  $L_{\tilde{g}_i}$  is regarded as a mapping  $L_{\tilde{g}_i} : R \rightarrow R$ , which is not a ring endomorphism of  $R$  in general but a derivation of  $R$  regarded as an  $\mathbf{R}$ -module. The differential  $d$  is also regarded as a mapping  $d : R \rightarrow (R^{\tilde{n}})^*$ , where  $(R^{\tilde{n}})^*$  denotes the dual module of  $R^{\tilde{n}}$ , and  $(R^{\tilde{n}})^*$  can be identified with  $R^{1 \times \tilde{n}}$ . Through the use of componentwise application of the substitution mapping  $\alpha^* : R \rightarrow \alpha^*(R) \subset \mathbf{R}(\alpha)$ , we can define  $\bar{\alpha}^* : R^{\tilde{n}} \rightarrow \alpha^*(R)^{\tilde{n}}$  and  $\underline{\alpha}^* : (R^{\tilde{n}})^* \rightarrow (\alpha^*(R)^{\tilde{n}})^*$ .

An important algebraic structure in a system over a ring is the invariance of an ideal under the Lie derivative.

**DEFINITION 3.3.** *An ideal  $I \subset R$  is said to be an invariant ideal of a system  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$  over  $R$  if*

$$L_{\tilde{g}_i} I \subset I, \quad i \in I_{0,m},$$

*holds.*

If the ring  $R$  is Noetherian, every ideal is finitely generated. In other words, for any ideal  $I \subset R$ , there exist a finite number of elements  $\tilde{f}_1, \dots, \tilde{f}_s \in R$  such that  $I = \{\sum_{i=1}^s a_i \tilde{f}_i : a_i \in R\}$ , which is denoted by  $I = (\tilde{f}_1, \dots, \tilde{f}_s)$ . For example,  $\mathbf{R}[\tilde{x}]$  is Noetherian by Hilbert's basis theorem, and its localization  $\mathbf{R}[\tilde{x}]_P$  is also Noetherian [17]. It is readily shown that a finitely generated ideal  $I = (\tilde{f}_1, \dots, \tilde{f}_s)$  is an invariant ideal if and only if

$$(3.1) \quad L_{\tilde{g}_i} \tilde{f}_j \in (\tilde{f}_1, \dots, \tilde{f}_s), \quad i \in I_{0,m}, \quad j \in I_{1,s},$$

holds. Then, it is meaningful to consider a differential algebraic equation (DAE) over  $R$ :

$$(3.2) \quad \tilde{\Sigma}_I \begin{cases} \dot{\tilde{x}} = \tilde{g}_0(x) + \sum_{i=1}^m \tilde{g}_i(\tilde{x}) u_i, \\ 0 = \tilde{f}(\tilde{x}), \end{cases}$$

where  $\tilde{f}(\tilde{x}) = [\tilde{f}_1(\tilde{x}), \dots, \tilde{f}_s(\tilde{x})]^T \in R^s$ . In this paper, we call  $\tilde{x}_0 \in \mathbf{R}^{\tilde{n}}$  a *regular point* of DAE  $\tilde{\Sigma}_I$  if all denominators in  $\tilde{g}_i$  and  $\tilde{f}_i$  are nonzero at  $x_0$ . Equation (3.1) implies that if a regular point  $x_0$  satisfies  $\tilde{f}(x_0) = 0$ , the trajectory starting from  $x_0$  satisfies  $\tilde{f}(\Phi_t^{\Sigma, u}(x_0)) = 0$  for every admissible input  $u \in \Omega$ , as long as the trajectory  $\Phi_t^{\Sigma, u}(x_0)$  is defined. If  $\tilde{\Sigma}$  is a PSR,  $R = \mathbf{R}[\tilde{x}]$  and every point in  $\mathbf{R}^{\tilde{n}}$  is a regular point of DAE  $\tilde{\Sigma}_I$ .

Since a geometric counterpart of an ideal is an affine variety [7], a geometric object related to an invariant ideal is naturally defined as an invariant variety.

**DEFINITION 3.4.** *Let  $I$  be an ideal of  $\mathbf{R}[\tilde{x}]$ . An affine variety (or an algebraic set) defined by  $I$  is a subset of  $\mathbf{R}^{\tilde{n}}$  given by*

$$\mathcal{V}(I) = \{\tilde{x} \in \mathbf{R}^{\tilde{n}} : \tilde{f}(\tilde{x}) = 0 \text{ for all } \tilde{f} \in I\}.$$

When  $I = (\tilde{f}_1, \dots, \tilde{f}_s)$ ,  $\mathcal{V}(I)$  is also denoted by  $\mathcal{V}(\tilde{f}_1, \dots, \tilde{f}_s)$ .

**DEFINITION 3.5.** *Let  $R$  be a partial differential ring such that  $\mathbf{R}[\tilde{x}] \subset R \subset \mathbf{R}(\tilde{x})$ , and let  $P$  be an ideal of  $\mathbf{R}[\tilde{x}]$ .  $\mathcal{V}(P)$  is called an invariant variety of a system over  $R$  if the ideal generated by  $P$  in  $R$ ,  $PR$  is an invariant ideal of the system.*

Note that if  $R = \mathbf{R}[\tilde{x}]$ , then  $PR = P$ , and if  $R = \mathbf{R}[\tilde{x}]_P$ , then  $PR = P\mathbf{R}[\tilde{x}]_P$ . Since  $\mathbf{R}[\tilde{x}]$  is Noetherian,  $\mathcal{V}(P)$  can be expressed as a set of the common zeros of a finite number of polynomials. By the invariance of the ideal  $PR$ , these polynomials are identically zero along a trajectory starting from a regular point  $\tilde{x}_0 \in \mathcal{V}(P)$  of  $\tilde{\Sigma}$ . That is, the trajectory stays in  $\mathcal{V}(P)$  as long as it is defined, which motivates the notion of the invariant variety.

The notions of an invariant ideal and an invariant variety can be regarded as generalizations of an *algebraic particular integral* and *invariant algebraic surface* [3, 25] of a polynomial vector field. It should be noted that an invariant variety may have a singular point as a variety and is not necessarily a manifold globally. In particular, the existence of an invariant variety does not necessarily imply the existence of a foliation of manifolds.

**3.3. Invariance in a system after immersion.** Through the use of the algebraic and geometric notions defined above, we can characterize an invariance in a system after immersion. Hereafter, we assume  $R$  to be a partial differential ring such that  $\mathbf{R}[\tilde{x}] \subset R \subset \mathbf{R}(\tilde{x})$ .

**THEOREM 3.6.** *Let  $\alpha$  be an invariant immersion of system  $\Sigma(g_0, \dots, g_m, h)$  defined on a domain  $U \subset \mathbf{R}^n$  into system  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$  over  $R$ , and let  $P \subset \mathbf{R}[\tilde{x}]$  be the relation ideal of  $\alpha$ . Then,  $PR$  is an invariant ideal of  $\tilde{\Sigma}$ .*

*Proof.* For  $r \in PR$ , we relate two Lie derivatives  $L_{\tilde{g}_i}r$  and  $L_{g_i}(r \circ \alpha)$  through the definition of an invariant immersion to show  $L_{\tilde{g}_i}r \in PR$ . First,  $L_{\tilde{g}_i}r$  belongs to  $R$  because  $R$  is a partial differential ring and  $\tilde{g}_i$  belongs to  $R^{\tilde{n}}$ . Moreover, since  $\text{Ker } \alpha^* = PR$ , there exists an open and dense subset  $U' \subset U$  such that  $r$  is analytic on an open set containing  $\alpha(U')$  and  $r(\alpha(x)) = 0$  for all  $x \in U'$ . Therefore, we have  $L_{g_i}r(\alpha(x)) = 0$  ( $i \in I_{0,m}$ ) on  $U'$ . Meanwhile, from the definition of an invariant immersion, we have

$$\begin{aligned} L_{g_i}r(\alpha(x)) &= \frac{\partial r(\alpha(x))}{\partial \tilde{x}} \frac{\partial \alpha(x)}{\partial x} g_i(x) \\ &= \frac{\partial r(\alpha(x))}{\partial \tilde{x}} \tilde{g}_i(\alpha(x)) = (L_{\tilde{g}_i}r)(\alpha(x)) \end{aligned}$$

for all  $x \in U'$ . In summary,  $(L_{\tilde{g}_i}r)(\tilde{x}) = 0$  for all  $\tilde{x} \in \alpha(U')$ , which means  $L_{\tilde{g}_i}r \in PR$ .  $\square$

Then, the invariance of an ideal implies the invariance of a variety in a system after immersion, which is characterized in terms of the Zariski closure [7].

**DEFINITION 3.7.** *The Zariski closure of a subset  $S \subset \mathbf{R}^{\tilde{n}}$  is the smallest variety containing  $S$ .*

**PROPOSITION 3.8.** *The Zariski closure of  $S \subset \mathbf{R}^{\tilde{n}}$  is given by  $\mathcal{V}(\mathcal{I}(S))$ .*

**THEOREM 3.9.** *Let  $\alpha$ ,  $\tilde{\Sigma}$ , and  $P$  be the same as in Theorem 3.6. Then,  $\mathcal{V}(P)$  is the Zariski closure of  $\alpha(U)$  and, moreover, an invariant variety of  $\tilde{\Sigma}$ .*

*Proof.* Since  $P$  is the relation ideal of  $\alpha$ , i.e.,  $P = \mathcal{I}(\alpha(U))$ , Proposition 3.8 implies that  $\mathcal{V}(P)$  is the Zariski closure of  $\alpha(U)$ . Moreover, since  $PR$  is an invariant ideal of  $\tilde{\Sigma}$  by Theorem 3.6,  $\mathcal{V}(P)$  is also an invariant variety.  $\square$

For an invariant immersion  $\alpha : U \rightarrow \mathbf{R}^{\tilde{n}}$  of a given system  $\Sigma$  on an open and dense subset  $U' \subset U$  into a system over  $R$ ,  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$ , its relation ideal  $P = \mathcal{I}(\alpha(U)) \subset \mathbf{R}[\tilde{x}]$  is always finitely generated according to Hilbert's basis theorem, and its generators are also generators of the ideal  $PR$  in  $R$ . If  $P = (\tilde{f}_1, \dots, \tilde{f}_s)$  holds, then an image of any trajectory of the original system by the immersion  $\alpha(\Phi_t^{\Sigma, u}(x_0))$

$(x_0 \in U')$  is always a solution of the DAE given in (3.2). That is,  $\alpha(\Phi_t^{\Sigma, u}(x_0))$  ( $x_0 \in U'$ ) belongs to  $\mathcal{V}(\tilde{f}_1, \dots, \tilde{f}_s)$ . Moreover, Theorem 3.9 implies that not only the image of a trajectory of the original system but also any trajectory starting from a point on  $\mathcal{V}(\tilde{f}_1, \dots, \tilde{f}_s)$  remains on  $\mathcal{V}(\tilde{f}_1, \dots, \tilde{f}_s)$ , as long as it is defined.

*Example 3.1.* Consider a one-dimensional analytic system on  $\mathbf{R}$ :

$$\Sigma \left\{ \begin{array}{l} \dot{x} = \frac{\sin x}{x}, \\ y = x. \end{array} \right.$$

The observation space of this system is given by

$$\mathcal{O}_\Sigma = \text{span}_{\mathbf{R}} \left\{ x, \frac{\sin x}{x}, \frac{\cos x \cdot x - \sin x}{x^2} \cdot \frac{\sin x}{x}, \dots \right\}.$$

We have  $\mathbf{R}(\mathcal{O}_\Sigma) = \mathbf{R}(x, \sin x, \cos x)$ , and  $\Sigma$  is immersible into an RSR with  $\alpha(x) = [x, \sin x, \cos x]^T$ . In fact, an RSR  $\tilde{\Sigma}(\tilde{g}_0, \tilde{h})$  can be readily constructed from  $(\partial\alpha/\partial x)\dot{x} = [\sin x/x, \sin x \cdot \cos x/x, -\sin^2 x/x]^T$  as follows:

$$\tilde{\Sigma} \left\{ \begin{array}{l} \begin{bmatrix} \dot{\tilde{x}}_1 \\ \dot{\tilde{x}}_2 \\ \dot{\tilde{x}}_3 \end{bmatrix} = \begin{bmatrix} \tilde{x}_2/\tilde{x}_1 \\ \tilde{x}_2\tilde{x}_3/\tilde{x}_1 \\ -\tilde{x}_2^2/\tilde{x}_1 \end{bmatrix}, \\ y = \tilde{x}_1. \end{array} \right.$$

The RSR  $\tilde{\Sigma}$  is analytic on an open set  $\tilde{U} = \{\tilde{x} \in \mathbf{R}^3 : \tilde{x}_1 \neq 0\} \supset \alpha(\mathbf{R} \setminus \{0\})$ . Therefore,  $\Sigma$  is immersible into the RSR  $\tilde{\Sigma}$  on  $\mathbf{R} \setminus \{0\}$ . The immersion  $\alpha$  itself is analytic on  $\mathbf{R}$  and its image is a helix along the  $\tilde{x}_1$  axis.

From the algebraic relation between the trigonometric functions,  $\sin^2 x + \cos^2 x - 1 = 0$ , the relation ideal of  $\alpha$  is  $P = (\tilde{x}_2^2 + \tilde{x}_3^2 - 1)$ . The maximal ideal of the local ring  $\mathbf{R}[\tilde{x}]_P$  has the form

$$P\mathbf{R}[\tilde{x}]_P = \left\{ \frac{n(\tilde{x})}{d(\tilde{x})}(\tilde{x}_2^2 + \tilde{x}_3^2 - 1) : n, d \in \mathbf{R}[\tilde{x}], \text{ and } d \notin P \right\}.$$

Note that every element of  $P\mathbf{R}[\tilde{x}]_P$  vanishes when  $\tilde{x} = \alpha(x)$  is substituted.

Theorem 3.6 implies that  $P\mathbf{R}[\tilde{x}]_P$  is an invariant ideal of  $\tilde{\Sigma}$ . In fact, for any  $n(\tilde{x})(\tilde{x}_2^2 + \tilde{x}_3^2 - 1)/d(\tilde{x}) \in P\mathbf{R}[\tilde{x}]_P$ , we have

$$\begin{aligned} & L_{\tilde{g}_0} \left[ \frac{n(\tilde{x})}{d(\tilde{x})}(\tilde{x}_2^2 + \tilde{x}_3^2 - 1) \right] \\ &= \left[ L_{\tilde{g}_0} \frac{n(\tilde{x})}{d(\tilde{x})} \right] (\tilde{x}_2^2 + \tilde{x}_3^2 - 1) + \frac{n(\tilde{x})}{d(\tilde{x})} L_{\tilde{g}_0} (\tilde{x}_2^2 + \tilde{x}_3^2 - 1) \\ &= \left[ L_{\tilde{g}_0} \frac{n(\tilde{x})}{d(\tilde{x})} \right] (\tilde{x}_2^2 + \tilde{x}_3^2 - 1) + \frac{n(\tilde{x})}{d(\tilde{x})} \left( 2\tilde{x}_2 \cdot \frac{\tilde{x}_2\tilde{x}_3}{\tilde{x}_1} + 2\tilde{x}_3 \cdot \frac{-\tilde{x}_2^2}{\tilde{x}_1} \right) \\ &= \left[ L_{\tilde{g}_0} \frac{n(\tilde{x})}{d(\tilde{x})} \right] (\tilde{x}_2^2 + \tilde{x}_3^2 - 1). \end{aligned}$$

Note that the Lie derivative of  $n(\tilde{x})(\tilde{x}_2^2 + \tilde{x}_3^2 - 1)/d(\tilde{x}) \in P\mathbf{R}[\tilde{x}]_P$  vanishes even when  $\tilde{x}$  does not belong to the image of  $\alpha$ .

FIG. 3.1. Trajectories on the invariant variety.

Finally, Theorem 3.9 claims that a variety  $\mathcal{V}(\tilde{x}_2^2 + \tilde{x}_3^2 - 1)$ , a cylinder along the  $\tilde{x}_1$  axis, is the Zariski closure of  $\alpha(\mathbf{R})$ , a helix, and an invariant variety of  $\tilde{\Sigma}$ . Then, for any solution  $x(t)$  of  $\Sigma$ , its image  $\alpha(x(t))$  satisfies the DAE

$$\tilde{\Sigma}_P \left\{ \begin{array}{l} \begin{bmatrix} \dot{\tilde{x}}_1 \\ \dot{\tilde{x}}_2 \\ \dot{\tilde{x}}_3 \end{bmatrix} = \begin{bmatrix} \tilde{x}_2/\tilde{x}_1 \\ \tilde{x}_2\tilde{x}_3/\tilde{x}_1 \\ -\tilde{x}_2^2/\tilde{x}_1 \end{bmatrix}, \\ 0 = \tilde{x}_2^2 + \tilde{x}_3^2 - 1. \end{array} \right.$$

Moreover, any solution of the state equation of  $\tilde{\Sigma}$  starting from a point on  $\mathcal{V}(\tilde{x}_2^2 + \tilde{x}_3^2 - 1)$  satisfies the DAE, as long as it is defined (see Figure 3.1).

*Example 3.2.* According to Proposition 2.5,  $\Sigma$  in Example 3.1 is invariantly immersible on  $\mathbf{R} \setminus \{0\}$  into not only an RSR but also a PSR. In fact, an invariant immersion into a PSR is readily obtained by augmenting  $\alpha(x)$  with  $1/x$  ( $= 1/\tilde{x}_1$  on  $\alpha(\mathbf{R})$ ) as  $\beta(x) = [x, \sin x, \cos x, 1/x]^T$ , and a PSR  $\bar{\Sigma}(\bar{g}_0, \bar{h})$  is obtained from  $(\partial\beta/\partial x)\dot{x} = [\sin x/x, \sin x \cdot \cos x/x, -\sin^2 x/x, -\sin x/x^3]^T$  as follows:

$$\bar{\Sigma} \left\{ \begin{array}{l} \begin{bmatrix} \dot{\bar{x}}_1 \\ \dot{\bar{x}}_2 \\ \dot{\bar{x}}_3 \\ \dot{\bar{x}}_4 \end{bmatrix} = \begin{bmatrix} \bar{x}_2\bar{x}_4 \\ \bar{x}_2\bar{x}_3\bar{x}_4 \\ -\bar{x}_2^2\bar{x}_4 \\ -\bar{x}_2\bar{x}_4^3 \end{bmatrix}, \\ y = \bar{x}_1. \end{array} \right.$$

The PSR  $\bar{\Sigma}$  is analytic on  $\mathbf{R}^4 \supset \beta(\mathbf{R} \setminus \{0\})$ .

From an additional algebraic relation  $x \cdot (1/x) - 1 = 0$ , the relation ideal of  $\beta$  is  $Q = (\bar{x}_2^2 + \bar{x}_3^2 - 1, \bar{x}_1\bar{x}_4 - 1)$ . Then, Theorem 3.6 implies that  $Q$  is an invariant ideal of  $\bar{\Sigma}$ . In fact, it is readily confirmed that  $L_{\bar{g}_0}Q \subset Q$ . For example, we have, for any  $p \in \mathbf{R}[\bar{x}]$ ,

$$\begin{aligned} L_{\bar{g}_0}[p(\bar{x})(\bar{x}_1\bar{x}_4 - 1)] &= [L_{\bar{g}_0}p(\bar{x})](\bar{x}_1\bar{x}_4 - 1) + p(\bar{x})[\bar{x}_4 \cdot \bar{x}_2\bar{x}_4 + \bar{x}_1 \cdot (-\bar{x}_2\bar{x}_4)] \\ &= [L_{\bar{g}_0}p(\bar{x}) - p(\bar{x})\bar{x}_2\bar{x}_4^2](\bar{x}_1\bar{x}_4 - 1) \in Q. \end{aligned}$$

Finally, Theorem 3.9 states that  $\mathcal{V}(\bar{x}_2^2 + \bar{x}_3^2 - 1, \bar{x}_1\bar{x}_4 - 1)$  is the Zariski closure of  $\beta(\mathbf{R} \setminus \{0\})$  and an invariant variety of  $\bar{\Sigma}$ . Then, for any solution  $x(t)$  of  $\Sigma$ , its image

$\beta(x(t))$  satisfies the DAE

$$\bar{\Sigma}_Q \left\{ \begin{array}{l} \begin{bmatrix} \dot{\bar{x}}_1 \\ \dot{\bar{x}}_2 \\ \dot{\bar{x}}_3 \\ \dot{\bar{x}}_4 \end{bmatrix} = \begin{bmatrix} \bar{x}_2 \bar{x}_4 \\ \bar{x}_2 \bar{x}_3 \bar{x}_4 \\ -\bar{x}_2^2 \bar{x}_4 \\ -\bar{x}_2 \bar{x}_4^3 \end{bmatrix}, \\ 0 = \bar{x}_2^2 + \bar{x}_3^2 - 1, \\ 0 = \bar{x}_1 \bar{x}_4 - 1. \end{array} \right.$$

Moreover, any solution of  $\bar{\Sigma}$  starting from a point on  $\mathcal{V}(\bar{x}_2^2 + \bar{x}_3^2 - 1, \bar{x}_1 \bar{x}_4 - 1)$  satisfies the DAE, as long as it is defined.

**4. Degrees of freedom in systems over a ring.** For a given nonlinear system, an immersion into a system over a ring is not unique, and it is meaningful to discuss how to choose an immersion, as in Theorem 2.7. Moreover, even if an immersion is fixed, a system over a ring is not unique. In order to choose an appropriate representation for system analysis and control design, it is important to clarify the degrees of freedom in systems over a ring obtained by one immersion.

From the definition of an invariant immersion and the fact  $\text{Ker } \alpha^* = PR$ , it is straightforward to show the following parameterization of all systems over  $R$  into which a given system is invariantly immersible with the same immersion  $\alpha$ .

**THEOREM 4.1.** *Let  $\Sigma$  be an analytic system defined on a domain  $U \subset \mathbf{R}^n$ , let  $\alpha : U \rightarrow \mathbf{R}^{\tilde{n}}$  be an invariant immersion of  $\Sigma$  on an open and dense subset of  $U$  into a system over a ring  $R$ ,  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$ , and let  $P \subset \mathbf{R}[\tilde{x}]$  be the relation ideal of  $\alpha$ . Then all systems over  $R$  into which  $\Sigma$  is invariantly immersible on an open and dense subset of  $U$  with  $\alpha$  can be parameterized as  $\tilde{\Sigma}'(\tilde{g}_0 + v_0, \dots, \tilde{g}_m + v_m, \tilde{h} + r)$  with  $v_i \in PR^{\tilde{n}}$  ( $i \in I_{0,m}$ ) and  $r \in PR_P^p$ .*

*Proof.* First, if  $\tilde{\Sigma}$ ,  $v_i \in PR^{\tilde{n}}$  ( $i \in I_{0,m}$ ), and  $r \in PR^p$  are analytic on the image of an open and dense subset  $U' \subset U$  by  $\alpha$ , then it is obvious from the definition of an invariant immersion and  $v_i(\alpha(x)) = 0$ ,  $r(\alpha(x)) = 0$  (for all  $x \in U'$ ) that  $\alpha$  is an invariant immersion of  $\Sigma$  on  $U'$  into a system over  $R$ ,  $\tilde{\Sigma}'(\tilde{g}_0 + v_0, \dots, \tilde{g}_m + v_m, \tilde{h} + r)$ .

Conversely, if  $\alpha$  is an invariant immersion of  $\Sigma$  on an open and dense subset  $U' \subset U$  into not only  $\tilde{\Sigma}$  but also another system over  $R$ ,  $\tilde{\Sigma}'(\tilde{g}'_0, \dots, \tilde{g}'_m, \tilde{h}')$ , then all elements of  $\tilde{g}'_i$  ( $i \in I_{0,m}$ ) and  $\tilde{h}'$  also belong to  $R$ , and we have, for all  $x \in U'$ ,

$$L_{g_i} \alpha(x) = \tilde{g}_i(\alpha(x)) = \tilde{g}'_i(\alpha(x)), \quad i \in I_{0,m},$$

$$h(x) = \tilde{h}(\alpha(x)) = \tilde{h}'(\alpha(x)).$$

Therefore, for all  $x \in U'$ ,

$$\alpha^*(\tilde{g}_i - \tilde{g}'_i)(x) = \tilde{g}_i(\alpha(x)) - \tilde{g}'_i(\alpha(x)) = 0, \quad i \in I_{0,m},$$

$$\alpha^*(\tilde{h} - \tilde{h}')(x) = \tilde{h}(\alpha(x)) - \tilde{h}'(\alpha(x)) = 0,$$

which implies  $\tilde{g}_i - \tilde{g}'_i \in PR^{\tilde{n}}$  ( $i \in I_{0,m}$ ) and  $\tilde{h} - \tilde{h}' \in RR^p$ .  $\square$

Note that, as mentioned previously,  $\tilde{\Sigma}$  and  $\tilde{\Sigma}'$  are RSRs if  $R = \mathbf{R}[\tilde{x}]_P$  and PSRs if  $R = \mathbf{R}[\tilde{x}]$ . It is obvious that if  $\tilde{\Sigma}$  is a QSR, the parameterization of all QSRs is obtained with such additional constraints to the case of PSRs as  $\tilde{g}_i + v_i \in \mathbf{R}[\tilde{x}]_{\leq 2}^{\tilde{n}}$  ( $i \in I_{0,m}$ ) and  $\tilde{h} + r \in \mathbf{R}[\tilde{x}]_{\leq 1}^p$ .

Now, the remaining problem is the characterization of all systems over  $R$  into which a given system is immersible with the same immersion  $\alpha$  that is not necessarily an invariant immersion.

**THEOREM 4.2.** *Let  $\Sigma$  be an analytic system defined on a domain  $U \subset \mathbf{R}^n$ , let  $\alpha : U \rightarrow \mathbf{R}^{\tilde{n}}$  be an invariant immersion of  $\Sigma$  on an open and dense subset of  $U$  into a system over  $R$ ,  $\tilde{\Sigma}(\tilde{g}_0, \dots, \tilde{g}_m, \tilde{h})$ , and let  $P \subset \mathbf{R}[\tilde{x}]$  be the relation ideal of  $\alpha$ . Let  $\tilde{\Sigma}'(\tilde{g}'_0, \dots, \tilde{g}'_m, \tilde{h}')$  be another system over  $R$ , and let  $v_i = \tilde{g}'_i - \tilde{g}_i$  ( $i \in I_{0,m}$ ) and  $r = \tilde{h}' - \tilde{h}$ . Then,  $\Sigma$  is immersible on an open and dense subset of  $U$  with  $\alpha$  into  $\tilde{\Sigma}'$  if and only if*

$$L_{v_i} \mathcal{L}_{\tilde{\Sigma}'} \subset PR, \quad i \in I_{0,m},$$

$$r \in PR^p.$$

*Proof.* Let  $U'$  be an open and dense subset of  $U$  such that both  $\tilde{\Sigma}$  and  $\tilde{\Sigma}'$  are analytic on  $\alpha(U')$ . From Proposition 2.2,  $\alpha$  is also an immersion of  $\Sigma$  on  $U'$  into  $\tilde{\Sigma}'$  if and only if, for all  $x \in U'$ ,

$$L_{\tilde{g}_{i_1}} \dots L_{\tilde{g}_{i_k}} \tilde{h}(\alpha(x)) - L_{\tilde{g}'_{i_1}} \dots L_{\tilde{g}'_{i_k}} \tilde{h}'(\alpha(x)) = 0,$$

$$(i_1, \dots, i_k) \in I_{0,m}^k, \quad k \in I_{0,\infty},$$

which is equivalent to

$$L_{\tilde{g}_{i_1}} \dots L_{\tilde{g}_{i_k}} \tilde{h}_j - L_{\tilde{g}'_{i_1}} \dots L_{\tilde{g}'_{i_k}} \tilde{h}'_j \in PR,$$

$$(4.1) \quad j \in I_{1,p}, \quad (i_1, \dots, i_k) \in I_{0,m}^k, \quad k \in I_{0,\infty}.$$

We will show that the claimed condition is equivalent to condition (4.1).

(If) We show the sufficiency by induction. First, for  $k = 0$ , condition (4.1) holds because  $\tilde{h}' - \tilde{h} = r \in PR^p$  by the assumption.

Next, suppose condition (4.1) holds for a certain  $k$ , and let  $\tilde{H} \in \mathcal{L}_{\tilde{\Sigma}}$  and  $\tilde{H}' \in \mathcal{L}_{\tilde{\Sigma}'}$  be  $k$ th order Lie derivatives corresponding to each other such that  $\tilde{H} - \tilde{H}' \in PR$ . Since  $PR$  is an invariant ideal of  $\tilde{\Sigma}$  by Theorem 3.6, we have, for any  $l \in I_{0,m}$ ,  $L_{\tilde{g}_l}(\tilde{H} - \tilde{H}') \in PR$ , which implies

$$\begin{aligned} L_{\tilde{g}_l} \tilde{H} - L_{\tilde{g}_l} \tilde{H}' &= L_{\tilde{g}_l} \tilde{H} - L_{\tilde{g}'_l - v_l} \tilde{H}' \\ &= L_{\tilde{g}_l} \tilde{H} - L_{\tilde{g}'_l} \tilde{H}' + L_{v_l} \tilde{H}' \in PR. \end{aligned}$$

Since  $L_{v_l} \tilde{H}' \in PR$  from the assumption, we have  $L_{\tilde{g}_l} \tilde{H} - L_{\tilde{g}'_l} \tilde{H}' \in PR$ , which means that condition (4.1) also holds for  $k + 1$ .

(Only if) First, condition (4.1) with  $k = 0$  implies  $\tilde{h}' - \tilde{h} = r \in PR^p$ . Condition (4.1) also implies

$$\begin{aligned} L_{\tilde{g}_{i_1}} \dots L_{\tilde{g}_{i_k}} \tilde{h}_j - L_{\tilde{g}'_{i_1}} \dots L_{\tilde{g}'_{i_k}} \tilde{h}'_j &= L_{\tilde{g}_{i_1}} (L_{\tilde{g}_{i_2}} \dots L_{\tilde{g}_{i_k}} \tilde{h}_j - L_{\tilde{g}_{i_2}} \dots L_{\tilde{g}'_{i_k}} \tilde{h}'_j) \\ &\quad - L_{v_{i_1}} (L_{\tilde{g}'_{i_2}} \dots L_{\tilde{g}'_{i_k}} \tilde{h}'_j) \in PR, \end{aligned}$$

$$j \in I_{1,p}, \quad (i_1, \dots, i_k) \in I_{0,m}^k, \quad k \in I_{0,\infty},$$

where  $L_{\tilde{g}_{i_2}} \dots L_{\tilde{g}_{i_k}} \tilde{h}_j - L_{\tilde{g}_{i_2}} \dots L_{\tilde{g}'_{i_k}} \tilde{h}'_j \in PR$  by condition (4.1) and its Lie derivative also belongs to  $PR$  by Theorem 3.6. Therefore,  $L_{v_{i_1}}(L_{\tilde{g}'_{i_2}} \dots L_{\tilde{g}'_{i_k}} \tilde{h}'_j)$  should also belong to  $PR$ , which means  $L_{v_i} \mathcal{L}_{\tilde{\Sigma}'} \in PR$ .  $\square$

It should be noted that the state equation of  $\tilde{\Sigma}'(\tilde{g}'_0, \dots, \tilde{g}'_m, \tilde{h}')$  can be rewritten as

$$\begin{aligned} \dot{\tilde{x}} &= \tilde{g}'_0(\tilde{x}) + \sum_{i=1}^m \tilde{g}'_i(\tilde{x}) u_i \\ &= \tilde{g}_0(\tilde{x}) + \sum_{i=1}^m \tilde{g}_i(\tilde{x}) u_i + \sum_{i=0}^m v_i(\tilde{x}) w_i, \end{aligned}$$

with  $w_0 = 1$ ,  $w_1 = u_1, \dots, w_m = u_m$ . That is,  $v_i$  can be viewed as vector fields corresponding to disturbances on  $\tilde{\Sigma}$ . Then, since every element of  $PR$  vanishes on  $\mathcal{V}(P)$ , Theorem 4.2 can be interpreted as a generalization of the condition for the output invariance [11, 21] with the initial state restricted to  $\mathcal{V}(P)$ .

According to Theorem 4.2, the output mapping of a system over  $R$  has a degree of freedom in  $PR^p$ , as in the case of an invariant immersion. However, the condition  $L_{v_i} \mathcal{L}_{\tilde{\Sigma}'} \subset PR$  is not useful for finding the free parameter  $v_i$  in the vector fields because  $\mathcal{L}_{\tilde{\Sigma}'}$  itself contains  $v_i$ . The following sufficient conditions give explicit expressions for  $v_i$  such that  $L_{v_i} \mathcal{L}_{\tilde{\Sigma}'} \subset PR$  holds. Note that  $\mathcal{L}_{\tilde{\Sigma}}$  in the following does not contain  $v_i$ .

**THEOREM 4.3.** *Let  $\alpha$ ,  $\tilde{\Sigma}$ ,  $P$ , and  $\tilde{\Sigma}'$  be the same as in Theorem 4.2.  $\Sigma$  is immersible on an open and dense subset of  $U$  with  $\alpha$  into  $\tilde{\Sigma}'$  if*

$$\begin{aligned} L_{v_i} \mathcal{L}_{\tilde{\Sigma}} &\subset PR, \quad L_{v_i} PR \subset PR, \quad i \in I_{0,m}, \\ r &\in PR^p, \end{aligned}$$

or, equivalently,

$$\begin{aligned} v_i &\in \bar{\alpha}^{*-1}(\text{Ker } \underline{\alpha}^*(d\mathcal{L}_{\tilde{\Sigma}} \cup d(PR))), \quad i \in I_{0,m}, \\ r &\in PR^p. \end{aligned}$$

*Proof.* We show that condition (4.1) holds by induction. First, for  $k = 0$ , condition (4.1) holds because  $\tilde{h}' - \tilde{h} = r \in PR^p$  by the assumption. Next, suppose condition (4.1) holds for a certain  $k$ , and let  $\tilde{H} \in \mathcal{L}_{\tilde{\Sigma}}$  and  $\tilde{H}' \in \mathcal{L}_{\tilde{\Sigma}'}$  be  $k$ th order Lie derivatives corresponding to each other such that  $\tilde{H} - \tilde{H}' \in PR$ . Then, we have, for any  $l \in I_{0,m}$ ,

$$\begin{aligned} L_{\tilde{g}_l} \tilde{H} - L_{\tilde{g}'_l} \tilde{H}' &= L_{\tilde{g}_l} \tilde{H} - L_{\tilde{g}_l + v_l}(\tilde{H} + (\tilde{H}' - \tilde{H})) \\ &= -L_{\tilde{g}_l}(\tilde{H}' - \tilde{H}) - L_{v_l} \tilde{H} - L_{v_l}(\tilde{H}' - \tilde{H}), \end{aligned}$$

where every term on the right-hand side belongs to  $PR$  by the invariance of  $PR$  and the assumptions. Therefore, we have  $L_{\tilde{g}_l} \tilde{H} - L_{\tilde{g}'_l} \tilde{H}' \in PR$ , which means that condition (4.1) also holds for  $k + 1$ .

Next, we derive an explicit expression for  $v_i$  from the conditions  $L_{v_i} \mathcal{L}_{\tilde{\Sigma}} \subset PR$  and  $L_{v_i} PR \subset PR$ . The conditions mean that, for any  $\tilde{H} \in \mathcal{L}_{\tilde{\Sigma}}$  and any  $s \in PR$ , we have

$$d\tilde{H}(v_i) = \frac{\partial \tilde{H}}{\partial \tilde{x}} v_i \in PR, \quad ds(v_i) = \frac{\partial s}{\partial \tilde{x}} v_i \in PR,$$

or, equivalently,

$$\begin{aligned}\alpha^*(d\tilde{H}(v_i)) &= \underline{\alpha}^*(d\tilde{H})(\bar{\alpha}^*(v_i)) = 0, \\ \alpha^*(ds(v_i)) &= \underline{\alpha}^*(ds)(\bar{\alpha}^*(v_i)) = 0.\end{aligned}$$

That is,

$$\bar{\alpha}^*(v_i) \in \text{Ker } \underline{\alpha}^*(d\tilde{H}), \quad \bar{\alpha}^*(v_i) \in \text{Ker } \underline{\alpha}^*(ds).$$

Therefore,

$$\begin{aligned}\bar{\alpha}^*(v_i) &\in \bigcap_{\tilde{H} \in \mathcal{L}_{\tilde{\Sigma}}} \text{Ker } \underline{\alpha}^*(d\tilde{H}) = \text{Ker } \underline{\alpha}^*(d\mathcal{L}_{\tilde{\Sigma}}), \\ \bar{\alpha}^*(v_i) &\in \bigcap_{s \in PR} \text{Ker } \underline{\alpha}^*(ds) = \text{Ker } \underline{\alpha}^*(d(PR)),\end{aligned}$$

and, moreover,

$$\bar{\alpha}^*(v_i) \in \text{Ker } \underline{\alpha}^*(d\mathcal{L}_{\tilde{\Sigma}}) \cap \text{Ker } \underline{\alpha}^*(d(PR)) = \text{Ker } \underline{\alpha}^*(d\mathcal{L}_{\tilde{\Sigma}} \cup d(PR)),$$

which is equivalent to  $v_i \in \bar{\alpha}^{*-1}(\text{Ker } \underline{\alpha}^*(d\mathcal{L}_{\tilde{\Sigma}} \cup d(PR)))$ .  $\square$

*Example 4.1.* Consider  $\Sigma$  in Example 3.1, which is invariantly immersible with  $\alpha$  into system  $\tilde{\Sigma}$  over the local ring  $\mathbf{R}[\tilde{x}]_P$ . Theorem 4.1 implies that all RSRs into which  $\Sigma$  is invariantly immersible with  $\alpha$  are parameterized as

$$(4.2) \quad \tilde{\Sigma}' \left\{ \begin{array}{l} \begin{bmatrix} \dot{\tilde{x}}_1 \\ \dot{\tilde{x}}_2 \\ \dot{\tilde{x}}_3 \end{bmatrix} = \begin{bmatrix} \tilde{x}_2/\tilde{x}_1 + v_{01}(\tilde{x}) \\ \tilde{x}_2\tilde{x}_3/\tilde{x}_1 + v_{02}(\tilde{x}) \\ -\tilde{x}_2^2/\tilde{x}_1 + v_{03}(\tilde{x}) \end{bmatrix}, \\ y = \tilde{x}_1 + r(\tilde{x}), \end{array} \right.$$

where  $v_{01}$ ,  $v_{02}$ ,  $v_{03}$ , and  $r$  belong to  $PR[\tilde{x}]_P$ . It can readily be shown that  $PR[\tilde{x}]_P$  is also the invariant ideal of  $\tilde{\Sigma}'$ .

In order to demonstrate Theorems 4.2 and 4.3, let us consider another mapping  $\beta(x) = [x, \sin x, \cos x, \tan x]^T$ . It is straightforward to show that  $\mathbf{R}(\mathcal{O}_{\Sigma}) = \mathbf{R}(\beta)$  and that  $\beta$  is an invariant immersion of  $\Sigma$  into the following RSR,  $\bar{\Sigma}(\bar{g}_0, \bar{h})$ :

$$\bar{\Sigma} \left\{ \begin{array}{l} \begin{bmatrix} \dot{\bar{x}}_1 \\ \dot{\bar{x}}_2 \\ \dot{\bar{x}}_3 \\ \dot{\bar{x}}_4 \end{bmatrix} = \begin{bmatrix} \bar{x}_2/\bar{x}_1 \\ \bar{x}_2\bar{x}_3/\bar{x}_1 \\ -\bar{x}_2^2/\bar{x}_1 \\ \bar{x}_2/(\bar{x}_1\bar{x}_3^2) \end{bmatrix}, \\ y = \bar{x}_1. \end{array} \right.$$

The relation ideal of  $\beta$  is  $\bar{P} = (\bar{x}_2^2 + \bar{x}_3^2 - 1, \bar{x}_2 - \bar{x}_3\bar{x}_4) \subset \mathbf{R}[\bar{x}]$ , and the maximal ideal  $\bar{P}\mathbf{R}[\bar{x}]_{\bar{P}}$  is an invariant ideal of  $\bar{\Sigma}$ . For  $\bar{v} \in \bar{P}\mathbf{R}[\bar{x}]_{\bar{P}}^4$  and  $\bar{r} \in \bar{P}\mathbf{R}[\bar{x}]_{\bar{P}}$ , all the conditions in Theorems 4.1, 4.2, and 4.3 hold, and  $\beta$  is an invariant immersion of  $\Sigma$  into an RSR  $\bar{\Sigma}'(\bar{g}_0 + \bar{v}, \bar{h} + \bar{r})$ .

If  $\bar{v} = [0, 0, 0, \bar{v}_4]^T$  with  $\bar{v}_4 \in \mathbf{R}[\bar{x}]_{\bar{P}}$  and  $\bar{r} \in PR[\bar{x}]_P \cap \mathbf{R}(\bar{x}_1, \bar{x}_2, \bar{x}_3)$ , the conditions in Theorem 4.2 hold, while the conditions in Theorems 4.1 and 4.3 do not hold. In

fact,  $\bar{v} \notin \bar{P}\mathbf{R}[\bar{x}]_{\bar{P}}^4$  implies that  $\beta$  is not an invariant immersion but an immersion into  $\bar{\Sigma}'(\bar{g}_0 + \bar{v}, \bar{h} + \bar{r})$ . Moreover,  $\bar{P}\mathbf{R}[\bar{x}]_{\bar{P}}$  is not invariant with respect to the Lie derivative along  $\bar{v}$ , which implies that Theorem 4.3 is not applicable. In summary, Theorem 4.2 allows an immersion that is not an invariant immersion, and there is a gap between the necessary and sufficient conditions in Theorem 4.2 and the sufficient conditions in Theorem 4.3.

**5. Conclusion.** In this paper, some algebraic structures and their geometric counterparts in nonlinear systems over rings obtained by immersion have been discussed. In a system over a ring, vector fields are viewed as elements of a free module rather than as sections of a tangent bundle, and an important algebraic structure is the invariance of an ideal under the Lie derivative, which corresponds to the invariance of an affine variety. In particular, it has been shown that the relation ideal of an invariant immersion is an invariant ideal of a system over a ring obtained by that immersion, and all systems over a ring obtained via the same invariant immersion can be parameterized with the relation ideal. In the case of general immersions that are not necessarily invariant immersions, it has also been shown in this paper that the degrees of freedom in systems over a ring correspond to a generalization of the output invariance. Aside from immersion-related problems, the notions of nonlinear systems over rings, an invariant ideal, and an invariant variety can be used as fundamental tools for the analysis and control of rational or polynomial systems.

## CONVEX DUALITY AND ENTROPY-BASED MOMENT CLOSURES: CHARACTERIZING DEGENERATE DENSITIES\*

CORY D. HAUCK<sup>†</sup>, C. DAVID LEVERMORE<sup>‡</sup>, AND ANDRÉ L. TITS<sup>§</sup>

**Abstract.** A common method for constructing a function from a finite set of moments is to solve a constrained minimization problem. The idea is to find, among all functions with the given moments, that function which minimizes a physically motivated, strictly convex functional. In the kinetic theory of gases, this functional is the kinetic entropy; the given moments are macroscopic densities; and the solution to the constrained minimization problem is used to formally derive a closed system of partial differential equations which describe how the macroscopic densities evolve in time. Moment equations are useful because they simplify the kinetic, phase-space description of a gas, and with entropy-based closures, they retain many of the fundamental properties of kinetic transport. Unfortunately, in many situations, macroscopic densities can take on values for which the constrained minimization problem does not have a solution. Essentially, this is because the moments are not continuous functionals with respect to the  $L^1$  topology. In this paper, we give a geometric description of these so-called *degenerate densities* in the most general possible setting. Our key tool is the complementary slackness condition that is derived from a dual formulation of a minimization problem with relaxed constraints. We show that the set of degenerate densities is a union of convex cones and, under reasonable assumptions, that this set is small in both a topological and a measure-theoretic sense. This result is important for further assessment and implementation of entropy-based moment closures.

**1. Introduction.** In gas dynamics, the kinetic description of a gas is often simplified by using moment equations. In this reduced setting, a gas is characterized by a finite-dimensional vector  $\rho$  of densities that are moments of the kinetic distribution function  $F$  with respect to polynomials of the microscopic velocity. Evolution equations for  $\rho$  are derived by taking moments of the Boltzmann equation which governs the evolution of  $F$ . The derivation requires that an approximation for  $F$  be reconstructed from the densities  $\rho$ , giving what is called a *closure*.

One well-known method for prescribing a closure is to find a function that minimizes the kinetic entropy subject to the constraint that its moments agree with  $\rho$ . Such closures are called *entropy-based closures*. In recent years, they have generated substantial interest due to important structural properties which they inherit from the Boltzmann equation. These properties were first brought to light in [24].

In cases where the moments are continuous with respect to the relevant topology, there is always an entropy minimizer [6, 21]. Unfortunately, in classical gas dynamics, this is not usually the case. As a result, there are often physically relevant densities for which the constrained entropy minimization problem does not have a solution. In such cases, entropy-based closures are not well-defined, and these densities are called *degenerate*. In this paper, we provide a geometric description for the set of degenerate densities in the most general possible setting. We believe that this description is an important step in assessing the practical usefulness of entropy-based closures.

**1.1. Moment systems and entropy-based closures.** Consider a gas that is enclosed in a container, represented mathematically by the set  $\Omega \subset \mathbb{R}^d$  (typically  $d = 3$ ). The kinetic distribution function  $F = F(v, x, t)$  which describes the kinetic state of the gas is a nonnegative function that is defined for positions  $x \in \Omega$ , velocities  $v \in \mathbb{R}^d$ , and times  $t \geq 0$  so that, for any measurable set  $\Lambda \subset \Omega \times \mathbb{R}^d$ ,

$$(1) \quad \int_{\Lambda} F(v, x, t) \, dv dx$$

gives the number of particles at time  $t$  with positions  $x$  and velocities  $v$  such that  $(v, x) \in \Lambda$ . The evolution of  $F$  is governed by the Boltzmann transport equation

$$(2) \quad \partial_t F + v \cdot \nabla_x F = \mathcal{C}(F),$$

where  $\mathcal{C}$  is an integral operator that describes the collisions between particles which drive the system to local thermal equilibrium.

Solutions of (2) formally satisfy the local balance law [9]

$$(3) \quad \partial_t \mathcal{H}(F) + \nabla_x \cdot \mathcal{J}(F) = \mathcal{S}(F),$$

where the functionals

$$(4) \quad \mathcal{H}(g) \equiv \langle g \log(g) - g \rangle \quad \text{and} \quad \mathcal{J}(g) \equiv \langle v(g \log(g) - g) \rangle$$

are the *kinetic entropy* and *kinetic entropy flux*, respectively, and

$$(5) \quad \mathcal{S}(g) \equiv \langle \log(g) \mathcal{C}(g) \rangle$$

is the *kinetic entropy dissipation*. Here and throughout this paper,  $\langle \cdot \rangle$  denotes Lebesgue integration over all  $v \in \mathbb{R}^d$ , and we assume for the moment that the integrals in (4) and (5) are well-defined. According to Boltzmann's "H-theorem" [9],

$$(6) \quad \mathcal{S}(g) \leq 0,$$

with equality if and only if  $\mathcal{C}(g) = 0$ . In such cases,  $g$  is said to be in a state of local thermal equilibrium, and it takes the form of a Maxwellian distribution

$$(7) \quad \mathcal{M}_{\rho, u, \theta}(v) \equiv \frac{\rho}{(2\pi\theta)^{d/2}} \exp\left(-\frac{|v - u|^2}{2\theta}\right),$$

where  $\rho$  and  $\theta$  are positive scalars and  $u \in \mathbb{R}^d$ . In this way,  $\mathcal{H}$  acts as a Lyapunov functional for (2).

In order to reduce computational cost, the kinetic description of a gas provided by  $F$  is often simplified by retaining only a finite number of its velocity averages,

or *moments*. Equations which govern the evolution of these moments are derived by integrating (2) with respect to a vector

$$(8) \quad \mathbf{m} = (m_0, \dots, m_{n-1})^T$$

whose components are polynomials in  $v$ . Since  $v$  commutes with the spatial gradient, these equations take the form

$$(9) \quad \partial_t \boldsymbol{\rho} + \nabla_x \cdot \langle v \mathbf{m} F \rangle = \langle \mathbf{m} \mathcal{C}(F) \rangle,$$

where the moments

$$(10) \quad \boldsymbol{\rho} = \boldsymbol{\rho}(x, t) \equiv \langle \mathbf{m} F \rangle$$

are the *spatial densities* associated with  $F$ . Here again, we assume that the integrals in (9) and (10) are well-defined.

In general, (9) is not a closed system because there is no way to express the flux terms  $\langle v \mathbf{m} F \rangle$  and collision terms  $\langle \mathbf{m} \mathcal{C}(F) \rangle$  in terms of  $\boldsymbol{\rho}$ . Furthermore, in a moment description, an exact expression for  $F$  is not available. An alternative is to approximate  $F$  by an ansatz of the form

$$(11) \quad \mathcal{F}[\boldsymbol{\rho}] = \mathcal{F}(v, \boldsymbol{\rho}(x, t)).$$

By substituting  $\mathcal{F}$  for  $F$  in (9), the evolution of  $\boldsymbol{\rho}$  can be approximated by the closed system of balance laws

$$(12) \quad \partial_t \boldsymbol{\rho} + \nabla_x \cdot \mathbf{f}(\boldsymbol{\rho}) = \mathbf{c}(\boldsymbol{\rho}),$$

where the flux term  $\mathbf{f}$  and collision term  $\mathbf{c}$  are given by

$$(13) \quad \mathbf{f}(\boldsymbol{\rho}) = \langle v \mathbf{m} \mathcal{F}[\boldsymbol{\rho}] \rangle \quad \text{and} \quad \mathbf{c}(\boldsymbol{\rho}) = \langle \mathbf{m} \mathcal{C}(\mathcal{F}[\boldsymbol{\rho}]) \rangle.$$

One way to specify  $\mathcal{F}$  is to invoke the principle of entropy minimization (or maximization in the physics community, where the term “entropy” refers to  $-\mathcal{H}$  and has been widely used for over a century). The probabilistic interpretation of entropy dates back to Boltzmann [4, 5], who argued that the entropy of a system of identical particles depends on the number of microstates (particle arrangements in phase space) that are consistent with the macroscopic state of the system. This dependence is expressed by the famous logarithmic relationship known as *Boltzmann’s entropy formula* [8] (and also as Boltzmann’s equation, although distinct from (2)) and was first presented in its popular form by Planck [28, 29]. The practical application of entropy as a tool for statistical inference was championed by Jaynes although, in [19], Jaynes himself attributes the original mathematical concepts to Gibbs, who generalized Boltzmann’s entropy formula [16]. Jaynes also credits Shannon [32] for illuminating the central role that entropy plays in the theory of information. The relationship between statistics and information theory was further pursued by Kullback [23]. Many of the first rigorous results concerning entropy minimization can be found in [10] and references therein.

Closures which are based on the entropy minimization principle use the ansatz

$$(14) \quad \mathcal{F}[\boldsymbol{\rho}] = \arg \min_{g \in \mathbb{F}_{\mathbf{m}}} \{ \mathcal{H}(g) : \langle \mathbf{m} g \rangle = \boldsymbol{\rho} \}$$

at each  $x$  and  $t$  to formally close (9). Here

$$(15) \quad \mathbb{F}_{\mathbf{m}} \equiv \{g \in L^1(\mathbb{R}^d) : g \geq 0 \text{ and } |\mathbf{m}g| \in L^1(\mathbb{R}^d)\},$$

and  $|\cdot|$  is the standard Euclidean norm.

It is readily checked that  $\mathcal{H}$  is strictly convex over  $\mathbb{F}_{\mathbf{m}}$ . Thus if the minimizer in (14) exists, it is unique and the closure is well-defined. In such cases, (12) is a hyperbolic system of PDEs whose solutions satisfy the local dissipation law

$$(16) \quad \partial_t h(\boldsymbol{\rho}) + \nabla_x \cdot j(\boldsymbol{\rho}) = s(\boldsymbol{\rho}),$$

where

$$(17) \quad h(\boldsymbol{\rho}) \equiv \mathcal{H}(\mathcal{F}[\boldsymbol{\rho}])$$

is a strictly convex function of  $\boldsymbol{\rho}$  and

$$(18) \quad j(\boldsymbol{\rho}) \equiv \mathcal{J}(\mathcal{F}[\boldsymbol{\rho}]), \quad s(\boldsymbol{\rho}) \equiv \mathcal{S}(\mathcal{F}[\boldsymbol{\rho}]) \leq 0.$$

Although any choice for the ansatz  $\mathcal{F}[\boldsymbol{\rho}]$  will yield a system of the form (12), the entropy ansatz ensures that  $s(\boldsymbol{\rho}) \leq 0$  and that  $h$  is strictly convex. These conditions are important for two reasons. First, the dissipation law for a strictly convex function of  $\boldsymbol{\rho}$ , as given by (16), implies the existence of a well-posed linear  $L^2$  (Hilbert space) theory for (12) [33]. Second,  $h$  acts as a Lyapunov function for (12). To see this, note that (16) is simply (3) evaluated at  $F = \mathcal{F}[\boldsymbol{\rho}]$ ; and like in Boltzmann's H-theorem,  $s(\boldsymbol{\rho})$  vanishes if and only if  $\mathcal{C}(\mathcal{F}[\boldsymbol{\rho}]) = 0$ , in which case  $\mathcal{F}[\boldsymbol{\rho}]$  takes the form of a Maxwellian distribution [24].

The entropy minimization procedure yields an entire hierarchy of systems with the aforementioned properties whose members are generated by appending an initial choice of  $\mathbf{m}$  with additional polynomial components. For this reason, entropy-based closures have been applied to other areas of kinetic theory such as radiation transport [12, 13] and charge transport in semiconductors [1, 11, 22]. (Additional references for charge transport can be found in [1].) In the case of gas dynamics, the moment hierarchy begins with the canonical choice  $\mathbf{m} = (1, v, \frac{1}{2}|v|^2)^T$ . For this choice,  $\mathcal{F}[\boldsymbol{\rho}]$  is always a Maxwellian, and the entropy-based closure generates Euler's equations for a compressible gas.

**1.2. Realizability and degenerate densities.** A density  $\boldsymbol{\rho}$  is said to be *realized* by a function  $g \in \mathbb{F}_{\mathbf{m}}$  if  $\boldsymbol{\rho} = \langle \mathbf{m}g \rangle$ . The set of all such *realizable* densities will be denoted by  $\mathcal{R}_{\mathbf{m}}$ . An entropy-based closure is applicable only to those realizable densities for which the minimization problem (14) with equality constraints has a solution. If the moments in (14) were continuous with respect to the  $L^1$  topology, then there would always be a minimizer. Indeed, for such cases, Borwein and Lewis have shown in [6] that a constrained minimizer exists for a large class of convex functionals that include the classical entropy  $\mathcal{H}$ . However, in gas dynamics, the moments are typically *not continuous* in the  $L^1$  topology. As a result, there are realizable densities for which the minimizer in (14) does not exist. For such densities, which we term *degenerate*, modifications must be made to the entropy-based procedure. There are essentially two approaches:

1. Show that the set of nondegenerate densities is invariant under the dynamics of the balance law (12) with the entropy-based closure (as discussed in [20]) or impose such a condition in a way that is physically reasonable and mathematically justifiable.

2. Develop a modified closure that (i) is well-posed for *all* physically realizable values of  $\rho$ , (ii) recovers the minimum entropy-based closures whenever the minimizer in (14) exists, and (iii) generates systems of hyperbolic PDEs that dissipate a physically meaningful, convex entropy. This is the approach taken in [31].

We define  $\mathcal{D}_{\mathbf{m}}$  to be the set of all degenerate densities. In general, the set  $\mathcal{D}_{\mathbf{m}}$  depends on  $\mathbf{m}$ , and understanding its geometry is critical to determining whether entropy-based closures can be used in practice. In either of the modified approaches listed above, it is important—at the very least—to show that  $\mathcal{D}_{\mathbf{m}}$  is small in some sense, thereby minimizing the number of physically realizable spatial densities which require special treatment. In the first approach, this means limiting the number of initial conditions which must be discarded; in the second, it means limiting the number of physically realizable densities which require a modified closure.

Another reason to study  $\mathcal{D}_{\mathbf{m}}$  is that the equilibrium densities, i.e., those densities which are moments of a Maxwellian distribution (7), lie on its boundary [20, 21, 24, 31]. Because the kinetic entropy drives solutions of (3) toward local thermal equilibrium, we expect that trajectories defined by solutions to (16) will, at times, come very close to  $\mathcal{D}_{\mathbf{m}}$ . Thus it is very important to have a detailed understanding of its geometry.

Previous studies of the set  $\mathcal{D}_{\mathbf{m}}$  can be found in [20, 21, 31]. In [20], Junk provides a geometric description for  $\mathcal{D}_{\mathbf{m}}$  in a one-dimensional setting ( $d = 1$ ) with  $\mathbf{m} = (1, v, v^2, v^3, v^4)^T$ . It turns out in this case that  $\mathcal{D}_{\mathbf{m}}$  is a codimension one manifold. This result was discovered, in part, by extending the definition of  $h$  given by (18) to include cases where the minimizer in (14) does not exist. This is done simply by replacing the minimum in (14) with an infimum, viz.,

$$(19) \quad h_J(\rho) \equiv \inf_{g \in \mathbb{F}_{\mathbf{m}}} \{\mathcal{H}(g) : \langle \mathbf{m}g \rangle = \rho\}.$$

Later, in [21], Junk considers a more general case in which  $\mathbf{m}$  consists of a radial component  $|v|^N$ , for some even integer  $N \geq 2$ , plus polynomial components of lower degree. For such cases, he provides an integrability condition to determine whether  $\mathcal{D}_{\mathbf{m}}$  is nonempty. In practice, this condition is easily checked and extensible to more general choices of  $\mathbf{m}$ . However, a description of the geometry of  $\mathcal{D}_{\mathbf{m}}$ , as given in [20], is still lacking for the general setting.

In [31], Schneider introduces a different extension for  $h$  by relaxing the constraints in (14):

$$(20) \quad h_S(\rho) \equiv \min_{g \in \mathbb{F}_{\mathbf{m}}} \{\mathcal{H}(g) : \langle \mathbf{m}g \rangle \preceq^{\circ} \rho\}.$$

Here the notation  $\langle \mathbf{m}g \rangle \preceq^{\circ} \rho$  means—roughly speaking—that inequalities between certain components are allowed. (See section 3.2 for a precise definition.) The key difference between (14) and (20) is that the constraint set of the latter is closed in the weak- $L^1(\mathbb{R}^d)$  topology, whereas the constraint set of the former is not. Schneider uses this fact to prove that the minimizer in (20) with relaxed constraints always exists and is equal to the minimizer with equality constraints (14) when that minimizer exists (see our Theorem 3 and Corollary 4 below). In doing so, he provides a necessary and sufficient condition to determine whether a given density  $\rho$  is an element of  $\mathcal{D}_{\mathbf{m}}$ . However, this condition gives little insight into the geometry of  $\mathcal{D}_{\mathbf{m}}$ .

The main contribution of the present paper is a geometrical description of the set  $\mathcal{D}_{\mathbf{m}}$  in the most general possible setting. Our results are based on a dual formulation of (20) and are summarized in the following theorems.

- In Theorems 14 and 16, we prove strong duality for both the equality constraint problem (19) and the relaxed constraint problem (20). One consequence of these theorems is that  $h_S = h_J$ , even when the infimum in (20) is not attained. In Theorem 14, we also prove *complementary slackness conditions* which relate the density  $\rho$  in (20) to the dual variable and serve as the basis of our geometrical description.
- In Theorem 25, we show that the set  $\mathcal{D}_{\mathbf{m}}$  is a union of convex cones. The vertices of these cones are *nondegenerate* densities that lie on the boundary between the degenerate and nondegenerate densities in  $\mathcal{R}_{\mathbf{m}}$ . This conical description is based on the complementary slackness condition from Theorem 14.
- In Theorem 28, we show that, under reasonable assumptions, the set  $\mathcal{D}_{\mathbf{m}}$  is a nowhere dense subset of  $\mathcal{R}_{\mathbf{m}}$  that has Lebesgue measure zero and is restricted to the boundary of the nondegenerate, realizable densities. The assumptions we employ hold in all known cases. Whether they hold in general is an interesting and (to our knowledge) open question in analysis and algebraic geometry.

In the process of investigating  $\mathcal{D}_{\mathbf{m}}$ , we also recover and extend many previous results from both [20, 21] and [31].

The organization of the paper is as follows. In section 2 we introduce some notation and background information. In section 3 we review the entropy minimization problem. In section 4 we give a dual formulation of the minimization problem with relaxed constraints (20) and prove duality theorems for both (19) and (20). We use these theorems to show that  $h_S = h_J$  (even when the infimum in (19) is not attained) and to establish a complementary slackness condition. In section 5 we review the formal structure of entropy-based closures for nondegenerate densities and determine how that structure differs for degenerate cases. In section 6 we use the complementary slackness condition to describe the geometry of  $\mathcal{D}_{\mathbf{m}}$ . We then introduce the assumptions that allow us to make further assertions about the “smallness” of  $\mathcal{D}_{\mathbf{m}}$ . At the end of the section, we present two examples. In section 7 we give conclusions and discuss future work. Finally, in the appendix we provide a diagram and tables to assist the reader with notation.

**2. Preliminaries.** In this section, we introduce notation and present preliminary results. We refer the reader to the appendix for help in recalling the notation and useful properties for sets and mappings given throughout the paper.

**2.1. Admissible spaces.** For a given moment system, the choice of  $\mathbf{m}$  must satisfy criteria based on physical considerations. We require that components of  $\mathbf{m}$  form a basis for an  $n$ -dimensional linear space  $\mathbb{M}$  of multivariate polynomials over the field of real numbers that satisfies the following conditions:

- I.  $\mathbb{M} \supset \text{span}\{1, v_1, \dots, v_d, |v|^2\}$ ;
- (21) II.  $\mathbb{M}$  is invariant under translation and rotation;
- III. the set  $\mathbb{M}_c \equiv \{p \in \mathbb{M} : \langle |p| \exp(p) \rangle < \infty\}$  has a nonempty interior.

Our definition of  $\mathbb{M}_c$  is slightly different than the original definition given in [24]. However, its interior is the same under both definitions.

Spaces that satisfy conditions I–III are called *admissible*. According to condition I, any set of moment equations will incorporate the conservation laws for mass, momentum, and energy which are given by the moments of the kinetic distribution

function with respect to  $1$ ,  $v$ , and  $\frac{1}{2}|v|^2$ , respectively. In condition II, invariance under translation and rotation means that, for every  $u \in \mathbb{R}^d$  and every orthogonal matrix  $O$ , the mappings  $v \mapsto v - u$  and  $v \mapsto O^T v$  map  $\mathbb{M}$  onto itself. These properties will ensure that the moment equations are Galilean invariant—that is, invariant under the transformations  $x \mapsto x - ut$  and  $x \mapsto O^T x$ . Condition III applies specifically to entropy-based closures. It turns out that the minimizer (14), if it exists, has the form  $e^p$ , where  $p \in \mathbb{M}_c$ . Hence a nonempty interior for  $\mathbb{M}_c$  is a necessary requirement for any practical applications.

Typically an admissible space  $\mathbb{M}$  is generated by the span of polynomial functions whose moments are physical quantities of specific interest. (Here the canonical examples are the polynomials  $1$ ,  $v$ , and  $\frac{1}{2}|v|^2$ .) It may be that additional polynomial components are added to  $\mathbf{m}$  to ensure that  $\mathbb{M}$  is admissible. It should be noted that the vector  $\mathbf{m}$  that generates a given  $\mathbb{M}$  is not unique.

For convenience, we will assume, without loss of generality, that the components of  $\mathbf{m}$  are homogeneous. We decompose  $\mathbf{m}$  into subvectors:

$$(22) \quad \mathbf{m} = (\mathbf{m}_0^T, \mathbf{m}_1^T, \mathbf{m}_2^T, \dots, \mathbf{m}_N^T)^T,$$

where the  $n_j$  components of  $\mathbf{m}_j$  are the  $j$ th degree polynomial components of  $\mathbf{m}$ . Consistency requires that  $\sum_{j=0}^N n_j = n$ . Any polynomial  $p \in \mathbb{M}$  can be expressed as the sum of its homogeneous components:

$$(23) \quad p = \boldsymbol{\alpha}^T \mathbf{m} = \sum_{j=1}^N \boldsymbol{\alpha}_j^T \mathbf{m}_j,$$

where  $\boldsymbol{\alpha} \in \mathbb{R}^n$  is a vector of constant coefficients that decomposes into subvectors

$$(24) \quad \boldsymbol{\alpha} = (\boldsymbol{\alpha}_0^T, \boldsymbol{\alpha}_1^T, \boldsymbol{\alpha}_2^T, \dots, \boldsymbol{\alpha}_N^T)^T.$$

We briefly outline how one can generate a space  $\mathbb{M}$ . Given the even integer  $N \geq 2$  and  $j < N$ , let  $\mathbb{Q}_j$  be the space of all homogeneous polynomials from  $\mathbb{R}^d$  to  $\mathbb{R}$  of degree  $j$ . For each  $j$ ,  $\mathbb{Q}_j$  can be composed into rotationally invariant subspaces in the following way [15, Corollary 2.60]:

$$(25) \quad \mathbb{Q}_j = \begin{cases} \mathbb{H}_j \oplus |v|^2 \mathbb{H}_{j-2} \oplus |v|^4 \mathbb{H}_{j-4} \oplus \dots \oplus |v|^j \mathbb{H}_0, & j \text{ even,} \\ \mathbb{H}_j \oplus |v|^2 \mathbb{H}_{j-2} \oplus |v|^4 \mathbb{H}_{j-4} \oplus \dots \oplus |v|^{j-1} \mathbb{H}_1, & j \text{ odd.} \end{cases}$$

Here  $\mathbb{H}_k$  is the space of harmonic polynomials of degree  $k$  given by

$$(26) \quad \mathbb{H}_k = |v|^k \text{span} \left\{ Y^k \left( \frac{v}{|v|} \right) \right\},$$

and  $Y^k$  maps vectors on the unit sphere  $\mathbb{S}^{d-1}$  to the  $k$ -fold spherical harmonic tensor, which is unique modulo constant multiples. (Here the term “span” refers to all real linear combinations of the scalar components of the tensor.)

The decomposition in (25) is unique in the sense that no proper subset of the subspaces in (25) is rotationally invariant [15]. Thus, in order to be rotationally invariant, an admissible space  $\mathbb{M}$  must be a direct sum of some combination of the subspaces in (25) taken from each  $\mathbb{Q}_j$ ,  $j \leq N$ . In addition, the condition of translational invariance implies that choices for larger values of  $j$  will directly affect choices for smaller values

of  $j$ . For example, inclusion of the term  $|v|^j$  requires inclusion of the lower degree terms in the expansion of  $|v - u|^j$ .

To satisfy condition III,  $\mathbb{M}$  must include polynomials from  $\mathbb{Q}_N$  which dominate the behavior of odd degree polynomials of lower degree for large  $|v|$ . In particular,  $\mathbb{M}$  must include multiples of  $|v|^N$ . This is because spherical harmonics (both odd and even) other than  $Y^0 \equiv 1$  take on both positive and negative values on the unit sphere. Excluding  $|v|^N$  would therefore lead to polynomials  $p$ , all of which satisfy  $\lim_{r \rightarrow \infty} p(r\omega) = \infty$  for all  $\omega$  contained in some subset of  $\mathbb{S}^{d-1}$  with positive Lebesgue measure. In such cases  $\exp(p)$  is not integrable for any  $p \in \mathbb{M}$ , and condition III is violated.

In applications it is sometimes convenient to represent components of  $\mathbf{m}$  in tensor format. There are two reasons for this. The first reason is the convenience with which one can express  $\mathbf{m}$  given (25) and (26). The second reason is that the evolution of the moment of  $\langle TF \rangle$  for any  $j$ -fold tensor  $T = T(v)$  depends on the divergence of the  $(j + 1)$ -fold tensor  $\langle vTF \rangle$  (refer to (9)).

The tensors in which we are interested are often symmetric and sometimes traceless. For example, the Gaussian closure which will be described in section 5.3 is based on the vector

$$(27) \quad \mathbf{m} = \begin{pmatrix} \mathbf{m}_0 \\ \mathbf{m}_1 \\ \mathbf{m}_2 \end{pmatrix} = \begin{pmatrix} 1 \\ v \\ v \vee v \end{pmatrix} = \begin{pmatrix} 1 \\ v \\ (v \vee v - \frac{1}{3}|v|^2 I) + \frac{1}{3}|v|^2 I \end{pmatrix},$$

where  $v \vee v$  is the symmetric tensor product of  $v$  with itself.<sup>1</sup> In the strict vector representation,  $\mathbf{m}_2$  is composed only of the  $d(d+1)/2$  linearly independent components of the tensor  $v \vee v$ . The components have the form  $v_i v_j$ , where  $1 \leq i \leq d$  and  $i \leq j \leq d$ .

Vectors  $\alpha \in \mathbb{R}^n$  can also be represented by tensors, in which case the product in (23) is interpreted as a sum of tensor inner products.<sup>2</sup> For a given a polynomial  $p$ , the tensor form of  $\alpha$  in (23) is unique under the additional requirement that it has the same symmetry properties as  $\mathbf{m}$ .

**2.2. Cones.** Many of the sets that we will encounter in this paper are cones [3, 30]. A subset  $C$  of  $\mathbb{R}^k$  is a *cone* if, for all real numbers  $\lambda > 0$ ,  $y \in C$  if and only if  $\lambda y \in C$ . A cone is *solid* if it has a nonempty interior. A closed cone  $C$  is *pointed* if  $-C \cap C$  is the origin. A closed cone that is convex, pointed, and solid is called *proper*. For example, the set  $\mathbb{F}_{\mathbf{m}}$  is a solid, convex cone, whose closure in  $L^1(\mathbb{R}^d)$  is proper. Several other cones will be introduced in the subsections that follow, and eventually we will see that the set  $\mathcal{D}_{\mathbf{m}}$  is also a cone.

Associated with every cone  $C$  is its polar cone<sup>3</sup>

$$(28) \quad C^\circ \equiv \{z \in \mathbb{R}^k : z^T y \leq 0 \quad \forall y \in C\}.$$

It is readily checked that the polar of a proper cone is proper.

A vector  $z \in \mathbb{R}^k$  is *tangent* to a subset  $\Omega \subset \mathbb{R}^k$  at a point  $y \in \Omega$  if  $z = 0$  or if

$$(29) \quad \lim_{j \rightarrow \infty} \frac{y_j - y}{|y_j - y|} = \frac{z}{|z|}$$

<sup>1</sup>Given a symmetric  $j$ -fold tensor  $S$  and a symmetric  $k$ -fold tensor  $T$ , the symmetric tensor product of  $S$  and  $T$  is  $S \vee T = T \vee S \equiv \frac{1}{(j+k)!} \sum_{\pi \in \Pi} S_{i_{\pi(1)}, \dots, i_{\pi(j)}} T_{i_{\pi(j+1)}, \dots, i_{\pi(j+k)}}$ , where  $\Pi$  is the set of all permutation of the integers  $1, \dots, j+k$ .

<sup>2</sup>For  $k > j$ , the symmetric inner product (or contraction) of a symmetric  $j$ -fold tensor  $S$  and a symmetric  $k$ -fold tensor  $T$  is  $(S \cdot T)_{i_{j+1}, \dots, i_{j+k}} \equiv \sum_{i_1, \dots, i_j} S_{i_1, \dots, i_j} T_{i_1, \dots, i_j, i_{j+1}, \dots, i_{j+k}}$ .

<sup>3</sup>The polar cone is the negative of the dual cone  $C^* \equiv \{z \in \mathbb{R}^k : z^T y \geq 0 \quad \forall y \in C\}$ .

for some sequence  $\{y_j\}_{j=1}^\infty \subset \Omega$  such that  $y_j \rightarrow y$ , but  $y_j \neq y$  for all  $j$ . The *tangent cone of  $\Omega$  at  $y$* , which we denote  $\mathcal{TC}(\Omega, y)$ , is the set of all vectors that are tangent to  $\Omega$  at  $y$ . A vector  $w \in \mathbb{R}^k$  is *normal* to  $\Omega$  at  $y \in \Omega$  if there exist sequences  $\{y_j\}_{j=1}^\infty \subset \Omega$  and  $\{w_j\}_{j=1}^\infty \subset \mathbb{R}^k$  such that

$$(30) \quad y_j \rightarrow y, \quad w_j \rightarrow w, \quad w_j \in (\mathcal{TC}(\Omega, y_j))^\circ \quad \forall j.$$

The *normal cone of  $\Omega$  at  $y$* , which we denote  $\mathcal{NC}(\Omega, y)$ , is the set of all vectors that are normal to  $\Omega$  at  $y$ . For the important case that  $\Omega$  is convex,

$$(31) \quad \mathcal{NC}(\Omega, y) = \{z \in \mathbb{R}^k : z^T(y' - y) \leq 0 \quad \forall y' \in \Omega\}.$$

In particular,  $\mathcal{NC}(\Omega, y)$  is convex. If  $\partial\Omega$  is a  $C^1$  (continuously differentiable) manifold containing  $y$ , then  $\mathcal{NC}(\Omega, y)$  is a ray with base point at the origin that points in the outward normal direction to  $\partial\Omega$  at  $y$ . More generally, given any  $C^1$  manifold  $M \ni y$  of dimension  $j$ ,  $\mathcal{NC}(M, y)$  is a subspace of dimension  $n - j$ . If  $M \subset \Omega$ , then  $\mathcal{NC}(\Omega, y) \subset \mathcal{NC}(M, y)$ . In sections 5.4 and 6.4, we will use the notation  $\mathcal{NC}_0(\Omega, y)$  to denote the normal cone without the origin:

$$(32) \quad \mathcal{NC}_0(\Omega, y) \equiv \mathcal{NC}(\Omega, y) \setminus \{0\}.$$

A particularly useful application of cones is to provide a partial ordering of elements in  $\mathbb{R}^k$  (or, more generally, in any vector space). Given a pointed, convex cone  $C$  and  $y_1$  and  $y_2$  in  $\mathbb{R}^k$ , we say that  $y_1 \leq_C y_2$ , or  $y_2 \geq_C y_1$ , if and only if  $y_2 - y_1 \in C$ .

**2.3. Realizable densities.** Our motivation for solving (14), (19), or (20) is to find a closure for the moment equations (9). Thus we are interested only in constraints based on densities which are realizable, i.e., elements of the set

$$(33) \quad \mathcal{R}_{\mathbf{m}} \equiv \{\rho \in \mathbb{R}^n : \rho = \langle \mathbf{m}g \rangle, g \in \mathbb{F}_{\mathbf{m}}\}.$$

With this notation we formally define the set  $\mathcal{D}_{\mathbf{m}}$ :

$$(34) \quad \mathcal{D}_{\mathbf{m}} \equiv \{\rho \in \mathcal{R}_{\mathbf{m}} : \text{the minimizer in (14) does not exist}\}.$$

A density  $\rho \in \mathcal{R}_{\mathbf{m}}$  has a natural decomposition based on the decomposition of  $\mathbf{m}$  in (22):

$$(35) \quad \rho = (\rho_0^T, \rho_1^T, \rho_2^T, \dots, \rho_N^T)^T,$$

where  $\rho_j = \langle \mathbf{m}_j g \rangle$  for some  $g \in \mathbb{F}_{\mathbf{m}}$ . The set  $\mathcal{R}_{\mathbf{m}}$  has several important properties, one of which is its relation to the cone

$$(36) \quad A_{\mathbf{m}} \equiv \{\alpha \in \mathbb{R}^n : \alpha^T \mathbf{m} \leq 0\}.$$

It is straightforward to verify that  $A_{\mathbf{m}}$  is a proper cone.

**THEOREM 1** (Junk [21]). *The set  $\mathcal{R}_{\mathbf{m}}$  is an open, convex, solid cone, and its closure is proper. In fact,  $\mathcal{R}_{\mathbf{m}} = \text{int } A_{\mathbf{m}}^\circ$ , and every vector in  $\mathcal{R}_{\mathbf{m}}$  is realized by a bounded, nonnegative function with compact support.*

*Proof.* We refer the reader to Theorem A.2 of [21] for a proof (which applies to the case  $\mathbf{m}_N = |v|^N$  but can be modified to the general case with little effort). However, to provide the reader with some intuition, we show here that  $\mathcal{R}_{\mathbf{m}} \subset \text{int } A_{\mathbf{m}}^\circ$ . Let  $\rho \in \mathcal{R}_{\mathbf{m}}$ . Then  $\rho = \langle \mathbf{m}g \rangle$  for some  $g \in \mathbb{F}_{\mathbf{m}}$  and according to (36)

$$(37) \quad \alpha^T \rho = \langle \alpha^T \mathbf{m}g \rangle \leq 0$$

for all  $\alpha \in A_{\mathbf{m}}$ . Further, since  $\alpha^T \mathbf{m}$  is a polynomial, it can be zero only on a set of zero Lebesgue measure. Hence  $\alpha^T \rho < 0$ , which proves that  $\rho \in \text{int } A_{\mathbf{m}}^\circ$ .  $\square$

**2.4. Exponentially realizable densities.** We will see below that the minimizer of (20) has the form

$$(38) \quad G_{\alpha} \equiv \exp(\alpha^T \mathbf{m}),$$

where  $\alpha$  solves the dual problem to (20). The integral of  $G_{\alpha}$  is the *density potential*

$$(39) \quad h^*(\alpha) \equiv \langle G_{\alpha} \rangle,$$

which was introduced in [25] as a tool for elucidating the formal structure of entropy-based closures. As the notation suggests,  $h^*$  is the Legendre dual of  $h$ . In section 5, we will discuss this relationship in more detail. The name “density potential” is derived from the fact that its formal derivative  $\mathbf{r}$  generates the moments of  $G_{\alpha}$ . Given the set

$$(40) \quad \mathcal{A}_{\mathbf{m}} \equiv \{\alpha \in \mathbb{R}^n : G_{\alpha} \in \mathbb{F}_{\mathbf{m}}\},$$

$\mathbf{r} : \mathcal{A}_{\mathbf{m}} \rightarrow \mathbb{R}^n$  is defined by

$$(41) \quad \mathbf{r}(\alpha) \equiv \langle \mathbf{m} G_{\alpha} \rangle.$$

It should be noted in (40) that the condition  $\alpha \in \mathcal{A}_{\mathbf{m}}$  is stronger than  $G_{\alpha} \in L^1(\mathbb{R}^d)$ , since the latter can still yield moments that are infinite. The image of  $\mathcal{A}_{\mathbf{m}}$  under  $\mathbf{r}$  is the set of *exponentially realizable densities*:

$$(42) \quad \mathcal{R}_{\mathbf{m}}^{\text{exp}} \equiv \mathbf{r}(\mathcal{A}_{\mathbf{m}}).$$

The set  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  is a solid cone. It need not be convex, nor is it necessarily open.

Since  $\mathbf{r}(\mathcal{A}_{\mathbf{m}}) = \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ , it is important to understand the structure of  $\mathcal{A}_{\mathbf{m}}$ . Its interior has a rather simple expression:

$$(43) \quad \text{int } \mathcal{A}_{\mathbf{m}} = \{\alpha \in \mathbb{R}^n : \alpha_N^T \mathbf{m}_N(v) < 0 \quad \forall v \neq 0\} = \{\alpha \in \mathbb{R}^n : \alpha_N \in \text{int } A_{\mathbf{m}_N}\},$$

where

$$(44) \quad A_{\mathbf{m}_j} \equiv \{\alpha_j \in \mathbb{R}^{n_j} : \alpha_j^T \mathbf{m}_j \leq 0\}, \quad 1 \leq j \leq N,$$

is a proper cone for  $j$  even. (It can be checked that condition III of section 2.1 is equivalent to  $\text{int } \mathcal{A}_{\mathbf{m}}$  being nonempty.) If  $\alpha \in \text{int } \mathcal{A}_{\mathbf{m}}$ , then the behavior of  $p = \alpha^T \mathbf{m}$  is dominated for large  $|v|$  by the homogeneous component  $p_N = \alpha_N^T \mathbf{m}_N$ , and

$$(45) \quad \lim_{|v| \rightarrow \infty} p(v) = \lim_{|v| \rightarrow \infty} p_N(v) = \lim_{|v| \rightarrow \infty} |v|^N p_N(v/|v|) = -\infty.$$

For such  $\alpha$ ,  $G_{\alpha}$  decays exponentially, and the moments  $\mathbf{r}(\alpha)$  are finite.

From (43), one can easily show that

$$(46) \quad \text{cl } \mathcal{A}_{\mathbf{m}} = \{\alpha \in \mathbb{R}^n : \alpha_N \in A_{\mathbf{m}_N}\} \quad \text{and} \quad \partial \mathcal{A}_{\mathbf{m}} \subset \{\alpha \in \mathbb{R}^n : \alpha_N \in \partial A_{\mathbf{m}_N}\}.$$

Even so, the boundary component  $\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$  is, in general, very complicated. If  $\alpha \in \partial \mathcal{A}_{\mathbf{m}}$ , then  $\alpha_N \in \partial A_{\mathbf{m}_N}$  and  $p_N(\lambda v) = 0$  for some  $v \neq 0$  and all  $\lambda \in \mathbb{R}$ , and it may be that there are unbounded sequences  $\{v_i\}_{i=1}^{\infty}$  such that  $\lim_{i \rightarrow \infty} p(v_i) > -\infty$ . In such cases, it is not clear whether the moments  $\mathbf{r}(\alpha)$  are finite, i.e., whether  $\alpha \in \mathcal{A}_{\mathbf{m}}$ . We will revisit this issue in section 6.3. For now, we turn our attention to the entropy minimization problem (20).

**3. Entropy minimization.** Most of this section reproduces and discusses the main result from [31]. In this setting, we then state Theorem 9, which is the basis for our new results.

**3.1. The entropy functional.** Recall that the strictly convex *entropy functional*  $\mathcal{H} : \mathbb{F}_{\mathbf{m}} \mapsto \mathbb{R} \cup \{\infty\}$  is given by

$$(47) \quad \mathcal{H}(g) \equiv \langle g \log g - g \rangle.$$

By employing the convention  $0 \log 0 = 0$ —which is consistent with the fact that  $\lim_{z \rightarrow 0} z \log z = 0$ —one can make sense of the integrand for those values of  $v$  where  $g(v) = 0$ . There are functions  $g \in \mathbb{F}_{\mathbf{m}}$  such that  $\mathcal{H}(g) = +\infty$ ; however, in order for  $\mathcal{H}(g)$  to be well-defined, the negative contribution to the integral  $\mathcal{H}^-(g)$  must be finite. We show that this is indeed the case.

LEMMA 2. *For each  $g \in \mathbb{F}_{\mathbf{m}}$ , let  $K_g = \{v \in \mathbb{R}^d : g(v) \log(g(v)) - g(v) < 0\}$ . Then*

$$(48) \quad \mathcal{H}^-(g) \equiv - \int_{K_g} (g(v) \log(g(v)) - g(v)) \, dv \leq \int_{\mathbb{R}^d} (|v|^2 g(v) + e^{-|v|^2}) \, dv.$$

*In particular,  $\mathcal{H}^-(g)$  is finite.*

The proof of this lemma is based on Young's inequality: For all  $z, y > 0$ ,

$$(49) \quad z \log z - z \geq y \log y - y + (\log y)(z - y)$$

or, equivalently,

$$(50) \quad z \log z - z \geq z \log y - y.$$

These two inequalities follow immediately from the convexity of the mapping  $z \mapsto z \log z - z$ .

*Proof.* Letting  $z = g(v)$  and  $y = e^{-|v|^2}$  in (50) gives, after integration over  $K_g$ ,

$$(51) \quad \mathcal{H}^-(g) \leq \int_{K_g} (|v|^2 g(v) + e^{-|v|^2}) \, dv \leq \int_{\mathbb{R}^d} (|v|^2 g(v) + e^{-|v|^2}) \, dv,$$

which is finite since  $|v|^2 \in \mathbb{M}$ .  $\square$

**3.2. Schneider's problem.** Given  $\boldsymbol{\rho} = (\boldsymbol{\rho}_0, \dots, \boldsymbol{\rho}_N) \in \mathcal{R}_{\mathbf{m}}$ , we seek a solution of (20), where the relation  $\langle \mathbf{m}g \rangle \preceq^\circ \boldsymbol{\rho}$  (or, equivalently,  $\boldsymbol{\rho} \succeq^\circ \langle \mathbf{m}g \rangle$ ) is shorthand for

$$(52a) \quad \langle \mathbf{m}_j g \rangle = \boldsymbol{\rho}_j, \quad 0 \leq j \leq N-1,$$

$$(52b) \quad \langle \mathbf{m}_N g \rangle \leq_{A_{\mathbf{m}_N}^\circ} \boldsymbol{\rho}_N,$$

and  $A_{\mathbf{m}_N}^\circ \equiv (A_{\mathbf{m}_N})^\circ$ . Note that (52b) means that

$$(53) \quad \boldsymbol{\alpha}_N^T \langle \mathbf{m}_N g \rangle \leq \boldsymbol{\alpha}_N^T \boldsymbol{\rho}_N \quad \text{whenever} \quad \boldsymbol{\alpha}_N^T \mathbf{m}_N \geq 0.$$

The components of  $\langle \mathbf{m}_j g \rangle$ ,  $0 \leq j < N$ , will be referred to as *lower-order moments*, and the components of  $\langle \mathbf{m}_N g \rangle$  will be referred to as *higher-order moments*.

The main result from [31] concerning the minimization problem with relaxed constraints (20) is the following theorem.

THEOREM 3 (Schneider [31]). *For any  $\boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}$ , there is a unique minimizer for the minimization problem (20). This minimizer has the form  $G_{\boldsymbol{\alpha}}$  given by (38), where  $\boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}}$ . Conversely, for each  $\boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}}$ ,*

$$(54) \quad \mathcal{H}(G_{\boldsymbol{\alpha}}) = \min_{g \in \mathbb{F}_{\mathbf{m}}} \{ \mathcal{H}(g) : \langle \mathbf{m}g \rangle \preceq^{\circ} \mathbf{r}(\boldsymbol{\alpha}) \},$$

where  $\mathbf{r}(\boldsymbol{\alpha})$  is given by (41). Moreover,  $G_{\boldsymbol{\alpha}}$  also satisfies the equality constraint problem (14) with  $\boldsymbol{\rho} = \mathbf{r}(\boldsymbol{\alpha})$ .

We define  $\mathbf{a} : \mathcal{R}_{\mathbf{m}} \rightarrow \mathcal{A}_{\mathbf{m}}$  as the mapping which assigns to  $\boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}$  the vector  $\boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}}$  such that  $G_{\boldsymbol{\alpha}}$  solves (20)—that is,

$$(55) \quad G_{\mathbf{a}(\boldsymbol{\rho})} \equiv \arg \min_{g \in \mathbb{F}_{\mathbf{m}}} \{ \mathcal{H}(g) : \langle \mathbf{m}g \rangle \preceq^{\circ} \boldsymbol{\rho} \}.$$

The converse statement of Theorem 3 implies the following.

COROLLARY 4. *Let  $\boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ . Then  $G_{\mathbf{a}(\boldsymbol{\rho})}$  is the unique minimizer of the entropy minimization problem with equality constraints (14).*

To help the reader's intuition, we provide a proof for Theorem 3 with the use of three lemmas. The first lemma is used to prove the existence of a minimizer for the minimization problem with relaxed constraints (20), and the first item of this lemma is a direct consequence of Lemma 2.

LEMMA 5 (Schneider [31]). *The entropy functional  $\mathcal{H}$  satisfies the following:*

1.  $\mathcal{H}(g) > -\infty$  for all  $g \in \mathbb{F}_{\mathbf{m}}$ .
2.  $\mathcal{H}$  is convex and lower semicontinuous with respect to the norm  $\|g\|_{L_{\mathbf{m}}^1(\mathbb{R}^d)} \equiv \langle \mathbf{m}g \rangle$ .
3. Subsets of  $\mathbb{F}_{\mathbf{m}}$  which are bounded in the  $L_{\mathbf{m}}^1(\mathbb{R}^d)$  topology and on which  $\mathcal{H}$  is bounded are weakly relatively compact in  $L^1(\mathbb{R}^d)$ .

The second lemma is a statement about the constraint set

$$(56) \quad C_{\mathbf{m}}(\boldsymbol{\rho}) \equiv \{ g \in \mathbb{F}_{\mathbf{m}} : \langle \mathbf{m}g \rangle \preceq^{\circ} \boldsymbol{\rho} \}.$$

LEMMA 6. *For each  $\boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}$ , the set  $C_{\mathbf{m}}(\boldsymbol{\rho})$  is closed in the weak- $L^1$  topology.*

*Proof.* Let  $\{g_k\}_{k=1}^{\infty}$  be any sequence in  $C_{\mathbf{m}}(\boldsymbol{\rho})$  that converges in weak- $L^1(\mathbb{R}^d)$  to a function  $g_*$ . For the highest-order moments, Fatou's lemma implies that if  $\boldsymbol{\alpha}_N^T \mathbf{m}_N \geq 0$ , then

$$(57) \quad \boldsymbol{\alpha}_N^T \langle \mathbf{m}_N g_* \rangle \leq \lim_{k \rightarrow \infty} \boldsymbol{\alpha}_N^T \langle \mathbf{m}_N g_k \rangle = \boldsymbol{\alpha}_N^T \boldsymbol{\rho}_N.$$

For  $j < N$ , more can be said. We break up the integral  $\langle \mathbf{m}_j g_k \rangle$  into two pieces:

$$(58) \quad \boldsymbol{\rho}_j = \langle \mathbf{m}_j g_k \rangle = \int_{|v| < R} \mathbf{m}_j g_k \, dv + \int_{|v| > R} \mathbf{m}_j g_k \, dv,$$

where  $R > 0$  is an arbitrary constant. For the first term in (58), weak- $L^1(\mathbb{R}^d)$  convergence implies that

$$(59) \quad \int_{|v| < R} \mathbf{m}_j g_k \, dv \xrightarrow{k \rightarrow \infty} \int_{|v| < R} \mathbf{m}_j g_* \, dv, \quad 0 \leq j \leq N.$$

Meanwhile, in the second term

$$(60) \quad \frac{|\mathbf{m}_j|}{|v|^N} < \frac{C_0}{R^{N-j}}, \quad |v| > R, \quad 0 \leq j < N,$$

for some constant  $C_0$  that is independent of  $R$ . Hence

$$(61) \quad \int_{|v|>R} \mathbf{m}_j g_k dv \leq \int_{|v|>R} \frac{|\mathbf{m}_j|}{|v|^N} |v|^N g_k dv < \frac{C_0}{R^{N-j}} \sup_k |\langle |v|^N g_k \rangle|.$$

Since  $\{g_k\}_{k=1}^\infty \subset C_{\mathbf{m}}$ , the sequence  $\{\langle |v|^N g_k \rangle\}_{k=1}^\infty$  is uniformly bounded in  $k$ , and it follows from (59) and (61) that

$$(62) \quad \begin{aligned} \lim_{k \rightarrow \infty} |\rho_j - \langle \mathbf{m}_j g_k \rangle| &\leq \lim_{k \rightarrow \infty} \int_{|v|>R} |\mathbf{m}_j g_k - \mathbf{m}_j g_*| dv \\ &\leq \frac{C_0}{R^{N-j}} \left( \sup_k \langle |v|^N g_k \rangle + \langle |v|^N g_* \rangle \right) < \frac{C_1}{R^{N-j}} \end{aligned}$$

for some constant  $C_1 > 0$  that is independent of  $R$ . Since  $R$  can be arbitrarily large, we conclude that  $\langle \mathbf{m}_j g_* \rangle = \rho_j$  for all  $j < N$ . Hence  $g_* \in C_{\mathbf{m}}(\rho)$ .  $\square$

The third lemma is used to prove the form of the minimizer. For any bounded measurable set  $K \subset \mathbb{R}^d$  and any locally integrable function  $g$ , let

$$(63) \quad \begin{aligned} \langle g \rangle_K &\equiv \int_K g(v) dv \quad \text{and} \quad \mathbb{F}_{\mathbf{m}}^K \equiv \{g \in L_1(\mathbb{R}^d) : g \geq 0 \\ &\text{and } \langle m_i g \rangle_K < \infty, i = 0, \dots, n-1\}. \end{aligned}$$

On  $\mathbb{F}_{\mathbf{m}}^K$ , we define

$$(64) \quad \mathcal{H}^K(g) \equiv \langle g \log g - g \rangle_K.$$

As with  $\mathcal{H}$ , the negative contribution to  $\mathcal{H}^K$  must be finite (see Lemma 2) in order for it to be well-defined, and restricting  $\text{Dom}(\mathcal{H}^K)$  to  $\mathbb{F}_{\mathbf{m}}^K$  ensures that this will be the case.

LEMMA 7 (Junk [20, 21], Borwein and Lewis [6]). *For any bounded set  $K \subset \mathbb{R}^d$  and any function  $f \in \mathbb{F}_{\mathbf{m}}^K$ , the problem*

$$(65) \quad \min_{g \in \mathbb{F}_{\mathbf{m}}^K} \{ \mathcal{H}^K(g) : \langle \mathbf{m} g \rangle_K = \langle \mathbf{m} f \rangle_K \}$$

*has a unique minimizer, which takes the form  $G_{\alpha}$  for some  $\alpha \in \mathbb{R}^n$ .*

*Proof of Theorem 3.* The proof has three parts.

1. *Existence and uniqueness.* Let  $\rho \in \mathcal{R}_{\mathbf{m}}$ . By Theorem 1, the set

$$(66) \quad C_{\mathbf{m}}(\rho) \equiv \{g \in \mathbb{F}_{\mathbf{m}} : \langle \mathbf{m} g \rangle \preceq^{\circ} \rho\}$$

contains bounded functions with compact support. Because such functions have finite entropy, the subset of  $C_{\mathbf{m}}(\rho)$  on which  $\mathcal{H}$  is finite is nonempty. Moreover, by Lemma 2,  $\mathcal{H}$  is bounded below on  $C_{\mathbf{m}}(\rho)$ . Hence  $h_S(\rho)$  is finite, and there exists  $\{g_i\}_{i=1}^\infty \subset C_{\mathbf{m}}(\rho)$  such that  $\mathcal{H}(g_i) \rightarrow h_S(\rho)$ . By Lemma 5, there is a subsequence  $\{g_{i_k}\}_{k=1}^\infty$  that converges in weak- $L^1$  to a function  $\hat{g}_\rho$ , and since  $C_{\mathbf{m}}(\rho)$  is closed (Lemma 6),  $\hat{g}_\rho \in C_{\mathbf{m}}(\rho)$ . Finally, since  $\mathcal{H}$  is lower semicontinuous (Lemma 5),

$$(67) \quad \mathcal{H}(\hat{g}_\rho) \leq \lim_{k \rightarrow \infty} \mathcal{H}(g_{i_k}) = h_S(\rho).$$

Thus  $\hat{g}_\rho$  attains the minimum in (20), and strict convexity of  $\mathcal{H}$  implies that the minimizer is unique.

2. *Form of the minimizer.* According to Lemma 7, for any bounded set  $K \subset \mathbb{R}^d$ ,

$$(68) \quad \min \{ \mathcal{H}^K(g) : \langle \mathbf{m}g \rangle_K = \langle \mathbf{m}\hat{g}_\rho \rangle_K \}$$

has a solution of the form  $G_\alpha$ . We conclude then that  $\hat{g}_\rho = G_\alpha$  on  $K$ ; otherwise, the function

$$(69) \quad g_\rho^*(v) = \begin{cases} G_\alpha(v), & v \in K, \\ \hat{g}_\rho, & v \notin K, \end{cases}$$

would satisfy  $\mathcal{H}(g_\rho^*) \leq \mathcal{H}(\hat{g}_\rho)$ , an obvious contradiction. Since  $K$  is arbitrary, we conclude that  $\hat{g}_\rho = G_\alpha$  and, in order to satisfy to constraints in (20), that  $\alpha \in \mathcal{A}_\mathbf{m}$ .

3. *Converse statement.* Applying Young's inequality (49) to  $z = g$  and  $y = G_\alpha$  and integrating over all velocity space gives

$$(70) \quad \mathcal{H}(g) \geq \mathcal{H}(G_\alpha) + \alpha^T \langle \mathbf{m}(g - G_\alpha) \rangle.$$

By hypothesis,  $\alpha \in \mathcal{A}_\mathbf{m}$ , which implies that  $\alpha_N \in \mathcal{A}_{\mathbf{m}_N}$ . Thus if  $g \in \mathbb{F}_\mathbf{m}$  satisfies  $\langle \mathbf{m}g \rangle \preceq^\circ \langle \mathbf{m}G_\alpha \rangle$ , then according to (52) and (53),

$$(71) \quad \alpha^T \langle \mathbf{m}(g - G_\alpha) \rangle = \sum_{j=1}^N \alpha_j^T \langle \mathbf{m}_j(g - G_\alpha) \rangle = \alpha_N^T \langle \mathbf{m}_N(g - G_\alpha) \rangle \geq 0.$$

Thus, from (70),  $\mathcal{H}(g) \geq \mathcal{H}(G_\alpha)$ . This concludes the proof.  $\square$

The existence part of this proof provides some intuition as to why the optimization problem with equality constraints (14) may not always have a minimizer. Suppose that the minimizing sequence  $\{g_{i_k}\}_{k=1}^\infty$  were restricted to the set

$$(72) \quad C_\mathbf{m}^0(\rho) \equiv \{g \in \mathbb{F}_\mathbf{m} : \langle \mathbf{m}g \rangle = \rho\}$$

rather than merely lying in  $C_\mathbf{m}(\rho)$ . Then  $\{g_{i_k}\}_{k=1}^\infty$  would still converge in the weak- $L^1(\mathbb{R}^d)$  topology to  $\hat{g}_\rho$ , with  $\langle \mathbf{m}_j \hat{g}_\rho \rangle = \rho_j$  for  $j < N$ . However, the bound in (61) does not help when  $j = N$ . Hence there is no way to ensure that  $\langle \mathbf{m}_N \hat{g}_\rho \rangle = \rho_N$ —only that  $\langle \mathbf{m}_N \hat{g}_\rho \rangle \leq_{A_\mathbf{m}} \rho_N$ . This is precisely why Schneider introduces the inequality constraint:  $C_\mathbf{m}(\rho)$  is closed in the weak- $L^1$  topology, whereas  $C_\mathbf{m}^0(\rho)$  is not.

Such behavior begs the following question: For what values of  $\rho$  does a minimizing sequence for (14) *not* converge inside  $C_\mathbf{m}^0(\rho)$ ? These will be the densities which make up the set  $\mathcal{D}_\mathbf{m}$ . In [31], Schneider attempts to address this question in the following corollary to Theorem 3.

**COROLLARY 8** (Schneider [31]). *Given  $\rho \in \mathcal{R}_\mathbf{m}$ , the minimizer in (14) exists if and only if there is no function of the form  $G_\alpha$  in  $C_\mathbf{m}(\rho) \setminus C_\mathbf{m}^0(\rho)$ .*

Unfortunately, this result provides little understanding of the geometry of  $\mathcal{D}_\mathbf{m}$ . A more insightful point of view is given by the following theorem.

**THEOREM 9.** *Given  $\rho \in \mathcal{R}_\mathbf{m}$ , the minimization problem with equality constraints (14) has a minimizer if and only if  $\rho \in \mathcal{R}_\mathbf{m}^{\text{exp}}$ . In other words,*

$$(73) \quad \mathcal{D}_\mathbf{m} = \mathcal{R}_\mathbf{m} \setminus \mathcal{R}_\mathbf{m}^{\text{exp}}.$$

*Proof.* The “if” part of this theorem is just Corollary 4. The “only if” part will be proved at the end of section 4.3.  $\square$

An immediate consequence of Theorem 9 is that  $\mathcal{D}_{\mathbf{m}}$  is a cone. However, the essential point of the theorem is that when  $\mathcal{D}_{\mathbf{m}}$  is nonempty there are realizable densities  $\boldsymbol{\rho}$  that *cannot* be realized by a functions of the form  $G_{\boldsymbol{\alpha}}$ . In other words,  $\boldsymbol{\rho} \notin \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  even though  $\mathbf{a}(\boldsymbol{\rho}) \in \mathcal{A}_{\mathbf{m}}$ . It is this idea which lays the foundation for the results in [20, 21], where a description of  $\mathcal{D}_{\mathbf{m}}$  is given for the case  $\mathbf{m}_N = |v|^N$ . Theorem 9 will also be the basis for the new results of this paper. However, for a general admissible space  $\mathbb{M}$ , we will need to formulate the dual for relaxed constraint problem (20) and derive complementary slackness conditions in order to find a useful geometric description for  $\mathcal{D}_{\mathbf{m}}$ . In the process, we will recover and extend many of the results from [20, 21, 31].

**4. Dual formulation.** Because  $\mathcal{H}$  is convex on  $\mathbb{F}_{\mathbf{m}}$  and the constraints in (20) are linear, it is reasonable to apply a dual treatment to the relaxed-constraint problem, e.g., [3, 7, 26]. In this section, we prove two important duality theorems and the complementary slackness conditions that accompany them. We also give an alternate proof of the form of the minimizer in Theorem 3 and a proof of the “only if” part of Theorem 9.

**4.1. The dual function.** We define the Lagrangian function  $\mathcal{L} : \mathbb{F}_{\mathbf{m}} \times \mathbb{R}^n \times \mathcal{R}_{\mathbf{m}} \rightarrow \mathbb{R} \cup \{\infty\}$  associated to (20) by

$$(74) \quad \mathcal{L}(g, \boldsymbol{\alpha}, \boldsymbol{\rho}) \equiv \mathcal{H}(g) + \boldsymbol{\alpha}^T(\boldsymbol{\rho} - \langle \mathbf{m}g \rangle)$$

and the dual function  $\psi : \mathbb{R}^n \times \mathcal{R}_{\mathbf{m}} \rightarrow \mathbb{R} \cup \{-\infty\}$  by

$$(75) \quad \psi(\boldsymbol{\alpha}, \boldsymbol{\rho}) \equiv \inf_{g \in \mathbb{F}_{\mathbf{m}}} \mathcal{L}(g, \boldsymbol{\alpha}, \boldsymbol{\rho}).$$

The dual function is closely related to the density potential  $h^*$ . In fact, we have the following.

**THEOREM 10.** *For all  $\boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}}$  and  $\boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}$ ,*

$$(76) \quad \psi(\boldsymbol{\alpha}, \boldsymbol{\rho}) = \mathcal{L}(G_{\boldsymbol{\alpha}}, \boldsymbol{\alpha}, \boldsymbol{\rho}) = \boldsymbol{\alpha}^T \boldsymbol{\rho} - h^*(\boldsymbol{\alpha}).$$

*Proof.* We apply Young’s inequality (50) and make the identification  $z = g$  and  $y = G_{\boldsymbol{\alpha}}$  to derive the pointwise inequality

$$(77) \quad (g \log g - g) - \boldsymbol{\alpha}^T \mathbf{m}g \geq -G_{\boldsymbol{\alpha}}.$$

Integration of (77) over  $\mathbb{R}^d$  and addition of  $\boldsymbol{\alpha}^T \boldsymbol{\rho}$  to both sides give a lower bound on  $\mathcal{L}$  and hence  $\psi$ :

$$(78) \quad \psi(\boldsymbol{\alpha}, \boldsymbol{\rho}) \geq \boldsymbol{\alpha}^T \boldsymbol{\rho} - h^*(\boldsymbol{\alpha}).$$

For  $\boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}}$ , the definitions of  $\mathcal{H}$ ,  $G_{\boldsymbol{\alpha}}$ , and  $h^*$  (given in (47), (38), and (39), respectively) imply that

$$(79) \quad \mathcal{H}(G_{\boldsymbol{\alpha}}) = \boldsymbol{\alpha}^T \langle \mathbf{m}G_{\boldsymbol{\alpha}} \rangle - \langle G_{\boldsymbol{\alpha}} \rangle = \boldsymbol{\alpha}^T \langle \mathbf{m}G_{\boldsymbol{\alpha}} \rangle - h^*(\boldsymbol{\alpha}).$$

Thus by (74),

$$(80) \quad \mathcal{L}(G_{\boldsymbol{\alpha}}, \boldsymbol{\alpha}, \boldsymbol{\rho}) = \boldsymbol{\alpha}^T \boldsymbol{\rho} - h^*(\boldsymbol{\alpha}),$$

so that, from (75),

$$(81) \quad \psi(\boldsymbol{\alpha}, \boldsymbol{\rho}) \leq \boldsymbol{\alpha}^T \boldsymbol{\rho} - h^*(\boldsymbol{\alpha}).$$

Together (78), (80), and (81) imply (76).  $\square$

**4.2. Smoothness properties of the dual function.** The following smoothness properties of  $\psi$  will be used throughout the remainder of the paper.

THEOREM 11. *Let  $\rho \in \mathcal{R}_{\mathbf{m}}$ . Then*

1.  $\psi(\cdot, \rho)$  is strictly concave on  $\mathcal{A}_{\mathbf{m}}$  and infinitely Fréchet differentiable on  $\text{int } \mathcal{A}_{\mathbf{m}}$ , with derivatives

$$(82a) \quad \frac{\partial \psi}{\partial \alpha}(\alpha, \rho) = \rho - \mathbf{r}(\alpha),$$

$$(82b) \quad \frac{\partial^{(i)} \psi}{\partial \alpha^{(i)}}(\alpha, \rho) = - \left\langle \mathbf{m}^{\vee(i)} G_{\alpha} \right\rangle, \quad i > 1,$$

where  $\mathbf{m}^{\vee(i)}$  is the  $i$ th tensor power of  $\mathbf{m}$ ,<sup>4</sup>

2. for any  $\alpha, \beta \in \mathcal{A}_{\mathbf{m}}$ , the function

$$(83) \quad \phi(\tau) \equiv \psi(\tau\alpha + (1 - \tau)\beta, \rho)$$

is twice differentiable at each  $\tau \in [0, 1]$  (one-sided at end points) with derivatives

$$(84a) \quad \phi'(\tau) = (\alpha - \beta)^T [\rho - \mathbf{r}(\tau\alpha + (1 - \tau)\beta)],$$

$$(84b) \quad \phi''(\tau) = - \left\langle \left( (\alpha - \beta)^T \mathbf{m} \right)^2 G_{\tau\alpha + (1 - \tau)\beta} \right\rangle.$$

In particular, the function  $\phi'(\tau)$  is a decreasing function of  $\tau$ ;

3. the function  $\psi(\cdot, \rho)$  is upper semicontinuous on  $\mathcal{A}_{\mathbf{m}}$ .

*Proof.* For the proofs of the first two statements above, we refer the reader to Lemmas 5.1 and 5.2 in [21] along with a few comments. First, the lemmas in [21] refer to  $h^*$  rather than to  $\psi(\cdot, \rho)$ . This makes little difference since the two functions differ only by a linear factor (see Theorem 10). Also, the proofs in [21] are constructed specifically for the special case when  $m_N = |v|^N$ ; however, modifications to the general setting are straightforward. To prove the third statement we simply invoke Fatou's lemma. Given a sequence  $\{\alpha_{(i)}\}_{i=1}^{\infty} \subset \mathcal{A}_{\mathbf{m}}$  with limit  $\alpha \in \mathcal{A}_{\mathbf{m}}$ ,

$$(85) \quad \langle G_{\alpha} \rangle \leq \lim_{i \rightarrow \infty} \langle G_{\alpha_{(i)}} \rangle.$$

Hence  $\lim_{i \rightarrow \infty} \psi(\alpha_{(i)}, \rho) \leq \psi(\alpha, \rho)$ .  $\square$

COROLLARY 12. *For all  $\alpha \in \text{int } \mathcal{A}_{\mathbf{m}}$ ,  $h_{\alpha}^*(\alpha) = \mathbf{r}(\alpha)$  and  $h_{\alpha\alpha}^*(\alpha) = \langle \mathbf{m}\mathbf{m}^T G_{\alpha} \rangle$ , which is positive-definite on  $\alpha \in \text{int } \mathcal{A}_{\mathbf{m}}$ .*

Several remarks should be made concerning Theorem 11. First, statement 1 implies statement 2, but only for  $\alpha, \beta \in \text{int } \mathcal{A}_{\mathbf{m}}$ . Second, for  $\alpha, \beta \in \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ ,  $\phi''$  need not be continuous and higher derivatives may not exist. Finally, in spite of the smoothness properties given by Theorem 11, the dual function need not even be continuous on  $\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ . Indeed, given a sequence  $\{\alpha_{(i)}\}_{i=1}^{\infty} \in \mathcal{A}_{\mathbf{m}}$  with limit  $\alpha \in \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ , it is possible that  $h^*(\alpha) < \lim_{i \rightarrow \infty} h^*(\alpha_{(i)})$ . As an example, consider the one-dimensional case ( $d = 1$ ) when  $\mathbf{m} = (1, v, v^2, v^3, v^4)^T$ . This case has been studied in detail in [20]. Given the following five points in the  $(v, w)$  plane:

$$\begin{aligned} (v_0, w_0) &= (0, 0), & (v_1, w_1) &= (1, 0), & (v_2, w_2) &= (i, -i^2), \\ (v_3, w_3) &= (2i, i), & (v_4, w_4) &= (2i + 1, 0), \end{aligned}$$

<sup>4</sup>The tensor power of a symmetric tensor  $S$  is defined recursively. For  $n > 1$ ,  $S^{\vee(n)} \equiv S \vee S^{\vee(n-1)}$  while  $S^{\vee(1)} \equiv S$ .

the unique degree-four polynomial interpolating these points is

$$(86) \quad p_i(v) = \alpha_{(i)}^T \mathbf{m}(v) = \sum_{j=0}^4 \alpha_{(i)j} v^j,$$

where

$$\begin{aligned} \alpha_{0(i)} &= 0, & \alpha_{1(i)} &= \frac{2i+1}{4i-2} + \frac{4i^2+2i}{i^2-1}, & \alpha_{2(i)} &= -\frac{4i^2+6i+1}{i^2-1} - \frac{2i^2+4i+1}{4i^2-2i}, \\ \alpha_{3(i)} &= \frac{4i+2}{i^2-1} + \frac{3i+2}{4i^2-2i}, & \alpha_{4(i)} &= -\frac{1}{i^2-1} - \frac{1}{4i^2-2i}. \end{aligned}$$

(The notation  $\alpha_{(i)}$  denotes a sequence of vectors rather than the usual notation  $\alpha_i$ , which denotes the components of a single vector  $\alpha$  corresponding to polynomials of degree  $i$ .) As  $i \rightarrow \infty$ ,

$$(87) \quad \alpha_{(i)} \rightarrow \alpha_* = \left(0, \frac{9}{2}, -\frac{9}{2}, 0, 0\right)^T \quad \text{and} \quad G_{\alpha_*} = \exp\left(-\frac{9}{2}v^2 + \frac{9}{2}v\right).$$

The density potential  $h^*(\alpha_*)$  moments  $\mathbf{r}(\alpha_*)$  are finite. Therefore  $\alpha_* \in \mathcal{A}_{\mathbf{m}}$ , but clearly  $\alpha_* \notin \text{int } \mathcal{A}_{\mathbf{m}}$ . Moreover, one may readily check that  $p_i$  is positive and concave on the interval  $[2i, 2i+1]$ , and hence

$$(88) \quad h^*(\alpha_{(i)}) = \langle G_{\alpha_{(i)}} \rangle > \int_{2i}^{2i+1} e^{p_i(v)} dv > \int_{2i}^{2i+1} (1 + p_i(v)) dv > 1 + \frac{i}{2} \rightarrow \infty \quad \text{as } i \rightarrow \infty.$$

Note that the second inequality above follows from the fact that  $e^x > 1+x$ , while the concavity of  $p_i$  on  $[2i, 2i+1]$  implies that the graph of  $p_i$  lies above the line segment  $\ell$  joining the points  $(2i, i)$  and  $(2i+1, 0)$  in the  $(v, w)$  plane. Therefore the integral of  $p_i$  over  $[2i, 2i+1]$  is bounded below by the area of the triangle formed by  $\ell$ , the  $v$ -axis, and the line  $\{v = 2i\}$ . The area of this triangle is  $i/2$ . A similar argument shows that, for any  $j \geq 0$ ,  $\langle |v|^j G_{\alpha_{(i)}} \rangle \rightarrow \infty$  as  $i \rightarrow \infty$  while  $\langle v^j G_{\alpha_*} \rangle$  is finite.

The reason that  $\psi(\cdot, \rho)$  is discontinuous at the boundary of  $\mathcal{A}_{\mathbf{m}}$  is the same reason that the minimization problem (14) with equality constraints fails: because mass at the tails of the functions escapes as  $i \rightarrow \infty$ . In the example above, this is precisely what happens to the mass of  $G_{\alpha_{(i)}}$  that is supported on the interval  $[2i, 2i+1]$ . The same thing occurs with the minimizing sequence  $\{g_{i_k}\}_{k=1}^\infty$  in the proof of Theorem 3. The difference is that, for  $\{g_{i_k}\}_{k=1}^\infty$ , only the highest moments fail to converge in the minimizing sequence, whereas none of the moments in this example converge. The reason for this difference is that the moments  $\langle \mathbf{m} g_{i_k} \rangle$  are all bounded. The moments of  $\{G_{\alpha_{(i)}}\}_{i=1}^\infty$  would converge if higher-order moments were controlled in some way. Controlling the moments is, in effect, the same as requiring  $\alpha_i \rightarrow \alpha_*$  along a specified path. In fact, we will see at the very end of section 5.4 that the map  $\rho \mapsto \psi(\mathbf{a}(\rho), \rho)$  is continuous on  $\mathcal{R}_{\mathbf{m}}$ .

**4.3. Duality theorems.** The main results of this subsection are based on the following strong duality theorem where, for a given cone  $C$ , the notations “ $\leq_C$ ” and “ $\geq_C$ ” are defined in the last paragraph of section 2.2.

**THEOREM 13** (see [26]). *Consider the problem*

$$(89) \quad \begin{aligned} &\text{minimize} && f_0(x) \\ &\text{subject to} && f_i(x) \leq_{K_i} 0, \quad i = 1, \dots, m; \quad Ax = b, \end{aligned}$$

where the functions  $f_0, \dots, f_m : \mathbb{X} \rightarrow \mathbb{R} \cup +\infty$  are convex over a vector space  $\mathbb{X}$ ,  $A : \mathbb{X} \rightarrow \mathbb{R}^k$  is a linear mapping,  $b \in \mathbb{R}^k$ , and each  $K_i$  is a proper cone for  $i = 1, \dots, m$ . Let  $D$  be the intersection of the domains of  $f_0, \dots, f_m$  (i.e.,  $D$  is a convex set over which each  $f_i$  is finite). Suppose there exists  $\tilde{x} \in D$ , with  $f_i(\tilde{x}) < 0$ ,  $i = 1, \dots, m$ , and  $A\tilde{x} = b$ . Further suppose that the set  $\{Ax - b : x \in D\}$  contains a neighborhood of the origin. Then strong duality holds, i.e.,

$$(90) \quad \inf\{f_0(x) : f_i(x) \leq_{K_i} 0, i = 1, \dots, m; Ax = b\} \\ = \sup_{\substack{\lambda_i \geq_{K_i^\circ} 0 \\ \nu \in \mathbb{R}^k}} \inf_{x \in D} \left\{ f_0(x) + \sum_{i=1}^m \lambda_i f_i(x) + \nu^T (Ax - b) \right\},$$

and the dual optimal value is attained whenever it is not  $-\infty$ .

Theorem 13 follows from [26, Exercise 8.7] and can be proven by using arguments found in [26, Chapter 8]. It can also be proven along the lines of similar results found in [7, sections 5.3.2 and 5.9.1]. However, whereas those results require the existence of some  $\tilde{x}$  in the relative interior of  $D$ , Theorem 13 requires only that  $\tilde{x} \in D$ . A side benefit of this is that there is no need to specify a topology on  $\mathbb{X}$ . In return, our condition that  $\{Ax - b : x \in D\}$  contains a neighborhood of the origin is not present in the statements in [7].

To prove Theorem 13, one may repeat the arguments found in [7, section 5.3.2] with the notation “ $\leq$ ” changed to curly “ $\preceq$ .” The only difference from that proof is in the contradiction argument showing (in the notation of [7]) that  $\mu = 0$  is not possible. The proof in [7] first shows, with logic that remains valid under our weaker assumptions on  $\tilde{x}$ , that if  $\mu = 0$ , then there must exist  $\nu \neq 0$  such that  $\nu^T (Ax - b) \geq 0$  for all  $x \in D$ . At that point, our assumption that  $\{Ax - b : x \in D\}$  contains a neighborhood of the origin immediately implies that  $\nu = 0$ , which yields the requisite contradiction.

The statement of Theorem 13 is of much interest in the present context for two reasons: (i) Our primal decision variable  $g$  lies in an infinite-dimensional vector space, and (ii) it is not straightforward to show that the relative interior condition on  $\tilde{x}$  (or in our case  $\tilde{g}$ ) actually applies. (However, see [6, Definition 2.1], where the authors introduce the notion of a *pseudo relative interior*.) On the other hand, that our additional condition on  $\{Ax - b : x \in D\}$  holds is a direct consequence of the openness of  $\mathcal{R}_m$ .

Direct application of Theorem 13 leads to the following results.

**THEOREM 14.** Let  $\rho \in \mathcal{R}_m$ , and let  $h_S$  and  $\psi$  be given by (20) and (75), respectively. Then

$$(91) \quad h_S(\rho) = \max_{\alpha \in \mathcal{A}_m} \psi(\alpha, \rho),$$

where the maximum on the right is attained by a unique  $\hat{\alpha} \in \mathcal{A}_m$ . If  $\hat{g}_\rho$  solves (20), then  $\hat{g}_\rho = G_{\hat{\alpha}}$ . Furthermore,  $\hat{g}_\rho$  and  $\hat{\alpha}$  satisfy the complementary slackness condition

$$(92) \quad \hat{\alpha}^T \rho = \hat{\alpha}^T \langle m \hat{g}_\rho \rangle = \hat{\alpha}^T \langle m G_{\hat{\alpha}} \rangle,$$

and  $\hat{g}_\rho$  minimizes  $\mathcal{L}(g, \hat{\alpha}, \rho)$  over  $\mathbb{F}_m$ , i.e.,

$$(93) \quad \psi(\hat{\alpha}, \rho) = \mathcal{L}(\hat{g}_\rho, \hat{\alpha}, \rho).$$

*Proof.* Theorem 14 may be recast in the form of Theorem 13 by setting  $m = 1$  and introducing the following mapping of notation:

$$\begin{aligned} \mathbb{X} &\mapsto L_{\mathbf{m}}^1(\mathbb{R}^d); & f_1(x) &\mapsto \boldsymbol{\rho}_N - \langle \mathbf{m}_N g \rangle; & Ax &\mapsto \langle \mathbf{m}_j g \rangle, & j = 1, \dots, N-1; \\ x &\mapsto g; & K_1 &\mapsto A_{\mathbf{m}_N}^\circ; & b &\mapsto \boldsymbol{\rho}_j, & j = 1, \dots, N-1; \\ f_0 &\mapsto \mathcal{H}; & \lambda &\mapsto \boldsymbol{\alpha}_N; & \nu &\mapsto \boldsymbol{\alpha}_j, & j = 1, \dots, N-1. \end{aligned}$$

All of the conditions of Theorem 13 hold. However, we must be careful to ensure that  $\mathcal{H}$  is restricted to a domain on which it is finite. Thus we consider the minimization problem over the set

$$(94) \quad \tilde{\mathbb{F}}_{\mathbf{m}} = \{g \in \mathbb{F}_{\mathbf{m}} : \mathcal{H}(g) < \infty\}.$$

This set is convex and includes all bounded functions in  $\mathbb{F}_{\mathbf{m}}$  with compact support. Thus by Theorem 1, the moment mapping  $g \mapsto \langle \mathbf{m} g \rangle$  maps  $\tilde{\mathbb{F}}_{\mathbf{m}}$  onto  $\mathcal{R}_{\mathbf{m}}$ , and since  $\mathcal{R}_{\mathbf{m}}$  is open, the set

$$(95) \quad \left\{ \langle \mathbf{m}_i g \rangle - \boldsymbol{\rho}_i : g \in \tilde{\mathbb{F}}_{\mathbf{m}}, i < N \right\}$$

contains a neighborhood of the origin. By the polar cone theorem [3, page 162],  $(A_{\mathbf{m}_N}^\circ)^\circ = A_{\mathbf{m}_N}$  so that strong duality holds, i.e.,

$$(96) \quad h_s(\boldsymbol{\rho}) = \max_{\boldsymbol{\alpha} \in \mathbb{R}^n} \{\psi(\boldsymbol{\alpha}, \boldsymbol{\rho}) : \boldsymbol{\alpha}_N \in A_{\mathbf{m}_N}\}.$$

Moreover, because  $\psi$  is strictly concave, the maximum in (96) is attained by a *unique*  $\hat{\boldsymbol{\alpha}} \in \{\boldsymbol{\alpha} \in \mathbb{R}^n : \boldsymbol{\alpha}_N \in A_{\mathbf{m}_N}\}$ . According to the constraint conditions in (52),

$$(97) \quad \langle \mathbf{m}_j \hat{g}_{\boldsymbol{\rho}} \rangle = \boldsymbol{\rho} \text{ for } j < N \quad \text{and} \quad \hat{\boldsymbol{\alpha}}_N^T \langle \mathbf{m}_N \hat{g}_{\boldsymbol{\rho}} \rangle \geq \hat{\boldsymbol{\alpha}}_N^T \boldsymbol{\rho}_N.$$

Thus  $\hat{\boldsymbol{\alpha}}^T(\boldsymbol{\rho} - \langle \mathbf{m} \hat{g}_{\boldsymbol{\rho}} \rangle) \leq 0$  and

$$(98) \quad \begin{aligned} h_s(\boldsymbol{\rho}) &= \psi(\hat{\boldsymbol{\alpha}}, \boldsymbol{\rho}) = \inf_{g \in \tilde{\mathbb{F}}_{\mathbf{m}}} \left\{ \mathcal{H}(g) + \hat{\boldsymbol{\alpha}}^T(\boldsymbol{\rho} - \langle \mathbf{m} g \rangle) \right\} \\ &\leq \mathcal{H}(\hat{g}_{\boldsymbol{\rho}}) + \hat{\boldsymbol{\alpha}}^T(\boldsymbol{\rho} - \langle \mathbf{m} \hat{g}_{\boldsymbol{\rho}} \rangle) \leq \mathcal{H}(\hat{g}_{\boldsymbol{\rho}}) = h_s(\boldsymbol{\rho}). \end{aligned}$$

Equations (92) and (93) follow immediately.

To finish the proof, we need only show that  $\hat{\boldsymbol{\alpha}} \in \mathcal{A}_{\mathbf{m}}$  and  $\hat{g}_{\boldsymbol{\rho}} = G_{\hat{\boldsymbol{\alpha}}}$ . For any nonnegative function  $g$ , straightforward calculation verifies that

$$(99) \quad g \log g - g - \hat{\boldsymbol{\alpha}}^T \mathbf{m} g = \phi(g) - G_{\hat{\boldsymbol{\alpha}}},$$

where

$$(100) \quad \phi(g) \equiv \left[ g \log \left( \frac{g}{G_{\hat{\boldsymbol{\alpha}}}} \right) + (G_{\hat{\boldsymbol{\alpha}}} - g) \right].$$

Applying (49) with  $z = g/G_{\hat{\boldsymbol{\alpha}}}$  and  $y = 1$  shows that, for each  $v \in \mathbb{R}^d$ ,  $\phi(g(v)) \geq 0$ , with equality if and only if  $G_{\hat{\boldsymbol{\alpha}}}(v) = g(v)$ . Now, for each  $R > 0$ , define the set  $B_R \equiv \{v \in \mathbb{R}^d : |v| < R\}$ . Setting  $g = \hat{g}_{\boldsymbol{\rho}}$  in (99) and integrating over  $B_R$  gives

$$(101) \quad \mathcal{H}^{B_R}(\hat{g}_{\boldsymbol{\rho}}) - \left\langle \hat{\boldsymbol{\alpha}}^T \mathbf{m} \hat{g}_{\boldsymbol{\rho}} \right\rangle_{B_R} = \langle \phi(\hat{g}_{\boldsymbol{\rho}}) \rangle_{B_R} - \langle G_{\hat{\boldsymbol{\alpha}}} \rangle_{B_R}.$$

(Note that, since  $\hat{g}_\rho \in \mathbb{F}_\mathbf{m}$ , all of the integrals above are well-defined.) From (74), (101), (76), and (39), it follows that

$$\begin{aligned}
 \mathcal{L}(\hat{g}_\rho, \hat{\alpha}, \rho) &= \mathcal{H}(\hat{g}_\rho) + \hat{\alpha}^T(\rho - \langle \mathbf{m}\hat{g}_\rho \rangle) \\
 &= \mathcal{H}^{B_R}(\hat{g}_\rho) + \mathcal{H}^{\mathbb{R}^d \setminus B_R}(\hat{g}_\rho) + \hat{\alpha}^T \left( \rho - \langle \mathbf{m}\hat{g}_\rho \rangle_{B_R} - \langle \mathbf{m}\hat{g}_\rho \rangle_{\mathbb{R}^d \setminus B_R} \right) \\
 (102) \quad &= \langle \phi(\hat{g}_\rho) \rangle_{B_R} - \langle G_{\hat{\alpha}} \rangle_{B_R} + \mathcal{H}^{\mathbb{R}^d \setminus B_R}(\hat{g}_\rho) + \hat{\alpha}^T \left( \rho - \langle \mathbf{m}\hat{g}_\rho \rangle_{\mathbb{R}^d \setminus B_R} \right) \\
 &= \mathcal{L}(G_{\hat{\alpha}}^{B_R}, \hat{\alpha}, \rho) + \langle \phi(\hat{g}_\rho) \rangle_{B_R} + \mathcal{H}^{\mathbb{R}^d \setminus B_R}(\hat{g}_\rho) - \hat{\alpha}^T \langle \mathbf{m}\hat{g}_\rho \rangle_{\mathbb{R}^d \setminus B_R},
 \end{aligned}$$

where

$$(103) \quad G_{\hat{\alpha}}^{B_R}(v) = \begin{cases} G_{\hat{\alpha}}(v), & v \in B_R, \\ 0, & v \notin B_R. \end{cases}$$

Now since  $\phi(g(v)) \geq 0$ , the function  $R \mapsto \Phi(R) \equiv \langle \phi(\hat{g}_\rho) \rangle_{B_R}$  is nonnegative and nondecreasing, and  $\Phi(R) = 0$  if and only if  $G_{\hat{\alpha}}$  and  $g$  agree on  $B_R$ . On the other hand, since  $\mathcal{H}(\hat{g}_\rho)$  and  $\langle \mathbf{m}\hat{g}_\rho \rangle$  are finite,

$$(104) \quad \mathcal{H}^{\mathbb{R}^d \setminus B_R}(\hat{g}_\rho) - \hat{\alpha}^T \langle \mathbf{m}\hat{g}_\rho \rangle_{\mathbb{R}^d \setminus B_R} \rightarrow 0 \quad \text{as } R \rightarrow \infty.$$

It follows then from (102) that, for  $R$  is sufficiently large,

$$(105) \quad \mathcal{L}(\hat{g}_\rho, \hat{\alpha}, \rho) > \mathcal{L}(G_{\hat{\alpha}}^{B_R}, \hat{\alpha}, \rho)$$

unless  $G_{\hat{\alpha}}^{B_R}$  agrees with  $\hat{g}_\rho$  on  $B_R$ . Since  $\hat{g}_\rho$  minimizes  $\mathcal{L}(\cdot, \hat{\alpha}, \rho)$ , we conclude that this exception is indeed the case. Moreover, since  $R$  is arbitrary, it follows that  $\hat{g}_\rho = G_{\hat{\alpha}}$ . Finally, the fact that  $\hat{g}_\rho \in \mathbb{F}_\mathbf{m}$  implies that  $\hat{\alpha} \in \mathcal{A}_\mathbf{m}$ .  $\square$

Several remarks are in order here.

1. If  $\rho \in \mathcal{R}_\mathbf{m}^{\text{exp}}$ , then Theorem 14 can be proven more directly using by Theorem 3.
3. Indeed, weak duality is easy to show: If  $g \in \mathbb{F}_\mathbf{m}$  satisfies the constraint conditions from (52), then

$$(106) \quad \mathcal{L}(g, \alpha, \rho) = \mathcal{H}(g) + \alpha^T(\rho - \langle \mathbf{m}g \rangle) \leq \mathcal{H}(g)$$

for all  $\alpha \in \mathcal{A}_\mathbf{m}$ . By invoking the definitions of  $\psi$  (75) and  $h_S$  (20), we find that

$$\begin{aligned}
 \psi(\alpha, \rho) &= \inf_{g \in \mathbb{F}_\mathbf{m}} \mathcal{L}(g, \alpha, \rho) \leq \inf_{g \in \mathbb{F}_\mathbf{m}} \{ \mathcal{L}(g, \alpha, \rho) : \langle \mathbf{m}g \rangle \preceq^\circ \rho \} \\
 (107) \quad &\leq \inf_{g \in \mathbb{F}_\mathbf{m}} \{ \mathcal{H}(g) : \langle \mathbf{m}g \rangle \preceq^\circ \rho \} = h_S(\rho).
 \end{aligned}$$

On the other hand, if  $\rho = \mathbf{r}(\hat{\alpha})$  for some  $\hat{\alpha} \in \mathcal{A}_\mathbf{m}$ , then it follows from Theorem 3, (76), and the definition of  $\mathcal{H}$  (47) that

$$(108) \quad h_S(\rho) = \mathcal{H}(G_{\hat{\alpha}}) = \psi(\hat{\alpha}, \rho).$$

From (107) and (108), one can easily deduce strong duality (91) and the complementary slackness condition (92).

2. If it is known a priori that the maximum in (96) is attained by  $\hat{\alpha} \in \mathcal{A}_\mathbf{m}$ , then the form of the minimizer follows almost immediately. In this case,  $G_{\hat{\alpha}} \in \mathbb{F}_\mathbf{m}$  (which is needed for  $\mathcal{L}$  to be well-defined) so that (76) and (93) imply (108). Because  $\mathcal{L}$  is strictly convex in its first argument, its minimizer is unique, and consequently  $\hat{g}_\rho = G_{\hat{\alpha}}$ .

3. Since  $\rho_j = \langle \mathbf{m}_j G_{\hat{\alpha}} \rangle$  for  $j < N$ , the only nontrivial part of the complementary slackness condition (92) is

$$(109) \quad \hat{\alpha}_N^T \rho_N = \hat{\alpha}_N^T \langle \mathbf{m}_N \hat{g}_\rho \rangle = \hat{\alpha}_N^T \langle \mathbf{m}_N G_{\hat{\alpha}} \rangle.$$

This relationship between  $\hat{\alpha}_N$  and  $\rho_N$  will be the key to characterizing the set  $\mathcal{D}_{\mathbf{m}}$ .

The following corollary will be used in section 6. It is an immediate consequence of the complementary slackness condition.

COROLLARY 15. *Let  $\rho \in \mathcal{R}_{\mathbf{m}}$ , and let  $\hat{\alpha} \in \mathcal{A}_{\mathbf{m}}$  solve (91). Then*

$$(110) \quad h_S(\rho) = \min_{g \in \mathbb{F}_{\mathbf{m}}} \left\{ \mathcal{H}(g) : \hat{\alpha}^T \langle \mathbf{m}g \rangle = \hat{\alpha}^T \rho \right\},$$

and  $G_{\hat{\alpha}}$  is the unique minimizer.

*Proof.* Let  $g \in \mathbb{F}_{\mathbf{m}}$  be given. Using Young's inequality (49) with  $z = g$  and  $y = G_{\hat{\alpha}}$  gives

$$(111) \quad \mathcal{H}(g) \geq \mathcal{H}(G_{\hat{\alpha}}) + \hat{\alpha}^T \langle \mathbf{m}(g - G_{\hat{\alpha}}) \rangle,$$

which, given the complementary slackness condition (92), implies that

$$(112) \quad \mathcal{H}(g) \geq \mathcal{H}(G_{\hat{\alpha}}) + \hat{\alpha}^T (\langle \mathbf{m}g \rangle - \rho).$$

Thus if  $g$  satisfies the constraints in (110), then  $\mathcal{H}(g) \geq \mathcal{H}(G_{\hat{\alpha}}) = h_S(\rho)$ .  $\square$

A duality theorem similar to Theorem 14 holds for the minimization problem in (19) that defines  $h_J(\rho)$ . Like Theorem 14, it is a consequence of Theorem 13, and its proof is essentially the same.

THEOREM 16. *Let  $\rho \in \mathcal{R}_{\mathbf{m}}$ , and let  $h_J(\rho)$  and  $\psi$  be given by (19) and (75), respectively. Then*

$$(113) \quad h_J(\rho) = \max_{\alpha \in \mathcal{A}_{\mathbf{m}}} \psi(\alpha, \rho),$$

where the maximum on the right is attained by a unique  $\tilde{\alpha} \in \mathcal{A}_{\mathbf{m}}$ . Furthermore, if the infimum in (19) is attained by some function  $\tilde{g}_\rho \in \mathbb{F}_{\mathbf{m}}$  which satisfies the equality constraints of (19), then  $\tilde{g}_\rho = G_{\tilde{\alpha}}$  and  $\tilde{g}_\rho$  minimizes  $\mathcal{L}(g, \tilde{\alpha}, \rho)$ , i.e.,  $\psi(\tilde{\alpha}, \rho) = \mathcal{L}(\tilde{g}_\rho, \tilde{\alpha}, \rho)$ .

The careful reader may note that application of Theorem 13 to proving Theorem 16 initially gives a statement similar to (96) but without any constraint on  $\alpha$ . However, the arguments which follow (96) show that  $\alpha \in \mathcal{A}_{\mathbf{m}}$  independently of this initial restriction.

Theorems 14 and 16 prove that the infima in (19) and (20) are equal—that is,

$$(114) \quad h_S(\rho) = h_J(\rho) = \max_{\alpha \in \mathcal{A}_{\mathbf{m}}} \psi(\alpha, \rho),$$

even if the infimum in (19) is not attained. In light of (114), the definition of  $h$  given in (17), which applies only to  $\rho \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ , can be extended to all of  $\mathcal{R}_{\mathbf{m}}$  by setting

$$(115) \quad h(\rho) \equiv \max_{\alpha \in \mathcal{A}_{\mathbf{m}}} \psi(\alpha, \rho).$$

In addition, we can now complete the proof of Theorem 9.

*Proof of Theorem 9.* We have already proven the “if” statement in Theorem 9. We now prove the “only if” statement. To this end, let  $\rho \in \mathcal{R}_{\mathbf{m}}$  be such that (14) has a minimizer. According to (114) this minimizer is also the minimizer of (20) and is therefore given by  $G_{\mathbf{a}(\rho)}$ . Hence, the equality constraint conditions in (14) imply that  $\rho = \langle \mathbf{m}G_{\mathbf{a}(\rho)} \rangle$ , which means  $\rho \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ .  $\square$

**5. The relationship between  $\alpha$  and  $\rho$ .** The formal structure of entropy-based closures depends heavily on the Legendre dual relationship between the functions  $h$  and  $h^*$  and their derivatives. In this section, we review this relationship for nondegenerate densities and show how Legendre duality ensures that the resulting system of PDEs is symmetric hyperbolic. We then discuss what aspects of the dual relationship hold in degenerate densities. A similar analysis can be found in [21] for the case  $\mathbf{m}_N = |v|^N$ .

**5.1. Properties for nondegenerate cases.** Recall that the function  $\mathbf{a}$  maps each  $\rho \in \mathcal{R}_{\mathbf{m}}$  to the unique vector  $\hat{\alpha} \in \mathcal{A}_{\mathbf{m}}$  that solves (91). In particular,

$$(116) \quad \hat{g}_{\rho} = G_{\mathbf{a}(\rho)} \quad \text{and} \quad h(\rho) = \psi(\mathbf{a}(\rho), \rho).$$

It turns out that  $\mathbf{a}$ , when restricted to  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$ , is the inverse of the function  $\mathbf{r}$  defined in (41).

**THEOREM 17.** *The function  $\mathbf{r}$  is one-to-one from  $\mathcal{A}_{\mathbf{m}}$  onto  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  with inverse  $\mathbf{a}$ . It is a diffeomorphism between  $\text{int } \mathcal{A}_{\mathbf{m}}$  and  $\text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ .*

*Proof.* We first identify  $\mathbf{a}$  as the inverse of  $\mathbf{r}$ . Since  $\mathbf{r}$  is (by definition) onto  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$ , we need only to show that  $\mathbf{a}(\mathbf{r}(\alpha)) = \alpha$  for each  $\alpha \in \mathcal{A}_{\mathbf{m}}$ . By the definition of  $\mathbf{a}$ ,

$$(117) \quad \mathcal{H}(G_{\mathbf{a}(\mathbf{r}(\alpha))}) = \min_{g \in \mathbb{F}_{\mathbf{m}}} \{ \mathcal{H}(g) : \langle \mathbf{m}g \rangle \preceq^{\circ} \mathbf{r}(\alpha) \}.$$

However, Theorem 3 implies that

$$(118) \quad \mathcal{H}(G_{\alpha}) = \min_{g \in \mathbb{F}_{\mathbf{m}}} \{ \mathcal{H}(g) : \langle \mathbf{m}g \rangle \preceq^{\circ} \mathbf{r}(\alpha) \}.$$

Since this minimizer is unique, it follows that  $\mathbf{a}(\mathbf{r}(\alpha)) = \alpha$ . If  $\alpha \in \text{int } \mathcal{A}_{\mathbf{m}}$ , then, according to Corollary 12,  $\mathbf{r}$  is the derivative of the density potential  $h^*$  on  $\text{int } \mathcal{A}_{\mathbf{m}}$  and its Jacobian

$$(119) \quad \frac{\partial \mathbf{r}}{\partial \alpha}(\alpha) = \frac{\partial^2 h^*}{\partial \alpha^2}(\alpha, \rho) = \langle \mathbf{m} \mathbf{m}^T G_{\alpha} \rangle$$

is a positive-definite matrix. The inverse function theorem implies then that  $\mathbf{r}$  is a diffeomorphism from  $\text{int } \mathcal{A}_{\mathbf{m}}$  onto  $\text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ .  $\square$

The following corollary implies that  $\mathcal{D}_{\mathbf{m}}$  cannot divide  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  into disjoint subsets.

**COROLLARY 18.** *The set  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  is pathwise-connected.*

*Proof.* Given  $\rho_{(0)}, \rho_{(1)} \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ , we seek a continuous function  $\Gamma : [0, 1] \rightarrow \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  such that

$$(120) \quad \Gamma(0) = \rho_{(0)} \quad \text{and} \quad \Gamma(1) = \rho_{(1)}.$$

Convexity of  $\mathcal{A}_{\mathbf{m}}$  implies that

$$(121) \quad \alpha_{\lambda} \equiv \lambda \mathbf{a}(\rho_{(0)}) + (1 - \lambda) \mathbf{a}(\rho_{(1)}) \in \mathcal{A}_{\mathbf{m}} \quad \forall \lambda \in [0, 1].$$

Thus, in view of Theorem 11, the function  $\Gamma(\lambda) = \mathbf{r}(\alpha_{\lambda})$  satisfies (120).  $\square$

An immediate consequence of Theorem 14 is that  $h$  (as the maximum of a family of linear functions in  $\rho$ ) is convex on  $\mathcal{R}_{\mathbf{m}}$ . However, more can be said if we restrict  $h$  to convex subsets of  $\text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ .

**THEOREM 19.** *When restricted to  $\text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  and  $\text{int } \mathcal{A}_{\mathbf{m}}$ , respectively, the functions  $h$  and  $h^*$  are locally strictly convex, Legendre duals of one another.*

*Proof.* We first show that  $h$  is the Legendre transform of  $h^*$ . From (76),

$$(122) \quad h(\mathbf{r}(\boldsymbol{\alpha})) + h^*(\boldsymbol{\alpha}) = \boldsymbol{\alpha}^T \mathbf{r}(\boldsymbol{\alpha}), \quad \boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}},$$

where, according to Corollary 12,

$$(123) \quad \mathbf{r}(\boldsymbol{\alpha}) = h_{\boldsymbol{\alpha}}^*(\boldsymbol{\alpha}), \quad \boldsymbol{\alpha} \in \text{int } \mathcal{A}_{\mathbf{m}}.$$

We next show that the Legendre transform of  $h^*$  recovers  $h$ . The inverse relationship between  $\mathbf{a}$  and  $\mathbf{r}$  (Theorem 17) implies that (122) may be rewritten in terms of  $\boldsymbol{\rho} = \mathbf{r}(\boldsymbol{\alpha})$ :

$$(124) \quad h(\boldsymbol{\rho}) + h^*(\mathbf{a}(\boldsymbol{\rho})) = \mathbf{a}(\boldsymbol{\rho})^T \boldsymbol{\rho}, \quad \boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}.$$

Differentiating (124) and using (123) again gives

$$(125) \quad \mathbf{a}(\boldsymbol{\rho}) = h_{\boldsymbol{\rho}}(\boldsymbol{\rho}), \quad \boldsymbol{\rho} \in \text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}.$$

Finally, for  $\boldsymbol{\rho} \in \text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ ,

$$(126) \quad h_{\boldsymbol{\rho}\boldsymbol{\rho}}(\boldsymbol{\rho}) = \frac{\partial \mathbf{a}}{\partial \boldsymbol{\rho}}(\boldsymbol{\rho}) = \left[ \frac{\partial \mathbf{r}}{\partial \boldsymbol{\alpha}}(\mathbf{a}(\boldsymbol{\rho})) \right]^{-1} = [h_{\boldsymbol{\alpha}\boldsymbol{\alpha}}^*(\mathbf{a}(\boldsymbol{\rho}))]^{-1},$$

which, by Corollary 12, is positive-definite. Thus  $h$  and  $h^*$  are strictly convex.  $\square$

**5.2. Application to kinetic moment closures.** The dual relationship between  $h$  and  $h^*$  is used in [24] to show that entropy-based closures formally produce hyperbolic systems which dissipate a convex entropy and satisfy an H-theorem. Indeed, if  $\boldsymbol{\rho} \in \text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  and  $\hat{\boldsymbol{\alpha}} = \mathbf{a}(\boldsymbol{\rho})$ , then, according to (123), the moment system (12) can be expressed in terms of  $\hat{\boldsymbol{\alpha}}$ :

$$(127) \quad \partial_t h_{\boldsymbol{\alpha}}^*(\hat{\boldsymbol{\alpha}}) + \nabla_x \cdot j_{\boldsymbol{\alpha}}^*(\hat{\boldsymbol{\alpha}}) = \mathbf{c}(h_{\boldsymbol{\alpha}}^*(\hat{\boldsymbol{\alpha}})),$$

where  $j^*(\boldsymbol{\alpha}) \equiv \langle v G_{\boldsymbol{\alpha}} \rangle$  is the flux potential and

$$(128) \quad j_{\boldsymbol{\alpha}}^*(\hat{\boldsymbol{\alpha}}) = \mathbf{f}(\boldsymbol{\rho}).$$

Carrying out the time and space derivatives in (127) gives

$$(129) \quad h_{\boldsymbol{\alpha}\boldsymbol{\alpha}}^*(\hat{\boldsymbol{\alpha}}) \partial_t \hat{\boldsymbol{\alpha}} + j_{\boldsymbol{\alpha}\boldsymbol{\alpha}}^*(\hat{\boldsymbol{\alpha}}) \cdot \nabla_x \hat{\boldsymbol{\alpha}} = \mathbf{c}(h_{\boldsymbol{\alpha}}^*(\hat{\boldsymbol{\alpha}})),$$

which has the form of a symmetric hyperbolic system [14]. Furthermore, by multiplying (12) by  $h_{\boldsymbol{\rho}}$  and applying relations (125) and (128), we find that  $h(\boldsymbol{\rho})$  satisfies:

$$(130) \quad \partial_t h(\boldsymbol{\rho}) + \nabla_x \cdot j(\boldsymbol{\rho}) = \mathbf{a}(\boldsymbol{\rho})^T \mathbf{c}(\boldsymbol{\rho}),$$

where  $j(\boldsymbol{\rho}) \equiv \mathbf{a}(\boldsymbol{\rho})^T \mathbf{f}(\boldsymbol{\rho}) - j^*(\mathbf{a}(\boldsymbol{\rho}))$ . Then by (5) and (6),

$$(131) \quad \mathbf{a}(\boldsymbol{\rho})^T \mathbf{c}(\boldsymbol{\rho}) = \mathcal{S}(G_{\mathbf{a}(\boldsymbol{\rho})}) \leq 0$$

with equality if and only if  $G_{\mathbf{a}(\boldsymbol{\rho})}$  is a local Maxwellian (7). This is a direct analogue of Boltzmann's H-theorem for (2). (See [24] for details.)

**5.3. Nondegenerate examples.** For  $N = 2$ , there are two possible closures: Maxwellian and Gaussian. Both are well-known, and in both cases  $\mathcal{A}_{\mathbf{m}} = \text{int } \mathcal{A}_{\mathbf{m}}$  and  $\mathcal{R}_{\mathbf{m}} = \mathcal{R}_{\mathbf{m}}^{\text{exp}} = \text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ . Traditionally, these closures are expressed by using so-called fluid variables:

(132)

$$\begin{aligned} \text{density: } \rho &= \langle F \rangle, & \text{temperature matrix: } \Theta &= \frac{\langle (v-u) \vee (v-u) F \rangle}{\langle F \rangle}, \\ \text{bulk velocity: } u &= \frac{\langle v F \rangle}{\langle F \rangle}, & \text{temperature: } \theta &= \frac{1}{3} \text{trace}(\Theta) = \frac{\langle |v-u|^2 F \rangle}{3 \langle F \rangle}. \end{aligned}$$

1. *Maxwellian closure.* If  $\mathbf{m} = (1, v, \frac{1}{2}|v|^2)^T$ , the ansatz  $\mathcal{F}[\rho]$  in (14) is a Maxwellian distribution:

$$(133) \quad \mathcal{M}_{\rho, u, \theta}(v) \equiv \frac{\rho}{(2\pi\theta)^{d/2}} \exp\left(-\frac{|v-u|^2}{2\theta}\right).$$

The fluid variables are related to the densities  $\rho_i$  by

$$(134) \quad \rho_0 = \rho, \quad \rho_1 = \rho u, \quad \rho_2 = \frac{1}{2}\rho u^2 + \frac{3}{2}\rho\theta$$

and to the vectors  $\hat{\alpha}_i$  by

$$(135) \quad \hat{\alpha}_0 = \log\left(\frac{\rho}{(2\pi\theta)^{d/2}}\right) - \frac{|u|^2}{2\theta}, \quad \hat{\alpha}_1 = \frac{u}{\theta}, \quad \hat{\alpha}_2 = -\frac{1}{\theta}.$$

The moment equations in this case are the compressible Euler equations for a gas of point particles:

$$(136a) \quad \partial_t \rho + \nabla_x \cdot (\rho u) = 0,$$

$$(136b) \quad \partial_t (\rho u) + \nabla_x \cdot (\rho u \vee u + \rho \theta I) = 0,$$

$$(136c) \quad \partial_t \left( \frac{1}{2} \rho |u|^2 + \frac{d}{2} \rho \theta \right) + \nabla_x \cdot \left( \frac{1}{2} \rho |u|^2 u + \frac{d+2}{2} \rho \theta u \right) = 0.$$

The spatial entropy

$$(137) \quad h(\rho) = \langle \mathcal{M}_{\rho, u, \theta} \log \mathcal{M}_{\rho, u, \theta} - \mathcal{M}_{\rho, u, \theta} \rangle = \rho \left[ \log \left( \frac{\rho}{(2\pi\theta)^{d/2}} \right) - \frac{d+2}{2} \right]$$

is locally conserved by smooth solutions for (136) but is dissipated along shocks.

2. *Gaussian closure.* If  $\mathbf{m} = (1, v, v \vee v)^T$ , the ansatz  $\mathcal{F}[\rho]$  in (14) is a Gaussian distribution:

$$(138) \quad \mathcal{G}_{\rho, u, \Theta}(v) = \frac{\rho}{\sqrt{\det(2\pi\Theta)}} \exp\left(-\frac{1}{2}(v-u) \cdot \Theta^{-1} \cdot (v-u)\right).$$

The fluid variables are related to the densities  $\rho_i$  by

$$(139) \quad \rho_0 = \rho, \quad \rho_1 = \rho u, \quad \rho_2 = \rho u \vee u + \rho \Theta$$

and to the vectors  $\hat{\alpha}_i$  by

$$(140) \quad \hat{\alpha}_0 = \log \left( \frac{\rho}{\sqrt{\det(2\pi\Theta)}} \right) - \frac{1}{2} u \cdot \Theta^{-1} \cdot u, \quad \hat{\alpha}_1 = \Theta^{-1} \cdot u, \quad \hat{\alpha}_2 = -\frac{1}{2} \Theta^{-1}.$$

The moment equations in this case are

$$(141a) \quad \partial_t \rho + \nabla_x \cdot (\rho u) = 0,$$

$$(141b) \quad \partial_t (\rho u) + \nabla_x \cdot (\rho u \vee u + \rho \Theta) = 0,$$

$$(141c) \quad \partial_t (\rho u \vee u + \rho \Theta) + \nabla_x \cdot (\rho u \vee u \vee u + 3\rho \Theta \vee u) = \langle v \vee v \mathcal{C}(\mathcal{G}_{\rho,u,\Theta}) \rangle,$$

and solutions to this system satisfy a local dissipation law for the spatial entropy

$$(142) \quad h(\rho) = \langle \mathcal{G}_{\rho,u,\Theta} \log \mathcal{G}_{\rho,u,\Theta} - \mathcal{G}_{\rho,u,\Theta} \rangle = \rho \left[ \log \left( \frac{\rho}{\sqrt{\det(2\pi\Theta)}} \right) - \frac{d+2}{2} \right].$$

Note that, in both of the examples above, the expressions for  $\hat{\alpha}$  and  $\rho$  can be used to determine  $\mathbf{a}(\rho)$  explicitly. However, generally speaking, an analytical solution is not available, and a numerical solution must be computed via (91).

**5.4. Properties for degenerate cases.** If  $\rho \in \mathcal{D}_{\mathbf{m}}$ , then the minimizer with equality constraints (14) does not exist, and the entropy-based closure is not well-defined. Although it is possible to recover a well-defined closure by using the relaxed constraints in (20), much of the formal structure is lost. For example, if  $\rho \in \mathcal{D}_{\mathbf{m}}$ , then (123) and (126) no longer hold because  $\mathbf{r}(\mathbf{a}(\rho)) \neq \rho$  and, as shown in Corollary 22 below,  $h_S$  fails to be strictly convex on  $\mathcal{R}_{\mathbf{m}}$  whenever  $\mathcal{D}_{\mathbf{m}}$  is nonempty. Since many of the properties of entropy-based closures require  $h$  to be strictly convex, this fact is critical.

The situation for degenerate densities may be best understood via the projection operator  $\pi : \mathcal{R}_{\mathbf{m}} \rightarrow \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ , which assigns to each vector  $\rho \in \mathcal{R}_{\mathbf{m}}$  the density which is realized by the minimizer of (20):

$$(143) \quad \pi(\rho) \equiv \mathbf{r}(\mathbf{a}(\rho)) = \langle \mathbf{m} G_{\mathbf{a}(\rho)} \rangle.$$

Before discussing  $\pi$  further, we introduce some notation that will be useful for the remainder of the paper. First we have the natural decompositions for  $\mathbf{r}$ ,  $\mathbf{a}$ , and  $\pi$  based on the decomposition of  $\mathbf{m}$  in (22):

$$(144) \quad \mathbf{r} = (\mathbf{r}_0^T, \mathbf{r}_1^T, \dots, \mathbf{r}_N^T)^T, \quad \mathbf{a} = (\mathbf{a}_0^T, \mathbf{a}_1^T, \dots, \mathbf{a}_N^T)^T, \quad \pi = (\pi_0^T, \pi_1^T, \dots, \pi_N^T)^T.$$

With this notation,

$$(145) \quad G_{\mathbf{a}(\rho)} = \exp \left( \sum_{j=1}^N \mathbf{a}_j(\rho)^T \mathbf{m}_j \right), \quad \mathbf{r}_j(\alpha) = \langle \mathbf{m}_j G_{\alpha} \rangle, \quad \pi_j(\rho) = \mathbf{r}_j(\mathbf{a}(\rho)).$$

Next, for any  $\rho \in \mathbb{R}^n$  and any  $\zeta \in \mathbb{R}^{n_N}$ , we define

$$(146) \quad \rho +_N \zeta \equiv (\rho_0^T, \rho_1^T, \dots, \rho_N^T + \zeta^T)^T.$$

This notation will often be applied to subsets of  $\mathbb{R}^n$  and  $\mathbb{R}^{n_N}$  in the context of set addition.

PROPOSITION 20. Let  $\bar{\rho} \in \mathcal{R}_m^{\text{exp}}$ , and let  $\bar{\alpha} = \mathbf{a}(\bar{\rho})$ . Then for any  $\rho \in \mathbb{R}^n$ , the following are equivalent:

$$(147a) \quad (i) \quad \rho_N - \bar{\rho}_N \in \mathcal{NC}(A_{m_N}, \bar{\alpha}_N);$$

$$(147b) \quad (ii) \quad (\alpha_N - \bar{\alpha}_N)^T (\rho_N - \bar{\rho}_N) \leq 0 \quad \forall \alpha_N \in A_{m_N};$$

$$(147c) \quad (iii) \quad \bar{\alpha}_N^T (\rho_N - \bar{\rho}_N) = 0 \quad \text{and} \quad \alpha_N^T (\rho_N - \bar{\rho}_N) \leq 0 \quad \forall \alpha_N \in A_{m_N}.$$

*Proof.* Here (i)  $\Leftrightarrow$  (ii) is just the definition of a normal cone (31), and the implication that (iii)  $\Rightarrow$  (ii) is clear. To prove that (ii)  $\Rightarrow$  (iii), we use the freedom to choose any  $\alpha_N \in A_{m_N}$ . Setting  $\alpha_N = 0$  and then  $\alpha_N = 2\bar{\alpha}_N$  in (147b) gives

$$(148) \quad \bar{\alpha}_N^T (\rho_N - \bar{\rho}_N) \geq 0 \quad \text{and} \quad \bar{\alpha}_N^T (\rho_N - \bar{\rho}_N) \leq 0,$$

respectively. We conclude that  $\bar{\alpha}_N^T (\rho_N - \bar{\rho}_N) = 0$ , which, when substituted back into (147b), gives the inequality in (iii).  $\square$

LEMMA 21. The projection  $\pi$  satisfies the following relations:

$$(149a) \quad (i) \quad \pi_j(\rho) = \rho_j \quad \forall \rho \in \mathcal{R}_m \text{ and } j < N;$$

$$(149b) \quad (ii) \quad \mathbf{a}_N(\rho)^T \pi_N(\rho) = \mathbf{a}_N(\rho)^T \rho_N \quad \forall \rho \in \mathcal{R}_m;$$

$$(149c) \quad (iii) \quad \pi(\rho) = \rho \text{ if and only if } \rho \in \mathcal{R}_m^{\text{exp}};$$

$$(149d) \quad (iv) \quad \pi(\{\bar{\rho} +_N \mathcal{NC}(A_{m_N}, \bar{\alpha}_N)\} \cap O) = \bar{\rho} \\ \forall \bar{\rho} \in \mathcal{R}_m^{\text{exp}} \text{ and any } O \subset \mathcal{R}_m \text{ containing } \bar{\rho};$$

$$(149e) \quad (v) \quad \pi(\mathcal{D}_m) = \mathbf{r}(\mathcal{A}_m \cap \partial \mathcal{A}_m) = \mathcal{R}_m^{\text{exp}} \cap \partial \mathcal{R}_m^{\text{exp}};$$

$$(149f) \quad (vi) \quad \mathbf{a}(\pi(\rho)) = \mathbf{a}(\rho) \quad \forall \rho \in \mathcal{R}_m;$$

$$(149g) \quad (vii) \quad h(\pi(\rho)) = h(\rho) \quad \forall \rho \in \mathcal{R}_m.$$

*Proof.* We prove each statement in order.

1. Equation (149a) follows from the constraint conditions in (52a).
2. Equation (149b) is just a restatement of the nontrivial component of the complementary slackness condition (109) with  $\hat{\alpha} = \mathbf{a}(\rho)$ .
3. By Theorem 17,  $\pi = \mathbf{r} \circ \mathbf{a}$  is the identity map on  $\mathcal{R}_m^{\text{exp}}$ . Thus  $\pi(\rho) = \rho$  if  $\rho \in \mathcal{R}_m^{\text{exp}}$ . However, the range of  $\pi$  is  $\pi(\mathcal{R}_m) = \mathbf{r}(\mathcal{A}_m) = \mathcal{R}_m^{\text{exp}}$ . Thus if  $\rho \notin \mathcal{R}_m^{\text{exp}}$ , then  $\pi(\rho)$  cannot equal  $\rho$ .
4. Let  $\bar{\rho} \in \mathcal{R}_m^{\text{exp}}$ , let  $O \subset \mathcal{R}_m$  be an open set containing  $\bar{\rho}$ , and let  $\bar{\alpha} = \mathbf{a}(\bar{\rho})$ . Choose any  $\rho \in \{\bar{\rho} +_N \mathcal{NC}(A_{m_N}, \bar{\alpha}_N)\}$ . Then  $\rho = \bar{\rho}$  for  $j < N$ , so by Proposition 20,  $\bar{\alpha}^T \rho = \bar{\alpha}^T \bar{\rho}$  and  $\alpha^T \rho \leq \alpha^T \bar{\rho}$  for all  $\alpha \in \mathcal{A}_m$ . Therefore

$$(150) \quad \psi(\bar{\alpha}, \bar{\rho}) = \psi(\bar{\alpha}, \rho) \leq \psi(\mathbf{a}(\rho), \rho) \leq \psi(\mathbf{a}(\rho), \bar{\rho}) \leq \psi(\bar{\alpha}, \bar{\rho}).$$

Here the equality in (150) follows immediately from the definition of  $\psi$  (75) and the fact that  $\bar{\alpha}^T \rho = \bar{\alpha}^T \bar{\rho}$ . The first inequality in (150) uses the fact that  $\psi(\mathbf{a}(\rho), \rho)$  maximizes  $\psi(\cdot, \rho)$  over all  $\alpha \in \mathcal{A}_m$ ; the second uses the fact that  $\alpha^T \rho \leq \alpha^T \bar{\rho}$  for all  $\alpha \in \mathcal{A}_m$ ; and the third uses the fact that  $\psi(\bar{\alpha}, \bar{\rho})$  maximizes  $\psi(\cdot, \bar{\rho})$  over all  $\alpha \in \mathcal{A}_m$ . We conclude from (150) that  $\psi(\mathbf{a}(\rho), \bar{\rho}) = \psi(\bar{\alpha}, \bar{\rho})$ . Since  $\bar{\alpha}$  is the *unique* maximizer of  $\psi(\cdot, \bar{\rho})$  over all  $\alpha \in \mathcal{A}_m$ , it follows that  $\mathbf{a}(\rho) = \bar{\alpha}$ . Therefore  $\pi(\rho) = \mathbf{r}(\mathbf{a}(\rho)) = \mathbf{r}(\bar{\alpha}) = \bar{\rho}$ .

5. We first argue by contraction to show that  $\pi(\mathcal{D}_m) \subset \mathbf{r}(\mathcal{A}_m \cap \partial \mathcal{A}_m)$ . Thus, suppose there exist  $\rho \in \mathcal{D}_m$  and  $\alpha \in \text{int } \mathcal{A}_m$  such that  $\pi(\rho) = \mathbf{r}(\alpha)$ . We know that

$$(151) \quad \psi(\pi(\rho), \mathbf{a}(\pi(\rho))) = \max_{\alpha \in \mathcal{A}_m} \psi(\pi(\rho), \alpha),$$

and since  $\psi$  is differentiable on  $\text{int } \mathcal{A}_{\mathbf{m}}$ , first order optimality conditions imply that

$$(152) \quad \frac{\partial \psi}{\partial \alpha}(\pi(\rho), \mathbf{a}(\pi(\rho))) = \rho - \pi(\pi(\rho)) = 0.$$

However,  $\pi$  is a projection; therefore, (152) implies that  $\rho = \pi(\rho)$ . According to (149c), this contradicts the assumption that  $\rho \in \mathcal{D}_{\mathbf{m}}$ .

We next show that  $\mathbf{r}(\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}) \subset \pi(\mathcal{D}_{\mathbf{m}})$ . Let  $\bar{\alpha} \in \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ , and let  $O \subset \mathcal{R}_{\mathbf{m}}$  be an open set containing  $\mathbf{r}(\bar{\alpha}) \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ . Then choose (see (32))

$$(153) \quad \rho \in \{\mathbf{r}(\bar{\alpha}) +_N \mathcal{NC}_0(\mathcal{A}_{\mathbf{m}_N}, \bar{\alpha}_N)\} \cap O.$$

Since  $\bar{\alpha} \in \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ ,  $\bar{\alpha}_N \in \partial \mathcal{A}_{\mathbf{m}_N}$  (see (46)), and this set is nonempty. By (149d),  $\pi(\rho) = \mathbf{r}(\bar{\alpha})$ . Thus we need only show that  $\rho \in \mathcal{D}_{\mathbf{m}}$ . If it is not, then  $\rho \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  and  $\pi(\rho) = \rho = \mathbf{r}(\bar{\alpha})$ , which contradicts (153). Thus  $\rho \in \mathcal{D}_{\mathbf{m}}$ .

Finally, we show that  $\mathbf{r}(\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}) = \mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ . Because  $\mathbf{r}$  is one-to-one on  $\mathcal{A}_{\mathbf{m}}$  (Theorem 17),

$$(154) \quad \mathbf{r}(\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}) = \mathbf{r}(\mathcal{A}_{\mathbf{m}}) \setminus \mathbf{r}(\text{int } \mathcal{A}_{\mathbf{m}}) = \mathcal{R}_{\mathbf{m}}^{\text{exp}} \setminus \text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}} = \mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}.$$

6. Given that  $\mathbf{a} \circ \mathbf{r}$  is the identity map on  $\mathcal{A}_{\mathbf{m}}$  (Theorem 17),  $\mathbf{a}(\pi(\rho)) = (\mathbf{a} \circ \mathbf{r})(\mathbf{a}(\rho)) = \mathbf{a}(\rho)$ .

7. The proof is a simple calculation. For any  $\rho \in \mathcal{R}_{\mathbf{m}}$ , (149a), (149b), and (149f) give

$$(155) \quad h(\pi(\rho)) = \psi(\mathbf{a}(\pi(\rho)), \pi(\rho)) = \psi(\mathbf{a}(\pi(\rho)), \rho) = \psi(\mathbf{a}(\rho), \rho) = h(\rho). \quad \square$$

**COROLLARY 22.** *The set  $\mathcal{D}_{\mathbf{m}}$  is empty if and only if  $\mathcal{A}_{\mathbf{m}}$  is open. If  $\mathcal{D}_{\mathbf{m}}$  is nonempty, then  $h$  fails to be strictly convex.*

*Proof.* The first statement is an immediate consequence of (149e). The second statement is a consequence of (149d) and (149g), which together imply that  $h$  is constant on the cone  $\{\bar{\rho} +_N \mathcal{NC}(\mathcal{A}_{\mathbf{m}_N}, \mathbf{a}_N(\bar{\rho}))\}$  for any  $\bar{\rho} \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ . If  $\mathcal{D}_{\mathbf{m}}$  is nonempty, then by (149e),  $\mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  is also nonempty; if  $\bar{\rho} \in \mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ , then  $\mathbf{a}(\bar{\rho}) \in \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$  and, consequently,  $\mathbf{a}_N(\bar{\rho}) \in \partial \mathcal{A}_{\mathbf{m}_N}$  (see (46)). As a result,  $\{\bar{\rho} +_N \mathcal{NC}(\mathcal{A}_{\mathbf{m}_N}, \mathbf{a}(\bar{\rho}))\}$  is nontrivial, and  $h$  cannot be strictly convex on all of  $\mathcal{R}_{\mathbf{m}}$ .  $\square$

It turns out that  $\mathcal{A}_{\mathbf{m}}$  is open only for  $N = 2$ . (To see this fact, one need only realize that, for  $N > 2$ , the vector  $\alpha \in \mathcal{A}_{\mathbf{m}}$  corresponding to any Maxwellian  $\mathcal{M}_{\rho, u, \theta}$  lies on the boundary  $\partial \mathcal{A}_{\mathbf{m}}$ .) Thus Corollary 22 shows that the Maxwellian and Gaussian closures are the exception rather than the rule. However, in spite of the difficulties encountered for  $\alpha \in \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ , (124) and (125) extend to all of  $\mathcal{R}_{\mathbf{m}}$ .

**THEOREM 23.** *For all  $\rho \in \mathcal{R}_{\mathbf{m}}$ ,*

$$(156) \quad h(\rho) + h^*(\mathbf{a}(\rho)) = \mathbf{a}(\rho)^T \rho,$$

*and the function  $\mathbf{a}$  is the continuous Fréchet derivative of  $h$  everywhere on  $\mathcal{R}_{\mathbf{m}}$ , i.e.,*

$$(157) \quad \mathbf{a}(\rho) = h_{\rho}(\rho).$$

*Proof.* Let  $\rho \in \mathcal{R}_{\mathbf{m}}$ , and set  $\bar{\rho} = \pi(\rho) \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ . By (124),

$$(158) \quad h(\pi(\rho)) + h^*(\mathbf{a}(\pi(\rho))) = \mathbf{a}(\pi(\rho))^T \pi(\rho).$$

However, according to Lemma 21,  $\mathbf{a}(\boldsymbol{\rho}) = \mathbf{a}(\bar{\boldsymbol{\rho}})$ ,  $h(\boldsymbol{\rho}) = h(\bar{\boldsymbol{\rho}})$ , and  $\mathbf{a}(\boldsymbol{\rho})^T \boldsymbol{\rho} = \mathbf{a}(\boldsymbol{\rho})^T \bar{\boldsymbol{\rho}}$ . Therefore (158) and (156) are equivalent.

We now move on to proving (157). By using (116), we find that

$$(159) \quad \begin{aligned} h(\boldsymbol{\rho} + \boldsymbol{\delta}) &= \psi(\mathbf{a}(\boldsymbol{\rho} + \boldsymbol{\delta}), \boldsymbol{\rho} + \boldsymbol{\delta}) \geq \psi(\mathbf{a}(\boldsymbol{\rho}), \boldsymbol{\rho} + \boldsymbol{\delta}) \\ &= \psi(\mathbf{a}(\boldsymbol{\rho}), \boldsymbol{\rho}) + \mathbf{a}(\boldsymbol{\rho})^T \boldsymbol{\delta} = h(\boldsymbol{\rho}) + \mathbf{a}(\boldsymbol{\rho})^T \boldsymbol{\delta} \end{aligned}$$

and, similarly, that

$$(160) \quad \begin{aligned} h(\boldsymbol{\rho}) &= \psi(\mathbf{a}(\boldsymbol{\rho}), \boldsymbol{\rho}) \geq \psi(\mathbf{a}(\boldsymbol{\rho} + \boldsymbol{\delta}), \boldsymbol{\rho}) = \psi(\mathbf{a}(\boldsymbol{\rho} + \boldsymbol{\delta}), \boldsymbol{\rho} + \boldsymbol{\delta}) - [\mathbf{a}(\boldsymbol{\rho} + \boldsymbol{\delta})]^T \boldsymbol{\delta} \\ &= h(\boldsymbol{\rho} + \boldsymbol{\delta}) - [\mathbf{a}(\boldsymbol{\rho} + \boldsymbol{\delta})]^T \boldsymbol{\delta}. \end{aligned}$$

Together (159) and (160) imply that

$$(161) \quad 0 \leq h(\boldsymbol{\rho} + \boldsymbol{\delta}) - h(\boldsymbol{\rho}) - \mathbf{a}(\boldsymbol{\rho})^T \boldsymbol{\delta} \leq |\boldsymbol{\delta}| |\mathbf{a}(\boldsymbol{\rho} + \boldsymbol{\delta}) - \mathbf{a}(\boldsymbol{\rho})|.$$

Hence, to complete the proof, we need only to show that  $\mathbf{a}$  is continuous.

Equation (159) implies also that  $\mathbf{a}(\boldsymbol{\rho})$  is a *subgradient* of  $h$  at  $\boldsymbol{\rho}$  [30, section 23, page 214]. The set of all subgradients is called the *subdifferential* of  $h$  at  $\boldsymbol{\rho}$  and is denoted by  $\partial h(\boldsymbol{\rho})$ . It is a general result from convex analysis [30, Theorem 24.7] that, because  $h$  is convex, the set  $\partial h(S) \equiv \bigcup_{\boldsymbol{\rho} \in K} \partial h(\boldsymbol{\rho})$  is bounded whenever  $K \subset \mathbb{R}^n$  is bounded. In particular, if  $\{\boldsymbol{\rho}_{(i)}\}_{i=1}^\infty \subset \mathcal{R}_{\mathbf{m}}$  converges to  $\boldsymbol{\rho}_* \in \mathcal{R}_{\mathbf{m}}$ , then  $\{\mathbf{a}(\boldsymbol{\rho}_{(i)})\}_{i=1}^\infty$  is a bounded sequence. Let  $\boldsymbol{\alpha}_*$  be any subsequential limit for this sequence. Then

$$(162) \quad \begin{aligned} \psi(\mathbf{a}(\boldsymbol{\rho}_*), \boldsymbol{\rho}_*) &= \lim_{i \rightarrow \infty} \psi(\mathbf{a}(\boldsymbol{\rho}_*), \boldsymbol{\rho}_{(i_k)}) \\ &\leq \lim_{i \rightarrow \infty} \psi(\mathbf{a}(\boldsymbol{\rho}_{(i_k)}), \boldsymbol{\rho}_{(i_k)}) \leq \psi(\boldsymbol{\alpha}_*, \boldsymbol{\rho}_*) \leq \psi(\mathbf{a}(\boldsymbol{\rho}_*), \boldsymbol{\rho}_*), \end{aligned}$$

where  $\{i_k\}_{k=1}^\infty$  is any sequence of integers such that  $\boldsymbol{\alpha}_* = \lim_{i \rightarrow \infty} \mathbf{a}(\boldsymbol{\rho}_{(i_k)})$ . The first and last inequalities in (162) follow because  $\psi(\mathbf{a}(\boldsymbol{\rho}), \boldsymbol{\rho})$  maximizes  $\psi(\cdot, \boldsymbol{\rho})$ , whereas the middle inequality is a consequence of the fact that  $\psi(\cdot, \boldsymbol{\rho})$  is upper semicontinuous (Theorem 11).

From (162), we deduce that  $\psi(\boldsymbol{\alpha}_*, \boldsymbol{\rho}) = \psi(\mathbf{a}(\boldsymbol{\rho}_*), \boldsymbol{\rho})$ , and, since  $\mathbf{a}(\boldsymbol{\rho}_*)$  is the *unique* minimizer of  $\psi(\cdot, \boldsymbol{\rho})$ , it follows that  $\boldsymbol{\alpha}_* = \mathbf{a}(\boldsymbol{\rho}_*)$ . Because  $\{\mathbf{a}(\boldsymbol{\rho}_{(i)})\}$  is bounded and all of its converging subsequences converge to  $\mathbf{a}(\boldsymbol{\rho}_*)$ , it follows then that

$$(163) \quad \lim_{i \rightarrow \infty} \mathbf{a}(\boldsymbol{\rho}_{(i)}) = \mathbf{a}(\boldsymbol{\rho}_*).$$

Thus  $\mathbf{a}$  is continuous, and  $h$  is continuously differentiable.  $\square$

Note that, as a consequence of Theorem 23,  $h(\boldsymbol{\rho}) = \psi(\mathbf{a}(\boldsymbol{\rho}), \boldsymbol{\rho})$  is a differentiable on all of  $\mathcal{R}_{\mathbf{m}}$  even though  $\psi(\cdot, \boldsymbol{\rho})$  may not be continuous for  $\boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ . We alluded to this fact earlier in section 4.2.

**6. Geometry of  $\mathcal{D}_{\mathbf{m}}$ .** In this section, we give a description of the geometry of the set  $\mathcal{D}$ . The main results are given in Theorem 25, which shows that  $\mathcal{D}$  is a union of cones, and in Theorem 28, which concludes that, with additional assumptions,  $\mathcal{D}$  is small in both a topological and a measure-theoretic sense. We begin with some motivation for why such results are important.

**6.1. Motivation: Behavior of the closure near degeneracy.** Even though  $\mathcal{D}_{\mathbf{m}}$  is usually nonempty, there is evidence to suggest that if  $\boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  initially, then

densities in  $\mathcal{D}_{\mathbf{m}}$  might never be attained. To investigate this possibility, we introduce the function  $\chi : \mathcal{R}_{\mathbf{m}} \rightarrow \mathbb{R}$ , defined by

$$(164) \quad \chi(\boldsymbol{\rho}) \equiv \int_{\mathbb{R}^d} |v \mathbf{m}(v)| G_{\mathbf{a}(\boldsymbol{\rho})}(v) dv.$$

For the entropy-based closure,  $\chi$  is closely related to the flux  $\mathbf{f}$  in (13), and we show below that  $\chi$  becomes unbounded as  $\boldsymbol{\rho}$  approaches  $\mathcal{D}_{\mathbf{m}}$ . As pointed out in [20], such divergent behavior raises the possibility that  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  is invariant under the dynamics of the closure.

**PROPOSITION 24.** *Let  $\{\boldsymbol{\rho}_{(j)}\}_{j=1}^{\infty}$  be a sequence in  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  such that  $\boldsymbol{\rho}_{(j)} \rightarrow \boldsymbol{\rho}_* \in \mathcal{D}_{\mathbf{m}}$ , and for each  $j$ , let  $\chi_j \equiv \chi(\boldsymbol{\rho}_{(j)})$ . Then  $\{\chi_j\}_{j=1}^{\infty}$  is unbounded.*

*Proof.* Since  $\{\boldsymbol{\rho}_{(j)}\}_{j=1}^{\infty} \subset \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ ,

$$(165) \quad \mathbf{r}(\mathbf{a}(\boldsymbol{\rho}_{(j)})) = \boldsymbol{\rho}_{(j)}, \quad j = 1, 2, \dots,$$

and taking limits on both sides gives

$$(166) \quad \lim_{j \rightarrow \infty} \mathbf{r}(\mathbf{a}(\boldsymbol{\rho}_{(j)})) = \boldsymbol{\rho}_*.$$

We proceed by showing that if  $\{\chi_j\}_{j=1}^{\infty}$  is bounded, then

$$(167) \quad \lim_{j \rightarrow \infty} \mathbf{r}(\mathbf{a}(\boldsymbol{\rho}_{(j)})) = \mathbf{r}(\mathbf{a}(\boldsymbol{\rho}_*)).$$

Together (166)–(167) will then imply that  $\boldsymbol{\rho}_* \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  which, by contradicting our hypothesis, proves the claim. Hence, suppose that  $\{\chi_j\}_{j=1}^{\infty}$  is bounded. To conclude (167), we calculate

$$(168) \quad \begin{aligned} \left| \mathbf{r}(\mathbf{a}(\boldsymbol{\rho}_*)) - \mathbf{r}(\mathbf{a}(\boldsymbol{\rho}_{(j)})) \right| &= \left| \langle \mathbf{m} G_{\mathbf{a}(\boldsymbol{\rho}_*)} \rangle - \langle \mathbf{m} G_{\mathbf{a}(\boldsymbol{\rho}_{(j)})} \rangle \right| \\ &\leq \int_{\mathbb{R}^d} |\mathbf{m}(v)| \left| G_{\mathbf{a}(\boldsymbol{\rho}_*)}(v) - G_{\mathbf{a}(\boldsymbol{\rho}_{(j)})}(v) \right| dv \\ &= \int_{|v| > R} |\mathbf{m}(v)| \left| G_{\mathbf{a}(\boldsymbol{\rho}_*)}(v) - G_{\mathbf{a}(\boldsymbol{\rho}_{(j)})}(v) \right| dv \end{aligned}$$

$$(169) \quad + \int_{|v| < R} |\mathbf{m}(v)| \left| G_{\mathbf{a}(\boldsymbol{\rho}_*)}(v) - G_{\mathbf{a}(\boldsymbol{\rho}_{(j)})}(v) \right| dv,$$

where  $R > 0$  is an arbitrary constant. We handle the integrals for  $|v| > R$  and  $|v| < R$  in (168) separately. For  $|v| > R$ ,

$$(170) \quad \begin{aligned} &\int_{|v| > R} |\mathbf{m}(v)| \left| G_{\mathbf{a}(\boldsymbol{\rho}_*)}(v) - G_{\mathbf{a}(\boldsymbol{\rho}_{(j)})}(v) \right| dv \\ &\leq \int_{|v| > R} \frac{|v \mathbf{m}(v)|}{R} \left| G_{\mathbf{a}(\boldsymbol{\rho}_*)}(v) - G_{\mathbf{a}(\boldsymbol{\rho}_{(j)})}(v) \right| dv \\ &\leq \frac{1}{R} \int_{\mathbb{R}^d} |v \mathbf{m}(v)| \left| G_{\mathbf{a}(\boldsymbol{\rho}_*)}(v) - G_{\mathbf{a}(\boldsymbol{\rho}_{(j)})}(v) \right| dv \leq \frac{C}{R}, \end{aligned}$$

where

$$(171) \quad C \equiv 2 \max \left\{ \chi(\boldsymbol{\rho}_*), \sup_j \{\chi_j\} \right\}.$$

For  $|v| < R$ , continuity of  $\mathbf{a}$  (see Theorem 23) implies that  $\mathbf{a}(\boldsymbol{\rho}_{(j)}) \rightarrow \mathbf{a}(\boldsymbol{\rho}_*)$ . Hence the sequence  $G_{\mathbf{a}(\boldsymbol{\rho}_{(j)})}$  is uniformly bounded on  $\{v \in \mathbb{R}^d : |v| \leq R\}$ . By the Lebesgue bounded convergence theorem,

$$(172) \quad \lim_{j \rightarrow \infty} \int_{|v| < R} |\mathbf{m}(v)| G_{\mathbf{a}(\boldsymbol{\rho}_j)}(v) dv = \int_{|v| < R} |\mathbf{m}(v)| G_{\mathbf{a}(\boldsymbol{\rho}_*)}(v) dv.$$

Together (168), (170), and (172) imply that

$$(173) \quad \lim_{j \rightarrow \infty} |\mathbf{r}(\mathbf{a}(\boldsymbol{\rho}_*)) - \mathbf{r}(\mathbf{a}(\boldsymbol{\rho}_j))| \leq \frac{C}{R}.$$

Because  $R$  can be arbitrarily large, we conclude that (167) holds, which proves the claim.  $\square$

Note that, by uniformly bounding  $\chi_j$  in the proof above, we are providing uniform control on the highest-order moments in  $\boldsymbol{\rho}_{(j)}$ . In general, such control is not possible, which is why the minimizer in (14) with equality constraints does not always exist. (See the discussion following the proof of Theorem 3.)

The behavior of  $\chi$  expressed in Proposition 24 was first observed by Junk for the one-dimensional example in [20]. In particular, for a sequence  $\{\boldsymbol{\rho}_{(j)}\}_{j=1}^\infty \in \text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ , it was found that  $\langle v \mathbf{m}_N G_{\mathbf{a}(\boldsymbol{\rho})} \rangle$  diverges to either positive or negative infinity as  $\boldsymbol{\rho}_{(j)} \rightarrow \boldsymbol{\rho}_* \in \mathcal{D}_{\mathbf{m}}$ , with the sign depending on the direction of approach.

Suppose now that it can be proven that  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  is invariant under the dynamics of the balance law (12) with the entropy-based closure. Then if  $\boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  initially, the entropy minimization problem with equality constraints (14) will always have a solution, and the formal properties of the closure based on the Legendre duality between  $h$  and  $h^*$  will be maintained. However, it must be shown—at a minimum—that  $\mathcal{D}_{\mathbf{m}}$  is small in some sense, thereby limiting the number of initial conditions in  $\mathcal{R}_{\mathbf{m}}$  which must be discarded in order to maintain a well-defined closure. In the following subsections, we use the complementary slackness conditions (92) to show that, under reasonable hypotheses,  $\mathcal{D}_{\mathbf{m}}$  is indeed a Lebesgue measure zero set.

**6.2. The complementary slackness condition and normal cones.** From the complementary slackness condition (149b), we obtain the following result.

**THEOREM 25.** *The set  $\mathcal{R}_{\mathbf{m}}$  can be expressed as the following union of cones:*

$$(174) \quad \mathcal{R}_{\mathbf{m}} = \bigcup_{\bar{\boldsymbol{\rho}} \in \mathcal{R}_{\mathbf{m}}^{\text{exp}}} \bar{\boldsymbol{\rho}} +_N \mathcal{NC}(A_{\mathbf{m}_N}, \mathbf{a}_N(\bar{\boldsymbol{\rho}})).$$

The proof of this theorem uses the following lemma.

**LEMMA 26.** *Let  $\mathbf{m}$  be a vector whose polynomial components form the basis for an admissible space  $\mathbb{M}$ . Then  $A_{\mathbf{m}} \subset \{\boldsymbol{\alpha} \in \mathbb{R}^n : \boldsymbol{\alpha}_N \in A_{\mathbf{m}_N}\}$ , where  $A_{\mathbf{m}}$  and  $A_{\mathbf{m}_N}$  are defined in (36) and (44), respectively.*

*Proof.* Let  $\boldsymbol{\alpha} \in A_{\mathbf{m}}$ , and let  $v_* \in \mathbb{R}^d$  be fixed. Because the components of  $\mathbf{m}_i$  are homogeneous polynomials of degree  $i$ , for any  $\lambda > 0$ ,

$$(175) \quad 0 \geq \frac{1}{\lambda^N} \boldsymbol{\alpha}^T \mathbf{m}(\lambda v_*) = \sum_{i=0}^N \frac{\lambda^i}{\lambda^N} \boldsymbol{\alpha}_i^T \mathbf{m}_i(v_*).$$

Taking the limit  $\lambda \rightarrow \infty$  in (175) gives  $\boldsymbol{\alpha}_N^T \mathbf{m}_N(v_*) \leq 0$ , and since  $v_*$  is arbitrary, we conclude that  $\boldsymbol{\alpha}_N \in A_{\mathbf{m}_N}$ .  $\square$

*Proof of Theorem 25.* Suppose that  $\rho \in \mathbb{R}^n$  and that  $\bar{\rho} \in \mathcal{R}_m^{\text{exp}}$ . Before making any further assumptions about  $\rho$  or any relationship between  $\rho$  and  $\bar{\rho}$ , we note that from Proposition 20 we obtain the following set of equivalent statements:

$$(176a) \quad (i) \quad \rho_N - \bar{\rho}_N \in \mathcal{NC}(A_{m_N}, \mathbf{a}_N(\bar{\rho}));$$

$$(176b) \quad (ii) \quad (\alpha_N - \mathbf{a}_N(\bar{\rho}))^T (\rho_N - \bar{\rho}_N) \leq 0 \quad \forall \alpha_N \in A_{m_N};$$

$$(176c) \quad (iii) \quad \mathbf{a}_N(\bar{\rho})^T (\rho_N - \bar{\rho}_N) = 0 \quad \text{and} \quad \alpha_N^T (\rho_N - \bar{\rho}_N) \leq 0 \quad \forall \alpha_N \in A_{m_N}.$$

We first show containment of the left-hand side of (174). Given  $\rho \in \mathcal{R}_m$ , let  $\bar{\rho} = \pi(\rho) \in \mathcal{R}_m^{\text{exp}}$ . Then  $\rho_j = \bar{\rho}_j$  for  $j < N$  and, by (149f),  $\mathbf{a}(\bar{\rho}) = \mathbf{a}(\rho)$ . Thus, from (149b),

$$(177) \quad \mathbf{a}_N(\bar{\rho})^T \rho_N = \mathbf{a}_N(\bar{\rho})^T \bar{\rho}_N.$$

Meanwhile, the constraint conditions in (52) imply that

$$(178) \quad \alpha_N^T \rho_N \leq \alpha_N^T \bar{\rho}_N \quad \forall \alpha \in A_m.$$

We conclude from (176)–(178) that  $\rho_N - \bar{\rho}_N \in \mathcal{NC}(A_{m_N}, \mathbf{a}_N(\bar{\rho}))$ .

Next we show containment in the other direction. Suppose that  $\rho_j = \bar{\rho}_j$  for  $j < N$  and that  $\rho_N - \bar{\rho}_N \in \mathcal{NC}(A_{m_N}, \mathbf{a}_N(\bar{\rho}))$ . By Theorem 1,  $\mathcal{R}_m = \text{int } A_m^\circ$ , so it is sufficient to prove that  $\rho \in \text{int } A_m^\circ$ . Because  $\bar{\rho} \in \mathcal{R}_m^{\text{exp}} \subset \mathcal{R}_m = \text{int } A_m^\circ$ , it follows that  $\alpha^T \bar{\rho} < 0$  for all  $\alpha \in A_m$ . Furthermore, by Lemma 26,  $\alpha_N \in A_{m_N}$  for all such  $\alpha$ . Hence from (178),

$$(179) \quad \alpha^T \rho = \alpha^T \bar{\rho} + \alpha_N^T (\rho_N - \bar{\rho}_N) < 0 \quad \forall \alpha \in A_m.$$

This shows that  $\rho \in \text{int } A_m^\circ$  and concludes the proof.  $\square$

For  $\bar{\rho} \in \text{int } \mathcal{R}_m^{\text{exp}}$ ,  $\mathcal{NC}(A_{m_N}, \mathbf{a}_N(\bar{\rho}))$  is just the origin in  $\mathbb{R}^{n_N}$ . In such cases, Theorem 25 is trivial, and the construction  $\bar{\rho} +_N \mathcal{NC}(A_{m_N}, \mathbf{a}_N(\bar{\rho}))$  does not generate any new densities. Therefore  $\mathcal{D}_m$  is constructed entirely by convex cones attached to  $\bar{\rho} \in \mathcal{R}_m^{\text{exp}} \cap \partial \mathcal{R}_m^{\text{exp}}$ . Recall from (32) that  $\mathcal{NC}_0(A_{m_N}, \mathbf{a}_N(\bar{\rho})) = \mathcal{NC}(A_{m_N}, \mathbf{a}_N(\bar{\rho})) \setminus \{0\}$ . We have the following corollary.

**COROLLARY 27.** *The degenerate densities are*

$$(180) \quad \mathcal{D}_m = \bigcup_{\bar{\rho} \in \mathcal{R}_m^{\text{exp}} \cap \partial \mathcal{R}_m^{\text{exp}}} \{\bar{\rho} +_N \mathcal{NC}_0(A_{m_N}, \mathbf{a}_N(\bar{\rho}))\} = \bigcup_{\bar{\alpha} \in \mathcal{A}_m \cap \partial \mathcal{A}_m} \{\mathbf{r}(\bar{\alpha}) +_N \mathcal{NC}_0(A_{m_N}, \bar{\alpha}_N)\}.$$

**6.3. Smoothness assumptions on  $\mathcal{A}_m \cap \partial \mathcal{A}_m$ .** Corollary 27 gives the degenerate densities associated with each  $\bar{\rho} \in \mathcal{R}_m^{\text{exp}} \cap \partial \mathcal{R}_m^{\text{exp}}$ . However, a clean description of  $\mathcal{D}_m$  requires also that  $\mathcal{R}_m^{\text{exp}} \cap \partial \mathcal{R}_m^{\text{exp}}$  itself have a nice structure. In particular, we would like to say that  $\mathcal{R}_m^{\text{exp}} \cap \partial \mathcal{R}_m^{\text{exp}}$  is a finite union of disjoint manifolds. At this point we are unable to prove such a result in general, in part due to the complicated structure of  $\mathcal{A}_m \cap \partial \mathcal{A}_m$  to which we alluded in section 2.4. We therefore make two assumptions. The first assumption says that  $\mathcal{A}_m \cap \partial \mathcal{A}_m$  is a union of disjoint manifolds with dimensional restrictions that are related to the dimensions of the normal cones in (180) in such a way as to ensure that  $\mathcal{D}_m$  is a lower-dimensional subset of  $\mathcal{R}_m$ . The second assumption says that the mapping  $\mathbf{r}$  is diffeomorphic when restricted to each of these manifolds. Thus each dimension  $k$  manifold in  $\mathcal{A}_m \cap \partial \mathcal{A}_m$  will map to

a dimension  $k$  manifold in  $\mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \partial\mathcal{R}_{\mathbf{m}}^{\text{exp}}$ . Before stating our assumptions, we define the orthogonal projections  $\mathcal{P}_N : \mathbb{R}^n \mapsto \mathbb{R}^{n_N}$  and  $\mathcal{P}_{\tilde{N}} : \mathbb{R}^n \mapsto \mathbb{R}^{n-n_N}$  by

$$(181) \quad \mathcal{P}_N(\boldsymbol{\alpha}) \equiv (0, \dots, 0, 0, \boldsymbol{\alpha}_N^T)^T \quad \text{and} \quad \mathcal{P}_{\tilde{N}}(\boldsymbol{\alpha}) \equiv \boldsymbol{\alpha} - \mathcal{P}_N(\boldsymbol{\alpha}) = (\boldsymbol{\alpha}_0^T, \boldsymbol{\alpha}_1^T, \dots, \boldsymbol{\alpha}_{N-1}^T, 0)^T.$$

*Assumption I.* The vector  $\mathbf{m}$  is such that the set  $\mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}}$  can be decomposed into a finite collection  $\mathcal{S}$  of disjoint, smooth ( $C^\infty$ ) manifolds in  $\mathbb{R}^n$ . Furthermore, if  $S$  is one such manifold, then  $\mathcal{P}_N$  projects  $S$  onto a manifold  $S_N \subset \partial\mathcal{A}_{\mathbf{m}_N}$  with codimension at least one in  $\mathbb{R}^{n_N}$  and  $\mathcal{P}_{\tilde{N}}$  projects  $S$  onto a manifold  $S_{\tilde{N}}$  of codimension at least one in  $\mathbb{R}^{n-n_N}$ .

We call  $\mathcal{S}$  a *stratification* of  $\mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}}$ ; the manifolds  $S$  that make up  $\mathcal{S}$  are called *strata*. We fully expect that  $\mathcal{S}$  can be chosen so that, for each  $S \in \mathcal{S}$ , the projection  $S_N$  is indeed a manifold. If so,  $S_N$  will certainly have codimension of one or more since, by (46),  $S_N \subset \partial\mathcal{A}_{\mathbf{m}_N}$ . Furthermore, if  $\boldsymbol{\alpha}_N \in \partial\mathcal{A}_{\mathbf{m}_N}$ , then  $\boldsymbol{\alpha}_N^T \mathbf{m}_N(\lambda\omega) = 0$  for some  $\omega \in \mathbb{S}^{d-1}$  and all  $\lambda \in \mathbb{R}$ , which means that  $\mathbf{m}_N$  no longer provides uniform control over lower-degree polynomials. Thus, in order to maintain the integrability condition (40) that defines  $\mathcal{A}_{\mathbf{m}}$ , we expect further restrictions on the components  $\boldsymbol{\alpha}_j$  for  $j < N$ . This is the motivation for the codimension one restriction on the manifold  $S_{\tilde{N}}$  in Assumption I. Since, in general,  $\dim(S) \leq \dim(S_N) + \dim(S_{\tilde{N}})$ , these restrictions together imply that  $S$  itself has codimension of at least two in  $\mathbb{R}^n$ .

It should be noted that Assumption I is known to hold for at least two cases:

$$(182a) \quad (i) \quad d = 1 \text{ and } N \geq 2;$$

$$(182b) \quad (ii) \quad d > 1, \quad N = 4, \text{ and } \mathbf{m}_4 = |v|^4.$$

(Whether or not Assumption I holds in any other case is, to our knowledge, an open question.) For the first case above,  $\boldsymbol{\alpha}_j = \alpha_j$  and  $n = N + 1$ . For  $i = 1, \dots, N/2$ , we define the sets

$$(183) \quad \mathcal{A}_{\mathbf{m}}^{2i} = \{\boldsymbol{\alpha} \in \mathbb{R}^n : \alpha_j = 0 \text{ for } 2i < j \leq N \text{ and } \alpha_{2i} < 0\}.$$

Clearly each  $\mathcal{A}_{\mathbf{m}}^{2i}$  is a manifold of dimension  $2i + 1$  such that

$$(184) \quad \mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}} = \bigcup_{i=1}^{N/2-1} \mathcal{A}_{\mathbf{m}}^{2i} \quad \text{and} \quad \mathcal{A}_{\mathbf{m}}^N = \text{int } \mathcal{A}_{\mathbf{m}}.$$

For the second case,  $\mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}} = \{\boldsymbol{\alpha} \in \mathbb{R}^n : \boldsymbol{\alpha}_2^T \mathbf{m}_2 < 0\}$ . If  $\mathbf{m}_2 = |v|^2$ , then  $G_{\boldsymbol{\alpha}}$  has the form of a Maxwellian distribution (133) on  $\mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}}$ ; if  $\mathbf{m}_2 = v \vee v$ , then  $G_{\boldsymbol{\alpha}}$  has the form of a Gaussian distribution (138) on  $\mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}}$ .

One possible way to prove that Assumption I always holds is to show that the integrability condition which defines  $\mathcal{A}_{\mathbf{m}}$  can be expressed as a family of polynomial equalities and inequalities for  $\boldsymbol{\alpha}$ . Sets expressed in this way are called *semialgebraic* and are known to have a stratification with special properties [2, 27]. One can show, for example, that the sets  $\mathcal{A}_{\mathbf{m}_j}$  ( $j$  even) and  $\text{cl } \mathcal{A}_{\mathbf{m}}$  are semialgebraic. One can also show that the interiors and boundaries of these sets are semialgebraic. See [17] for details.

*Assumption II.* The vector  $\mathbf{m}$  is such that if Assumption I holds and if  $S$  is an element of the stratification of  $\mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}}$ , then for each  $\boldsymbol{\rho} \in \mathcal{R}_{\mathbf{m}}$ , the restriction of  $\psi(\cdot, \boldsymbol{\rho})$  to  $S$  is infinitely Fréchet differentiable on  $S$ .

One may easily verify that Assumption II also holds for the cases in (182). When both Assumptions I and II hold,  $\mathbf{r}$  is a smooth diffeomorphism with inverse  $\mathbf{a}$  when restricted to any manifold in the stratification of  $\mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}}$ .

**6.4. Fiber bundles.** The construction of  $\mathcal{D}_{\mathbf{m}}$  by attaching cones to the densities  $\mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  is very similar to the construction of a fiber bundle. A (*continuous*) *fiber bundle*  $(\mathcal{B}, B, F, \mathcal{P})$  [18] consists of topological spaces  $\mathcal{B}$ ,  $B$ , and  $F$  along with a projection  $\mathcal{P} : \mathcal{B} \rightarrow B$  such that, for every  $y \in B$ , there is a neighborhood  $O \subset B$  containing  $y$  such that  $\mathcal{P}^{-1}(O)$  is homeomorphic to  $O \times F$ . In addition, if  $\phi$  is this homeomorphism and  $\Pi$  is the natural projection of  $O \times F$  onto  $O$  (i.e.,  $\Pi(y \times F) = y$  for all  $y \in O$ ), then  $\Pi(\phi(\mathcal{P}^{-1}))$  is the identity on  $O$ . The space  $B$  is called the *base space*,  $F$  is called the *fiber space*, and often  $\mathcal{B}$  itself is called the bundle. Roughly speaking,  $\mathcal{B}$  is constructed by attaching to each point in  $B$  a (topologically equivalent) copy of  $F$  that varies continuously from point to point in the base space. If Assumptions I and II hold, then for each manifold  $S$  in a stratification  $\mathcal{S}$  of  $\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ , the manifold  $\mathbf{r}(S)$  acts like a base space; the cones  $\mathcal{NC}(A_{\mathbf{m}_N}, \alpha_N)$ ,  $\alpha \in S$ , are like fibers; and  $\pi$  is the projection onto the base space. The entire structure is

$$(185) \quad \mathcal{B}(S) = \bigcup_{\alpha \in S} \{\mathbf{r}(\alpha) +_N \mathcal{NC}(A_{\mathbf{m}_N}, \alpha_N)\},$$

and, in view of Corollary 27,  $\mathcal{D}_{\mathbf{m}} = \bigcup_{S \in \mathcal{S}} \mathcal{B}_0(S)$ , where

$$(186) \quad \mathcal{B}_0(S) = \mathcal{B}(S) \setminus \mathbf{r}(S) = \bigcup_{\alpha \in S} \{\mathbf{r}(\alpha) +_N \mathcal{NC}_0(A_{\mathbf{m}_N}, \alpha_N)\}.$$

Unfortunately, we cannot conclude that  $\mathcal{B}(S)$  is a bundle even with Assumptions I and II. In short, we have been unable to show a local homeomorphism between the base-fiber product space and the inverse image  $\pi^{-1}(S)$ . However, the sets taken from the examples in section 6.6 below are all fiber bundles. This is fairly easy to check because, in these examples, the convex cones  $A_{\mathbf{m}_N}$  and  $\mathcal{NC}(A_{\mathbf{m}_N}, \alpha_N)$ ,  $\alpha_N \in \partial A_{\mathbf{m}_N}$ , have explicit expressions that are (relatively) simple.

**6.5. Smallness of  $\mathcal{D}_{\mathbf{m}}$ .** If Assumptions I and II hold, we can show that  $\mathcal{D}_{\mathbf{m}}$  is small in the following sense.

**THEOREM 28.** *Suppose that Assumptions I and II hold. Then  $\mathcal{D}_{\mathbf{m}}$  has zero Lebesgue measure,  $\text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  is a dense subset of  $\mathcal{R}_{\mathbf{m}}$ , and  $\mathcal{D}_{\mathbf{m}} \subset \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ .*

*Proof.* The basic idea of the argument is that the image of a smooth map from a lower-dimensional space to a higher-dimensional space has zero Lebesgue measure. We will construct such a map  $F$  whose image covers a portion of  $\mathcal{D}_{\mathbf{m}}$ . We can then cover  $\mathcal{D}_{\mathbf{m}}$  with the images from a countable number of similar maps.

Let  $\mathcal{S}$  be a stratification of  $\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$  as provided by Assumption I, and let  $S \in \mathcal{S}$  have dimension  $j$ . According to Assumption I,  $S_N \equiv \mathcal{P}_N S \subset \partial A_{\mathbf{m}_N}$  and  $S_{\tilde{N}} \equiv \mathcal{P}_{\tilde{N}} S$  are smooth manifolds with dimensions which we denote by  $j_N$  and  $j_{\tilde{N}}$ , respectively. In general,  $\dim(S) \leq \dim(S_N) + \dim(S_{\tilde{N}})$ , and in view of Assumption I,  $\dim(S_{\tilde{N}}) < n - n_N$ . Therefore

$$(187) \quad j \leq j_N + j_{\tilde{N}} < j_N + (n - n_N).$$

This inequality is the key to our result. For any  $\alpha \in S$ , the normal cone  $\mathcal{NC}(S_N, \alpha_N)$  is a subspace of dimension  $n_N - j_N$ , and one can readily show that

$$(188) \quad \mathcal{NC}(A_{\mathbf{m}_N}, \alpha_N) \subset \mathcal{NC}(S_N, \alpha_N), \quad \alpha \in S.$$

We can therefore proceed with the proof by considering the set

$$(189) \quad \mathcal{K}_{\mathbf{m}} \equiv \bigcup_{S \in \mathcal{S}} \bigcup_{\alpha \in S} K(\alpha) \supset (\mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}) \cup \mathcal{D}_{\mathbf{m}},$$

where the affine spaces

$$(190) \quad K(\alpha) \equiv \mathbf{r}(\alpha) +_N \mathcal{NC}(S_N, \alpha_N), \quad \alpha \in S,$$

are constructed by attaching  $\mathcal{NC}(S_N, \alpha_N)$  to  $\mathbf{r}(\alpha) \in \mathbf{r}(S) \subset \mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ .

Let  $U \subset S$  be the nonempty intersection of  $S$  with a bounded open ball in  $\mathbb{R}^n$ . Because  $S$  is a manifold, there exists a smooth diffeomorphism  $\tau : U \rightarrow \mathbb{R}^j$  such that  $\tau(U)$  is the open unit disk  $\mathbb{D}^j$ . Define a second mapping  $\mathbf{V} : U \rightarrow \mathbb{R}^{n_N \times (n_N - j_N)}$  such that  $\mathbf{V}(\alpha)$  is a matrix whose  $(n_N - j_N)$  columns are vectors in  $\mathbb{R}^{n_N}$  that form a basis for  $\mathcal{NC}(S, \alpha_N)$ . Since  $S$  is smooth, this basis can be chosen to vary smoothly over  $\alpha \in U$ . Then by using  $\tau$  and  $\mathbf{V}$ , define  $F : \mathbb{R}^j \times \mathbb{R}^{n_N - j_N} \rightarrow \mathbb{R}^n$  by

$$(191) \quad F(\mathbf{y}, \mathbf{b}) \equiv \mathbf{r}(\tau^{-1}(\mathbf{y})) +_N \mathbf{V}(\tau^{-1}(\mathbf{y})) \cdot \mathbf{b}.$$

In view of Assumption II,  $F$  is smooth, and by (187),  $j + (n_N - j_N) < n$ . Thus, by [18, Proposition 1.2], the image  $F(\mathbb{D}^j \times \mathbb{R}^{n_N - j_N}) = \bigcup_{\alpha \in U} K(\alpha)$  has zero Lebesgue measure. Because measure is countably subadditive, repeating this argument for each  $j$ -ball  $U$  in a countable cover of  $S$  and then for each  $S \in \mathcal{S}$  shows that  $\mathcal{K}_{\mathbf{m}}$  has zero Lebesgue measure. Since  $\mathcal{D}_{\mathbf{m}} \subset \mathcal{K}_{\mathbf{m}}$ ,  $\mathcal{D}_{\mathbf{m}}$  also has zero Lebesgue measure, and since  $\mathcal{R}_{\mathbf{m}} \setminus \mathcal{K}_{\mathbf{m}} \subset \text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ ,  $\text{int } \mathcal{R}_{\mathbf{m}}^{\text{exp}}$  and  $\mathcal{R}_{\mathbf{m}}$  have the same closure. (Otherwise, there would exist an open set of positive measure contained in  $\mathcal{K}_{\mathbf{m}}$ .) Therefore  $\mathcal{D}_{\mathbf{m}} \subset \partial \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ .  $\square$

**6.6. Examples.** We will assume that Assumptions I and II hold in the following examples.

1. *Junk's example.* The case  $m_N = |v|^N$  has been studied in [20, 21, 31], particularly when  $N = 4$ . For general  $N$ ,

$$(192) \quad \mathcal{A}_{\mathbf{m}_N} = \{\alpha_N \in \mathbb{R} : \alpha_N \leq 0\} \quad \text{and} \quad \partial \mathcal{A}_{\mathbf{m}_N} = \{0\}.$$

If  $\rho \in \mathcal{R}_{\mathbf{m}}$  and  $\mathbf{a}_N(\rho) = 0$ , then  $\mathbf{a}_{N-1}(\rho) = 0$  as well; otherwise,  $G_{\mathbf{a}(\rho)} \notin \mathbb{F}_{\mathbf{m}}$ . With this fact in mind, we conclude from Corollary 15 that  $G_{\mathbf{a}(\rho)}$  is actually the minimizer of  $\mathcal{H}$  subject to fewer constraints:

$$(193) \quad \mathcal{H}(G_{\mathbf{a}(\rho)}) = \min_{g \in \mathbb{F}_{\mathbf{m}}} \{\mathcal{H}(g) : \langle \mathbf{m}_j g \rangle = \rho_j, \ j \leq N-2\}.$$

Let  $\bar{\mathbf{m}}$  contain the components of  $\mathbf{m}$  of degree  $\bar{N} \equiv N-2$  and less:

$$(194) \quad \bar{\mathbf{m}} \equiv (\mathbf{m}_0, \mathbf{m}_1, \dots, \mathbf{m}_{N-2})^T,$$

and let the variables  $\bar{\rho}$  and  $\bar{\alpha}$  and the functions  $\bar{\mathbf{r}}$  and  $\bar{\mathbf{a}}$  be defined similarly. For this example,

$$(195) \quad \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}} \subset \{\alpha \in \mathbb{R}^n : \bar{\alpha} \in \mathcal{A}_{\bar{\mathbf{m}}}, \ \alpha_{N-1} = 0, \ \alpha_N = 0\},$$

but these two sets are not necessarily equal, since the latter may include  $\alpha$  for which  $G_{\alpha} \in \mathbb{F}_{\bar{\mathbf{m}}}$ , but  $G_{\alpha} \notin \mathbb{F}_{\mathbf{m}}$ . However, one may readily conclude that  $G_{\alpha} \in \mathbb{F}_{\mathbf{m}}$  for all  $\bar{\alpha} \in \text{int } \mathcal{A}_{\bar{\mathbf{m}}}$ . Hence,

$$(196) \quad \{\alpha \in \mathbb{R}^n : \bar{\alpha} \in \text{int } \mathcal{A}_{\bar{\mathbf{m}}}, \ \alpha_{N-1} = 0, \ \alpha_N = 0\} \subset \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}.$$

Let  $\mathcal{S}$  be a stratification of  $\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ . The projection of any manifold  $S \in \mathcal{S}$  onto  $\partial \mathcal{A}_{\mathbf{m}_N}$  is the origin in  $\mathbb{R}^{n_N}$ , so the normal cone attached to  $\alpha \in S$  is just the nonnegative axis:

$$(197) \quad \mathcal{NC}(\mathcal{A}_{\mathbf{m}_N}, \alpha_N) = \{\sigma_N \in \mathbb{R} : \sigma_N \geq 0\} = A_{\mathbf{m}_N}^{\circ}.$$

Therefore

$$(198) \quad \mathcal{D}_{\mathbf{m}} = \{\boldsymbol{\rho} : \rho_N > \mathbf{r}_N(\boldsymbol{\alpha}), \boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}\}.$$

Because  $A_{\mathbf{m}_N}$  is one-dimensional, the inequality in (198) is scalar.

If  $N = 4$ , the situation simplifies further, because  $\text{int } \mathcal{A}_{\bar{\mathbf{m}}} = \mathcal{A}_{\bar{\mathbf{m}}}$  and the inclusion in (195) becomes an equality. In addition,  $\mathcal{R}_{\bar{\mathbf{m}}} = \mathcal{R}_{\bar{\mathbf{m}}}^{\text{exp}}$  and  $\bar{\mathbf{r}}$  is a diffeomorphism on all of  $\mathcal{A}_{\bar{\mathbf{m}}}$ . Therefore

$$(199) \quad \begin{aligned} \mathcal{D}_{\mathbf{m}} &= \{\boldsymbol{\rho} : \rho_N > \mathbf{r}_N(\boldsymbol{\alpha}), \bar{\boldsymbol{\alpha}} \in \mathcal{A}_{\bar{\mathbf{m}}}, \boldsymbol{\alpha}_N = \boldsymbol{\alpha}_{N-1} = 0\} \\ &= \{\boldsymbol{\rho} : \rho_N > \mathbf{r}_N(0, 0, \bar{\mathbf{a}}(\bar{\boldsymbol{\rho}})), \rho_{N-1} = \mathbf{r}_{N-1}(0, 0, \bar{\mathbf{a}}(\bar{\boldsymbol{\rho}})), \bar{\boldsymbol{\rho}} \in \mathcal{R}_{\bar{\mathbf{m}}}\}. \end{aligned}$$

The components  $\mathbf{r}_N(0, 0, \bar{\mathbf{a}}(\bar{\boldsymbol{\rho}}))$  and  $\mathbf{r}_{N-1}(0, 0, \bar{\mathbf{a}}(\bar{\boldsymbol{\rho}}))$  are simple to compute since  $\mathbf{r}(0, 0, \bar{\mathbf{a}}(\bar{\boldsymbol{\rho}})) = \langle \mathbf{m} G_{\bar{\mathbf{a}}(\bar{\boldsymbol{\rho}})} \rangle$  and  $\bar{\mathbf{a}}(\bar{\boldsymbol{\rho}})$  has an explicit formula when  $\bar{N} = 2$ . (See the examples in section 5.3.)

2. *A non-Junkian example.* The situation becomes more complicated when  $\mathbf{m}_N$  includes polynomials other than  $|v|^N$ , because the inequality constraints from the relaxed minimization problem (20) are no longer scalar. The simplest example of this type occurs when

$$(200) \quad \mathbf{m}_N = (v \vee v) |v|^{N-2}.$$

We examine in detail the two-dimensional case ( $d = 2$ ) and write  $\boldsymbol{\alpha}_N \in A_{\mathbf{m}_N}$  in the form of a symmetric matrix:

$$(201) \quad \boldsymbol{\alpha}_N = \begin{pmatrix} (\boldsymbol{\alpha}_N)_{11} & (\boldsymbol{\alpha}_N)_{12} \\ (\boldsymbol{\alpha}_N)_{21} & (\boldsymbol{\alpha}_N)_{22} \end{pmatrix} = \begin{pmatrix} a+b & c \\ c & a-b \end{pmatrix}.$$

As a matrix,  $\boldsymbol{\alpha}_N$  must be negative-definite. Thus, with respect to the  $(a, b, c)$  coordinates, the set  $A_{\mathbf{m}_N}$  is a cone in  $\mathbb{R}^3$  that can be found in a high school geometry text:

$$(202) \quad \begin{aligned} A_{\mathbf{m}_N} &= \{(a, b, c) \in \mathbb{R}^3 : a \leq -\sqrt{b^2 + c^2}\} \\ \text{and} \quad \partial A_{\mathbf{m}_N} &= \{(a, b, c) \in \mathbb{R}^3 : a = -\sqrt{b^2 + c^2}\}. \end{aligned}$$

Let  $\mathcal{S}$  be the stratification of  $\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}}$ , and let  $S \in \mathcal{S}$  so that  $S_N \in \partial A_{\mathbf{m}_N}$ . The set  $\partial A_{\mathbf{m}_N}$  itself has a stratification  $\mathcal{T}$  consisting of two manifolds:  $T_1$  is the origin in  $\mathbb{R}^3$ , and  $T_2$  is the remainder of the cone. We consider  $S_N$  as a subset of each manifold separately.

- (a)  $\boldsymbol{\alpha}_N \in T_1$ . In this case,  $a = b = c = 0$  and

$$(203) \quad \mathcal{NC}(A_{\mathbf{m}_N}, \boldsymbol{\alpha}_N) = A_{\mathbf{m}_N}^\circ = \{\boldsymbol{\alpha}_N : \boldsymbol{\alpha}_N \geq 0\}.$$

The situation essentially reduces to the Junkian case. The fiber bundle associated with  $S \subset \{\mathcal{A}_{\mathbf{m}} \cap \partial \mathcal{A}_{\mathbf{m}} : \boldsymbol{\alpha}_N = 0\}$  is

$$(204) \quad \mathcal{B}(S) = \{\boldsymbol{\rho} : \rho_N \geq A_{\mathbf{m}_N}^\circ \mathbf{r}_N(\boldsymbol{\alpha}), \boldsymbol{\alpha} \in S\},$$

and if  $N = 4$ ,

$$(205) \quad \begin{aligned} \mathcal{B}(S) &= \{\boldsymbol{\rho} : \rho_N \geq A_{\mathbf{m}_N}^\circ \mathbf{r}_N(0, 0, \bar{\mathbf{a}}(\bar{\boldsymbol{\rho}})), \rho_{N-1} \\ &= \mathbf{r}_{N-1}(0, 0, \bar{\mathbf{a}}(\bar{\boldsymbol{\rho}})), \bar{\boldsymbol{\rho}} \in \mathcal{R}_{\bar{\mathbf{m}}}\}, \end{aligned}$$

where  $\bar{\mathbf{a}}(\bar{\boldsymbol{\rho}})$  has an explicit formula. (See the examples in section 5.3.) However, unlike the Junkian case, the inequalities in (204) and (205) are no longer scalar. Rather, it must be understood in terms of the polar cone  $A_{\mathbf{m}_N}^\circ$ .

- (b)  $\boldsymbol{\alpha}_N \in T_2$ . In this case  $a \leq -|b| < 0$ . In the  $(a, b, c)$  coordinates,  $\mathcal{NC}(A_{\mathbf{m}_N}, \boldsymbol{\alpha}_N)$  is a ray:

$$(206) \quad \mathcal{NC}(A_{\mathbf{m}_N}, \boldsymbol{\alpha}_N) = \left\{ \lambda \left( \sqrt{b^2 + c^2}, b, c \right) : \lambda \geq 0 \right\},$$

which can then be reexpressed in terms of the components of  $\boldsymbol{\alpha}_N$  by inverting (201). The bundle associated with any  $S \subset \{\boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}} : \boldsymbol{\alpha}_N \neq 0\}$  is

$$(207) \quad \mathcal{B}(S) = \{\boldsymbol{\rho} : \boldsymbol{\rho}_N = \mathbf{r}_N(\boldsymbol{\alpha}) + \mathcal{NC}(A_{\mathbf{m}_N}, \boldsymbol{\alpha}_N), \boldsymbol{\rho}_j = \mathbf{r}_j(\boldsymbol{\alpha}), j < N, \boldsymbol{\alpha} \in S\}.$$

The set  $\mathcal{D}_{\mathbf{m}}$  is the union of sets of the form  $\mathcal{B}_0(S) = \mathcal{B}(S) \setminus \mathbf{r}(S)$ , where  $\mathcal{B}(S)$  is a bundle of the type given in (204) or (207).

One should note from these examples that our ability to identify degenerate densities is currently limited by our inability to explicitly identify the elements of  $\mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}}$ . However, because the set  $\mathcal{A}_{\mathbf{m}_N}$  is semialgebraic, one should presumably be able to compute  $\mathcal{NC}(A_{\mathbf{m}_N}, \boldsymbol{\alpha}_N)$  for any given  $\boldsymbol{\alpha} \in \mathcal{A}_{\mathbf{m}} \cap \partial\mathcal{A}_{\mathbf{m}}$ , even though such computations will likely be much more tedious than in the examples given above.

**7. Conclusions and discussion.** We have given in this paper a description of the set  $\mathcal{D}_{\mathbf{m}}$  of degenerate densities based on a geometric interpretation of the complementary slackness conditions associated with the dual formulation of (20). Roughly speaking, the set  $\mathcal{D}_{\mathbf{m}}$  is constructed by attaching a convex cone to every point in the boundary component  $\partial\mathcal{R}_{\mathbf{m}}^{\text{exp}} \cap \mathcal{R}_{\mathbf{m}}^{\text{exp}}$ . This description recovers and extends previous results concerning the constrained entropy minimization problem.

Analytically, we see three important open questions that must be solved. First, one must determine if Assumptions I and II hold in a setting that is more general than the examples in (182). Concerning Assumption I, this means understanding the structure of the set of polynomials  $p$  for which  $v \mapsto p(v)e^{p(v)}$  is Lebesgue integrable. For example, do the coefficients of such polynomials form a semialgebraic set? Second, it must be determined whether the sets  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  and  $\mathcal{R}_{\mathbf{m}}$  are invariant under the dynamics of the balance law (12) with the entropy-based closure. (Although not discussed in this paper, such a condition on  $\mathcal{R}_{\mathbf{m}}$  is obviously necessary for entropy-based closures to have any practical application.) Finally, it must be determined whether the existence of degenerate densities and the dynamics of (12) near such densities are simply artifacts of the entropy-based closure or if they actually reflect some physically relevant properties of the original Boltzmann equation (2).

Numerically speaking, a full implementation of entropy-based closures for gas dynamics faces many challenges. (An implementation has been attempted in [34], although the issue of degenerate densities was not addressed.) Clearly a discretization of (12) must preserve any invariant properties of  $\mathcal{R}_{\mathbf{m}}$  and  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  with respect to the balance law (12). As pointed out in [20], even if  $\mathcal{R}_{\mathbf{m}}^{\text{exp}}$  is invariant under (12), solving the dual optimization problem (74) becomes extremely difficult for  $\boldsymbol{\rho}$  near  $\mathcal{D}_{\mathbf{m}}$  because the function  $h^*$  is very hard to evaluate. The reason for this is that, as  $\boldsymbol{\alpha}$  approaches  $\partial\mathcal{A}_{\mathbf{m}}$ , the function  $G_{\boldsymbol{\alpha}}$  can develop isolated modes that are often overlooked in a numerical quadrature. The result is a regularization effect in which accuracy is lost. In addition, the matrix  $\langle \mathbf{m}\mathbf{m}^T G_{\boldsymbol{\alpha}} \rangle$  becomes poorly conditioned near the boundary of

$\mathcal{A}_{\mathbf{m}}$ . Any minimization algorithm for (74) must be carefully formulated in order to overcome these challenges. Furthermore, as with the degenerate densities themselves, one must determine if these difficulties are by-products of the closure or related in some way to the dynamics of the Boltzmann equation.

**Appendix.** The purpose of this appendix is to provide the reader with a reference for important notation used in the main body of the paper. We includes tables of important sets and mappings (Tables 1 and 2) and also a diagram (Figure 1)

TABLE 1

# INPUT-OUTPUT MODEL EQUIVALENCE OF SPIN SYSTEMS: A CHARACTERIZATION USING LIE ALGEBRA HOMOMORPHISMS\*

FRANCESCA ALBERTINI<sup>†</sup> AND DOMENICO D'ALESSANDRO<sup>‡</sup>

**Abstract.** In this paper, we consider the problem of model equivalence for quantum systems. Two models are said to be (input-output) equivalent if they give the same output for every admissible input. In the case of quantum systems, we take as output the expectation value of a given observable or, more generally, a probability distribution for the result of a quantum measurement. We link the input-output equivalence of two models to the existence of a homomorphism of the underlying Lie algebra. In several cases, a Cartan decomposition of the Lie algebra  $su(N)$  is useful to find such a homomorphism and to determine the classes of equivalent models. We consider in detail the important cases of two level systems with a Cartan structure and of spin networks. In the latter case, complete results are given generalizing previous results to networks of spin particles with arbitrary values of the spins. In treating this problem, we give independent proofs of some instrumental results on the subalgebras of  $su(N)$ .

**1. Introduction.** Structural properties of quantum systems recently have been the subject of investigation with methods of control theory. Appropriate definitions of controllability and observability of quantum systems have been given and practical conditions for checking these properties have been proposed (see, e.g., [1], [10], [17], [23]). In many cases, the tools used are those of Lie algebra and Lie group theory. Information on the properties of the dynamics is obtained by a study of the structure of a Lie algebra associated with the system and how this relates to the particular equations at hand. This geometric approach has proved useful not only to analyze the dynamics but also to design control laws (see, e.g., [3], [21], [22], [13]). This approach can also be used to study problems of parameter identification of quantum systems, and this is the subject of the present paper.

The problem we shall study is the classification of models of quantum systems whose behavior cannot be distinguished by an external observer. We shall call these models (*input-output*) *equivalent*. This problem is motivated by several experimental scenarios. In particular consider a molecule which is a network of particles with spin with all the other degrees of freedom neglected. A model Hamiltonian is associated with this system in which parameters modeling the interaction between particles as well as the interaction with an external electromagnetic field are unknown. Also, the initial state of the system might be unknown. In experimental scenarios such as nuclear magnetic resonance and electron paramagnetic resonance, it is possible to drive the system with a magnetic field and measure the expectation value of a given observable, for example, the total spin in a given direction. The question of

fundamental and practical importance is to what extent, with this type of experiments, it is possible to distinguish between different models. As we shall see in this paper, this question is related to the existence of a particular Lie algebra homomorphism which maps one into the other the equations of the two models (definitions of Lie algebra theory are given in section 3). Further motivation for this research can be found in [27] where it was shown that thermodynamic methods commonly used to identify the parameters of spin networks such as in molecular magnets [5], [8] are not always adequate.

The main results of this paper are the solution of the model equivalence problem for a class of two level systems in Theorem 2 and Theorem 7 where we completely solve the problem of characterizing equivalent models for networks of spin. The latter result generalizes results previously obtained in [2] and [11], which were proven only for networks of spin  $\frac{1}{2}$  and 1's, to networks of interacting spins of any value and where the spin itself is an unknown parameter to be identified. The generalization given in this paper is obtained through a Cartan decomposition technique recently presented in [12] which helps in determining the homomorphism between equivalent models in the form of a Cartan involution. In the process we shall prove a number of auxiliary results (Theorems 4–6) on the structure of the Lie algebra  $su(N)$  and in particular on its subalgebras. These results could be formulated in terms of representation theory of Lie algebras (see, e.g., [18]), but we give here independent proofs which use only linear algebra arguments.

The paper is organized as follows. In section 2, we describe the problem of model equivalence for quantum systems. In section 3 we provide some background definitions of Lie algebra theory and describe how the quantum mechanical models we consider are related to mathematical notions in this theory. In section 4, we link the equivalence of two models to the existence of an appropriate Lie algebra homomorphism. This is the content of Theorem 1. In several cases the structure of the dynamics is related to a Cartan decomposition of  $su(N)$  and suggests the form of such a homomorphism as well as of the classes of equivalent models. We give a two level example in section 5 and treat the case of general spin networks in section 6. Instrumental to the solution of the model equivalence problem for spin networks are some results of independent interest concerning the existence of subalgebras of  $su(N)$  with specific features. The proofs of these results are presented in section 7. Concluding remarks are given in section 8.

**2. The problem of model equivalence for quantum systems.** Consider a model Hamiltonian for a quantum system,  $H(t) := H(u(t))$ , where, in a semiclassical description, the dependence on time is due to the interaction with classical external fields,  $u := u(t)$ , which play the role of *controls*. For every  $t$ ,  $H(t)$  is a Hermitian operator on a Hilbert space  $\mathcal{H}$ . The state of a quantum system is described by a density matrix  $\rho$ , i.e., a positive, trace one, Hermitian operator on  $\mathcal{H}$ . The evolution of the state of the system,  $\rho := \rho(t)$ , is determined, other than by  $H$ , by the initial state  $\rho(0) = \rho_0$ . In particular,  $\rho$  is the solution of the *Liouville's equation*,

$$(1) \quad \dot{\rho} = [-iH, \rho],$$

with initial condition  $\rho(0) = \rho_0$ . Here and in the following, for two matrices  $A$  and  $B$ , the commutator  $[A, B]$  is defined as  $[A, B] := AB - BA$ . According to the measurement postulate of quantum mechanics, with any measured quantity there is associated an observable  $S$  which is a Hermitian operator on  $\mathcal{H}$ . There are various

types of measurements (see, e.g., [6]). Considering, for simplicity, a Von Neumann–Lüders measurement,<sup>1</sup> writing  $S$  in terms of orthogonal projections

$$(2) \quad S := \sum_j \lambda_j \Pi_j,$$

the probability of having a result  $\lambda_j$ , when the state is  $\rho$ , is given by

$$(3) \quad P_j := \text{Tr}(\Pi_j \rho).$$

As the probabilities  $P_j$  are the only information that can be gathered by an external observer, we are motivated to ask what classes of models  $\{H, \rho_0\}$  will give the same probabilities, for any functional form of the control  $u$ . In other words, we ask what classes of models are indistinguishable by experiments that involve driving the system with controls, in a given set of functions, and measuring a given observable. These models will be called (*input-output*) *equivalent*.

*Remark 2.1.* The term *output* for the probabilities (3) or for the expectation value (4) below needs to be clarified. We have called output the information that can be gathered measuring a given observable  $S$ . In particular, consider a large number of identical systems. By measuring the observable  $S$  at a fixed time  $t$  and recording the various results, we obtain the probabilities (3). Two models that have the same probabilities (output) at any time  $t$  are exactly equivalent from the input-output point of view, because a measurement of  $S$  on any of them will give exactly the same result with exactly the same probability (or will have exactly the same expectation value if that is what interests us). Therefore, while it is convenient to call the functions (3) and (4) output and make a mathematical analogy with classical systems, the situation is not the same as for classical systems. In particular, for classical systems it is possible to monitor the output continuously. For quantum systems we consider measurements that in practice happen only at one instant of time. However, we can still ask what the classes of models would give *at any time* the same expectation value (output (4)) or the same result with the same probability (output (3)).<sup>2</sup>

It is appropriate to treat the case where the result of the measurement is the *expectation value* of the measurable  $S$ , i.e.,

$$(4) \quad y := \text{Tr}(S\rho).$$

Therefore, we take (4) as the *output* of the system. Not only is this the case in several experimental situations, such as nuclear magnetic resonance, but it is not a significant restriction as compared to the case where the probabilities (3) are considered. As the structure of the output (4) is the same as that of the outputs (3), the passage from the treatment for the expectation value to the one for probabilities corresponds to extending a single output treatment to a multiple output treatment. This can be accomplished without difficulties.

We need to assume some structure on the Hamiltonian  $H$ , in order to render the problem of characterizing the classes of equivalent models tractable. This corresponds to the passage from *unstructured uncertainty* to *parametric uncertainty*, often

<sup>1</sup>Natural extensions of what we shall say can be made to general measurements.

<sup>2</sup>Considering continuous measurements in quantum mechanics is possible and of interest in several experimental scenarios. In these cases, however, the equations of the dynamics (1) have to be modified to take into account the back-action of the measurement (see, e.g., [6]). These types of models will not be considered here.

discussed in identification theory (see, e.g., [26]). In particular, it is often the case that the Hamiltonian  $H = H(u)$  has the *bilinear* form

$$(5) \quad H := H_0 + \sum_{j=1}^m H_j u_j(t)$$

for some control functions  $u_1, \dots, u_m$ , and *internal Hamiltonian*  $H_0$  and *interaction Hamiltonians*  $H_j$ 's,  $j = 1, \dots, m$ . In this paper we shall consider only *finite dimensional models*, and therefore  $H_0$ ,  $H_j$ ,  $j = 1, \dots, m$ , and  $\rho$  are Hermitian matrices of finite dimension  $N \times N$ .

*Remark 2.2.* A classical problem in nonlinear control theory related to the one considered here is the *realization problem*. In the relevant literature, one considers a map from a space of input functions to a space of output functions. This map can be given in an abstract way [20], [28], or through Volterra [7], [9], [14], [19] or Fliess [15] series. Then conditions are given for the *existence* and *uniqueness* of a dynamical model which implements the given input-output relations. An algorithm for the construction of this model for bilinear systems on  $\mathbb{R}^N$  is given, for example, in [24]. In our case, the input-output map is already given as realizable with a given class of models where only the parameters and the dimensions are unknown. The problem is to characterize the class of equivalence of models giving the specified input-output map. Therefore the problem considered here is essentially a *uniqueness* problem in realization theory while the existence is already assumed. In this sense the question treated here is more in the spirit of the work done in [4] for neural networks. The a priori assumptions on the structure of the system allow us to obtain stronger results. In particular, while in [20], [28] (under a suitable hypothesis) the realization is proved to be unique up to a diffeomorphism, in the results of sections 5 and 6 we shall give the explicit map between two different realizations of the same input-output map and therefore the explicit construction of all the input-output equivalent models. We notice that since the model (1), (5), (4) is bilinear, we could have followed a different approach by looking at the input-output map associated with the system, transforming the system into a system on  $\mathbb{R}^{N^2}$ , where  $N^2$  is the dimension of the space of Hermitian matrices, and applying the results of [24]. This, however, does not seem to be the most natural approach. In fact, in doing this, we would have hidden some of the structure of the problem, as, for example, the fact that the linear map for the dynamics in (1) is given in terms of the commutator with a Hermitian matrix.

**3. Lie algebra theory and modeling of quantum systems.** In this paper we are interested in matrix *Lie algebras* over the real field, i.e., real vector spaces of matrices closed under the commutator. Particularly important Lie algebras for us are the Lie algebra of *skew-Hermitian*  $N \times N$  matrices, which is denoted by  $u(N)$ , and the Lie algebra of *skew-Hermitian*  $N \times N$  matrices with trace equal to zero, which is denoted by  $su(N)$ . Accordingly the spaces of Hermitian matrices and Hermitian matrices with zero trace will be denoted by  $iu(N)$  and  $isu(N)$ , as their elements are obtained from those of  $u(N)$  or  $su(N)$  by multiplication by the imaginary unit  $i := \sqrt{-1}$ . In general, we shall often use the notation  $i\mathcal{L}$  to denote a subspace of  $iu(N)$  corresponding to a subspace  $\mathcal{L}$  of  $u(N)$  (or vice versa). All the spaces are inner product spaces when equipped with the inner product  $\langle A, B \rangle := \text{Tr}(AB^*)$ . A subalgebra  $\mathcal{L}$  of  $u(N)$  is a subspace of  $u(N)$  which is also a Lie algebra. To every matrix Lie algebra  $\mathcal{L}$  is associated a *Lie group* which is the group generated by elements  $e^A$  with  $A$  in  $\mathcal{L}$  equipped with the structure of an analytic manifold. We shall denote this Lie

group by  $e^{\mathcal{L}}$ . The Lie group associated with  $u(N)$  ( $su(N)$ ) is the Lie group of unitary matrices (with determinant equal to 1) and is denoted by  $U(N)$  ( $SU(N)$ ).

In the model Hamiltonian (5) it is often true that  $H_0$  and the  $H_j$ 's belong to two orthogonal complementary subspaces of  $iu(N)$  corresponding to a Cartan decomposition [16] of  $u(N)$ . These are two orthogonal subspaces  $i\mathcal{K}$  and  $i\mathcal{P}$  such that the corresponding subspaces of  $u(N)$ ,  $\mathcal{K}$  and  $\mathcal{P}$ , satisfy<sup>3</sup>

$$(6) \quad u(N) = \mathcal{K} \oplus \mathcal{P}$$

and the commutation relations

$$(7) \quad [\mathcal{K}, \mathcal{K}] \subseteq \mathcal{K}, \quad [\mathcal{K}, \mathcal{P}] \subseteq \mathcal{P}, \quad [\mathcal{P}, \mathcal{P}] \subseteq \mathcal{K}.$$

If  $\mathcal{L}$  and  $\mathcal{L}'$  are two (matrix) Lie algebras, a *homomorphism*  $\phi$  is a linear map  $\phi : \mathcal{L} \rightarrow \mathcal{L}'$ , which preserves the commutation operation, i.e.,  $\phi([A, B]) = [\phi(A), \phi(B)]$ , where the commutators on the left and right are calculated in  $\mathcal{L}$  and  $\mathcal{L}'$ , respectively. If  $\mathcal{L}$  and  $\mathcal{L}'$  are two inner product spaces, associated with every linear map  $\phi$  is a dual map  $\phi^*$  which is a linear map  $\mathcal{L}' \rightarrow \mathcal{L}$  defined by the property  $\langle A, \phi(B) \rangle_{\mathcal{L}'} = \langle \phi^*(A), B \rangle_{\mathcal{L}}$ , where the inner product  $\langle \cdot, \cdot \rangle_{\mathcal{L}'}$  ( $\langle \cdot, \cdot \rangle_{\mathcal{L}}$ ) is defined on  $\mathcal{L}'$  ( $\mathcal{L}$ ). A bijective homomorphism is called an *isomorphism*. An isomorphism is called an *automorphism* if  $\mathcal{L} = \mathcal{L}'$ . An automorphism  $\theta$  is called a *Cartan involution* if  $\theta^2$  is the identity map. Associated with every Cartan decomposition satisfying (7) is a Cartan involution  $\theta$  such that  $\mathcal{K}$  and  $\mathcal{P}$  are the  $+1$  and  $-1$  eigenspaces of  $\theta$ . The following simple example illustrates these concepts.

*Example 3.1.* Consider the decomposition (6) of  $u(N)$  where  $\mathcal{K}$  and  $\mathcal{P}$  are the subspaces of purely real and purely imaginary matrices, respectively. It is clear that the commutation relations (7) are verified. Moreover, the associated Cartan involution  $\theta$  is the complex conjugation which leaves unchanged the elements in  $\mathcal{K}$  and changes the sign of the elements in  $\mathcal{P}$ .

Another type of automorphism of (subalgebras of)  $u(N)$  is a *conjugacy* which is defined as  $\phi_P(A) := PAP^*$ , where  $P$  is a unitary matrix and in particular such that  $PP^* = P^*P = \mathbf{1}$ , where  $\mathbf{1}$  is the identity matrix. Notice that if  $\mathcal{K}$  and  $\mathcal{P}$  define a Cartan decomposition of  $u(N)$  as in (6),  $P\mathcal{K}P^*$  and  $P\mathcal{P}P^*$  also define a decomposition.

Up to conjugacies, there are three types of Cartan decompositions of  $u(N)$  labeled **AI**, **AII**, and **AIII**. In a decomposition **AI**,  $\mathcal{K} = so(N)$  and  $\mathcal{P} = (so(N))^{\perp}$  up to conjugacy.  $so(N)$  is the subalgebra of  $u(N)$  of real skew-symmetric matrices. This is the decomposition presented in Example 3.1. In a decomposition **AII**,  $N$  is even and  $\mathcal{K} = sp(N/2)$  and  $\mathcal{P} = (sp(N/2))^{\perp}$  up to conjugacy.  $sp(N/2)$  is the subalgebra of  $u(N)$  of symplectic matrices, namely, matrices  $A$  satisfying  $AJ + JA^T = 0$ , where  $J$  is the matrix

$$J := \begin{pmatrix} 0 & \mathbf{1}_{N/2 \times N/2} \\ -\mathbf{1}_{N/2 \times N/2} & 0 \end{pmatrix}.$$

The third type labeled **AIII** is not relevant here (see [16] for details).

<sup>3</sup>In the literature (see, e.g., [16]) Cartan decompositions are defined for general semisimple Lie algebras, and the results of Cartan parametrize all the possible decompositions for  $su(N)$ . From decompositions of  $su(N)$  one can obtain decompositions of  $u(N)$  by including multiples of the identity in one of the two subspaces  $\mathcal{K}$  or  $\mathcal{P}$ . Although in the literature one often refers to decompositions of  $su(N)$ , we have preferred to define decompositions in terms of  $u(N)$  to ease notation.

If the system is a multipartite system, every  $H_j$ ,  $j = 1, \dots, m$ , in (5) is a linear combination of Hamiltonians modeling the interaction of each individual system with the external field. In matrix notation,  $H_j$  is a linear combination of elements of the type  $\mathbf{1} \otimes \mathbf{1} \otimes \dots \otimes \mathbf{1} \otimes L \otimes \mathbf{1} \otimes \dots \otimes \mathbf{1}$ , where  $L$  is a Hermitian matrix of appropriate dimensions and all the other places are occupied by identities  $\mathbf{1}$ . Also,  $H_0$  is very often a linear combination of elements modeling the interaction between two subsystems, which can be written as tensor products of matrices equal to the identity, except in two locations. In these cases, using the Cartan decomposition (6) described in the recent paper [12] one finds that  $iH_0 \in \mathcal{P}$  and  $iH_j \in \mathcal{K}$ ,  $j = 1, \dots, m$ . Also if  $S$  is a sum of observables on each individual subsystem, i.e., total spin angular momentum (see, e.g., [25]), it can always be written as a sum of tensor products all equal to the identity, except in one position. In these cases,  $iS \in \mathcal{K}$  belongs to the subspace  $\mathcal{K}$  of the above Cartan decomposition of [12].<sup>4</sup> We shall describe this structure in detail in section 6 because it is the main feature we use for the solution of the input-output equivalence problem.

According to the results in [1], [10], [17], [23], the controllability and observability properties of system (1), (4), (5) depend on the Lie algebra  $\mathcal{L}$  generated by  $iH_0$  and  $iH_j$ ,  $j = 1, \dots, m$ , i.e., the smallest subalgebra of  $u(N)$  containing these matrices. In particular the set of states reachable from a density matrix  $\rho_0$  is given by

$$(8) \quad \mathcal{O}_{\rho_0} := \{X\rho_0X^* \mid X \in e^{\mathcal{L}}\}.$$

If, for every  $\rho_0$ ,  $\mathcal{O}_{\rho_0}$  is the set of all the density matrices with the same spectrum as  $\rho_0$ , the system is called *controllable*. This is the case if and only if  $\mathcal{L} = u(N)$  or  $\mathcal{L} = su(N)$ . The system is *observable* if there are no pairs of states indistinguishable by input-output experiments. This is the case if and only if

$$(9) \quad isu(N) \subseteq \mathcal{O}_S := \{XSX^* \mid X \in e^{\mathcal{L}}\}.$$

Controllability implies observability for nonscalar  $S$  [10].

In the following, we shall consider, as a standing assumption, only finite dimensionality of the Hamiltonian  $H$  and the bilinear form (5) and will make precise the assumptions on the (Cartan) structure of the Hamiltonian when needed.

**4. Model equivalence and Lie algebra homomorphisms.** Consider two models with a Hamiltonian of the form (5) and an output of the form (4):

$$(10) \quad \dot{\rho} = \left[ -i \left( H_0 + \sum_{j=1}^m H_j u_j \right), \rho \right], \quad \rho(0) = \rho_0, \quad y = \text{Tr}(S\rho),$$

$$(11) \quad \dot{\rho}' = \left[ -i \left( H'_0 + \sum_{j=1}^m H'_j u_j \right), \rho' \right], \quad \rho'(0) = \rho'_0, \quad y' = \text{Tr}(S'\rho').$$

The following theorem links the existence of an appropriate Lie algebra homomorphism to the equivalence of the two models.

**THEOREM 1.** *Let  $N$  and  $N'$  be the dimensions of the two models (10), (11), respectively. Let  $\phi$  be a homomorphism,  $\phi : u(N) \rightarrow u(N')$ , and  $\phi^*$  its dual with respect to the standard inner product  $\langle A, B \rangle := \text{tr}(AB^*)$ . Assume*

$$(12) \quad -iH'_0 = \phi(-iH_0), \quad -iH'_j = \phi(-iH_j), \quad \phi^*(iS') = iS.$$

<sup>4</sup>Notice that the situation may be different if we consider the case of a single output given by the expectation value (4) and the case of several outputs given by the probabilities in (3).

Then if

$$(13) \quad i\rho'_0 = \phi(i\rho_0),$$

the models are equivalent. Vice versa, if the models are equivalent and (11) is observable, then (13) holds.

*Proof.* Multiply (10) and (11) by  $i$  and then apply  $\phi$  to the equation obtained from (10). Combining the two resulting equations, using the first two of (12), we obtain

$$(14) \quad \frac{d}{dt}(i\rho' - \phi(i\rho)) = \left[ \phi(-iH_0) + \sum_j \phi(-iH_j)u_j, i\rho' - \phi(i\rho) \right].$$

If (13) is verified, then  $i\rho'(t) = \phi(i\rho(t))$  for every  $t$  and for every control. Therefore we have from the third one in (12),

$$(15) \quad \text{Tr}(S'\rho') = \text{Tr}(-iS'i(\rho')) = \text{Tr}(-iS'\phi(i\rho)) = \text{Tr}(\phi^*(-iS')i\rho) = \text{Tr}(S\rho),$$

and the two models are equivalent. Vice versa, assume that the two models are equivalent. From (15), we have

$$(16) \quad \text{Tr}(iS'(i\rho' - \phi(i\rho))(t)) = 0$$

for every  $t$ . Writing the solution of (14) as  $(i\rho' - \phi(i\rho))(t) = X(i\rho' - \phi(i\rho))(0)X^*$ , where  $X$  is the solution of the (Schrödinger) operator equation

$$(17) \quad \dot{X} = \left( \phi(-iH_0) + \sum_j \phi(-iH_j)u_j \right) X, \quad X(0) = \mathbf{1},$$

we have

$$(18) \quad \text{Tr}(X^*iS'X(i\rho'_0 - \phi(i\rho_0))) = 0.$$

As the system (11) is observable, we have that  $X^*iS'X$  span all of  $su(n')$ , which implies  $i\rho'_0 = \phi(i\rho_0)$ .  $\square$

Summarizing, the theorem says that if the equation describing the dynamics is related through a Lie algebra homomorphism  $\phi$ , and under an observability condition, then the two models are equivalent if and only if the initial states are related through the same Lie algebra homomorphism  $\phi$ . As we shall show in the remainder of the paper (cf. also [2]), it is possible for cases of physical interest to give a stronger version of Theorem 1. In particular, it is possible to show that the existence of a homomorphism  $\phi$  satisfying (12) is also necessary for equivalence of two models. Moreover, it is possible to construct such a homomorphism. This way, we can characterize the class of equivalent models. We shall do this for a two level example in the next section and for general spin networks in section 6. In both cases we exploit a Cartan decomposition underlying the dynamics of the models.

In general, more structure will have to be assumed to avoid trivial cases. For example, if  $S = S'$  is a scalar matrix, then every two models are equivalent. To avoid this case, an appropriate extra assumption is the *observability* of the two models. Also, we need to assume that the initial states are not both perfect mixtures (i.e., multiples of the identity); otherwise, with  $S = S'$ , the output for any two equivalent models will be the same, independently of the dynamics. Moreover,  $-iH_j$  and  $-iH'_j$ ,  $j = 0, \dots, m$ , may be generally assumed traceless, as the trace only adds an extra common phase factor to the dynamics, which cannot be detected. We shall use these assumptions in the following.

**5. Model equivalence of two level systems.** Consider a spin  $\frac{1}{2}$  particle which is driven by an electromagnetic control field along the  $z$  axis, interacts with a constant unknown magnetic field along an (unknown) direction in the  $x$ - $y$  plane, and has an unknown initial state. The practical question is to what extent, by driving the system with the control field and measuring the average value of the spin magnetization in the  $z$  direction, it is possible to obtain information about the unknown parameters of the system. This type of model has a Cartan structure which is shared by several other models of physical interest and is instrumental in finding a homomorphism between equivalent models. We describe this below.

The Lie algebra  $su(2)$ , which is the relevant Lie algebra in the two level case, has, up to conjugacy, only one Cartan decomposition which corresponds to the classical Euler decomposition of the Lie group  $SU(2)$  [16]. This extends to a decomposition of  $u(2)$  which can always be written as

$$(19) \quad u(2) = \mathcal{K} \oplus \mathcal{P}.$$

Here  $\mathcal{K}$  and  $\mathcal{P}$  satisfy the commutation relations in (7) and are given, up to conjugacy, by

$$(20) \quad \mathcal{K} := \text{span}\{i\sigma_z\}, \quad \mathcal{P} := \text{span}\{i\sigma_x, i\sigma_y, i\mathbf{1}_{2 \times 2}\}.$$

Here,  $\mathbf{1}_{2 \times 2}$  is the  $2 \times 2$  identity matrix and  $\sigma_x$ ,  $\sigma_y$ , and  $\sigma_z$  are the *Pauli matrices*

$$(21) \quad \sigma_x := \frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_y := \frac{1}{2} \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}, \quad \sigma_z := \frac{1}{2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

which satisfy the commutation relations

$$(22) \quad [i\sigma_x, i\sigma_y] = i\sigma_z, \quad [i\sigma_y, i\sigma_z] = i\sigma_x, \quad [i\sigma_z, i\sigma_x] = i\sigma_y.$$

The dynamical and output equations, for the above model of a spin  $\frac{1}{2}$  particle in an electromagnetic field, can be written as

$$(23) \quad \dot{\rho} = [A + i\sigma_z u(t), \rho], \quad y = \text{Tr}(\sigma_z \rho), \quad \rho(0) = \rho_0,$$

where  $\rho_0$  is an unknown initial density matrix and  $A := x i\sigma_x + y i\sigma_y$ , with  $x$  and  $y$  unknown. This model has a *Cartan structure* in that  $A$  is in  $\mathcal{P}$  and  $i\sigma_z$  (the control and observation part) is in  $\mathcal{K}$ , with  $\mathcal{K}$  and  $\mathcal{P}$  defined as in (20). We assume  $x^2 + y^2 \neq 0$  which implies controllability and therefore observability [10] for this model. The following result characterizes all the classes of equivalent models in terms of Lie algebra homomorphisms.

**THEOREM 2.** *Consider two models*

$$(24) \quad \dot{\rho} = [A + i\sigma_z u(t), \rho], \quad y = \text{Tr}(\sigma_z \rho), \quad \rho(0) = \rho_0,$$

$$(25) \quad \dot{\rho}' = [A' + i\sigma_z u(t), \rho], \quad y = \text{Tr}(\sigma_z \rho'), \quad \rho'(0) = \rho'_0,$$

with  $\rho_0$  and  $\rho'_0$  not both equal to scalar matrices (representing perfect mixtures) and  $A$  and  $A'$  of the form

$$(26) \quad A := x i\sigma_x + y i\sigma_y \quad \text{and} \quad A' := x' i\sigma_x + y' i\sigma_y$$

for real parameters  $x, y, x', y'$ . Assume

$$(27) \quad x^2 + y^2 \neq 0 \quad \text{and} \quad x'^2 + y'^2 \neq 0.$$

Then the two models are equivalent if and only if there exists an automorphism  $\phi : u(2) \rightarrow u(2)$  with

$$(28) \quad \phi^*(i\sigma_z) = i\sigma_z$$

and

$$(29) \quad A' = \phi(A), \quad \phi(i\sigma_z) = i\sigma_z, \quad i\rho'_0 = \phi(i\rho_0).$$

*Proof.* It is clear that if the automorphism  $\phi$  exists, satisfying (28) and (29), the two models are equivalent. This follows from a direct application of Theorem 1, with (28) and (29) replacing (12) and (13). To prove the opposite, first notice that, from the equivalence assumption, we have

$$(30) \quad y(t) := \text{Tr}(\sigma_z \rho(t)) = \text{Tr}(\sigma_z \rho'(t)) := y'(t)$$

for every  $t \geq 0$  and every admissible control.

We consider an automorphism  $\phi$  of the type

$$(31) \quad \phi(L) := e^{-i\alpha\sigma_z} L e^{i\alpha\sigma_z}, \quad L \in u(2),$$

as  $\alpha$  varies in  $\mathbb{R}$ .

Clearly (28) and the second equation of (29) are verified for any  $\alpha \in \mathbb{R}$ . Moreover,

$$(32) \quad \phi(A) = \bar{x}i\sigma_x + \bar{y}i\sigma_y,$$

with

$$(33) \quad \begin{pmatrix} \bar{x} \\ \bar{y} \end{pmatrix} = K_\alpha \begin{pmatrix} x \\ y \end{pmatrix},$$

and

$$(34) \quad K_\alpha := \begin{pmatrix} \cos(\alpha) & \sin(\alpha) \\ -\sin(\alpha) & \cos(\alpha) \end{pmatrix}.$$

Also, if we write

$$(35) \quad \begin{aligned} i\rho_0 &:= \rho_x i\sigma_x + \rho_y i\sigma_y + \rho_z i\sigma_z + \frac{1}{2}i\mathbf{1}, \\ i\rho'_0 &:= \rho'_x i\sigma_x + \rho'_y i\sigma_y + \rho'_z i\sigma_z + \frac{1}{2}i\mathbf{1}, \end{aligned}$$

we have

$$(36) \quad \phi(i\rho_0) = \bar{\rho}_x i\sigma_x + \bar{\rho}_y i\sigma_y + \bar{\rho}_z i\sigma_z + \frac{1}{2}i\mathbf{1},$$

with

$$(37) \quad \begin{pmatrix} \bar{\rho}_x \\ \bar{\rho}_y \end{pmatrix} = K_\alpha \begin{pmatrix} \rho_x \\ \rho_y \end{pmatrix}.$$

Using the equivalence assumption (30) at  $t = 0$ , we obtain

$$(38) \quad \rho_z = \rho'_z.$$

Moreover, differentiating (30), using the dynamical equations (24) and (25), we obtain

$$(39) \quad \text{Tr}(\rho[\sigma_z, A]) = \text{Tr}(\rho'[\sigma_z, A']).$$

Writing this at time  $t = 0$  and using the definitions (26) and (35) along with the commutation relation for the Pauli matrices (22), we obtain

$$(40) \quad \rho_y x - \rho_x y = \rho'_y x' - \rho'_x y'.$$

Differentiating (39) and using the fact that the resulting equation has to be valid for every value of the control, we obtain the two equations

$$(41) \quad \text{Tr}(\sigma_z[A, [A, \rho]]) = \text{Tr}(\sigma_z[A', [A', \rho']])$$

and

$$(42) \quad \text{Tr}(i\sigma_z[A, [\sigma_z, \rho]]) = \text{Tr}(i\sigma_z[A', [\sigma_z, \rho']]).$$

From (42), as for (40), we obtain

$$(43) \quad x\rho_x + y\rho_y = x'\rho'_x + y'\rho'_y.$$

From (41), we obtain

$$(44) \quad (x^2 + y^2)\text{Tr}(\sigma_z\rho) = (x'^2 + y'^2)\text{Tr}(\sigma_z\rho').$$

Using the fact that  $\text{Tr}(\sigma_z\rho)$  is not always zero (because of the controllability condition (27))<sup>5</sup> and (30), we have

$$(46) \quad x^2 + y^2 = x'^2 + y'^2.$$

Therefore, for some  $\alpha$ , we can write

$$(47) \quad \begin{pmatrix} x' \\ y' \end{pmatrix} = K_\alpha \begin{pmatrix} x \\ y \end{pmatrix},$$

with  $K_\alpha$  in (34), and this, compared with (33) and (32), gives the first term of (29). To obtain the third term (with the same  $\phi$ ), we recall from (27) that  $x^2 + y^2 \neq 0$ . Letting  $J := \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$  and using (47), we can write (40) and (43), respectively, as

$$(48) \quad [x, y]J[\rho_x, \rho_y]^T = [x, y]K_\alpha^T J[\rho'_x, \rho'_y]^T,$$

$$(49) \quad [x, y][\rho_x, \rho_y]^T = [x, y]K_\alpha^T [\rho'_x, \rho'_y]^T.$$

Since  $K_\alpha^T$  commutes with  $J$ , we can write these as

$$(50) \quad \begin{pmatrix} [x, y]J \\ [x, y] \end{pmatrix} [\rho_x, \rho_y]^T = \begin{pmatrix} [x, y]J \\ [x, y] \end{pmatrix} K_\alpha^T [\rho'_x, \rho'_y]^T.$$

---

<sup>5</sup>From controllability (27), we cannot have

$$(45) \quad \text{Tr}(\sigma_z\rho(t)) \equiv \text{Tr}(\sigma_z\rho'(t)) \equiv 0$$

for every control. This would mean that, for every reachable evolution operator  $X$ , the solution of the (Schrödinger) operator equation  $\dot{X} = (A + i\sigma_z u)X$ , with  $X(0) = \mathbf{1}$ ,  $X^* \sigma_z X$ , would be orthogonal to  $\rho_0$ . However, because of controllability,  $X$  may attain all the values in  $SU(2)$ , and therefore  $X^* \sigma_z X$  span, as  $X$  varies, may attain all of  $isu(2)$ . Therefore,  $X^* \sigma_z X$  is always orthogonal to  $\rho_0$  only if  $\rho_0$  is a multiple of the identity, which we have excluded.

Since

$$x^2 + y^2 = -\det \begin{pmatrix} [x, y]^J \\ [x, y] \end{pmatrix} \neq 0,$$

we can write

$$(51) \quad [\rho'_x, \rho'_y]^T = K_\alpha [\rho_x, \rho_y]^T,$$

and therefore

$$(52) \quad [\rho'_x, \rho'_y] = [\bar{\rho}_x, \bar{\rho}_y],$$

which along with  $\rho'_z = \rho_z$  gives

$$(53) \quad i\rho' = \phi(i\rho).$$

This concludes the proof of the theorem.  $\square$

*Remark 5.1.* The proof of the above theorem also gives the explicit form of the homomorphism relating two equivalent models.

## 6. Model equivalence of spin networks.

**6.1. A set of models of spin networks.** We consider a network of  $n$  particles with spin that interact according to Heisenberg interaction. In particular, we denote the spin of the  $j$ th particle by  $l_j$  and by  $N_j := 2l_j + 1$  the dimension of the Hilbert space for the state of the  $j$ th particle. The dimension of the Hilbert state space associated with the entire network is  $N := \prod_{j=1}^n N_j$ . The class of Hamiltonians we consider is of the form

$$(54) \quad H(t) := i(A + B_x u_x(t) + B_y u_y(t) + B_z u_z(t)),$$

where  $A$ , modeling the *Heisenberg interaction* among the particles, and  $B_{x,y,z}$ , modeling the interaction with external fields, are given by

$$(55) \quad \begin{aligned} A &:= -i \sum_{k < l, k, l=1}^n J_{kl} (I_{kx, lx} + I_{ky, ly} + I_{kz, lz}), \\ B_v &:= -i \left( \sum_{k=1}^n \gamma_k I_{kv} \right) \quad \text{for } v = x, y, \text{ or } z, \end{aligned}$$

respectively. Here and in the following we denote by  $I_{k_1 v_1, \dots, k_r v_r}$ , for  $1 \leq k_1 < \dots < k_r \leq n$  and  $v_j \in \{x, y, z\}$ , the  $N \times N$  matrix which is the Kronecker product of  $n$  matrices where in the  $j$ th position we have the  $N_j \times N_j$  identity if  $j \notin \{k_1, \dots, k_r\}$ , while if  $j = k_s$  we have the  $N_j \times N_j$  representation of the  $v_s$  component of spin angular momentum for a particle with spin  $l_j$ . Such matrices are given by the Pauli matrices (21) in the case where  $l_j = \frac{1}{2}$  and can be calculated for every value of the spin (see, e.g., [25, section 3.5]). For convenience of the reader, and since these matrices will be used several times in the following, we give their explicit form in Appendix B. With some abuse of notation, we shall continue denoting these matrices by  $\sigma_x$ ,  $\sigma_y$ , and  $\sigma_z$  without explicit reference to the value of the spin. Therefore, for instance, we have that for a system of three spin,

$$(56) \quad I_{1x, 3y} := \sigma_x \otimes \mathbf{1} \otimes \sigma_y$$

is the Kronecker product of three matrices.  $\sigma_x$  is the representation of the spin angular momentum in the  $x$  direction for the first spin (dimension  $N_1 \times N_1$ ),  $\sigma_y$  is the representation of the spin angular momentum in the  $y$  direction for the third spin (dimension  $N_3 \times N_3$ ), and the matrix  $\mathbf{1}$  is the identity matrix for the second spin (dimension  $N_2 \times N_2$ ). In all dimensions, the matrices  $\sigma_x$ ,  $\sigma_y$ , and  $\sigma_z$  have several properties we shall use in the following. In particular, they satisfy the commutation relations (22) and

$$(57) \quad \sigma_x^2 + \sigma_y^2 + \sigma_z^2 = l_j(l_j + 1)\mathbf{1}_{N_j \times N_j}$$

(see, e.g., formula (3.5.34a) in [25]).

The real scalar parameter  $J_{kl}$  in (55) is the *exchange constant* between particle  $k$  and particle  $l$ , and the real scalar parameter  $\gamma_k$  is the gyromagnetic ratio of particle  $k$ . We assume that the spins of the network have all nonzero and different gyromagnetic ratios. We can associate a graph with the model, where each node represents a particle and an edge connects two nodes if and only if the corresponding exchange constant is different from zero. It is not difficult to see that if the model is controllable, then, necessarily, this graph is connected. We shall assume this to be the case. Moreover, controllability implies observability for every output of the form (4) where  $S$  is a nonscalar matrix [10]. In our case, we presume to measure the expectation values of the total magnetization in the  $x$ ,  $y$ , and  $z$  directions given as in (4), where  $S$  is one of the matrices:

$$(58) \quad S_v := \sum_{k=1}^n I_{kv} \quad \text{with} \quad v \in \{x, y, z\}.$$

*Remark 6.1.* We have chosen to model the interaction between spins with Heisenberg interaction of the form  $A$  in (55) because we have in mind applications to molecular magnets as described in [27], which was the first motivation for this research. The Heisenberg interaction is the most common model of interaction between spins when relativistic effects (and higher order terms) are neglected (see, e.g., [29]). However, other types of interaction can be more appropriate for modeling the interaction between spins for other systems. If we consider two-body interaction, the proof of Theorem 7 still holds in the first half but the computations in the second half use explicitly the form of the interaction.

A model of the type described above will be denoted by  $\Sigma := \Sigma(n, l_j, J_{kl}, \gamma_k, \rho_0)$ , where the parameters  $n, l_j, J_{kl}, \gamma_k, \rho_0$ , which determine the model, are unknown. We will assume to have two controllable models  $\Sigma$  and  $\Sigma' := \Sigma'(n', l'_j, J'_{kl}, \gamma'_k, \rho'_0)$  which satisfy the previous requirements, and we look for necessary and sufficient conditions for these two models to be equivalent. We shall mark with a prime,  $'$ , all the quantities concerning the system  $\Sigma'$ .

**6.2. Relevant homomorphism of  $u(N)$ .** In [12] a method was described to construct a Cartan decomposition of the Lie algebra  $su(N)$  for a multipartite system, starting from decompositions of the Lie algebras  $su(N_j)$  associated with the single subsystems, each of dimension  $N_j$ , with  $N := \prod_{j=1}^n N_j$ . In particular, we have the following result.

**THEOREM 3** (see [12, section 5]). *Consider a multipartite system with  $n$  subsystems of dimensions  $N_1, \dots, N_n$ . Consider the Lie algebra  $u(N_j)$  related to the  $j$ th subsystem and a Cartan decomposition*

$$(59) \quad u(N_j) = \mathcal{K}_j \oplus \mathcal{P}_j$$

of type **AI** or **AII**. Denote by  $\sigma_j$  ( $S_j$ ) a generic element of an orthogonal basis of  $i\mathcal{K}_j$  ( $i\mathcal{P}_j$ ). Let the (total) Lie algebra  $u(N_1 N_2 \cdots N_n)$  be decomposed as

$$(60) \quad iu(N_1 N_2 \cdots N_n) = \mathcal{I}_o \oplus \mathcal{I}_e.$$

$\mathcal{I}_o$  ( $\mathcal{I}_e$ ) is the vector space spanned by matrices which are the tensor products of an odd (even) number of elements of type  $\sigma_j$ . Then  $u(N_1 N_2 \cdots N_n) = i\mathcal{I}_o \oplus i\mathcal{I}_e$  is a Cartan decomposition, i.e.,

$$(61) \quad [i\mathcal{I}_o, i\mathcal{I}_o] \subseteq i\mathcal{I}_o, \quad [i\mathcal{I}_o, i\mathcal{I}_e] \subseteq i\mathcal{I}_e, \quad [i\mathcal{I}_e, i\mathcal{I}_e] \subseteq i\mathcal{I}_o.$$

The decomposition (60) is called a decomposition of the *odd-even type*.

Associated with Cartan decomposition (61) is a Cartan involution  $\phi$  which is the identity on  $i\mathcal{I}_o$  and multiplication by  $-1$  on  $i\mathcal{I}_e$ . The structure of system (54) and (55) suggests that it is possible to choose this Cartan involution as a homomorphism mapping the equations of two equivalent models as in (12). In fact, assume that there is the same number of subsystems (spin particles) in the two models and that corresponding subsystems have the same dimensions (namely, the same spin). If we can display a decomposition (59) of type **AI** or **AII** for every (spin)  $u(N_j)$  such that  $i\sigma_{x,y,z} \in \mathcal{K}_j$ , then, for every value of the parameters, it holds that  $B_{x,y,z}(\cdot) \in i\mathcal{I}_o$  and  $A(\cdot) \in i\mathcal{I}_e$ . As shown in Theorems 4–6 following, decompositions of this type exist. We shall see in the following subsection that the Cartan involution associated with an odd-even type of Cartan decomposition is the correct homomorphism to describe classes of equivalent spin networks. In fact, not only are models which are related by such a homomorphism equivalent (according to Theorem 1) but the opposite is true as well. In other words, two equivalent models are either exactly the same or are related through such a homomorphism.

The following three theorems show the existence of a decomposition (59) of  $u(N_j)$  of type **AI** or **AII** where the subalgebra  $\mathcal{K}_j$  contains the matrices  $i\sigma_x$ ,  $i\sigma_y$ , and  $i\sigma_z$ . Equivalently, they show the existence of a subalgebra of  $sp(\frac{N_j}{2})$  (type **AII**) or  $so(N_j)$  (type **AI**) conjugate to the Lie algebra spanned by  $i\sigma_x$ ,  $i\sigma_y$ , and  $i\sigma_z$ . The proofs are presented in the following section. We shall see that the situation is different for integer and half-integer spins.

**THEOREM 4.** *If the dimension  $N_j$  of the system is even (half-integer spin (Fermions)), there exists a subalgebra of  $sp(\frac{N_j}{2})$  conjugate to the Lie algebra spanned by  $i\sigma_x$ ,  $i\sigma_y$ , and  $i\sigma_z$ .*

**THEOREM 5.** *If the dimension  $N_j$  of the system is odd (integer spin (Bosons)), there exists a subalgebra of  $so(N_j)$  conjugate to the Lie algebra spanned by  $i\sigma_x$ ,  $i\sigma_y$ , and  $i\sigma_z$ .*

**THEOREM 6.** *If the dimension  $N_j$  of the system is even (half-integer spin (Fermions)), there is no subalgebra of  $so(N_j)$  conjugate to the Lie algebra spanned by  $i\sigma_x$ ,  $i\sigma_y$ , and  $i\sigma_z$ .*

**6.3. Necessary and sufficient conditions for model equivalence.** In this subsection we shall prove the equivalence result concerning models of spin networks. This is given by the following theorem.

**THEOREM 7.** *Let  $\Sigma := \Sigma(n, l_j, J_{kl}, \gamma_k, \rho_0)$  and  $\Sigma' := \Sigma(n', l'_j, J'_{kl}, \gamma'_k, \rho'_0)$  be two given models (see (54), (55)). Assume that both models are controllable, that for model  $\Sigma$  ( $\Sigma'$ ), all the  $\gamma_k$  ( $\gamma'_k$ ) are nonzero and different from each other, and that  $\rho_0$  and  $\rho'_0$  are not both scalar matrices. Then  $\Sigma$  is equivalent to  $\Sigma'$  i.e.,*

$$(62) \quad y_v(t) := \text{Tr}(S_v \rho(t)) \equiv y'_v(t) := \text{Tr}(S'_v \rho'(t)) \quad \text{for } v \in \{x, y, z\}$$

and for every control  $u_x, u_y, u_z$ , if and only if the following condition holds:

**Condition (\*):**

1.  $n = n'$ ,

Up to a permutation of the set  $\{1, \dots, n\}$  (i.e., a permutation of the indices for the particles), the following three conditions hold:

2.

$$\gamma_k = \gamma'_k,$$

3.

$$(63) \quad l_k = l'_k,$$

and

4. one of the following two conditions holds:

(a)

$$(64) \quad A = A' \text{ and } \rho_0 = \rho'_0.$$

(b) Given the Cartan involution  $\phi$  associated with the decomposition of the odd-even type as from Theorem 3 (see also Remark 6.2 below),

$$(65) \quad A' = \phi(A) \text{ and } i\rho'_0 = \phi(i\rho_0).$$

*Remark 6.2.* The simplest way to describe the Cartan involution  $\phi$  associated with the odd-even decomposition is in terms of its action on the subspaces  $i\mathcal{I}_o$  and  $i\mathcal{I}_e$  defined in Theorem 3; that is,  $\phi$  leaves unchanged the elements of  $i\mathcal{I}_o$  and multiplies by  $-1$  the elements of  $i\mathcal{I}_e$ .  $\mathcal{I}_o$  and  $\mathcal{I}_e$  are defined in terms of the Cartan decompositions on the single subsystems. In our case, this is done according to Theorems 4 and 5. In particular consider the  $j$ th subsystem and assume that it has even dimension. Then with the unitary transformation  $U$  defined in (87),  $u(N_j)$  has the Cartan decomposition (59) of type **AII**, with  $\mathcal{K}_j$ , given by  $\mathcal{K}_j := U^* sp(N_j/2)U$  and  $\mathcal{P}_j = U^* sp(N_j/2)^\perp U$ . Analogously if the  $j$ th system has odd dimension, one considers the unitary transformation  $U$  defined in (92). Then  $u(N_j)$  has the Cartan decomposition (59) of the type **AI**, with  $\mathcal{K}_j$ , given by  $\mathcal{K}_j := U^* so(N_j)U$ , and  $\mathcal{P}_j = U^* so(N_j)^\perp U$ . According to Theorems 4 and 5, in both cases  $i\sigma_{x,y,z}$  are in  $\mathcal{K}_j$ . If we call  $\sigma_j$  a generic element of  $i\mathcal{K}_j$ ,  $\mathcal{I}_o$  ( $\mathcal{I}_e$ ) is spanned by an odd (even) number of  $\sigma_j$ 's. Notice in particular that in the model (55),  $A \in i\mathcal{I}_e$  and  $B_v \in i\mathcal{I}_o$ , so that  $\phi$  changes the sign of  $A$  and leaves the  $B_v$ 's unchanged.

Theorem 7 says that, under appropriate controllability assumptions, two equivalent models for spin networks are equivalent if and only they have the same number of particles, corresponding particles have the same spin, and their dynamical models and initial states are either exactly the same or are related through the Cartan involution associated with a decomposition of the odd-even type. In practical terms, given a general spin network, by driving the network with an external electromagnetic field and measuring the total spin in the  $x$ ,  $y$ , and  $z$  direction, it is, in principle, possible to identify the number of particles, their spin, the gyromagnetic ratios of every spin, and the exchange constants only up to a common sign factor, if the initial state is not known. The proof that Condition (\*) implies equivalence is an application of the

general property of Theorem 1. The proof that equivalence implies Condition (\*) is considerably longer. However, several results can be obtained with proofs that are formal modifications of the ones presented in [2] for the special case of spin  $\frac{1}{2}$  particles. We shall focus on the new part of the proof needed to generalize to the case of unknown spins:

*Condition (\*) implies equivalence.*

It is clear that if Condition (\*) holds with (64), then the two models differ possibly only by a permutation of the indices of the particles. So they are equivalent. Assume now that Condition (\*) holds with (65) and assume for simplicity (and without loss of generality) that the permutation of indices is the trivial permutation. Let  $\phi$  be the Cartan involution associated with the decomposition of the odd-even type. We notice that

$$(66) \quad \phi^*(iS_v) = iS_v = iS'_v, \quad v = x, y, z.$$

In fact, given any  $C \in \mathfrak{u}(N)$ , we can write  $C = C_o + C_e$ , with  $C_o \in i\mathcal{I}_o$  and  $C_e \in i\mathcal{I}_e$ . It holds that

$$\text{Tr}(\phi^*(iS_v)C) := \text{Tr}((iS_v)\phi(C)) = \text{Tr}((iS_v)(C_o - C_e)) = \text{Tr}((iS_v)C_o) = \text{Tr}((iS_v)C),$$

which, since it has to hold for every  $C$ , gives (66). Equations (65) and (66) imply that (12) of Theorem 1 holds. Since we also have (13), from (65) we conclude that the two models are equivalent using Theorem 1 as follows.

*Equivalence implies Condition (\*).*

The technique used in [2] to prove this result for networks of spin  $\frac{1}{2}$  particles extends to the general case treated here. However, further analysis is required in this case, in particular to prove that equivalent spin networks have the same values of the spins, while in [2] it was assumed that the networks were composed by all spin  $\frac{1}{2}$ 's. The main reason why the proof in [2] can be extended to this case is that the basic commutation relations, which were the essential ingredient of the proofs in [2], still hold. More precisely, the matrices  $\sigma_x$ ,  $\sigma_y$ , and  $\sigma_z$  still satisfy, for every value of the spin, the commutation relations (22). This fact implies that it also holds that

$$(67) \quad [I_{k_1 v_1, \dots, k_r v_r}, I_{\bar{k} v_{\bar{k}}}] = \begin{cases} 0 & \text{if } \bar{k} \notin \{k_1, \dots, k_r\}, \\ 0 & \text{if } \exists j \text{ with } \bar{k} = k_j \text{ and } v_{\bar{k}} = v_j, \\ iI_{k_1 v_1, \dots, k_j [v_j v_{\bar{k}}], \dots, k_r v_r} & \text{if } \exists j \text{ with } \bar{k} = k_j \text{ and } v_{\bar{k}} \neq v_j \end{cases}$$

independently of the values of the spins.<sup>6</sup>

Assume now that the two models  $\Sigma$  and  $\Sigma'$  are equivalent. Then, using exactly the same arguments as in the proof of Proposition 4.1 of [2], we obtain that the number of the spin particle must be the same, namely,  $n = n'$ , and, up to a permutation of the indices,  $\gamma_k = \gamma'_k$  for all  $k \in \{1, \dots, n\}$ , which is parts 1 and 2 of Condition (\*). Moreover, as in Proposition 4.1 of [2], we obtain

$$(68) \quad \text{Tr}(I_{kv}\rho(t)) = \text{Tr}(I'_{kv}\rho'(t)) \quad \forall k \in \{1, \dots, n\}, \quad \forall v \in \{x, y, z\}.$$

<sup>6</sup>In the notation used here  $[v\bar{v}]$  give a result in agreement with the commutator of  $i\sigma_v$  and  $i\sigma_{\bar{v}}$  (cf. (22)). Therefore, for example,  $[xy] := z$ . Moreover,  $I_{k_1 v_1, \dots, k_j (-v_j), \dots, k_r v_r} := -I_{k_1 v_1, \dots, k_j (v_j), \dots, k_r v_r}$ .

Here  $I'_{kv}$  is defined as  $I_{kv}$  but for  $\Sigma'$  and, at this point, it may be different from  $I_{kv}$  since we have not shown yet that corresponding spins must be equal. To prove this fact, we shall use Lemma 8 below. The proof of this lemma is a generalization of the proof of Lemma 5.2 in [2], where we use the general property (57) instead of the corresponding property for spin  $\frac{1}{2}$ 's. We postpone this proof to Appendix A.

LEMMA 8. *Assume that for all  $t \geq 0$ , all possible trajectories  $\rho(t)$  of  $\Sigma$ , and corresponding  $\rho'(t)$  of  $\Sigma'$ , for fixed values  $1 \leq k_1, \dots, k_r \leq n$ ,  $v_j \in \{x, y, z\}$  and for given constants  $\beta$  and  $\beta'$ , we have*

$$(69) \quad \beta \text{Tr} (I_{k_1 v_1, \dots, k_r v_r} \rho(t)) = \beta' \text{Tr} (I'_{k_1 v_1, \dots, k_r v_r} \rho'(t)).$$

Then

1. *for any pair of indices  $\bar{k}, \bar{d} \in \{1, \dots, n\}$  with  $\bar{k} \in \{k_1, \dots, k_r\}$  and  $\bar{d} \notin \{k_1, \dots, k_r\}$ ,*

$$(70) \quad \beta J_{\bar{k}\bar{d}} \text{Tr} (I_{k_1 v_1, \dots, k_r v_r, \bar{d} \bar{v}} \rho(t)) = \beta' J'_{\bar{k}\bar{d}} \text{Tr} (I'_{k_1 v_1, \dots, k_r v_r, \bar{d} \bar{v}} \rho'(t))$$

*for any value  $\bar{v} \in \{x, y, z\}$ .*

2. *For any pair of indices  $\bar{k}, \bar{d}$  both in  $\{k_1, \dots, k_r\}$  (for example,  $\bar{k} = k_1, \bar{d} = k_2$ ),*

$$(71) \quad \begin{aligned} & \beta (l_{\bar{d}}(l_{\bar{d}} + 1)) J_{\bar{k}\bar{d}} \text{Tr} (I_{k_1 v_1, k_3 v_3, \dots, k_r v_r} \rho(t)) \\ &= \beta' (l'_{\bar{d}}(l'_{\bar{d}} + 1)) J'_{\bar{k}\bar{d}} \text{Tr} (I'_{k_1 v_1, k_3 v_3, \dots, k_r v_r} \rho'(t)). \end{aligned}$$

In other words, formula (71) means that from (69), it is possible to derive a new formula as follows. Select two indices in the set  $\{k_1, \dots, k_r\}$ ,  $\bar{k}$  and  $\bar{d}$ . One of the two indices (say,  $\bar{d}$ ) disappears from the subscript in the matrices  $I$  and corresponding  $I'$ . However, a coefficient  $l_{\bar{d}}(l_{\bar{d}} + 1)$  and  $l'_{\bar{d}}(l'_{\bar{d}} + 1)$  appears in the left- and right-hand side, respectively, as well as a coefficient  $J_{\bar{k}\bar{d}}$  and  $J'_{\bar{k}\bar{d}}$ .

Analogously, for formula (70) one selects two indices  $\bar{k}$  and  $\bar{d}$  corresponding to two given particles, with  $\bar{k} \in \{k_1, \dots, k_r\}$  and  $\bar{d} \notin \{k_1, \dots, k_r\}$ .  $J_{\bar{k}\bar{d}}$  and  $J'_{\bar{k}\bar{d}}$  denote the coupling constants between the  $\bar{k}$ th and  $\bar{d}$ th particle in the two models. Formula (70) is in fact three formulas, one for each value of  $\bar{v} = x, y, z$ .

We shall now prove that, under the assumption of equivalence, the squares of the exchange constants  $J_{dk}$  and  $J'_{dk}$  must be proportional, with a proportionality factor common to all pairs of indices  $d$  and  $k$ , and this will also be instrumental in the proof of part 3 of Condition (\*).

Fix any  $1 \leq k_1 < k_2 \leq n$ . Then, by applying statement 1 of Lemma 8, i.e., (70) with  $\bar{k} = k_1, \bar{d} = k_2$ , to (68) with  $k = k_1$ , we have

$$(72) \quad J_{k_1 k_2} \text{Tr} (I_{k_1 v_1, k_2 v_2} \rho(t)) = J'_{k_1 k_2} \text{Tr} (I'_{k_1 v_1, k_2 v_2} \rho'(t)) \quad \forall v_1, v_2 \in \{x, y, z\}.$$

Now, to the previous equality we apply statement 2 of Lemma 8, i.e., (71) with  $\bar{k} = k_1$  and  $\bar{d} = k_2$ , to get

$$(l_{k_2}(l_{k_2} + 1)) J_{k_1 k_2}^2 \text{Tr} (I_{k_1 v_1} \rho(t)) = (l'_{k_2}(l'_{k_2} + 1)) J_{k_1 k_2}'^2 \text{Tr} (I'_{k_1 v_1} \rho'(t)),$$

which, by (68), implies

$$(73) \quad (l_{k_2}(l_{k_2} + 1)) J_{k_1 k_2}^2 = (l'_{k_2}(l'_{k_2} + 1)) J_{k_1 k_2}'^2.$$

Using the facts that the two indices  $k_1$  and  $k_2$  above are arbitrary and that the graph associated with the network is connected, by the controllability assumption (cf. the

discussion at the end of subsection 6.1) it is easy to see that there exists a positive constant  $\alpha \in \mathbb{R}$  such that, for all  $1 \leq d < k \leq n$ ,

$$(74) \quad J_{dk}^2 = \alpha^2 J'_{dk}{}^2 \quad \text{and} \quad l_k(l_k + 1) = \frac{1}{\alpha^2} l'_k(l'_k + 1).$$

Using (74), we can now prove part 3 of Condition (\*). We will do this using some lemmas and arguing by contradiction. First, notice that from (74), we have that if there exists a  $\bar{k} \in \{1, \dots, n\}$  such that  $l_{\bar{k}} = l'_{\bar{k}}$ , then necessarily  $\alpha^2 = 1$ , and thus  $l_j = l'_j$  for all  $j = 1, \dots, n$ , namely, all the particles have the same spin. So if we assume that (63) does not hold, without loss of generality, we can assume  $l_1 > l'_1$ . Using (74), we get that  $l_j > l'_j$  for all  $j = 1, \dots, n$ , and thus also  $N_j > N'_j$ . Let  $R := \frac{N}{N_1} = \prod_{j=2}^n N_j$  and  $R' := \frac{N'}{N'_1} = \prod_{j=2}^n N'_j$ .

LEMMA 9. *For all  $t \in \mathbb{R}$  and all the admissible trajectories  $\rho$  and corresponding trajectories  $\rho'$ , we have*

$$(75) \quad \begin{aligned} & Tr \left( (e^{i\sigma_z t} \otimes \mathbf{1}_{R \times R}) I_{1v} (e^{-i\sigma_z t} \otimes \mathbf{1}_{R \times R}) \rho(s) \right) \\ &= Tr \left( (e^{i\sigma_z t} \otimes \mathbf{1}_{R' \times R'}) I'_{1v} (e^{-i\sigma_z t} \otimes \mathbf{1}_{R' \times R'}) \rho'(s) \right) \end{aligned}$$

for all  $s \geq 0$ .

*Proof.* First, we notice that from the Campbell–Baker–Hausdorff formula, we have

$$(76) \quad (e^{i\sigma_z t} \otimes \mathbf{1}_{R \times R}) I_{1v} (e^{-i\sigma_z t} \otimes \mathbf{1}_{R \times R}) = \sum_{k=0}^{\infty} \left( ad_{i\sigma_z \otimes \mathbf{1}_{R \times R}}^k I_{1v} \right) \frac{t^k}{k!} \quad \forall v \in \{x, y, z\}$$

and an analogous equation for  $\Sigma'$ . Moreover, by applying Lemma 11 in Appendix A, with  $W = I_{1v}$ ,  $W' = I'_{1v}$ , and  $k = 1$ ,  $v = z$ , we have

$$Tr \left( ad_{i\sigma_z \otimes \mathbf{1}_{R \times R}} I_{1v} \rho(s) \right) = Tr \left( ad_{i\sigma_z \otimes \mathbf{1}_{R' \times R'}} I'_{1v} \rho'(s) \right).$$

Now we can apply again Lemma 11 to the previous equality to get

$$Tr \left( ad_{i\sigma_z \otimes \mathbf{1}_{R \times R}}^2 I_{1v} \rho(s) \right) = Tr \left( ad_{i\sigma_z \otimes \mathbf{1}_{R' \times R'}}^2 I'_{1v} \rho'(s) \right).$$

By applying this procedure repeatedly we obtain

$$Tr \left( ad_{i\sigma_z \otimes \mathbf{1}_{R \times R}}^k I_{1v} \rho(s) \right) = Tr \left( ad_{i\sigma_z \otimes \mathbf{1}_{R' \times R'}}^k I'_{1v} \rho'(s) \right)$$

for all  $k \geq 0$ . Using this in (76), equation (75) follows.  $\square$

The proof of the following lemma is given in Appendix A.

LEMMA 10. *The following formula holds:*

$$(77) \quad (e^{i\sigma_z t} \otimes \mathbf{1}_{R \times R}) I_{1x} (e^{-i\sigma_z t} \otimes \mathbf{1}_{R \times R}) := P_{N_1}(t) \otimes \mathbf{1}_{R \times R},$$

where the matrix  $P_{N_1}(\cdot)$  is periodic with period  $2\pi$ . Moreover,

$$(78) \quad P_{N_1}(\pi) = -P_{N_1}(0) = -\sigma_x.$$

Using Lemmas 9 and 10, we can now conclude the proof that the spins are the same. Let  $\bar{\rho}(s) \otimes \mathbf{1}_{R \times R}$  (resp.,  $\bar{\rho}'(s) \otimes \mathbf{1}_{R' \times R'}$ ) be the orthogonal component of  $\rho(s)$

(resp.,  $\rho'(s)$ ) along  $\sigma_x \otimes \mathbf{1}_{R \times R}$  (resp.,  $\sigma_x \otimes \mathbf{1}_{R' \times R'}$ ). Using (77), equality (75) with  $v = x$  can be written as

$$(79) \quad \text{Tr} (P_{N_1}(t)\bar{\rho}(s)) R = \text{Tr} (P_{N'_1}(t)\bar{\rho}'(s)) R'.$$

Since we have assumed by contradiction  $R > R'$ , from (79) we have for every  $t$ ,

$$(80) \quad \text{Tr} (P_{N_1}(t)\bar{\rho}(s)) < \text{Tr} (P_{N'_1}(t)\bar{\rho}'(s)).$$

Now we will derive a contradiction by evaluating the previous inequality at  $t = 0$  and  $t = \pi$  and using (78). In fact we have

$$\text{Tr} (P_{N_1}(0)\bar{\rho}(s)) < \text{Tr} (P_{N'_1}(0)\bar{\rho}'(s)),$$

and thus

$$\text{Tr} (P_{N_1}(\pi)\bar{\rho}(s)) = -\text{Tr} (P_{N_1}(0)\bar{\rho}(s)) > -\text{Tr} (P_{N'_1}(0)\bar{\rho}'(s)) = \text{Tr} (P_{N'_1}(\pi)\bar{\rho}'(s)).$$

The previous inequality contradicts (80). Thus we conclude that  $l_1 = l'_1$ , which implies that (63) holds.

Since the two equivalent models  $\Sigma$  and  $\Sigma'$  have the same spin, the positive constant  $\alpha$  in (74) is equal to one. Therefore, for every pair  $d, k \in \{1, \dots, n\}$ ,  $J_{dk}$  and  $J'_{dk}$  only differ possibly by the sign factor. Using the same argument as in the main theorem of [2] we can in fact conclude that there are only two possible cases: The case where  $J_{dk} = J'_{dk}$  for every pair  $d, k$ , and the case where  $J_{dk} = -J'_{dk}$  for every pair  $d, k$ . If we are in the first case, then from the observability (which follows from controllability) of the model, we must have  $\rho_0 = \rho'_0$ , and thus (64) holds. This is case (a) of part 4 of Condition (\*). On the other hand, if  $J'_{kd} = -J_{kd}$  for every pair  $1 \leq k < d \leq n$ , we may conclude using Theorem 1. In fact we consider the homomorphism  $\phi$  given by the Cartan involution associated with the odd-even decomposition as in the previous part of the proof. Conditions (12) hold, and thus, since the models are equivalent and observable, we get that

$$i\rho'_0 = \phi(i\rho_0),$$

and thus (65) holds. This concludes the proof of the theorem.

**7. Proofs of Theorems 4–6.** In the proofs of Theorems 4 and 5, we shall use the following two types of elementary  $k \times k$  matrices:

$$(81) \quad C_k = \text{diag}(-1, 1, -1, \dots, (-1)^k), \quad T_k = \text{adiag}(1, 1, 1, \dots, 1) = \begin{pmatrix} 0 & \cdots & 0 & 1 \\ 0 & \cdots & 1 & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 1 & 0 & \cdots & 0 \end{pmatrix}.$$

Thus, the matrix  $C_k$  is diagonal with alternating elements while  $T_k$  is antidiagonal with all ones on the secondary diagonal and zeros everywhere else. Obvious properties of these matrices are the following:

$$(82) \quad C_k^2 = T_k^2 = \mathbf{1}_{k \times k}, \quad T_k = T_k^T.$$

We are interested in the action of these matrices by similarity transformation on diagonal and tridiagonal  $k \times k$  matrices.<sup>7</sup> In particular, let us denote by  $D$  a generic, real, diagonal,  $k \times k$  matrix and by  $F$  a generic, real,  $k \times k$ , tridiagonal matrix which is also symmetric and has zero diagonal; thus  $F$  will be of the type

$$F = \begin{pmatrix} 0 & a_1 & 0 & 0 & \cdots & 0 \\ a_1 & 0 & a_2 & 0 & \cdots & 0 \\ 0 & a_2 & 0 & a_3 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a_{k-2} & 0 & a_{k-1} \\ 0 & 0 & \cdots & 0 & a_{k-1} & 0 \end{pmatrix}.$$

If  $M^a$  denotes the antitransposed of  $M$ , namely, the matrix obtained by reflecting about the secondary diagonal, we can easily verify the following properties:

1.

$$(83) \quad C_k D C_k = D, \quad C_k F C_k = -F,$$

2.

$$(84) \quad T_k D T_k = D^a, \quad T_k F T_k = F^a.$$

*Remark 7.1.* In the proofs of Theorems 4 and 5 below we do not need to write explicitly the matrices  $\sigma_x$ ,  $\sigma_y$ , and  $\sigma_z$ , which are the representation of the  $x$ ,  $y$ , and  $z$  components of spin angular momentum; nevertheless we need to write their structure. This structure is given by (85) and (86) for half-integer spin and by (90) and (91) for integer spin (see, e.g., [25, section 3.5] and Appendix B). In both proofs we make the explicit computation only for  $i\sigma_x$  and  $i\sigma_z$ ; this is possible since the third of the commutation relations (22) gives  $i\sigma_y = [i\sigma_z, i\sigma_x]$ .

Now we are ready to prove Theorems 4 and 5.

*Proof of Theorem 4.* The matrices  $i\sigma_z$  and  $i\sigma_x$  have (for every value of the spin) the following structure:

$$(85) \quad i\sigma_z = i \begin{pmatrix} D & 0 \\ 0 & -D^a \end{pmatrix},$$

$$(86) \quad i\sigma_x = i \begin{pmatrix} F & P \\ P^T & F^a \end{pmatrix},$$

where  $F$  and  $D$  have the structure above specified with  $k := \frac{N_j}{2}$ , and  $P$  is a  $k \times k$  real matrix of all zeros except in the  $(k, 1)$ st position. Now use

$$(87) \quad U := \begin{pmatrix} C_k & 0 \\ 0 & T_k \end{pmatrix},$$

which is orthogonal and therefore unitary.

We calculate, using the first terms of (83) and (84),

$$(88) \quad i\tilde{\sigma}_z := U i\sigma_z U^* = i \begin{pmatrix} D & 0 \\ 0 & -D \end{pmatrix}.$$

<sup>7</sup>A matrix  $F$  is tridiagonal if  $f_{ij} = 0$  when  $|i - j| > 1$ .

Moreover, using the second terms of (83) and (84), we have

$$(89) \quad i\tilde{\sigma}_x := Ui\sigma_xU^* = i \begin{pmatrix} -F & C_kPT_k \\ T_kPC_k & F \end{pmatrix}.$$

It is easily seen that  $i\tilde{\sigma}_z$  and  $i\tilde{\sigma}_x$  are symplectic by observing that  $C_kPT_k$  is a real symmetric matrix (only the  $(k, k)$ th element is different from zero). Therefore  $\text{sp}(\frac{N_j}{2})$  contains a subalgebra conjugate to the one spanned by  $i\sigma_x$  and  $i\sigma_z$ , and therefore  $i\sigma_y$  and the theorem is proved.  $\square$

We now proceed to the proof of Theorem 5.

*Proof of Theorem 5.* In this case we set  $k := \frac{N_j-1}{2}$ . The matrix  $i\sigma_z$  has the form

$$(90) \quad i\sigma_z := i \begin{pmatrix} -D & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & D^a \end{pmatrix},$$

with  $D$  of dimension  $k \times k$ . Moreover,  $i\sigma_x$  has the form

$$(91) \quad i\sigma_x := i \begin{pmatrix} F & v & 0 \\ v^T & 0 & w^t \\ 0 & w & F^a \end{pmatrix},$$

where  $F$  is as above and  $v$  ( $w$ ) is a vector of dimension  $k$  with only the last (the first) component different from zero, and the components different from zero are equal for  $v$  and  $w$ . We use the unitary matrix

$$(92) \quad U := \begin{pmatrix} \frac{i}{\sqrt{2}}C_k & 0 & (-1)^k \frac{i}{\sqrt{2}}T_k \\ 0 & 1 & 0 \\ \frac{1}{\sqrt{2}}T_k & 0 & \frac{1}{\sqrt{2}}C_k \end{pmatrix},$$

which is easily seen to be unitary by (81) and (82). We calculate

$$(93) \quad \begin{aligned} i\tilde{\sigma}_z &:= Ui\sigma_zU^* \\ &= i \begin{pmatrix} \frac{1}{2}(T_kD^aT_k - C_kDC_k) & 0 & \frac{i}{2}((-1)^kT_kD^aC_k - C_kDT_k) \\ 0 & 0 & 0 \\ \frac{i}{2}(T_kDC_k - (-1)^kC_kD^2T_k) & 0 & \frac{1}{2}(C_kD^aC_k - T_kDT_k) \end{pmatrix}. \end{aligned}$$

Using the first terms of (83) and (84), we find that the diagonal blocks are zero. Moreover, the remaining elements of the matrix are real so that  $i\tilde{\sigma}_z$  is real. Analogously, we calculate

$$(94) \quad \begin{aligned} i\tilde{\sigma}_x &:= Ui\sigma_xU^* \\ &= i \begin{pmatrix} \frac{1}{2}(C_kFC_k + (-1)^{2k}T_kF^aT_k) & \frac{i}{\sqrt{2}}(C_kv + (-1)^kT_kw) & \frac{i}{2}(C_kFT_k + (-1)^kT_kF^aC_k) \\ * & 0 & \frac{1}{\sqrt{2}}(v^TT_k + w^TC_k) \\ * & * & \frac{1}{2}(T_kFT_k + C_kF^aC_k) \end{pmatrix}, \end{aligned}$$

where we have denoted by  $*$  the components that can be obtained from the requirement that the matrix is skew-Hermitian. Now the  $(1, 1)$  and  $(3, 3)$  blocks are zero from the second terms of properties (83) and (84), while the  $(2, 3)$  block is zero because of

the structure of the vectors  $v$  and  $w$ . All the other blocks are purely real matrices so that  $i\tilde{\sigma}_x$  is also in  $so(N)$ , and this completes the proof.  $\square$

We now give the proof of the negative result in Theorem 6.

*Proof of Theorem 6.* Assume that there exists a matrix  $X \in SU(N_j)$  such that

$$(95) \quad Xi\sigma_x X^* := \tilde{R}_x,$$

$$(96) \quad Xi\sigma_y X^* := \tilde{R}_y,$$

$$(97) \quad Xi\sigma_z X^* := \tilde{R}_z,$$

with  $\tilde{R}_x$ ,  $\tilde{R}_y$ , and  $\tilde{R}_z$  in  $so(N_j)$ . Then we can use the **AI** Cartan decomposition of  $SU(N_j)$  [16] to write  $X$  as

$$(98) \quad X = K_1 A K_2,$$

with  $K_1$  and  $K_2$  in  $SO(N_j)$  and  $A$  diagonal, i.e.,

$$(99) \quad A := \text{diag} \left( e^{i\phi_1}, \dots, e^{i\phi_{\frac{N_j}{2}}} \right).$$

Therefore we can write

$$(100) \quad K_1 A K_2 i\sigma_{x,y,z} K_2^T \bar{A} K_1^T = \tilde{R}_{x,y,z},$$

or, defining  $R_{x,y,z} := K_1^T \tilde{R}_{x,y,z} K_1$ , which is also real skew-symmetric, we can write

$$(101) \quad K_2 i\sigma_{x,y,z} K_2^T = \bar{A} R_{x,y,z} A.$$

The real matrices  $R_{x,y,z}$  must satisfy the same basic commutation relations (22) of  $i\sigma_x$ ,  $i\sigma_y$ , and  $i\sigma_z$  and have the same eigenvalues of  $i\sigma_x$ ,  $i\sigma_y$ , and  $i\sigma_z$ , namely, for a (half-integer) spin  $j$ ,  $\pm ji$ ,  $\pm(j+1)i$ ,  $\dots$ ,  $\pm\frac{1}{2}i$ . We now study the structure of  $R_{x,y,z}$  in (101) and get a contradiction with these facts.

First notice that, since  $A$  is diagonal as in (99), the action of  $A$  on the right-hand side of (101), namely,  $R \rightarrow \bar{A} R A$ , changes the (real) element  $r_{jk}$  of  $R$  into  $r_{jk} e^{-i(\phi_j - \phi_k)}$ . Since the entries on the left-hand side of (101) are either all purely imaginary or all purely real, if  $\phi_j - \phi_k$  is not a multiple of  $\frac{\pi}{2}$ , then we must have  $r_{jk} = 0$ . Consider the indices  $1, \dots, N_j$  and let  $\mathcal{O}$  be the set of indices  $k$  such that  $\phi_1 - \phi_k$  is an odd multiple of  $\frac{\pi}{2}$  and  $\mathcal{E}$  the set of indices  $k$  such that  $\phi_1 - \phi_k$  is an even multiple of  $\frac{\pi}{2}$ , and  $\mathcal{N}$  the set of indices  $k$  such that  $\phi_1 - \phi_k$  is not an integer multiple of  $\frac{\pi}{2}$ .

From (101) it follows that since  $i\sigma_y$  is real, the terms  $r_{jk}$  of  $R_y$ , where  $j$  and  $k$  belong to different sets, must be zero because in that case  $e^{i(\phi_j - \phi_k)}$  in (99) has a nonzero imaginary part. Therefore only the elements  $r_{jk}$ , where both  $j$  and  $k$  belong to  $\mathcal{O}$  or  $\mathcal{E}$  or  $\mathcal{N}$ , are possibly different from zero. Therefore after possibly reordering rows and columns, which corresponds to a similarity transformation by a permutation matrix,  $R_y$  must be of block diagonal form, and without loss of generality and for simplicity we shall assume only two blocks (rather than three). Therefore we write

$$(102) \quad R_y := \begin{pmatrix} Y_{11} & 0 \\ 0 & Y_{22} \end{pmatrix},$$

where  $Y_{11}$  has dimensions  $n_o \times n_o$  with  $n_o$  the cardinality of  $\mathcal{O}$ , and  $Y_{22}$  has dimension  $(N_j - n_o) \times (N_j - n_o)$ . Both  $Y_{11}$  and  $Y_{22}$  are skew-symmetric matrices. An analogous argument shows that, after possibly the same reordering of column and row indices,  $R_z$  can be written as

$$(103) \quad R_z := \begin{pmatrix} 0 & Z_{12} \\ -Z_{12}^T & 0 \end{pmatrix},$$

where  $Z_{12}$  is a general matrix of dimensions  $n_o \times (N_j - n_o)$ .

Now consider the possible values for  $n_o$ .  $n_o$  odd is to be excluded because this would cause  $\det Y_{11} = 0$  in (102), and this contradicts the fact that  $R_y$  has no zero eigenvalues. Moreover,  $n_o \neq (N_j - n_o)$  (i.e.,  $n_o \neq \frac{N_j}{2}$ ) would cause  $R_z$  to have a determinant equal to zero. This can be easily verified by calculating

$$(104) \quad \det(R_z^2) = (\det R_z)^2 = \det \begin{pmatrix} -Z_{12}Z_{12}^T & 0 \\ 0 & -Z_{12}^TZ_{12} \end{pmatrix}$$

since, in this case, at least one of the matrices on the diagonal blocks does not have full rank. These considerations already exclude the cases where  $\frac{N_j}{2}$  is an odd number as for spins  $\frac{1}{2}$ ,  $\frac{5}{2}$ ,  $\frac{9}{2}$ , etc., and we can assume  $R_y$  and  $R_z$  of the form (102) and (103) with  $n_o = \frac{N_j}{2}$ . To obtain a contradiction in this case too, we first notice that, since  $Y_{11}$  and  $Y_{22}$  have even dimension and are skew-symmetric, we can apply a similarity transformation  $T := \begin{pmatrix} T_1 & 0 \\ 0 & T_2 \end{pmatrix}$ , with  $T_1$  and  $T_2$  orthogonal so that  $TR_yT^T$  is block diagonal,

$$(105) \quad TR_yT^T = \left( D_1, D_2, \dots, D_{\frac{N_j}{2}} \right),$$

where the  $2 \times 2$  block  $D_k$  has the form

$$(106) \quad D_k := \begin{pmatrix} 0 & l_k \\ -l_k & 0 \end{pmatrix},$$

where each  $l_k$  corresponds to a pair of complex conjugate eigenvalues of  $R_y$  so that  $l_k = \frac{p}{2}$  with  $p$  odd corresponds to the pair  $\pm \frac{p}{2}i$ . Moreover, we choose  $T$  so that the first  $\frac{N_j}{4}$  blocks are ordered according to the increasing value of  $l_k$ , and the same holds for the last  $\frac{N_j}{4}$  blocks. We shall therefore assume this structure of  $R_y$  in the remainder of the proof. We notice also that the transformation  $TR_zT^T$  does not change the structure of  $R_z$ , as  $Z_{12}$  in (103) was chosen to be a general  $\frac{N_j}{2} \times \frac{N_j}{2}$  real matrix. Express  $Z_{12}$  in terms of  $2 \times 2$  blocks  $L_{fk}$ ,  $f, k = 1, \dots, \frac{N_j}{4}$ ,  $k = \frac{N_j}{4} + 1, \dots, \frac{N_j}{2}$ , which is possible since  $\frac{N_j}{2}$  is an even number. Now, we impose the fact that  $R_y$  and  $R_z$  have to satisfy the same commutation relations as  $i\sigma_y$  and  $i\sigma_z$ . In particular, we must have

$$(107) \quad [[R_y, R_z], R_y] = R_z.$$

This equation gives the following for the  $L_{fk}$  block:

$$(108) \quad 2D_f L_{fk} D_k - L_{fk} D_k^2 - D_f^2 L_{fk} = L_{fk}.$$

If we write the generic  $L_{fk}$  as

$$(109) \quad L_{fk} := \begin{pmatrix} a_1 & a_2 \\ a_3 & a_4 \end{pmatrix},$$

and recall the structure of  $D_f$  and  $D_k$ ,

$$(110) \quad D_f := \begin{pmatrix} 0 & l_f \\ -l_f & 0 \end{pmatrix}, \quad D_k := \begin{pmatrix} 0 & l_k \\ -l_k & 0 \end{pmatrix},$$

we obtain the following equations for  $a_2$  and  $a_3$  (and analogous equations for  $a_1$  and  $a_4$ ):

$$(111) \quad 2l_k l_f a_3 = (1 - l_f^2 - l_k^2) a_2,$$

$$(112) \quad 2l_k l_f a_2 = (1 - l_f^2 - l_k^2) a_3.$$

Combining these, we obtain

$$(113) \quad 4l_k^2 l_f^2 a_3 = (1 - l_k^2 - l_f^2)^2 a_3,$$

which shows, taking the square root of both sides, that the only possible ways to have  $a_3$  and therefore  $a_2$  different from zero are the cases  $l_f + l_k = \pm 1$ . In these cases we can easily see that

$$(114) \quad a_3 = -a_2.$$

Similarly, one finds that we have  $a_4$  and  $a_1$  in (109) different from zero if and only if  $l_f + l_k = \pm 1$ , and in these cases we have

$$(115) \quad a_1 = a_4.$$

In conclusion, all the blocks  $L_{fk}$  are zero except the ones corresponding to indices  $f$  and  $k$  with neighboring values of  $l_f$  and  $l_k$ , which have the structure

$$(116) \quad L_{fk} := \begin{pmatrix} x & y \\ -y & x \end{pmatrix}.$$

Therefore  $R_z$  has the form in (103) where the  $f$ th block row of  $Z_{12}$  has at most two blocks different from zero and with the structure in (116). We denote these blocks by  $P_f$  and  $S_f$ , where  $P$  ( $S$ ) stands for “predecessor” (“successor”) and corresponds to the index  $k$  such that  $l_k = l_f - 1$  and  $l_k = l_f + 1$ , respectively. Now, we argue that a matrix  $R_z$  with this structure must necessarily have all the (purely imaginary) eigenvalues with multiplicity at least two, and this gives the desired contradiction because  $R_z$  should have the same spectrum of  $i\sigma_{x,y,z}$ , which consists of all simple eigenvalues. In order to see this fact, reconsider the block structure of  $R_y$  in (105). If the blocks corresponding to eigenvalues  $\pm \frac{1}{2}i$  and  $\pm \frac{3}{2}i$  belong to the same half, then the corresponding matrix  $R_z$  will have a two-dimensional block row (or column) equal to zero, and therefore 0 will be an eigenvalue with multiplicity at least 2. Therefore we can assume that these two blocks belong to two different halves, and by the ordering we have imposed they must be the first ones of each half. Assume that the block corresponding to  $\pm \frac{1}{2}i$  is in the first half. If this is not the case, consider the transpose of  $R_z$  and repeat the arguments that follow. It is possible to choose a block diagonal similarity transformation

$$(117) \quad U := \text{diag} \left( G_1, G_2, \dots, G_{\frac{N_j}{4}}, F_1, F_2, \dots, F_{\frac{N_j}{4}} \right),$$

with all the  $G_f$ 's and  $F_f$ 's being  $2 \times 2$  orthogonal matrices so that  $UR_zU^T$  has the same structure as before, but all the matrices  $P_j$  and  $S_j$  are *scalar* matrices. We construct the matrix  $U$  proceeding by block rows. The first block row contains only  $S_1$ , as  $\frac{1}{2}$  has no predecessors. All the zero blocks remain zero and  $S_1$  is transformed into

$$(118) \quad G_1 S_1 F_1^T.$$

We choose  $F_1 = \mathbf{1}_{2 \times 2}$  and  $G_1$ , which has the general form

$$(119) \quad G_1 := \begin{pmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{pmatrix},$$

so that  $\sin(\theta)x + \cos(\theta)y = 0$  if  $S_1 := \begin{pmatrix} x & y \\ -y & x \end{pmatrix}$ . This will give a scalar matrix. At the generic  $f$ th block row, we have at most two nonzero blocks  $P_{fk}$  and  $S_{fb}$ , where we now use an extra index  $k$  and  $b$  to indicate the block column to which they belong. They transform into

$$(120) \quad P_{fk} \rightarrow G_f P_{fk} F_k^T$$

and

$$(121) \quad S_{fb} \rightarrow G_f S_{fb} F_b^T,$$

respectively, while all the other blocks remain zero. If  $F_k$  has not been chosen before, we set  $F_k = \mathbf{1}_{2 \times 2}$ . In any case, we choose  $G_f$  as before to make  $G_f P_{fk} F_k^T$  a scalar matrix. We then choose  $F_b$  to make  $G_f S_{fb} F_b^T$  a scalar matrix.  $G_f$  and  $F_b$  had not been chosen at previous steps. This is obvious for  $G_f$  and follows by an induction argument for  $F_b$  since all the  $F$  matrices chosen before the  $f$ th step correspond to predecessors and successors with (column) indices strictly less than  $b$  (recall that in the two halves of the matrix  $R_y$  the blocks are arranged in increasing order of (absolute value of) eigenvalue). In conclusion, modulo the similarity transformation defined by  $U$  in (117), we can assume that  $R_z$  has the form

$$(122) \quad R_z = K \otimes I_{2 \times 2},$$

where  $K$  is a skew-symmetric  $\frac{N_j}{2} \times \frac{N_j}{2}$  matrix. By known results on the eigenvalues of the Kronecker products of two matrices, it follows that the eigenvalues of  $R_z$  are the same as those of  $K$ , each with multiplicity at least 2. This gives the desired contradiction and concludes the proof of the theorem.  $\square$

**8. Conclusions.** This paper has presented a collection of mathematical results concerning the input-output equivalence of quantum systems. Models that are equivalent cannot be distinguished by an external observer and therefore the determination of parameters in a quantum Hamiltonian can be obtained only up to equivalent models. Motivated by recent results on the isospectrality of quantum Hamiltonians [27] in molecular magnets, we have completely characterized the classes of spin networks which are equivalent. In several cases, the characterization of equivalent models can be obtained through a Lie algebra homomorphism, which is suggested by a Cartan structure of the underlying dynamics.

We believe many of the results and the concepts presented in this paper for quantum systems could be generalized to classes of systems relevant in other applications with both dynamics and output linear in the state. This will be the subject of further research.

**Appendix A: Additional results and proofs.** The proof of the following lemma can be obtained with a formal modification of the proof of Lemma 4.4 in [2] and is therefore omitted.

LEMMA 11. *Let  $\Sigma$  and  $\Sigma'$  be two equivalent models. If  $W$  and  $W'$  are two given Hermitian matrices such that*

$$(123) \quad \text{Tr}(W\rho(t)) = \text{Tr}(W'\rho'(t))$$

*for every pair of corresponding trajectories  $\rho(t)$  and  $\rho'(t)$ , then it also holds that*

$$(124) \quad \text{Tr}([W, I_{kv}]\rho(t)) = \text{Tr}([W', I'_{(k)v}]\rho'(t)) \quad \forall k \in \{1, \dots, n\}, \quad \forall v \in \{x, y, z\},$$

*up to a permutation of the indices.*<sup>8</sup>

*Proof of Lemma 8.* We first state a lemma whose proof can be obtained from the proof of Lemma 5.1 in [2] and then proceed to the proof of Lemma 8.

LEMMA 12. *Assume that for all  $t \geq 0$ , all the possible trajectories  $\rho(t)$  of  $\Sigma$  and corresponding  $\rho'(t)$  of  $\Sigma'$ , for fixed values  $1 \leq k_1, \dots, k_r \leq n$ , and fixed  $v_j \in \{x, y, z\}$ , we have*

$$(125) \quad \text{Tr}(I_{k_1 v_1, \dots, k_r v_r} \rho(t)) = \text{Tr}(I'_{k_1 v_1, \dots, k_r v_r} \rho'(t)).$$

*Then*

1. *equation (125) holds for any possible choice of the values of  $v_j \in \{x, y, z\}$ ;*
- 2.

$$(126) \quad \begin{aligned} & \text{Tr} \left( \left[ \left[ iI_{\bar{d}v_{\bar{d}}}, [iI_{\bar{k}v_{\bar{k}}}, A] \right], I_{k_1 v_1, \dots, k_r v_r} \right] \rho(t) \right) \\ &= \text{Tr} \left( \left[ \left[ iI'_{\bar{d}v_{\bar{d}}}, [iI'_{\bar{k}v_{\bar{k}}}, A'] \right], I'_{k_1 v_1, \dots, k_r v_r} \right] \rho'(t) \right) \end{aligned}$$

*for all the indices  $1 \leq \bar{d} \neq \bar{k} \leq n$  and every  $\{v_{\bar{d}} \neq v_{\bar{k}}\} \in \{x, y, z\}$ .*

We now proceed to the proof of Lemma 8. First notice that from Lemma 12, it is enough to prove (70) and (71) for a particular choice of  $\{v_j\}$  and  $\bar{v}$ . Moreover, we have, for  $\bar{d} > \bar{k}$ ,

$$(127) \quad [iI_{\bar{d}z}, [iI_{\bar{k}x}, A]] = -J_{\bar{k}\bar{d}} iI_{\bar{k}z, \bar{d}x}.$$

1. By applying Lemma 12 (equation (126)) to (69) and using (127) we get:

$$(128) \quad \beta \text{Tr} \left( [-J_{\bar{k}\bar{d}} iI_{\bar{k}z, \bar{d}x}, I_{k_1 v_1, \dots, k_r v_r}] \rho(t) \right) = \beta' \text{Tr} \left( \left[ -J'_{\bar{k}\bar{d}} iI'_{\bar{k}z, \bar{d}x}, I'_{k_1 v_1, \dots, k_r v_r} \right] \rho'(t) \right).$$

We may assume, without loss of generality, that  $\bar{k} = k_j$  and  $v_j = x$ . In this case we have

$$-J_{\bar{k}\bar{d}} [iI_{\bar{k}z, \bar{d}x}, I_{k_1 v_1, \dots, k_r v_r}] = J_{\bar{k}\bar{d}} iI_{k_1 v_1, \dots, k_j y, \dots, k_r v_r, \bar{d}x}.$$

Combining the previous equality with (128), equation (70) follows easily.

2. Using the same procedure, we obtain again (128), but now both indices  $\bar{k}$  and  $\bar{d}$  are in  $\{k_1, \dots, k_r\}$ . Assume, for example that  $k_1 = \bar{k}$  and  $k_2 = \bar{d}$ , and take  $v_{k_1} = v_{k_2} = x$ .

<sup>8</sup>This permutation is the same and fixed for all the results in which it is mentioned.

Now we have

$$(129) \quad [I_{k_1 z, k_2 x}, I_{k_1 x, k_2 x, \dots, k_r v_r}] = I_{k_1 y, k_2 x^2, k_3 v_3, \dots, k_r v_r},$$

where, with this notation, we mean that in the  $k_2$ th position we have the matrix  $\sigma_x^2$ . Thus, combining (128) and (129), we get

$$(130) \quad \beta J_{k_1 k_2} \text{Tr} (I_{k_1 y, k_2 x^2, k_3 v_3, \dots, k_r v_r} \rho(t)) = \beta' J'_{k_1 k_2} \text{Tr} (I'_{k_1 y, k_2 x^2, k_3 v_3, \dots, k_r v_r} \rho'(t)).$$

Using the same procedure, we conclude that

$$(131) \quad \beta J_{k_1 k_2} \text{Tr} (I_{k_1 y, k_2 y^2, k_3 v_3, \dots, k_r v_r} \rho(t)) = \beta' J'_{k_1 k_2} \text{Tr} (I'_{k_1 y, k_2 y^2, k_3 v_3, \dots, k_r v_r} \rho'(t))$$

and

$$(132) \quad \beta J_{k_1 k_2} \text{Tr} (I_{k_1 y, k_2 z^2, k_3 v_3, \dots, k_r v_r} \rho(t)) = \beta' J'_{k_1 k_2} \text{Tr} (I'_{k_1 y, k_2 z^2, k_3 v_3, \dots, k_r v_r} \rho'(t)).$$

Adding together (130), (131), and (132) and using (57), we get

$$\beta(l_{k_2}(l_{k_2}+1))J_{k_1 k_2} \text{Tr} (I_{k_1 y, k_3 v_3, \dots, k_r v_r} \rho(t)) = \beta'(l'_{k_2}(l'_{k_2}+1))J'_{k_1 k_2} \text{Tr} (I'_{k_1 y, k_3 v_3, \dots, k_r v_r} \rho'(t)),$$

as desired.

*Proof of Lemma 10.* We recall the formulas (77) and (78) to be proved, i.e.,

$$(133) \quad (e^{i\sigma_z t} \otimes \mathbf{1}_{R \times R}) I_{1x} (e^{-i\sigma_z t} \otimes \mathbf{1}_{R \times R}) := P_{N_1}(t) \otimes \mathbf{1}_{R \times R},$$

where the matrix  $P(\cdot)$  is periodic with period  $2\pi$ , and

$$(134) \quad P_{N_1}(\pi) = -P_{N_1}(0) = \sigma_x.$$

The proof can be done directly by computing the matrix above. This is simplified by the fact that the matrix  $\sigma_z$  is always a diagonal matrix. We will give an outline of the argument when  $l_1$  is a half-integer spin. The idea is to use the representations for the matrices  $\sigma_z$  and  $\sigma_x$  given by (85) and (86). The case of integer spin can be derived similarly starting with the representations given by (90) and (91).

Using (85) and (86), we obtain

$$(135) \quad e^{i\sigma_z t} i\sigma_x e^{-i\sigma_z t} = \begin{pmatrix} e^{iDt} F e^{-iDt} & e^{iDt} P e^{iD^a t} \\ e^{iD^a t} P^T e^{-iDt} & e^{-iD^a t} F^a e^{iD^a t} \end{pmatrix}.$$

The properties of the matrices  $D$ ,  $P$ , and  $F$  are described in section 7. Moreover,  $D = \text{diag}(j, j-1, \dots, \frac{1}{2})$  for a half-integer spin  $j$ . By using these properties, it follows that all the time-dependent terms in (135) are of the form  $e^{it}$ . Thus matrix (135) is periodic of period  $2\pi$ . The fact that the dependence is of type  $e^{it}$ , in turn, implies that (133) and (134) hold.

## Appendix B: Matrix elements of spin angular momentum operator.

For a spin  $l$ , the matrices  $\sigma_{x,y,z}$  are of dimensions  $2l+1$ . It is convenient to label the rows and columns by the index  $-l, -l+1, \dots, l-1, l$ . With this convention we have that  $\sigma_z$  is diagonal, and in particular,

$$(\sigma_z)_{m,s} := m\delta_{ms}, \quad m, s = -l, -l+1, \dots, l-1, l.$$

$\sigma_x$  and  $\sigma_y$  are defined through the matrices  $J_+$  and  $J_-$  as

$$\sigma_x := \frac{J_+ + J_-}{2}, \quad \sigma_y := \frac{J_+ - J_-}{2i}$$

with

$$(J_+)_{m,s} := \sqrt{(l-m)(l+m+1)}\delta_{s(m+1)}, \quad m, s = -l, -l+1, \dots, l-1, l,$$

$$(J_-)_{m,s} := \sqrt{(l+m)(l-m+1)}\delta_{(s+1)(m)}, \quad m, s = -l, -l+1, \dots, l-1, l.$$

## GLOBAL SMOOTH SOLUTIONS OF THE QUASI-LINEAR WAVE EQUATION WITH INTERNAL VELOCITY FEEDBACK\*

ZHI-FEI ZHANG<sup>†</sup> AND PENG-FEI YAO<sup>†</sup>

**Abstract.** We study the existence of global smooth solutions for the quasi-linear wave equation by an internal local damping when initial data are close to a given equilibrium. Our interest is in studying the structure of the damping region, which guarantees the existence of global solutions. Our results show that the structure of the damping region depends on the geometric properties of a Riemannian metric, based on the coefficients and the equilibrium of the system. Some geometrical conditions are presented to obtain the damping region.

**Key words.** quasi-linear wave equation, Riemannian metric, internal velocity feedback

**DOI.** 10.1137/070679454

**1. Introduction and main results.** Let  $n \geq 2$  be an integer,  $\Omega \subset R^n$  be a bounded open set with smooth boundary  $\Gamma$ , and

$$\mathbf{a}(x, y) = (a_1(x, y), a_2(x, y), \dots, a_n(x, y))$$

be a smooth mapping from  $\overline{\Omega} \times R^n$  to  $R^n$  with

$$(1.1) \quad \mathbf{a}(x, 0) = 0, \quad x \in \overline{\Omega},$$

such that  $(a_{ij}(x, y))$  is symmetrical and

$$(1.2) \quad (a_{ij}(x, y)) > 0 \quad \forall (x, y) \in \overline{\Omega} \times R^n,$$

where  $a_{ij} = a_{i y_j}$  are the partial derivatives of  $a_i$  with respect to the variable  $y$ . Let  $f(x, s): \overline{\Omega} \times R \rightarrow R$  be a smooth function such that

$$(1.3) \quad f(x, 0) = 0, \quad x \in \overline{\Omega}.$$

We consider the following problem:

$$(1.4) \quad \ddot{u}(t, x) - \operatorname{div} \mathbf{a}(x, \nabla u) + f(x, \dot{u}) = 0 \quad \text{in } (0, +\infty) \times \Omega,$$

$$u = w \quad \text{on } (0, +\infty) \times \Gamma,$$

$$u(0, x) = u_0(x), \quad \dot{u}(0, x) = u_1(x) \quad \text{on } (0, +\infty) \times \Gamma,$$

where  $w$  is an equilibrium solution, which satisfies

$$(1.5) \quad \operatorname{div} \mathbf{a}(x, \nabla w) = 0, \quad x \in \Omega.$$

It is well known that solutions to the problem (1.4) usually develop singularities after some time even if initial data  $(u_0, u_1)$  are close enough to  $(w, 0)$  [11]. In this paper we study what condition on  $f$  can guarantee that the problem (1.4) admits global smooth solutions when initial data  $(u_0, u_1)$  are close enough to  $(w, 0)$ . For this purpose, we assume that  $f$  satisfies

$$(1.6) \quad f_s(x, s) \geq 0, \quad x \in \overline{\Omega}, \quad |s| \leq 1,$$

$$\text{where } f_s(x, s) = \frac{\partial f(x, s)}{\partial s}.$$

Let

$$(1.7) \quad G = \{ x \in \overline{\Omega} \mid f_s(x, 0) > 0 \}.$$

We call  $G$  the damping region of the system (1.4). The structure of  $G$  reflects the effect of the internal dissipation  $f$ . We seek geometric conditions on  $G$  such that the problem (1.4) has global smooth solutions in time; moreover, we aim to establish energy decay estimates. We note that  $G = \overline{\Omega}$  is one of the choices for such purposes (see Theorems 1.1 and 1.2). However, we are particularly interested in the case where  $G$  is not the whole domain  $\Omega$  and is as small as possible in a technical sense. We show that such geometric conditions depend closely on a Riemannian metric, given by (1.10) below; see Corollaries 1.1–1.3. An example is presented at the end of this section.

Problems like (1.4) have been extensively studied, and a wealth of results on this subject is available in the literature. For bounded domains, see [2], [6], [8], [10], [12], [13], [14], [15], [19], [20], [24], [25], [26], [28], [39]. For the Cauchy problem, see [29], [30], [31], [40]. For exterior domains, see [21], [22], and the references therein. Reference [14] proved the global existence of solutions for the Kirchhoff wave equation with a boundary feedback. The piecewise multiplier method was introduced in [19] to study the structure of the damping region. To cope with a principal part with variable coefficients, the geometrical method was used in [8]. This method was introduced in [34] for the controllability of the wave equation with variable coefficients and was extended in [3], [4], [5], [16], [17], [18], [23], [32], [35], [36], and many others. For a recent survey on the geometric method, see [9]. Very recently, this method was used to study problems with quasi-linear principal parts in [37], [38], and the present paper.

We state our main results in detail, and their proofs will be given in the subsequent sections.

Let  $m \geq [\frac{n}{2}] + 3$  be a given positive integer. Let  $w \in H^m(\Omega)$  be an equilibrium of the system (1.4).

**DEFINITION 1.1.** *We say that  $(u_0, u_1) \in H^m(\Omega) \times H^{m-1}(\Omega)$  satisfies the compatibility conditions of  $m$  order with  $w$  if*

$$(1.8) \quad u_0|_{\Gamma} = w|_{\Gamma}, \quad u_k|_{\Gamma} = 0, \quad 1 \leq k \leq m-1,$$

where for  $k \geq 2$ ,

$$(1.9) \quad u_k = u^{(k)}(0),$$

as computed formally (and recursively) in terms of  $u_0$  and  $u_1$ , using (1.4).

Inspired by [7], we seek to find suitable geometric conditions on  $G$  such that the problem (1.4) has solutions  $u(t, x)$  in

$$\bigcap_{k=0}^m C^k((0, +\infty), H^{m-k}(\Omega)),$$

if

$$(u_0, u_1) \in H^m(\Omega) \times H^{m-1}(\Omega)$$

are close to  $(w, 0) \in H^m(\Omega) \times H^{m-1}(\Omega)$ , and satisfies the compatibility conditions of  $m$  order with  $w$ .

Let  $A(x, y) = (a_{ij}(x, y))$  be the  $n \times n$  matrix, given in (1.2), for each  $(x, y) \in \overline{\Omega} \times R^n$ . We define

$$(1.10) \quad g = A^{-1}(x, \nabla w(x)), \quad x \in \overline{\Omega},$$

as a Riemannian metric on  $\overline{\Omega}$  and consider the couple  $(\overline{\Omega}, g)$  as a Riemannian manifold with the boundary  $\Gamma$ . Here the metric  $g$  depends not only on the coefficients  $a_{ij}(\cdot, \cdot)$  but also on the equilibrium  $w$ . For each  $x \in \Omega$ , the metric  $g$  induces the inner product and the norm on the tangent space  $R_x^n = R^n$  by

$$(1.11) \quad g(X, Y) = \sum_{ij} g_{ij}(x) \alpha_i \beta_j, \quad |X|_g = g(X, X)^{1/2},$$

$$(1.12) \quad (g_{ij}(x)) = (a_{ij}(x, \nabla w(x)))^{-1}, \quad X = \sum_{i=1}^n \alpha_i \frac{\partial}{\partial x_i}, \quad Y = \sum_{i=1}^n \beta_i \frac{\partial}{\partial x_i}.$$

We denote the covariant differential of the metric  $g$  by  $D_g$ . If  $H$  is a vector field on  $\overline{\Omega}$ , then the covariant differential  $D_g H$  of  $H$  is a two order tensor field defined by

$$D_g H(X, Y) = g(D_{g_Y} H, X), \quad X, Y \in R_x^n, \quad x \in \overline{\Omega}.$$

We make the following assumption:

(H) There exist  $\varepsilon > 0$ ,  $\alpha > 0$ ,  $\Omega_i \subseteq \Omega$  with  $C^\infty$  boundary  $\partial\Omega_i$  and vector fields  $H^i$ ,  $i = 1, 2, \dots, I$ , such that  $\Omega_i \cap \Omega_j = \emptyset$  for  $1 \leq i < j \leq I$  and

$$(1.13) \quad D_g H^i(X, X) \geq \alpha |X|_g^2 \quad \forall X \in R_x^n, \quad x \in \Omega_i,$$

$$(1.14) \quad G \supseteq \overline{\Omega} \cap \mathcal{N}_\varepsilon \left[ \bigcup_{i=1}^I \Gamma_0^i \cup \left( \Omega \setminus \bigcup_{i=1}^I \Omega_i \right) \right],$$

where

$$\mathcal{N}_\varepsilon(S) = \bigcup_{x \in S} \{y \in R^n \mid |y - x| < \varepsilon\}, \quad S \subset R^n, \quad \Gamma_0^i = \{x \in \partial\Omega_i \mid H^i(x) \cdot \nu^i(x) > 0\},$$

and  $\nu^i(x)$  is the unit normal of  $\partial\Omega_i$  at  $x$  in the metric  $g$ , pointing towards the exterior of  $\Omega_i$ .

The results on the existence of short time solutions to the quasi-linear wave equation have been established in [7], [27]. Our first goal is to obtain the global smooth solution in time and the decay of the energy under the above assumption (H).

THEOREM 1.1. *Let equilibrium  $w \in H^m(\Omega)$  be such that assumption (H) holds. Suppose that  $(u_0, u_1) \in H^m(\Omega) \times H^{m-1}(\Omega)$  satisfies the compatibility conditions of  $m$  order with  $w$ . Then for  $(u_0 - w, u_1)$  small in  $H^m(\Omega) \times H^{m-1}(\Omega)$ , the system (1.4) has a global solution  $u$  in*

$$\bigcap_{k=0}^m C^k((0, +\infty), H^{m-k}(\Omega)).$$

THEOREM 1.2. *Under the same assumptions as in Theorem 1.1, we have that the energy of the problem (1.4) decays exponentially; that is, there exist positive constants  $C > 0$ ,  $k > 0$  such that*

$$(1.15) \quad \mathcal{E}(t) \leq Ce^{-kt}, \quad t \geq 0,$$

where  $\mathcal{E}(t) = \|u - w\|_{H^m(\Omega)}^2 + \sum_{k=1}^m \|u^{(k)}\|_{H^{m-k}(\Omega)}^2$ .

Since the set in the right-hand side of (1.14) is always a subset of  $\overline{\Omega}$ , the results in Theorems 1.1 and 1.2 hold if the damping region is the closure of the whole domain, that is,  $G = \overline{\Omega}$ . However, we are particularly interested in the case  $G \neq \overline{\Omega}$ .

If there is just one vector field  $H$  such that the inequality (1.13) holds for all  $x \in \Omega$ , we can take  $I = 1$  and  $\Omega_1 = \Omega$ . In this case, to obtain global smooth solutions and the decay of the energy, the damping region  $G$  need only be supported in a neighborhood of  $\Gamma_0$ , where

$$(1.16) \quad \Gamma_0 = \{x \in \Gamma \mid H(x) \cdot \nu(x) > 0\}.$$

This roughly means that we can dig out almost the whole  $\Omega$  from the domain  $\overline{\Omega}$  and that the damping region is supported only in a neighborhood of a subset of the boundary.

Suppose that the principal part in the problem (1.4) is linear, that is,  $\operatorname{div} \mathbf{a}(x, \nabla u) = \Delta u$ ; then

$$g_{ij}(x) = \delta_{ij}, \quad x \in \overline{\Omega},$$

$g = \cdot$  is the standard metric of  $R^n$ , and  $D_g = \nabla$  is the gradient of the standard metric. Let  $x_0 \in R^n$  be given. Then the vector field  $H(x) = x - x_0$  on  $\overline{\Omega}$  meets condition (1.13) with  $\alpha = 1$ . Thus, the damping region need only be supported in a neighborhood of

$$\Gamma_0 = \{x \in \Gamma \mid (x - x_0) \cdot \nu(x) > 0\}.$$

This is the case studied in [28].

The structure of the sets in (1.14) was given in [19] for the linear wave equation with constant coefficients, where  $\operatorname{div} \mathbf{a}(x, \nabla u) = \Delta u$ ,  $g_{ij}(x) = \delta_{ij}$ , and  $D_g = \nabla$ . Reference [19] also presents several examples where the number of the vector fields is larger than one. The present form in a general metric  $g$  was used in [8] for the linear wave equation, but with variable coefficients.

In general, whether there exists one vector field  $H$  satisfying estimate (1.13) on the whole domain  $\Omega$  largely depends on the sectional curvature of the Riemannian metric  $g$ . We show that if the sectional curvature of the Riemannian metric  $g$  is nonpositive, then such a vector field exists. More generally, we can always find a finite number of vector fields  $H^i$  and suitable subsets  $\Omega_i \subset \Omega$  such that the estimate (1.13) holds. (See Corollary 1.2 below.)

For  $x \in \overline{\Omega}$  let  $\Pi \subset R_x^n$  be a two-dimensional subspace. Denote by  $k_x(\Pi)$  the sectional curvature of the subspace  $\Pi$  at  $x$  under the Riemannian metric  $g$ . Let

$$(1.17) \quad \kappa = \sup_{x \in \overline{\Omega}, \Pi \subset R_x^n} k_x(\Pi).$$

Let  $x_0 \in \overline{\Omega}$  be given. Let  $\rho(x) = \rho(x, x_0)$  be the distance function from  $x \in \overline{\Omega}$  to  $x_0$  in the metric  $g$ . If  $g = \cdot$  is the standard metric of  $R^n$ , then  $\rho(x) = |x - x_0|$ . For a general metric  $g$ , such as (1.10), the structure of  $\rho(x)$  is very complicated. For the properties of this function, see any Riemannian geometry book, for example, [33]. We define a vector field  $H(x, x_0)$  on  $\overline{\Omega}$  by

$$(1.18) \quad H(x, x_0) = \rho(x) D_g \rho(x), \quad x \in \overline{\Omega}.$$

If  $g = \cdot$ , then  $D_g = \nabla$  and  $H(x, x_0) = x - x_0$ .

We have the following.

**COROLLARY 1.1.** *Suppose that  $\kappa \leq 0$ . Then the results in Theorems 1.1 and 1.2 hold for initial data close to  $(w, 0)$  if the damping region  $G$  is supported in a neighborhood of*

$$(1.19) \quad \Gamma_0 = \{x \in \Gamma \mid H(x, x_0) \cdot \nu(x) > 0\}.$$

If  $\kappa > 0$ , one vector field satisfying (1.13) on the whole  $\overline{\Omega}$  does not exist in general. A counterexample was given in [34]. But we can dig out a finite number of geodesic balls with the radius  $\leq \pi/2\sqrt{\kappa}$  from  $\overline{\Omega}$  and let the feedback region be supported in a neighborhood of the remaining part of  $\overline{\Omega}$ . This is the following.

**COROLLARY 1.2.** *Let  $\kappa > 0$ . Suppose that there are points  $x_i \in \overline{\Omega}$  for  $1 \leq i \leq I$  such that*

$$\rho(x_i, x_j) > \frac{\pi}{\sqrt{\kappa}}, \quad 1 \leq i, j \leq I, \quad i \neq j.$$

*Let  $B(x_i, r_0)$  and  $S(x_i, r_0)$  be the geodesic ball and the geodesic sphere centered at  $x_i$  with radius  $r_0$  in the metric  $g$ , respectively, where  $r_0 < \pi/2\sqrt{\kappa}$ . Let  $\Gamma_0^i = \{x \mid x \in S(x_i, r_0), H(x, x_i) \cdot \nu(x) > 0\}$ . If*

$$G \supseteq \overline{\Omega} \cap \mathcal{N}_\varepsilon \left[ \bigcup_{i=1}^I \Gamma_0^i \cup \left( \Omega \setminus \bigcup_{i=1}^I B(x_i, r_0) \right) \right],$$

*then the results in Theorems 1.1 and 1.2 hold for initial data close to  $(w, 0)$ .*

Since we can dig out from  $\Omega$  as many as possible geodesic balls with radii small, the following results are immediate.

**COROLLARY 1.3.** *For  $\varepsilon > 0$  given, we can choose a damping region  $G \subset \overline{\Omega}$  with*

$$\text{meas}(G) < \varepsilon,$$

*where  $\text{meas}(G)$  is the  $n$ -dimensional Lebesgue measure of  $G$  such that the results in Theorems 1.1 and 1.2 hold for initial data close to  $(w, 0)$ .*

We consider next a dissipation much weaker than those studied in most papers. See [14] for boundary feedbacks and see [24] for internal ones. Let  $f$  satisfy (1.6) and let there exist constants  $r > 0$  and  $c > 0$  such that

$$(1.20) \quad \left| \frac{\partial f}{\partial x_i}(x, s) \right| \leq c|s|^{2r-1}, \quad x \in \Omega, \quad s \in R, \quad 1 \leq i \leq n.$$

Let  $G$  be defined in the following way:  $G$  consists of all the points  $x \in \overline{\Omega}$  for which there are constants  $c(x) > 0$  such that

$$(1.21) \quad f(x, s)s \geq c(x)|s|^{\beta+2}, \quad s \in R,$$

where  $\beta \geq 0$  is a fixed number; that is,

$$(1.22) \quad G = \{x \in \overline{\Omega} \mid f(x, s)s \geq c(x)|s|^{\beta+2}, \ c(x) > 0\}.$$

For the Kirchhoff wave system, as was studied in [14] and [24], the following estimates are obtained. The energy of the first order decays as

$$(1.23) \quad \|\dot{u}(t)\|_{L^2(\Omega)} + \|u(t)\|_{H^1(\Omega)} \leq \frac{C}{(1+t)^{2/\beta}},$$

and the second order energy is just bounded as

$$(1.24) \quad \|\ddot{u}(t)\|_{L^2(\Omega)} + \|u(t)\|_{H^2(\Omega)} \leq C.$$

For the Kirchhoff system it is not clear whether or not a dissipation such as (1.21) can make the energy of the second order decay at the same rate as in (1.23).

Since the Kirchhoff system has a local regularity in time in the space  $H^2(\Omega) \times H^1(\Omega)$ , a dissipation such as (1.21) ensures the existence of global  $H^2(\Omega)$  solutions (1.24) and the decay of the first order energy (1.23). But, for the system (1.4) with a general quasi-linear principal part, we have only a local regularity in  $H^m(\Omega) \times H^{m-1}(\Omega)$  that is much higher,  $m \geq [\frac{n}{2}] + 3$ . Roughly speaking, for existence of global solutions to such systems with a local regularity in  $H^m(\Omega) \times H^{m-1}(\Omega)$ , the energies of all the orders from 1 to  $m-1$  should decay in the same way and the energy of order  $m$  should be bounded. In the case (1.7), the energy of order  $m$  actually decays exponentially. Since we do not know whether or not a dissipation such as (1.21) makes the energies of order larger than one decay, we consider some special quasi-linear principal parts to lower the local regularity to let (1.21) work.

We consider the problem

$$(1.25) \quad \ddot{u}(t, x) - \sum_{ij=1}^n \left( a_{ij}(x, \|\nabla u\|^{2r}) u_{x_i} \right)_{x_j} + f(x, \dot{u}) = 0 \quad \text{in } (0, +\infty) \times \Omega,$$

$$u = 0 \quad \text{on } \partial D,$$

$$u(0, x) = u_0(x), \dot{u}(0, x) = u_1(x) \quad \text{on } (0, +\infty) \times \Gamma,$$

where  $\|\cdot\|$  is the  $L^2(\Omega)$  norm and  $r$  is a constant satisfying

$$(1.26) \quad r > \frac{\beta+1}{2}.$$

In the problem (1.25), we assume that  $a_{ij}(x, s)$  are smooth functions on  $\Omega \times R$  such that the matrices  $A(x, s) = (a_{ij}(x, s))$  are symmetrical on  $\Omega \times R$  satisfying

$$(1.27) \quad \sum_{i,j=1}^n (a_{ij}(x, s)) \xi_i \xi_j \geq a_0 |\xi|^2 \quad \forall (x, s) \in \overline{\Omega} \times R, \quad \forall \xi \in R^n,$$

where  $a_0$  is a positive constant. We define a Riemann metric on  $\Omega$  by

$$(1.28) \quad g = A^{-1}(x, 0).$$

If  $a_{ij}(x, s) = a(s)$  for all  $1 \leq i, j \leq n$ , the problem (1.25) represents a Kirchhoff wave model; see [14] or [24].

We make the following assumption.

**(H1)** For any  $(u_0, u_1) \in H^2(\Omega) \times H^1(\Omega)$  with appropriate compatibility, the system (1.25) has a solution of short time in  $H^2(\Omega) \times H^1(\Omega)$ .

We have the following.

**THEOREM 1.3.** *Let the assumptions **(H)** and **(H1)** hold where  $G$  is given by (1.22). Suppose that  $(u_0, u_1) \in H^2(\Omega) \times H^1(\Omega)$  satisfies the compatibility conditions of order 2. Then for  $(u_0, u_1)$  small in  $H^2(\Omega) \times H^1(\Omega)$ , system (1.25) has a global solution  $u$  in*

$$\bigcap_{k=0}^2 C^k((0, +\infty), H^{2-k}(\Omega)).$$

Moreover, the estimates in (1.23) and (1.24) hold, where  $u(t)$  is the solution to the system (1.25).

Finally, we give an example to verify Corollary 1.1.

Let

$$\mathbf{a}(y) = \begin{pmatrix} a_1(y_1), a_2(y_2) \end{pmatrix}: \quad R^2 \rightarrow R^2,$$

where  $a_i$  are smooth functions on  $R$  for  $i = 1, 2$  such that

$$a'_i(s) > 0, \quad s \in R.$$

Let

$$w(x) = x_1 x_2, \quad x = (x_1, x_2) \in R^2.$$

Then

$$\operatorname{div} \mathbf{a}(\nabla w) = 0, \quad x \in R^2.$$

The metric is

$$g = A^{-1}(x, \nabla w) = \begin{pmatrix} 1/a'_1(x_2) & 0 \\ 0 & 1/a'_2(x_1) \end{pmatrix}.$$

We let

$$a_1(s) = a_2(s) = \arctan s, \quad s \in R.$$

Then

$$g = \begin{pmatrix} 1 + x_2^2 & 0 \\ 0 & 1 + x_1^2 \end{pmatrix}.$$

By [34, Lemma 3.2], the Gauss curvature of  $(R^2, g)$  is

$$(1.29) \quad \kappa(x) = -\frac{2 + |x|^2}{(1 + x_1^2)^2(1 + x_2^2)^2} \leq 0, \quad x = (x_1, x_2) \in R^2.$$

**Conclusion.** The results in Corollary 1.1 hold true for the following problem:

$$\begin{aligned}
 (1.30) \quad & \ddot{u}(t, x) - \frac{u_{x_1 x_1}(t, x)}{1 + u_{x_1}^2} - \frac{u_{x_2 x_2}(t, x)}{1 + u_{x_2}^2} + f(x, \dot{u}) = 0 \quad \text{in } (0, +\infty) \times \Omega, \\
 & u = 0 \quad \text{on } \partial D, \\
 & u(0, x) = u_0(x), \dot{u}(0, x) = u_1(x) \quad \text{on } (0, +\infty) \times \Gamma
 \end{aligned}$$

for any domain  $\Omega \subset \mathbb{R}^2$  bounded and  $m = 4$ .

**2. Energy estimates.** We assume that solutions to the system (1.4) exist for some  $T > 0$  when initial data  $(u_0, u_1)$  are in  $H^m(\Omega) \times H^{m-1}(\Omega)$  satisfying the  $m$  order compatibility conditions with a given equilibrium  $w \in H^m(\Omega)$ , and we write those as  $u = w + \phi$ . Since  $w$  does not depend on  $t$ , the system (1.4) is equivalent to

$$\begin{aligned}
 (2.1) \quad & \ddot{\phi}(t, x) - \operatorname{div} \mathbf{b}(x, \nabla \phi) + f(x, \dot{\phi}) = 0 \quad \text{in } (0, +\infty) \times \Omega, \\
 & \phi = 0 \quad \text{on } (0, +\infty) \times \Gamma, \\
 & \phi(0, x) = \phi_0(x), \dot{\phi}(0, x) = \phi_1(x) \quad \text{on } (0, +\infty) \times \Gamma,
 \end{aligned}$$

where we have set

$$(2.2) \quad \mathbf{b}(x, y) = \mathbf{a}(x, \nabla w + y), \quad (x, y) \in \overline{\Omega} \times \mathbb{R}^n,$$

$$(2.3) \quad \phi_0 = u_0 - w, \quad \phi_1 = u_1, \quad x \in \Omega.$$

Let  $\phi$  solve the problem (2.1) for some  $T > 0$ . Denote

$$(2.4) \quad B(x, y) = (b_{ij}(x, y)), \quad b_{ij}(x, y) = a_{ij}(x, \nabla w + y), \quad (x, y) \in \overline{\Omega} \times \mathbb{R}^n;$$

then

$$(2.5) \quad \dot{\mathbf{b}}(x, \nabla \phi) = B_\phi(t) \nabla \dot{\phi},$$

and for  $j \geq 2$ ,

$$(2.6) \quad \mathbf{b}^{(j)}(x, \nabla \phi) = B_\phi(t) \nabla \phi^{(j)} + \sum_{k=1}^{j-1} B_\phi^{(k)}(t) \nabla \phi^{(j-k)},$$

where

$$(2.7) \quad B_\phi(t) = B(x, \nabla \phi).$$

We compute the  $j$  order derivatives of  $f(x, \dot{\phi})$  with respect to  $t$  and obtain

$$\begin{aligned}
 (2.8) \quad & (f(x, \dot{\phi}))^{(j)} = \sum_{i=1}^j \sum_{l_1 + \dots + l_i = j} f_y^{(i)}(x, \dot{\phi}) \dot{\phi}^{(l_1)} \dot{\phi}^{(l_2)} \dots \dot{\phi}^{(l_i)} \\
 & = f_y(x, \dot{\phi}) \dot{\phi}^{(j)} + \sum_{i=2}^j \sum_{l_1 + \dots + l_i = j} f_y^{(i)}(x, \dot{\phi}) \dot{\phi}^{(l_1)} \dot{\phi}^{(l_2)} \dots \dot{\phi}^{(l_i)}.
 \end{aligned}$$

We define

$$(2.9) \quad \mathcal{B}_\phi(t)v = \operatorname{div} B_\phi(t) \nabla v, \quad v \in H^2(\Omega),$$

and

$$(2.10) \quad v_{\nu_B} = \langle B_\phi(t) \nabla v, \nu \rangle, \quad v \in H^2(\Omega), \quad x \in \Gamma;$$

then

$$(2.11) \quad (\mathcal{B}_\phi(t)v, \phi)_{L^2(\Omega)} = -(B_\phi(t) \nabla v, \nabla \phi)_{L^2(\Omega)}, \quad v, \phi \in H^2(\Omega) \cap H_\Gamma^1(\Omega),$$

where

$$H_\Gamma^1(\Omega) = \{v \in H^1(\Omega), v|_{\Gamma} = 0\}.$$

For  $T > 0$ , differentiating the system (2.1)  $j$  times with respect to  $t$ , we get

$$(2.12) \quad \begin{aligned} \phi^{(j)}(t, x) - \mathcal{B}_\phi(t) \phi^{(j)} + f_y(x, \dot{\phi}) \dot{\phi}^{(j)} + r_j(t) &= 0 \quad \text{in } (0, +\infty) \times \Omega, \\ \phi^{(j)} &= 0 \quad \text{on } (0, +\infty) \times \Gamma, \end{aligned}$$

where  $r_j(t)$  is defined by

$$(2.13) \quad r_j(t) = \sum_{i=2}^j \sum_{l_1+\dots+l_i=j} f_y^{(i)}(x, \dot{\phi}) \dot{\phi}^{(l_1)} \dot{\phi}^{(l_2)} \dots \dot{\phi}^{(l_i)} - \sum_{k=1}^{j-1} \operatorname{div} B_\phi^{(k)}(t) \nabla \phi^{(j-k)}$$

for  $2 \leq j \leq m-1$  and  $r_1(t) = 0$ .

For the system (2.12), we define the corresponding energy as

$$(2.14) \quad V_j(t) = \|\dot{\phi}^{(j)}(t, x)\|_{L^2(\Omega)}^2 + (B_\phi(t) \nabla \phi^{(j)}(t, x), \nabla \phi^{(j)}(t, x))_{L^2(\Omega)}.$$

Moreover, we introduce an operator

$$(2.15) \quad \mathcal{N}_\phi(t)v = \operatorname{div} N_\phi(t) \nabla v, \quad v \in H^2(\Omega),$$

where

$$N_\phi(t) = \int_0^1 B(x, s \nabla \phi) ds.$$

Then the system (2.1) can be rewritten as

$$(2.16) \quad \begin{aligned} \ddot{\phi}(t, x) - \mathcal{N}_\phi(t) \phi + f(x, \dot{\phi}) &= 0 \quad \text{in } (0, +\infty) \times \Omega, \\ \phi &= 0 \quad \text{on } (0, +\infty) \times \Gamma, \end{aligned}$$

with the energy defined as

$$(2.17) \quad V_0(t) = \|\dot{\phi}(t, x)\|_{L^2(\Omega)}^2 + (N_\phi(t) \nabla \phi(t, x), \nabla \phi(t, x))_{L^2(\Omega)}.$$

Next, we define

$$(2.18) \quad \mathcal{E}(t) = \sum_{k=0}^m \|\phi^{(k)}(t, x)\|_{H^{m-k}(\Omega)}^2,$$

$$(2.19) \quad \mathcal{Q}(t) = \sum_{j=0}^{m-1} V_j(t),$$

$$(2.20) \quad P(t) = \|\phi(t, x)\|_{L^2(\Omega)}^2 + \|\dot{\phi}(t, x)\|_{L^2(\Omega)}^2 + (N_\phi(t) \nabla \phi(t, x), \nabla \phi(t, x))_{L^2(\Omega)},$$

$$(2.21) \quad R(t) = \sum_{j=0}^{m-1} \|\phi^{(j)}(t, x)\|_{L^2(\Omega)}^2,$$

$$(2.22) \quad \mathcal{L}(t) = \sum_{k=3}^{2m} \mathcal{E}^{k/2}(t).$$

**THEOREM 2.1.** *Let  $\gamma > 0$  be given and let  $\phi$  be a solution to the problem (2.1) on the interval  $[0, T]$  for some  $T > 0$  such that*

$$(2.23) \quad \sup_{0 \leq t \leq T} \|\phi(t, x)\|_{H^m(\Omega)} \leq \gamma, \quad \sup_{0 \leq t \leq T} \|\dot{\phi}(t, x)\|_{H^{m-1}(\Omega)} \leq \gamma.$$

*Then there are constants  $C_{0,\gamma} > 0$  and  $C_\gamma > 0$ , which depend only on  $\gamma$ , such that for  $0 \leq t \leq T$ ,*

$$(2.24) \quad C_{0,\gamma} \mathcal{Q}(t) \leq \mathcal{E}(t) \leq C_\gamma \mathcal{Q}(t) + C_\gamma \mathcal{L}(t) + C_\gamma \|\phi(t, x)\|_{L^2(\Omega)}^2,$$

$$(2.25) \quad -\dot{\mathcal{Q}}(t) \leq C_\gamma \mathcal{L}(t) + 2(f_y(x, \dot{\phi}) \phi^{(j+1)}, \phi^{(j+1)})_{L^2(\Omega)} + 2(f(x, \dot{\phi}), \dot{\phi})_{L^2(\Omega)},$$

$$(2.26) \quad \dot{\mathcal{Q}}(t) \leq C_\gamma \mathcal{L}(t),$$

$$(2.27) \quad P(t) \leq \left( P(0) + C_\gamma \int_0^t \mathcal{E}^{3/2}(\tau) d\tau \right) e^t.$$

We collect here a few basic properties of Sobolev spaces.

(1) Let  $s_1 \geq s_2 > 0$ . For any  $\varepsilon > 0$  there exists  $C_\varepsilon > 0$  such that

$$\|v\|_{H^{s_2}(\Omega)}^2 \leq \varepsilon \|v\|_{H^{s_1}(\Omega)}^2 + C_\varepsilon \|v\|_{L^2(\Omega)}^2 \quad \forall v \in H^{s_1}(\Omega).$$

(2) If  $s > n/2$ , then for each  $k = 0, \dots$ , we have  $H^{s+k}(\Omega) \subset C^k(\bar{\Omega})$  with continuous embedding.

(3) If  $r := \min\{s_1, s_2, s_1 + s_2 - [n/2] - 1\} \geq 0$ , then there exists a constant  $C > 0$  such that

$$\|f_1 f_2\|_{H^r(\Omega)} \leq C \|f_1\|_{H^{s_1}(\Omega)} \|f_2\|_{H^{s_2}(\Omega)} \quad \forall f_1 \in H^{s_1}(\Omega), f_2 \in H^{s_2}(\Omega).$$

(4) Let  $s_j \geq 0$ ,  $j = 1, \dots, k$ , and  $r := \min_{1 \leq i \leq k} \min_{j_1 \leq \dots \leq j_i} \{s_{j_1} + \dots + s_{j_i} - (i-1)([n/2] + 1)\} \geq 0$ ; then there exists a constant  $C > 0$  such that, for  $1 \leq j \leq k$ ,

$$(2.28) \quad \|f_1 \cdots f_k\|_{H^r(\Omega)} \leq C \|f_1\|_{H^{s_1}(\Omega)} \cdots \|f_k\|_{H^{s_k}(\Omega)} \quad \forall f_j \in H^{s_j}(\Omega).$$

LEMMA 2.1. *Let  $\gamma > 0$  be given. Let  $\phi \in H^m(\Omega)$  satisfy the conditions (2.23). Let  $p(\cdot, \cdot)$  and  $\lambda(\cdot, \cdot)$  be smooth functions on  $\bar{\Omega} \times R^n$  and on  $\bar{\Omega} \times R$ , respectively. Set*

$$P(x) = p(x, \nabla \phi), \quad \Lambda(x) = \lambda(x, \dot{\phi}).$$

*Then there exists a constant  $C_\gamma > 0$ , depending on  $\gamma$ , such that for  $0 \leq k \leq m-1$ ,*

$$(2.29) \quad \|P\|_{H^k(\Omega)} \leq C_\gamma \sum_{j=0}^k (1 + \|\phi\|_{H^m(\Omega)})^j,$$

$$(2.30) \quad \|\Lambda\|_{H^k(\Omega)} \leq C_\gamma \sum_{j=0}^k (1 + \|\dot{\phi}\|_{H^{m-1}(\Omega)})^j.$$

*Proof.* We prove the estimates by induction on  $k$ .

For  $k = 0$ , since  $\sup |\nabla \phi| \leq C\|\phi\|_{H^m(\Omega)} \leq C_\gamma$ , we have

$$\|\Lambda\|_{L^2(\Omega)} = \left( \int_{\Omega} \lambda^2(x, \nabla \phi) dx \right)^{\frac{1}{2}} \leq \sup_{x \in \bar{\Omega}, |y| \leq C_\gamma} |\lambda(x, y)| \sqrt{\text{meas}(G)} \leq C_\gamma.$$

We assume that the estimate (2.30) is true for  $0 \leq k \leq m-2$ . We aim to prove that it is true with  $k$  replaced by  $k+1$ . Note that

$$\Lambda_{x_i}(x) = \lambda_{x_i}(x, \dot{\phi}) + \sum_{j=1}^n \lambda_s(x, \dot{\phi}) \dot{\phi}_{x_i}, \quad i = 1, 2, \dots, n,$$

and that we have

$$\begin{aligned} \|\Lambda\|_{H^{k+1}(\Omega)} &= \left( \sum_{i=1}^n \|\Lambda_{x_i}\|_{H^k(\Omega)}^2 + \|\Lambda\|_{L^2(\Omega)}^2 \right)^{1/2} \\ &\leq C_\gamma + C_\gamma \sum_{i=1}^n \|\lambda_{x_i}(x, \dot{\phi})\|_{H^k(\Omega)} + \sum_{i=1}^n \|\lambda_s(x, \dot{\phi}) \dot{\phi}_{x_i}\|_{H^k(\Omega)} \\ &\leq C_\gamma + C_\gamma \sum_{j=1}^k (1 + \|\dot{\phi}\|_{H^{m-1}(\Omega)})^j \\ &\quad + C_\gamma \sum_{i,j=1}^n \|\lambda_s(x, \dot{\phi})\|_{H^k(\Omega)} \cdot \|\dot{\phi}_{x_i}\|_{H^{m-2}(\Omega)} \\ &\leq C_\gamma \sum_{j=0}^{k+1} (1 + \|\dot{\phi}\|_{H^{m-1}(\Omega)})^j. \end{aligned}$$

The same procedure yields the estimate on  $P(x)$ .  $\square$

LEMMA 2.2. *Let  $\gamma > 0$  be given and let  $\phi$  be a solution to the problem (2.1) on  $[0, T)$  such that the condition (2.23) holds. Then for  $2 \leq j \leq m-1$ , there exists a constant  $C_\gamma > 0$ , depending on  $\gamma$ , such that*

$$(2.31) \quad \|r_j(t)\|_{H^{m-1-j}(\Omega)}^2 \leq C_\gamma \sum_{k=2}^{m-1} \mathcal{E}^k(t),$$

where  $r_j(t)$  is given by (2.13).

*Proof.* Let  $b(\cdot, \cdot)$  be a function on  $\Omega \times R^n$ . For  $1 \leq k \leq j-1$ , we have the formulas

$$(2.32) \quad b^{(k)}(x, \nabla \phi) = \sum_{s=1}^k \sum_{r_1+\dots+r_s=k} D_y^s b \left( \nabla \phi^{(r_1)}(t, x), \dots, \nabla \phi^{(r_s)}(t, x) \right),$$

where  $D_y^s b$  denotes the covariant differential of order  $s$  of the function  $b(x, y)$ , given in (2.4), with respect to the variable  $y$  in the standard metric of  $R^n$ . Then  $r_j(t)$  are the sum of such functions in the form

$$(2.33) \quad \left( f(x, \nabla \phi) \phi_{x_{j_1}}^{(r_1)} \dots \phi_{x_{j_s}}^{(r_s)} \phi_{x_p}^{(j-k)} \right)_{x_q} \quad \text{or} \quad g(x, \dot{\phi}) \dot{\phi}^{(l_1)} \dots \dot{\phi}^{(l_i)},$$

with  $r_1 + \dots + r_s = k$  for  $1 \leq s \leq k \leq j-1$  and with  $l_1 + \dots + l_i = j$  for  $2 \leq i \leq j$ , respectively. Using the estimates (2.28)–(2.30), we have

$$(2.34) \quad \left\| \left( f(x, \nabla \phi) \phi_{x_{j_1}}^{(r_1)} \dots \phi_{x_{j_s}}^{(r_s)} \phi_{x_p}^{(j-k)} \right)_{x_q} \right\|_{H^{m-1-j}(\Omega)}^2 \\ \leq \|f(x, \nabla \phi) \phi_{x_{j_1}}^{(r_1)} \dots \phi_{x_{j_s}}^{(r_s)} \phi_{x_p}^{(j-k)}\|_{H^{m-j}(\Omega)}^2 \\ \leq C_\gamma \|\phi_{x_{j_1}}^{(r_1)}\|_{H^{m-r_1-1}(\Omega)}^2 \dots \|\phi_{x_{j_s}}^{(r_s)}\|_{H^{m-r_s-1}(\Omega)}^2 \|\phi_{x_p}^{(j-k)}\|_{H^{m-1-j+k}(\Omega)}^2 \\ \leq C_\gamma \|\phi^{(r_1)}\|_{H^{m-r_1}(\Omega)}^2 \dots \|\phi^{(r_s)}\|_{H^{m-r_s}(\Omega)}^2 \|\phi^{(j-k)}\|_{H^{m-j+k}(\Omega)}^2 \leq C_\gamma \mathcal{E}^{s+1}(t).$$

For the second term in (2.33), noticing  $2 \leq i \leq j \leq m-1$ , we have

$$(2.35) \quad \|g(x, \dot{\phi}) \dot{\phi}^{(l_1)} \dots \dot{\phi}^{(l_i)}\|_{H^{m-j-1}(\Omega)}^2 \\ \leq \|g(x, \dot{\phi})\|_{H^{m-j-1}(\Omega)}^2 \|\dot{\phi}^{(l_1)}\|_{H^{m-l_1-1}(\Omega)}^2 \dots \|\dot{\phi}^{(l_i)}\|_{H^{m-l_i-1}(\Omega)}^2 \\ \leq C_\gamma \mathcal{E}^i(t).$$

The estimate (2.31) follows from (2.34) and (2.35).  $\square$

LEMMA 2.3 (see [37]). *Let  $\gamma > 0$  be given and let  $\phi$  be a solution to the problem (2.1) on  $[0, T]$  for some  $T > 0$  such that the condition (2.23) holds. Then there exists a constant  $C_\gamma > 0$ , depending on  $\gamma$ , such that*

$$(2.36) \quad \|v\|_{H^{k+1}(\Omega)}^2 \leq C_\gamma (\|\mathcal{B}_\phi(t)v\|_{H^{k-1}(\Omega)}^2 + \|v\|_{H^k(\Omega)}^2)$$

for  $v \in H^{k+1}(\Omega) \cap H_0^1(\Omega)$ ,  $0 \leq k \leq m-1$ ,  $t \in [0, T]$ .

*Proof of Theorem 2.1.* It is clear that there exists a constant  $C_{0,\gamma}$  such that

$$C_{0,\gamma} \mathcal{Q}(t) \leq \mathcal{E}(t).$$

Let us prove the right-hand side of the inequality (2.24).

First, we prove

$$(2.37) \quad \|\phi^{(j)}\|_{H^{m-j}(\Omega)}^2 \leq C_\gamma \mathcal{Q}(t) + C_\gamma \mathcal{L}(t) + \|\phi(t)\|_{L^2(\Omega)}^2$$

for  $1 \leq j \leq m$  by induction on  $j$ . We have

$$\begin{aligned} & \|\phi^{(m)}\|_{L^2(\Omega)}^2 + \|\phi^{(m-1)}\|_{H^1(\Omega)}^2 \\ & \leq \|\phi^{(m)}\|_{L^2(\Omega)}^2 + C_\gamma(B_\phi(t)\nabla\phi^{(m-1)}, \nabla\phi^{(m-1)}) + \|\phi^{(m-1)}\|_{L^2(\Omega)}^2 \\ & \leq C_\gamma\mathcal{Q}(t), \end{aligned}$$

which means that the inequality (2.37) holds for  $j = m$  or  $j = m - 1$ . Assume the inequality (2.37) is valid for  $j = l$  and  $j = l - 1$ . Using the formulas (2.11), (2.12), (2.28), and (2.36), we obtain

$$\begin{aligned} \|\phi^{(l-2)}\|_{H^{m-l+2}(\Omega)}^2 & \leq C_\gamma\|\mathcal{B}_\phi(t)\phi^{(l-2)}\|_{H^{m-l}(\Omega)}^2 + C_\gamma\|\phi^{(l-2)}\|_{H^{m-l+1}(\Omega)}^2 \\ & \leq C_\gamma\|\phi^{(l)}\|_{H^{m-l}(\Omega)}^2 + C_\gamma\|f_y(x, \dot{\phi})\phi^{(l-1)}\|_{H^{m-l}(\Omega)}^2 + C_\gamma\mathcal{L}(t) \\ & \quad + \varepsilon\|\phi^{(l-2)}\|_{H^{m-l+2}(\Omega)}^2 + C_{\varepsilon,\gamma}\|\phi^{(l-2)}\|_{L^2(\Omega)}^2 \\ & \leq C_\gamma\|\phi^{(l)}\|_{H^{m-l}(\Omega)}^2 + C_\gamma\|\phi^{(l-1)}\|_{H^{m-l+1}(\Omega)}^2 + C_\gamma\mathcal{L}(t) \\ & \quad + \varepsilon\|\phi^{(l-2)}\|_{H^{m-l+2}(\Omega)}^2 + C_{\varepsilon,\gamma}\|\phi^{(l-2)}\|_{L^2(\Omega)}^2, \end{aligned}$$

where the following inequality is used:

$$\|f_y(x, \dot{\phi})\phi^{(l-1)}\|_{H^{m-l}(\Omega)}^2 \leq C_\gamma\|f_y(x, \dot{\phi})\|_{H^{m-2}(\Omega)}^2\|\phi^{(l-1)}\|_{H^{m-l+1}(\Omega)}^2.$$

By induction the estimate (2.37) follows.

On the other hand, using an ellipticity estimate for the operator  $\mathcal{N}_\phi(t)$  in (2.15) similar to that for  $\mathcal{B}_\phi(t)$  in Lemma 2.3 and (2.16), we obtain

$$\begin{aligned} \|\phi(t, x)\|_{H^m(\Omega)}^2 & \leq C_\gamma\|\mathcal{N}_\phi(t)\phi\|_{H^{m-2}(\Omega)}^2 + C_\gamma\|\phi(t, x)\|_{H^{m-1}(\Omega)}^2 \\ (2.38) \quad & \leq C_\gamma\|\phi^{(2)}\|_{H^{m-2}(\Omega)}^2 + C_\gamma\|f(x, \dot{\phi})\|_{H^{m-2}(\Omega)}^2 + C_\gamma\mathcal{L}(t) \\ & \quad + \varepsilon\|\phi\|_{H^m(\Omega)}^2 + C_{\varepsilon,\gamma}\|\phi\|_{L^2(\Omega)}^2. \end{aligned}$$

Combining (2.37) and (2.38), the proof of the estimate (2.24) is complete.

Let  $V_j(t)$  and  $V_0(t)$  be defined by (2.14) and (2.17), respectively. We differentiate  $V_j(t)$  and have

$$\begin{aligned} (2.39) \quad \dot{V}_j(t) & = 2(\phi^{(j+2)}(t), \phi^{(j+1)}(t))_{L^2(\Omega)} \\ & \quad + (\dot{B}_\phi(t)\nabla\phi^{(j)}, \nabla\phi^{(j)})_{L^2(\Omega)} + 2(B_\phi(t)\nabla\phi^{(j)}, \nabla\phi^{(j+1)})_{L^2(\Omega)}. \end{aligned}$$

Using the formulas (2.12) and (2.11) in (2.39), and by Lemma 2.2, we obtain

$$\begin{aligned} (2.40) \quad -\dot{V}_j(t) & = -(\dot{B}_\phi(t)\nabla\phi^{(j)}, \nabla\phi^{(j)})_{L^2(\Omega)} + 2(r_j(t), \phi^{(j+1)}(t, x))_{L^2(\Omega)} \\ & \quad + 2(f_y(x, \dot{\phi})\phi^{(j+1)}, \phi^{(j+1)})_{L^2(\Omega)} \\ & \leq C_\gamma\mathcal{L}(t) + 2(f_y(x, \dot{\phi})\phi^{(j+1)}, \phi^{(j+1)})_{L^2(\Omega)} \\ & \leq C_\gamma\mathcal{L} + 2(f_y(x, \dot{\phi})\phi^{(j+1)}, \phi^{(j+1)})_{L^2(\Omega)}. \end{aligned}$$

Moreover, we also have, by (2.16),

$$(2.41) \quad -\dot{V}_0(t) = -(\dot{\mathcal{N}}_\phi(t) \nabla \phi, \nabla \phi)_{L^2(\Omega)} + 2(f(x, \dot{\phi}), \dot{\phi})_{L^2(\Omega)}.$$

The inequalities (2.26) and (2.25) follow from (2.40) and (2.41).

Similarly we have

$$\dot{P}(t) \leq C_\gamma \mathcal{E}^{3/2}(t) + P(t), \quad 0 \leq t \leq T,$$

which yields (2.27) by Gronwall's inequality.

**3. Energy estimates in integral form.** In this section, we establish the following.

**THEOREM 3.1.** *Let all assumptions in Theorem 1.1 hold. Let  $\gamma > 0$  be given and let  $\phi$  be a solution to the problem (2.1) on the interval  $[0, T]$  for some  $T > 0$  such that the condition (2.23) holds. Then there are constants  $C_\gamma > 0$  and  $T_\gamma > 3 \sup_{x \in \bar{\Omega}} |H|_g / \alpha$  such that for  $0 \leq s \leq t \leq T$ ,  $t - s \geq T_\gamma$ ,*

$$(3.1) \quad \int_s^t \mathcal{Q}(\tau) d\tau + C_\gamma \mathcal{Q}(t) \leq C_\gamma \mathcal{Q}(s) + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau,$$

where  $\mathcal{L}(t)$  and  $\alpha$  are as given in (2.22) and (1.13), respectively.

Let  $\gamma > 0$  be given and let  $\phi$  satisfy the problem (2.1) on the interval  $[0, T]$  for some  $T > 0$  such that the condition (2.23) holds. For  $t \in [0, T]$ , let  $g_\phi$  be the metric on  $\bar{\Omega}$  given by

$$(3.2) \quad g_\phi = B_\phi^{-1}(t),$$

where the matrix  $B_\phi(t)$  is defined by (2.7). Consider the pair  $(\bar{\Omega}, g_\phi)$  as a Riemannian manifold for fixed  $t$ . Let  $X, Y$  be vector fields on  $\bar{\Omega}$  and let  $f$  be a function. Then

$$(3.3) \quad \langle X, Y \rangle_{g_\phi} = \langle B_\phi^{-1}(t) X, Y \rangle, \quad \nabla_{g_\phi} f = B_\phi(t) \nabla f,$$

where  $\langle \cdot, \cdot \rangle$  and  $\langle \cdot, \cdot \rangle_{g_\phi}$  are the products in the standard metric and the metric  $g_\phi$ , respectively, and where  $\nabla$  and  $\nabla_{g_\phi}$  are the gradients in the standard metric and the metric  $g_\phi$ , respectively. In addition, it is easy to check from (3.3) that there are constants  $C_{0,\gamma} > 0$  and  $C_\gamma > 0$  such that, for  $t \in [0, T]$ ,

$$(3.4) \quad C_{0,\gamma} |\nabla_g f|_g^2 \leq |\nabla_{g_\phi} f|_{g_\phi}^2 = \langle B_\phi(t) \nabla f, \nabla f \rangle \leq C_\gamma |\nabla_g f|_g^2, \quad f \in C^\infty(\Omega),$$

under the condition (2.23). Let

$$(3.5) \quad (b_{ij}(x, y))^{-1} = (b^{ij}(x, y)), \quad (x, y) \in \bar{\Omega} \times \mathbb{R}^n,$$

where  $(b_{ij}(x, y))$  are as given in (2.4). Then

$$(3.6) \quad A^{-1}(x, \nabla w) = (b^{ij}(x, 0)).$$

Let  $D_{g_\phi}$  and  $D_g$  be the Levi-Civita connections in the Riemannian metrics  $g_\phi$  and  $g$ , respectively. Let  $H$  be a vector field on  $\bar{\Omega}$ . Denote by  $D_{g_\phi} H$  and  $D_g H$  the covariant differentials in the metrics  $g_\phi$  and  $g$ , respectively. They are two order tensor fields on  $\bar{\Omega}$ . We define

$$(3.7) \quad \zeta = D_{g_\phi} H - D_g H.$$

LEMMA 3.1 (see [37]). Let  $H$  be a vector field on  $\overline{\Omega}$ . Suppose that the tensor field  $\zeta = \zeta(\cdot, \cdot)$  of order two is given in the formula (3.7). Let  $\gamma > 0$  be given and let  $\phi$  be such that  $\sup_{x \in \overline{\Omega}} |\nabla \phi| \leq \gamma$ . Then there exists a constant  $C_\gamma > 0$  such that

$$(3.8) \quad |\zeta(X, Y)| \leq C_\gamma(|D\phi| + |D^2\phi|)|X||Y| \quad \forall X, Y \in R_x^n, \quad x \in \overline{\Omega},$$

where  $D$  is the covariant differential of the standard product of the Euclidean space  $R^n$ .

LEMMA 3.2. Let  $\phi^{(j)}$  be a solution to (2.12) and let  $\hat{\Omega} \subseteq \Omega$  be a subset.

(1) Suppose that  $\mathcal{H}$  is a vector field on  $\hat{\Omega}$ . Then

$$(3.9) \quad \begin{aligned} & \int_s^t \int_{\partial \hat{\Omega}} \left[ \mathcal{H}(\phi^{(j)}) \phi_{\nu_B}^{(j)} + \frac{1}{2}((\phi^{(j)})^2 - |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2) \langle \mathcal{H}, \nu \rangle \right] d\sigma d\tau \\ &= (\phi^{(j)}, \mathcal{H}(\phi^{(j)}))_{L^2(\hat{\Omega})} \Big|_s^t + \int_s^t \int_{\hat{\Omega}} [r_j \mathcal{H}(\phi^{(j)}) + f_y(x, \dot{\phi}) \phi^{(j)} \mathcal{H}(\phi^{(j)})] dx d\tau \\ & \quad + \int_s^t \int_{\hat{\Omega}} \left\{ D_{g_\phi} \mathcal{H}(\nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \phi^{(j)}) + \frac{1}{2}(\phi^{(j)})^2 - |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 \right\} \operatorname{div} \mathcal{H} \Big\} dx d\tau. \end{aligned}$$

(2) Let  $h \in C^2(\hat{\Omega})$ . We have

$$(3.10) \quad \begin{aligned} & \int_s^t \int_{\hat{\Omega}} h[(\phi^{(j)})^2 - |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2] dx d\tau \\ &= (\phi^{(j)}, h\phi^{(j)})_{L^2(\hat{\Omega})} \Big|_s^t + \int_s^t \int_{\partial \hat{\Omega}} \left( \frac{1}{2}(\phi^{(j)})^2 h_{\nu_B} - h\phi^{(j)} \phi_{\nu_B}^{(j)} \right) d\sigma d\tau \\ & \quad + \int_s^t \int_{\hat{\Omega}} \left[ r_j(\tau) h\phi^{(j)} + f_y(x, \dot{\phi}) \phi^{(j)} h\phi^{(j)} - \frac{1}{2}(\phi^{(j)})^2 \mathcal{B}_\phi(\tau) h \right] dx d\tau. \end{aligned}$$

LEMMA 3.3. Let all assumptions in Theorem 1.1 hold. Let  $\gamma > 0$  be given and let  $\phi$  be a solution to the problem (2.1) on the interval  $[0, T]$  for some  $T > 0$  such that the condition (2.23) holds. Then there exist constants  $C_\gamma > 0$  and  $T_\gamma > 3 \sup_{x \in \overline{\Omega}} |H|_g / \alpha$  such that, if  $0 \leq s \leq t \leq T$ ,  $t - s \geq T_\gamma$ , then

$$(3.11) \quad \begin{aligned} \int_s^t \mathcal{Q}(\tau) d\tau &\leq C_\gamma \int_s^t \mathcal{L}(\tau) d\tau + C_\gamma \int_s^t R(\tau) d\tau \\ & \quad + C_\gamma \int_s^t \int_{\Omega} (f_y(x, \dot{\phi}) \phi^{(j+1)} \phi^{(j+1)} + f(x, \dot{\phi}) \dot{\phi}) dx d\tau, \end{aligned}$$

where  $R(t)$  and  $\mathcal{L}(t)$  are as given in (2.21) and (2.22), respectively.

*Proof.* For  $0 < \varepsilon_2 < \varepsilon_1 < \varepsilon_0 < \varepsilon$ , set

$$(3.12) \quad Q_k = \mathcal{N}_{\varepsilon_k} \left[ \bigcup_{i=1}^I \Gamma_0^i \cup \left( \Omega \setminus \bigcup_{j=1}^I \Omega_i \right) \right], \quad k = 0, 1, 2.$$

Obviously we have

$$(3.13) \quad Q_2 \subset Q_1 \subset \overline{Q_0} \subset G.$$

Let  $\beta^i, i = 1, \dots, I$ , satisfy

$$(3.14) \quad \begin{aligned} \beta^i &\in C_0^\infty(R^n), \quad 0 \leq \beta^i \leq 1, \\ \beta^i &= \begin{cases} 1 & \text{on } \overline{\Omega_i} \setminus Q_1, \\ 0 & \text{on } Q_2. \end{cases} \end{aligned}$$

For each  $i, 1 \leq i \leq I$ , set

$$(3.15) \quad \hat{\Omega} := \Omega_i, \quad \mathcal{H} := \beta^i H^i, \quad h := \frac{1}{2} \operatorname{div}(\beta^i H^i).$$

*Step 1.* For  $1 \leq j \leq m-1$ , we estimate the energy  $V_j(t)$ .

(1) We estimate the integral

$$\int_s^t \int_{\Omega \setminus Q_1} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 dx d\tau,$$

where  $|\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 = \langle B_\phi(t) \nabla \phi^{(j)}, \nabla \phi^{(j)} \rangle$ .

Applying the identity (3.9), we obtain

$$(3.16) \quad \begin{aligned} &\int_s^t \int_{\partial\Omega_i} \left[ \beta^i H^i(\phi^{(j)}) \phi_{\nu_B}^{(j)} + \frac{1}{2} (\dot{\phi}^{(j)})^2 - |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 \langle \beta^i H^i, \nu \rangle \right] d\sigma d\tau \\ &\quad - \frac{1}{2} \int_s^t \int_{\partial\Omega_i} \left[ \frac{1}{2} (\phi^{(j)})^2 (\operatorname{div} \beta^i H^i)_{\nu_B} - \operatorname{div}(\beta^i H^i) \phi^{(j)} \phi_{\nu_B}^{(j)} \right] d\sigma d\tau \\ &= \left( \phi^{(j)}, \frac{1}{2} \operatorname{div}(\beta^i H^i) \phi^{(j)} \right)_{L^2(\Omega_i)} \Big|_s^t + \int_s^t \int_{\Omega_i} D_{g_\phi}(\beta^i H^i)(\nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \phi^{(j)}) dx d\tau \\ &\quad + (\phi^{(j)}, \beta^i H^i(\phi^{(j)}))_{L^2(\Omega_i)} \Big|_s^t - \frac{1}{4} \int_s^t \int_{\Omega_i} (\phi^{(j)})^2 \mathcal{B}_\phi(\tau) \operatorname{div}(\beta^i H^i) dx d\tau \\ &\quad + \int_s^t \int_{\Omega_i} [r_j(\tau) + f_y(x, \dot{\phi}) \phi^{(j)}] \left[ \beta^i H^i(\phi^{(j)}) + \frac{1}{2} \operatorname{div}(\beta^i H^i) \phi^{(j)} \right] dx d\tau. \end{aligned}$$

Next, we show that the left-hand side of (3.16) is nonpositive. In fact, we notice that

$$\partial\Omega_i = \Gamma_0^i \cup (\partial\Omega_i \setminus \Gamma) \cup ((\partial\Omega_i \setminus \Gamma_0^i) \cap \Gamma) \equiv I_1 \cup I_2.$$

Since  $\partial\Omega_i \setminus \Gamma \subseteq \Omega \setminus \cup_{i=1}^I \Omega_i$ , we have  $\beta^i = 0$  in  $I_1 \subseteq Q_2$ . Since  $I_2 \subseteq \Gamma$ , it follows from [34] that

$$\beta^i H^i(\phi^{(j)}) \phi_{\nu_B}^{(j)} = |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 \langle \beta^i H^i, \nu^i \rangle, \quad \phi^{(j)} = 0 \quad \text{on } I_2.$$

We get

$$(3.17) \quad \begin{aligned} &\int_s^t \int_{\partial\Omega_i} \left[ \beta^i H^i(\phi^{(j)}) \phi_{\nu_B}^{(j)} + \frac{1}{2} (\dot{\phi}^{(j)})^2 - |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 \langle \beta^i H^i, \nu \rangle \right] d\sigma d\tau \\ &= \frac{1}{2} \int_s^t \int_{(\partial\Omega_i \setminus \Gamma_0^i) \cap \Gamma} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 \beta^i H^i \nu d\sigma d\tau \leq 0. \end{aligned}$$

Furthermore, we decompose  $\partial\Omega_i = (\partial\Omega_i \setminus \Omega) \cup (\partial\Omega_i \cap \Omega) \equiv J_1 \cup J_2$ . Since  $J_1 \subseteq \Gamma$ , by the boundary condition, we get

$$(3.18) \quad -\frac{1}{2} \int_s^t \int_{J_1} \left[ \frac{1}{2} \phi^{(j)2} (\operatorname{div} \beta^i H^i)_{\nu_B} - \operatorname{div}(\beta^i H^i) \phi^{(j)} \phi_{\nu_B}^{(j)} \right] dx d\tau = 0.$$

It is easy to verify that  $J_2 = \partial\Omega_i \cap \Omega \subseteq \Omega \setminus \cup_{i=1}^I \Omega_i \subseteq Q_2$ ; thus

$$(3.19) \quad -\frac{1}{2} \int_s^t \int_{J_2} \left[ \frac{1}{2} \phi^{(j)2} (\operatorname{div} \beta^i H^i)_{\nu_B} - \operatorname{div}(\beta^i H^i) \phi^{(j)} \phi_{\nu_B}^{(j)} \right] dx d\tau = 0.$$

Combining (3.17)–(3.19), it follows that the left-hand side of (3.16) is nonpositive.

We sum up (3.16) from  $i = 1$  to  $i = I$  and obtain

$$(3.20) \quad \begin{aligned} & \sum_{i=1}^I \int_s^t \int_{\Omega_i \setminus Q_1} D_{g_\phi}(\beta^i H^i)(\nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \phi^{(j)}) dx d\tau \\ & \leq - \sum_{i=1}^I (\dot{\phi}^{(j)}, M^i(\phi^{(j)}))_{L^2(\Omega_i)} \Big|_s^t + \frac{1}{4} \sum_{i=1}^I \int_s^t \int_{\Omega_i} (\phi^{(j)})^2 \mathcal{B}_\phi(\tau) \operatorname{div}(\beta^i H^i) dx d\tau \\ & \quad - \sum_{i=1}^I \int_s^t \int_{\Omega_i} r_j(\tau) M^i(\phi^{(j)}) dx d\tau - \sum_{i=1}^I \int_s^t \int_{\Omega_i} f_y(x, \dot{\phi}) \dot{\phi}^{(j)} M^i(\phi^{(j)}) dx d\tau \\ & \quad - \sum_{i=1}^I \int_s^t \int_{\Omega_i \cap Q_1} D_{g_\phi}(\beta^i H^i)(\nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \phi^{(j)}) dx d\tau, \end{aligned}$$

where  $M^i(\phi^{(j)}) = \beta^i H^i(\phi^{(j)}) + \frac{1}{2} \operatorname{div}(\beta^i H^i) \phi^{(j)}$ . We estimate every item on the right-hand side of the inequality (3.20) as

$$(3.21) \quad \sum_{i=1}^I \left| (\dot{\phi}^{(j)}, M^i(\phi^{(j)}))_{L^2(\Omega_i)} \Big|_s^t \right| \leq C_\gamma V_j(t) + C_\gamma V_j(s),$$

$$(3.22) \quad \sum_{i=1}^I \left| - \int_s^t \int_{\Omega_i} \frac{1}{4} \phi^{(j)2} \mathcal{B}_\phi(t) \operatorname{div}(\beta^i H^i) \right| \leq C_r \int_s^t \int_{\Omega} (\phi^{(j)})^2 dx d\tau,$$

$$(3.23) \quad \begin{aligned} & \sum_{i=1}^I \left| \int_s^t \int_{\Omega_i} r_j(t) M^i(\phi^{(j)}) dx dt \right| \\ & \leq C_\gamma \int_s^t \left( \int_{\Omega} r_j^2(t) dx \right)^{\frac{1}{2}} \cdot \left( \int_{\Omega_i} (M^i(\phi^{(j)}))^2 dx \right)^{\frac{1}{2}} dt \\ & \leq C_\gamma \int_s^t V_j^{\frac{1}{2}}(\tau) \cdot \left( \sum_{k=2}^{m-1} \mathcal{E}^{\frac{k}{2}}(\tau) \right) d\tau \leq \varepsilon \int_s^t V_j(\tau) d\tau + C_\varepsilon \int_s^t \mathcal{L}(\tau) d\tau. \end{aligned}$$

Due to (2.40), there exists  $C_\gamma > 0$  such that

$$(3.24) \quad \dot{V}_j(t) - C_\gamma \mathcal{L}(t) \leq -2 \int_{\Omega} f_y(x, \dot{\phi}) (\phi^{(j+1)})^2 dx.$$

Thus we have

$$\begin{aligned}
 (3.25) \quad & \sum_{i=1}^I \left| \int_s^t \int_{\Omega_i} f_y(x, \dot{\phi}) \dot{\phi}^{(j)} \left[ \beta^i H^i(\phi^{(j)}) + \frac{1}{2} \operatorname{div}(\beta^i H^i) \phi^{(j)} \right] \right| \\
 & \leq C_\gamma \int_s^t V_j^{\frac{1}{2}}(\tau) \left[ \int_{\Omega} f_y^2(x, \dot{\phi}) (\dot{\phi}^{(j)})^2 dx \right]^{\frac{1}{2}} d\tau \\
 & \leq C_\gamma \int_s^t V_j^{\frac{1}{2}}(\tau) (C_\gamma \mathcal{L}(\tau) - \dot{V}_j(\tau))^{\frac{1}{2}} d\tau \\
 & \leq \varepsilon \int_s^t V_j(\tau) d\tau + C_\varepsilon \int_s^t (C_\gamma \mathcal{L}(\tau) - \dot{V}_j(\tau)) d\tau \\
 & \leq \varepsilon \int_s^t V_j(\tau) d\tau + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau + C_\varepsilon V_j(s).
 \end{aligned}$$

We also have

$$(3.26) \quad \sum_{i=1}^I \left| \int_s^t \int_{\Omega_i \cap Q_1} D_{g_\phi}(\beta^i H^i)(\nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \phi^{(j)}) dx d\tau \right| \leq C_\gamma \int_s^t \int_{\Omega \cap Q_1} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 dx d\tau.$$

On the other hand, by (3.7)–(3.8) and (1.13), (3.4), (3.14), we have

$$\begin{aligned}
 (3.27) \quad & \sum_{i=1}^I \int_s^t \int_{\Omega_i \setminus Q_1} D_{g_\phi}(\beta^i H^i)(\nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \phi^{(j)}) dx d\tau \\
 & = \sum_{i=1}^I \int_s^t \int_{\Omega_i \setminus Q_1} [D_g(\beta^i H^i)(\nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \phi^{(j)}) + \eta(\nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \phi^{(j)})] dx d\tau \\
 & \geq \alpha \int_s^t \int_{\Omega \setminus Q_1} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 dx d\tau - C_\gamma \int_s^t \mathcal{L}(\tau) d\tau \\
 & \geq \alpha C_{0,\gamma} \int_s^t \int_{\Omega \setminus Q_1} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 dx d\tau - C_\gamma \int_s^t \mathcal{L}(\tau) d\tau.
 \end{aligned}$$

Combining (3.20)–(3.27), we obtain

$$\begin{aligned}
 (3.28) \quad & \alpha C_{0,\gamma} \int_s^t \int_{\Omega \setminus Q_1} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 dx d\tau \leq C_\gamma V_j(t) + C_\gamma V_j(s) + \varepsilon \int_s^t V_j(\tau) d\tau \\
 & + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau + C_\gamma \int_s^t \int_{\Omega} (\phi^{(j)})^2 dx d\tau + C_\gamma \int_s^t \int_{\Omega \cap Q_1} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 dx d\tau.
 \end{aligned}$$

(2) We estimate

$$\int_s^t \int_{\Omega \cap Q_1} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 dx d\tau.$$

Let  $\xi \in C_0^\infty(R^n)$  such that  $0 \leq \xi \leq 1$ , and let

$$(3.29) \quad \xi = \begin{cases} 0 & \text{on } R^n \setminus Q_0, \\ 1 & \text{on } Q_1. \end{cases}$$

We have

$$(3.30) \quad 0 = \int_s^t \int_\Omega [\ddot{\phi}^{(j)} - \mathcal{B}_\phi(\tau)\phi^{(j)} + r_j(\tau) + f_y(x, \dot{\phi})\dot{\phi}^{(j)}] \xi \phi^{(j)} dx d\tau,$$

that is,

$$\begin{aligned} 0 &= \int_\Omega \dot{\phi}^{(j)} \xi \phi^{(j)} dx \Big|_s^t - \int_s^t \int_\Omega \xi (\dot{\phi}^{(j)})^2 dx d\tau + \int_s^t \int_\Omega f_y(x, \dot{\phi}) \dot{\phi}^{(j)} \xi \phi^{(j)} dx d\tau \\ &\quad + \int_s^t \int_\Omega [\xi |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 + \phi^{(j)} \langle \nabla_{g_\phi} \phi^{(j)}, \nabla_{g_\phi} \xi \rangle_{g_\phi}] dx d\tau + \int_s^t \int_\Omega r_j(\tau) \xi \phi^{(j)} dx d\tau. \end{aligned}$$

We can easily get

$$\begin{aligned} (3.31) \quad &\int_s^t \int_{\Omega \cap Q_1} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 = \int_s^t \int_{\Omega \cap Q_1} \xi |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 \leq \int_s^t \int_\Omega \xi |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 \\ &\leq C_\gamma V_j(s) + C_\gamma V_j(t) + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau + C_\varepsilon \int_s^t \int_\Omega (\phi^{(j)})^2 dx d\tau \\ &\quad + \varepsilon \int_s^t \int_\Omega |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 + \varepsilon \int_s^t \int_\Omega (\dot{\phi}^{(j)})^2 dx d\tau + C_\gamma \int_s^t \int_{Q_0} (\phi^{(j)})^2 dx d\tau. \end{aligned}$$

(3) We need to further estimate

$$\int_s^t \int_{Q_0} (\dot{\phi}^{(j)})^2 dx d\tau.$$

By (1.7) and (3.13), we see that there exists  $c_0 > 0$  such that

$$(3.32) \quad f_s(x, 0) \geq c_0 > 0, \quad x \in \overline{Q_0}.$$

We can take  $\gamma$  small in (2.23), which can guarantee that

$$(3.33) \quad f_s(x, \dot{\phi}) \geq \frac{1}{2}c_0, \quad x \in \overline{Q_0},$$

by the embedding theorem. Since  $\dot{\phi}^{(j)}(x) = 0$  on  $\partial\Omega$ , we obtain

$$\begin{aligned} (3.34) \quad &\frac{1}{2}c_0 \int_s^t \int_{Q_0} (\dot{\phi}^{(j)})^2 dx d\tau \leq \int_s^t \int_\Omega f_y(x, \dot{\phi}) (\dot{\phi}^{(j)})^2 dx d\tau \\ &\leq C_\gamma V_j(s) + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau. \end{aligned}$$

(4) Taking  $h := \frac{1}{2}\alpha C_{0,\gamma}$  and  $\hat{\Omega} = \Omega$  in the identity (3.10) yields

$$(3.35) \quad \begin{aligned} \frac{1}{2}\alpha C_{0,\gamma} \int_s^t \int_{\Omega} [(\dot{\phi}^{(j)})^2 - |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2] dx d\tau &\leq C_\gamma V_j(s) + C_\gamma V_j(t) + \varepsilon \int_s^t V_j(\tau) d\tau \\ &+ C_\varepsilon \int_s^t \int_{\Omega} (\phi^{(j)})^2 dx d\tau + C_\gamma \int_s^t \int_{Q_0} (\dot{\phi}^{(j)})^2 dx d\tau + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau. \end{aligned}$$

Substituting (3.31) and (3.34) into (3.28), we obtain

$$(3.36) \quad \begin{aligned} \alpha C_{0,\gamma} \int_s^t \int_{\Omega} |\nabla_{g_\phi} \phi^{(j)}|_{g_\phi}^2 dx d\tau &\leq C_\gamma V_j(s) + C_\gamma V_j(t) + C_\varepsilon \int_s^t \int_{\Omega} (\phi^{(j)})^2 dx d\tau \\ &+ \varepsilon \int_s^t V_j(\tau) d\tau + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau. \end{aligned}$$

Combining the inequalities (3.34)–(3.36), for  $1 \leq j \leq m-1$ , we finally get

$$(3.37) \quad \begin{aligned} \frac{1}{2}\alpha C_{0,\gamma} \int_s^t V_j(\tau) d\tau \\ \leq C_\gamma V_j(t) + C_\gamma V_j(s) + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau + C_\gamma \int_s^t \int_{\Omega} (\phi^{(j)})^2 dx d\tau. \end{aligned}$$

*Step 2.* We shall estimate  $V_0(t)$ . We define

$$(3.38) \quad h_\phi = N_\phi^{-1}(t),$$

and replace  $g_\phi$  in Step 1 by  $h_\phi$ . By a similar process, there exists a constant denoted by  $C_\gamma$  such that

$$(3.39) \quad \dot{V}_0(t) - C_\gamma \mathcal{L}(t) \leq -2 \int_{\Omega} f(x, \dot{\phi}) \dot{\phi} dx.$$

In light of

$$(3.40) \quad f(x, \dot{\phi}) - f(x, 0) = \left( \int_0^1 f_y(x, s \nabla \phi) ds \right) \dot{\phi},$$

we have

$$(3.41) \quad \begin{aligned} \sum_{i=1}^I \left| \int_s^t \int_{\Omega_i} f(x, \dot{\phi}) M^i(\phi) \right| &\leq C_\gamma \int_s^t V_0^{1/2}(\tau) \left( \int_{\Omega} f^2(x, \dot{\phi}) dx \right)^{1/2} d\tau \\ &\leq C_\gamma \int_s^t V_0^{1/2}(\tau) \left[ \int_{\Omega} f(x, \dot{\phi}) \dot{\phi} dx \right]^{1/2} d\tau \\ &\leq C_\gamma \int_s^t V_0^{1/2}(\tau) \left[ C_\gamma \mathcal{L}(\tau) - \dot{V}_0(\tau) \right]^{1/2} d\tau \\ &\leq \varepsilon \int_s^t V_0(\tau) d\tau + C_\varepsilon \int_s^t \mathcal{L}(\tau) d\tau + C_\gamma V_0(t) + C_\gamma V_0(s). \end{aligned}$$

Using a method similar to that in Step 1, we obtain

$$(3.42) \quad \frac{1}{2}\alpha C_{0,\gamma} \int_s^t V_0(\tau) d\tau \leq C_\gamma \left( V_0(t) + V_0(s) + \int_s^t \mathcal{L}(\tau) d\tau \right) + C_\gamma \int_s^t \int_\Omega \phi^2 dx d\tau.$$

Step 3. Combining (3.37) and (3.42), we have

$$(3.43) \quad \frac{1}{2}\alpha C_{0,\gamma} \int_s^t Q(\tau) d\tau \leq C_\gamma \left( Q(t) + Q(s) + \int_s^t \mathcal{L}(\tau) d\tau \right) + C_\gamma \int_s^t R(\tau) dx d\tau,$$

where  $R(t)$  is given in (2.21). Moreover, the inequalities (2.26) in section 2 imply that

$$(3.44) \quad \max\{Q(t), Q(s)\} \leq \frac{1}{t-s} \int_s^t Q(\tau) d\tau + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau \\ + 2 \int_s^t \int_\Omega (f_y(x, \dot{\phi})(\phi^{(j+1)})^2 + f(x, \dot{\phi})\dot{\phi}) dx d\tau.$$

Substituting (3.44) into (3.43), we finally obtain  $C_\gamma$  and  $T_\gamma > 3 \sup_{x \in \bar{\Omega}} |H|_g / \alpha$  such that the inequality (3.11) holds.  $\square$

We now absorb the lower order terms in (3.11). This will be accomplished by applying the following nonlinear version of the compactness-uniqueness argument.

LEMMA 3.4. *Let all assumptions in Theorem 3.1 hold. Then for  $1 \leq j \leq m-1$  we have*

$$(3.45) \quad \int_s^t \int_\Omega (\phi^{(j)})^2 dx d\tau \leq C_\gamma \int_s^t \mathcal{L}(\tau) d\tau + C_\gamma \int_s^t \int_\Omega f_y(x, \dot{\phi})(\phi^{(j+1)})^2 dx d\tau,$$

and for  $j = 0$ ,

$$(3.46) \quad \int_s^t \int_\Omega \phi^2 dx d\tau \leq C_\gamma \int_s^t \mathcal{L}(\tau) d\tau + C_\gamma \int_s^t \int_\Omega f(x, \dot{\phi})\dot{\phi} dx d\tau,$$

respectively, for  $t - s \geq T_0$ , where  $T_0 \geq 3 \sup_{x \in \bar{\Omega}} |H|_g / \alpha$ .

*Proof.* By Lemma 4 in [8], we need only prove that for some  $T_0$  large enough there is  $C_\gamma > 0$  such that

$$(3.47) \quad \int_0^{T_0} \int_\Omega (\phi^{(j)})^2 dx d\tau \leq C_\gamma \int_0^{T_0} \mathcal{L}(\tau) d\tau + C_\gamma \int_0^{T_0} \int_\Omega f_y(x, \dot{\phi})(\phi^{(j+1)})^2 dx d\tau.$$

For convenience, we denote  $\psi := \phi^{(j)}$  and  $V(t) := V_j(t)$  for  $1 \leq j \leq m-1$ . Recall that there exists a constant  $C_\gamma > 0$  such that

$$\dot{V}(t) - C_\gamma \mathcal{L}(t) \leq -2 \int_\Omega f_y(x, \dot{\phi})\dot{\psi}^2 dx < 0,$$

which means that  $V(t) - C_\gamma \int_0^t \mathcal{L}(\tau) d\tau$  is decreasing. Hence we have

$$T_0 \left( V(T_0) - C_\gamma \int_0^{T_0} \mathcal{L}(\tau) d\tau \right) \leq \int_0^{T_0} \left( V(t) - C_\gamma \int_0^t \mathcal{L}(\tau) d\tau \right) dt,$$

that is,

$$T_0 \left( V(T_0) - C_\gamma \int_0^{T_0} \mathcal{L}(\tau) d\tau \right) \leq \int_0^{T_0} V(\tau) d\tau.$$

Using the inequality (3.37), we obtain from the above inequality that

$$(3.48) \quad V(T_0) \leq \frac{C_\gamma}{T_0} V(0) + \left( C_\gamma + \frac{C_\gamma}{T_0} \right) \int_0^{T_0} \mathcal{L}(\tau) d\tau + \frac{C_\gamma}{T_0} \int_0^{T_0} \int_\Omega \psi^2 dx d\tau.$$

On the other hand, there exists  $C_\gamma > 0$  such that

$$-\dot{V}(t) \leq 2 \int_\Omega f_y(x, \dot{\phi}) \dot{\psi}^2 dx + C_\gamma \mathcal{L}(t).$$

Integrating the above inequality on interval  $[0, T_0]$ , we easily get

$$(3.49) \quad V(0) \leq V(T_0) + C_\gamma \int_0^{T_0} \mathcal{L}(\tau) d\tau + 2 \int_0^{T_0} \int_\Omega f_y(x, \dot{\phi}) \dot{\psi}^2 dx d\tau.$$

For  $T_0$  large enough, the inequalities (3.48) and (3.49) imply that

$$(3.50) \quad V(0) \leq C_\gamma \int_0^{T_0} \int_\Omega \psi^2 dx d\tau + C_\gamma \int_0^{T_0} \mathcal{L}(\tau) d\tau + 2 \int_0^{T_0} \int_\Omega f_y(x, \dot{\phi}) \dot{\psi}^2 dx d\tau.$$

Now we prove (3.47) by contradiction. Let  $\phi_k(t)$  be a sequence of solutions to the system (2.1) such that

$$(3.51) \quad \int_0^{T_0} \int_\Omega \psi_k^2 dx d\tau = 1,$$

$$(3.52) \quad \lim_{k \rightarrow \infty} \int_0^{T_0} \int_\Omega f_y(x, \dot{\phi}_k) \dot{\psi}_k^2 dx d\tau = 0, \quad \lim_{k \rightarrow \infty} \int_0^{T_0} \mathcal{L}_k(\tau) d\tau = 0,$$

where  $V_k$  is the energy of  $\psi_k$ .

By (3.50)–(3.52), we get

$$(3.53) \quad V_k(0) \text{ is bounded } \forall k.$$

Then there is a subsequence of  $\psi_k$  (denoted by  $\psi_k$  again) such that

$$(3.54) \quad \psi_k(0) \rightarrow \text{some } \bar{\psi}_0 \text{ weakly in } H^1(\Omega),$$

$$(3.55) \quad \dot{\psi}_k(0) \rightarrow \text{some } \bar{\psi}_1 \text{ weakly in } L^2(\Omega).$$

Denote by  $\bar{\psi}$  the solution corresponding to the initial data  $(\bar{\psi}_0, \bar{\psi}_1)$ :

$$(3.56) \quad \bar{\psi}(0, x) = \bar{\psi}_0(x), \quad \dot{\bar{\psi}}(0, x) = \bar{\psi}_1(x) \quad \text{in } \Omega.$$

Then

$$(3.57) \quad \{\psi_k, \dot{\psi}_k\} \rightarrow \{\bar{\psi}, \dot{\bar{\psi}}\} \text{ in } L^\infty(0, T_0; H^1(\Omega) \times L^2(\Omega)) \text{ weakly } \star.$$

By Aubin's compactness results (see [1]), it follows that

$$(3.58) \quad \psi_k \rightarrow \bar{\psi} \text{ strongly in } L^\infty(0, T_0; L^2(\Omega)).$$

Since

$$\int_0^{T_0} \mathcal{E}_k(\tau) d\tau \leq \sqrt{T_0} \left( \int_0^{T_0} \mathcal{L}_k(\tau) d\tau \right)^{\frac{1}{2}} \rightarrow 0,$$

we have

$$\phi_k \rightarrow 0 \text{ in } H^m((0, T_0) \times \Omega), \quad \dot{\phi}_k \rightarrow 0 \text{ in } H^{m-1}((0, T_0) \times \Omega).$$

By using the imbedding theorem, we have

$$(3.59) \quad \sup_{(\tau, x) \in [0, T_0] \times \bar{\Omega}} |\phi_k| \rightarrow 0, \quad \sup_{(\tau, x) \in [0, T_0] \times \Omega} |\dot{\phi}_k| \rightarrow 0,$$

as  $k$  goes to infinity. The relationships (3.52), (3.59), and (1.7) imply that

$$(3.60) \quad \dot{\psi}_k \rightarrow 0 \text{ strongly in } L^2(0, T_0; L^2(G)).$$

Then passing to the limit in (2.12), for  $\bar{\psi}$  we get

$$(3.61) \quad \begin{aligned} \ddot{\bar{\psi}} - \mathcal{A}\bar{\psi} &= 0 \quad \text{in } (0, T_0) \times \Omega, \\ \dot{\bar{\psi}} &= 0 \quad \text{on } (0, T_0) \times G, \\ \bar{\psi} &= 0 \quad \text{on } (0, +\infty) \times \Gamma, \end{aligned}$$

where  $\mathcal{A}\psi = \operatorname{div} A(x, \nabla w) \nabla \psi$ .

Let  $\dot{\bar{\psi}} = z$ . The above system implies

$$(3.62) \quad \begin{aligned} \ddot{z} - \mathcal{A}z &= 0 \quad \text{in } (0, T_0) \times \Omega, \\ z &= 0 \quad \text{on } (0, T_0) \times G, \\ z &= 0 \quad \text{on } (0, +\infty) \times \Gamma. \end{aligned}$$

For  $T_0 \geq 3 \sup_{x \in \bar{\Omega}} |H|_g / \alpha$ , the problem (3.62) implies  $z = 0$ . Since  $\bar{\psi}|_\Gamma = 0$ , we have  $\bar{\psi} = 0$  on  $(0, T) \times \Omega$ , which contradicts (3.51). We use the same method to absorb the lower term in (3.42), which yields (3.46).  $\square$

*Proof of Theorem 3.1.* From (3.24) we obtain

$$2 \int_\Omega f_y(x, \dot{\phi}) (\phi^{(j+1)})^2 dx \leq -\dot{V}_j(t) + C_\gamma \mathcal{L}(t)$$

for  $1 \leq j \leq m$ , and consequently

$$2 \int_s^t \int_\Omega f_y(x, \dot{\phi}) (\phi^{(j+1)})^2 dx d\tau \leq V_j(s) - V_j(t) + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau.$$

Similarly we have

$$\int_s^t \int_\Omega 2f(x, \dot{\phi}) \dot{\phi} dx d\tau \leq V_0(s) - V_0(t) + C_\gamma \int_s^t \mathcal{L}(\tau) d\tau.$$

The inequality (3.1) follows from Lemmas 3.3 and 3.4.

By an argument similar to Lemma 3.2, the inequality in (2.24) in Theorem 2.1 of section 2 can be improved into the following.

LEMMA 3.5. *Let all assumptions in Theorem 1.1 hold. Let  $\gamma > 0$  be given and let  $\phi$  satisfy the problem (2.1) on the interval  $[0, T]$  for some  $T > 0$  such that the condition (2.23) holds. Then there exist constants  $C_\gamma > 0$  and  $T_\gamma > 0$  such that*

$$(3.63) \quad \mathcal{E}(t) \leq C_\gamma \mathcal{Q}(t) + C_\gamma \mathcal{L}(t)$$

for  $t \geq T_\gamma \geq 3 \sup_{x \in \bar{\Omega}} |H|_g / \alpha$ .

#### 4. Global smooth solutions.

*Proof of Theorem 1.1.* All the notations remain the same as before. Let  $(\phi_0, \phi_1) \in H^m(\Omega) \times H^{m-1}(\Omega)$  be given such that the problem (2.1) has a short time solution. We look for a constant  $\eta_0$  such that if

$$(4.1) \quad \mathcal{E}(0) \leq \eta_0,$$

then solutions of the system (2.1) are global.

Throughout this section we take  $\gamma = 1$ . Let  $C_{0,1}, C_1 \geq 1$ , and  $T_1 > 3 \sup_{x \in \bar{\Omega}} |H|_g / \alpha$  be given according to  $\gamma = 1$  in the theorems of sections 2 and section 3. Let

$$(4.2) \quad \Xi(\eta) = \sum_{k=0}^{2m-3} \eta^{k/2},$$

$$(4.3) \quad \theta(\eta) = 2e^\eta \max\{C_1 C_{0,1}^{-1}, 2C_1 \Xi(1), 2C_1^2 \Xi(1)\eta\}$$

for  $\eta \in (0, \infty)$ .

Let

$$(4.4) \quad 0 < \eta < \min\{1, \theta^{-2}(2T_1)/4\}$$

be given. We assume that

$$(4.5) \quad \mathcal{E}(0) \leq \eta^{3/2} < \eta.$$

Then there is some  $\delta > 0$  such that

$$(4.6) \quad \mathcal{E}(t) < \eta$$

for  $t \in [0, \delta)$ . Let  $\delta_0 > 0$  be the largest number such that inequality (4.6) holds for  $t \in [0, \delta_0)$ .

We show that  $\delta_0 = +\infty$ .

*Step 1.* We claim  $\delta_0 > 2T_1$ . Suppose that this is not true, i.e.,  $\delta_0 \leq 2T_1$ . We have a contradiction as follows.

Using the inequalities (2.24), (3.44), and (2.27), we obtain

$$Q(0) \leq C_{0,1}^{-1} \mathcal{E}(0), \quad Q(t) \leq C_{0,1}^{-1} \mathcal{E}(0) + 2C_1 T_1 \eta^{3/2} \Xi(1),$$

$$P(0) \leq Q(0) + \mathcal{E}(0) \leq (C_{0,1}^{-1} + 1) \mathcal{E}(0),$$

and

$$C_1 \|\phi\|_{L^2(\Omega)}^2 \leq C_1 P(t) \leq C_1 e^{2T_1} \{(C_{0,1}^{-1} + 1) \mathcal{E}(0) + 2C_1 T_1 \eta^{3/2} \Xi(1)\}.$$

Since

$$\mathcal{L}(t) = \sum_{k=3}^{2m} \mathcal{E}^{k/2}(t) \leq \eta^{3/2} \Xi(\eta) \leq \eta^{3/2} \Xi(1),$$

we have, via (4.5) and (4.6),

(4.7)

$$\begin{aligned} \mathcal{E}(t) &\leq C_1 \mathcal{Q}(t) + C_1 \|\phi(t)\|_{L^2(\Omega)}^2 + C_1 \mathcal{L}(t) \\ &\leq [C_1 C_{0,1}^{-1} + e^{2T_1} C_1 (C_{0,1}^{-1} + 1)] \mathcal{E}(0) + [2C_1^2 T_1 \Xi(1) + 2C_1^2 T_1 e^{2T_1} \Xi(1) + C_1 \Xi(1)] \eta^{3/2} \\ &\leq 2e^{2T_1} C_1 (C_{0,1}^{-1} + 1) \mathcal{E}(0) + 2e^{2T_1} [2C_1^2 T_1 \Xi(1) + C_1 \Xi(1)] \eta^{3/2} \\ &\leq 2e^{2T_1} \max\{C_1 (C_{0,1}^{-1} + 1), 4C_1^2 T_1 \Xi(1), 2C_1 \Xi(1)\} [\mathcal{E}(0) + \eta^{3/2}] \\ &\leq \Theta(2T_1) [\mathcal{E}(0) + \eta^{3/2}] \leq 2\Theta(2T_1) \eta^{1/2} \eta < \eta \end{aligned}$$

for all  $t \in [0, \delta_0]$ . This contradicts the definition of  $\delta_0$ .

*Step 2.* Next, we prove that  $\delta_0 = +\infty$  by contradiction. Let  $T_1 \leq s < t < \delta_0$  with  $t - s \geq T_1$ . Integrating the inequality (3.63) over interval  $(s, t)$  yields

$$\int_s^t \mathcal{E}(\tau) d\tau \leq C_1 \int_s^t \mathcal{Q}(\tau) d\tau + C_1 \Xi(1) \eta^{1/2} \int_s^t \mathcal{E}(\tau) d\tau,$$

that is,

$$(4.8) \quad \int_s^t \mathcal{E}(\tau) d\tau \leq C_1 [1 - C_1 \Xi(1) \eta^{1/2}]^{-1} \int_s^t \mathcal{Q}(\tau) d\tau.$$

The inequality (4.8), in turn, shows

$$(4.9) \quad \int_s^t \mathcal{L}(\tau) d\tau \leq \Xi(1) \eta^{1/2} \int_s^t \mathcal{E}(\tau) d\tau \leq h(\eta^{1/2}) \int_s^t \mathcal{Q}(\tau) d\tau,$$

where

$$(4.10) \quad h(x) = C_1 \Xi(1) x [1 - C_1 \Xi(1) x]^{-1}, \quad 0 \leq x \leq 1.$$

Furthermore, combining the inequalities (3.1) and (4.9), we obtain

$$C_1 \mathcal{Q}(t) + \int_s^t \mathcal{Q}(\tau) d\tau \leq C_1 \mathcal{Q}(s) + C_1 h(\eta^{1/2}) \int_s^t \mathcal{Q}(\tau) d\tau,$$

that is,

$$(4.11) \quad \mathcal{Q}(t) + w(\eta) \int_s^t \mathcal{Q}(\tau) d\tau \leq \mathcal{Q}(s),$$

where  $w(\eta) = C_1^{-1} - h(\eta^{1/2})$ .

We fix  $\eta > 0$  small such that

$$(4.12) \quad \eta^{1/2} \leq \left\{ \max\{1, 4C_1 C_{0,1}^{-1} \Theta(2T_1), 2\Theta(2T_1), 2C_1 \Xi(1)\} \right\}^{-1},$$

$$w(\eta) > 0.$$

If  $\delta_0 < \infty$ , we find a contradiction as follows. Combining (3.63) and (4.11) yields

$$\begin{aligned}
 (4.13) \quad \mathcal{E}(t) &\leq C_1 \mathcal{Q}(t) + C_1 \mathcal{L}(t) \\
 &\leq C_1 \mathcal{Q}(T_1) + C_1 \Xi(1) \eta^{3/2} \\
 &\leq C_1 C_{0,1}^{-1} \mathcal{E}(T_1) + C_1 \Xi(1) \eta^{3/2} \\
 &\leq 2C_1 C_{0,1}^{-1} \Theta(2T_1) \eta^{3/2} + C_1 \Xi(1) \eta^{3/2} < \eta,
 \end{aligned}$$

for  $0 \leq t \leq \delta_0$ , where the estimate  $\mathcal{E}(T_1) \leq 2\Theta(2T_1)\eta^{3/2}$  is as obtained in Step 1. This again contradicts the definition of  $\delta_0$ .

*Proof of Theorem 1.2.* The inequality (4.11) yields

$$(4.14) \quad \mathcal{Q}(t) - \mathcal{Q}(s) + w(\eta) \int_s^t \mathcal{Q}(\tau) d\tau \leq 0$$

for  $T_1 \leq s < t < \delta_0$  with  $t - s \geq T_1$ . Thus we have

$$(4.15) \quad \int_0^{t-T_1} s^k \mathcal{Q}(s) ds \geq \frac{(t-T_1)^{k+1}}{k+1} \mathcal{Q}(t) + \frac{w(\eta)}{k+1} \int_0^{t-T_1} \tau^{k+1} \mathcal{Q}(\tau) d\tau, \quad k \geq 0,$$

which yields

$$(4.16) \quad \mathcal{Q}(t) \leq \mathcal{Q}(0) e^{-w(\eta)(t-T_1)}, \quad t \geq T_1.$$

The estimate (1.15) follows from (4.16).

*Proof of the corollaries.* We show that assumption **(H)** holds under the assumption of Corollaries 1.1 and 1.2.

(1) Let  $\kappa \leq 0$ . We will verify that the vector field  $H(x, x_0) = \rho(x) D_g \rho(x)$  meets the inequality (1.13) for all  $x \in \overline{\Omega}$  where  $\rho(x) = \rho(x, x_0)$  is the distance function of the metric  $g$  in (1.10). To this end, we consider a space form  $M$  of constant curvature  $\kappa$  with a Riemannian metric  $\langle \cdot, \cdot \rangle_M$  and use the Hessian comparison theorem.

Let  $\tilde{D}$  be the Levi-Civita connection on  $M$ . Let  $p \in M$ . Let  $\tilde{\rho}(q)$  be the distance function on  $M$  from  $p$  to  $q \in M$ . Also let  $\tilde{r} : [0, b] \rightarrow M$  be a normal geodesic from  $p$  to  $q$  such that there is no conjugate point of  $p$  on  $\tilde{r}$ ; then  $\tilde{\rho}(q) = b$ .  $\tilde{X} \in M_q$  is a vector such that  $\langle \tilde{X}, \tilde{r}'(b) \rangle_M = 0$  and  $|\tilde{X}|_M = 1$ . We have (see [33])

$$(4.17) \quad \tilde{D}^2 \tilde{\rho}(q)(\tilde{X}, \tilde{X}) = \begin{cases} \sqrt{\kappa} \cot(\sqrt{\kappa} b), & \kappa > 0, \\ \frac{1}{b}, & \kappa = 0, \\ \sqrt{-\kappa} \coth(\sqrt{-\kappa} b), & \kappa < 0. \end{cases}$$

Let  $x \in \Omega$  and  $r : [0, b] \rightarrow R^n$  be a normal minimal geodesic from  $x_0$  to  $x$  with  $\rho(x) = b$ . Let  $X \in R_x^n$  such that  $g(X, r'(b)) = 0$ , where  $g$  is defined as in (1.11).

Since  $\kappa \leq 0$ , the exponential map  $\exp_x : R^n \rightarrow R^n$  is a diffeomorphism by the Cartan-Hadamard theorem. Then  $\rho(x) = \rho(x, x_0)$  is smooth on  $\Omega \setminus x_0$ . For all  $x \in \Omega$ ,

we obtain from the Hessian comparison theorem that

$$\begin{aligned}
 (4.18) \quad D_g^2 \rho(X, X)(x) &= |X|_g^2 D_g^2 \rho \left( \frac{X}{|X|_g}, \frac{X}{|X|_g} \right) \geq |X|_g^2 \tilde{D}^2 \tilde{\rho}(\tilde{X}, \tilde{X}) \\
 &= \begin{cases} \frac{1}{\rho(x)} |X|_g^2, & \kappa = 0, \\ \sqrt{-\kappa} \coth(\sqrt{-\kappa} \rho(x)) |X|_g^2, & \kappa < 0 \end{cases} \\
 &\geq \frac{1}{\rho(x)} |X|_g^2, \quad \kappa \leq 0,
 \end{aligned}$$

where we have used the inequality

$$\sqrt{-\kappa} \rho (e^{\sqrt{-\kappa} \rho} + e^{-\sqrt{-\kappa} \rho}) \geq e^{\sqrt{-\kappa} \rho} - e^{-\sqrt{-\kappa} \rho}, \quad \kappa < 0, \quad \rho > 0.$$

For any vector  $Y \in R_x^n$ , we have the decomposition as

$$(4.19) \quad Y = X + g(Y, r'(b))r'(b),$$

where  $g(X, r'(b)) = 0$ .

Define a vector field on  $\bar{\Omega}$  by  $H(x, x_0) = \rho(x)D_g \rho(x)$ . Combining (4.18) and (4.19), we obtain

$$\begin{aligned}
 (4.20) \quad DH(Y, Y)(x) &= \rho D_g^2 \rho(Y, Y) + g^2(Y, r'(b)) \\
 &= \rho D_g^2 \rho(X, X) + g^2(Y, r'(b)) \geq |X|_g^2 + g^2(Y, r'(b)) = |Y|_g^2;
 \end{aligned}$$

that is, (1.13) is true for  $I = 1$ , and  $\Omega_1 = \Omega$ . Also the damping region  $G$  need only be supported in a neighborhood of  $\Gamma_0$ , which is defined in (1.19).

(2) We assume that  $\kappa > 0$ . Then  $\rho(x) = \rho(x, x_i)$  is smooth on each  $B(x_i, r_0) \setminus x_i$ , where  $\rho(x) \leq r_0 < \pi/2\sqrt{\kappa}$ . Using a procedure similar to (4.18), we have

$$(4.21) \quad D_g^2 \rho(X, X)(x) \geq |X|_g^2 \tilde{D}^2 \tilde{\rho}(\tilde{X}, \tilde{X}) = \sqrt{\kappa} \cot(\sqrt{\kappa} \rho(x)) |X|_g^2$$

for  $\kappa > 0$  and  $x \in \bar{B}(x_i, r_0)$ . In general, the inequality (4.21) does not hold true on the whole  $\bar{\Omega}$ . It is easily checked that the function  $t\sqrt{\kappa} \cot(\sqrt{\kappa} t)$  is monotonically decreasing in  $t \in (0, \infty)$ , and thus

$$\rho(x)\sqrt{\kappa} \cot(\sqrt{\kappa} \rho) > \sqrt{\kappa} r_0 \cot(\sqrt{\kappa} r_0) \quad \text{for } \rho(x) < r_0,$$

and

$$t\sqrt{\kappa} \cot(\sqrt{\kappa} t) \leq 1 \quad \forall t \in (0, \infty).$$

For  $\kappa > 0$ , we set

$$\alpha = \sqrt{\kappa} r_0 \cot(\sqrt{\kappa} r_0).$$

Thus, for  $x \in \bar{B}(x_i, r_0)$ , we have

$$DH^i(Y, Y)(x) = \rho D_g^2 \rho(X, X) + g^2(Y, r'(b)) \geq \alpha(|X|_g^2 + g^2(Y, r'(b))) = \alpha|Y|_g^2,$$

where  $H^i = H(x, x_i) = \rho(x, x_i)D_g \rho(x, x_i)$  and  $\alpha \leq 1$ . Since the radius of the geodesic balls is fixed, there exists a finite number of vector fields  $H^i$  satisfying the assumption **(H)**.

**5. Proof of Theorem 1.3.** Let  $T > 0$  be given and let  $u \in C([0, T], H^2(\Omega))$  satisfy the problem (1.25) on the interval  $[0, T]$ . Let  $\gamma > 0$  be given. We assume that the solution  $u$  of (1.25) satisfies

$$(5.1) \quad \|\nabla u\| \leq \gamma, \quad 0 \leq t < T.$$

Let  $g_u$  be the metric on  $\bar{\Omega}$  given by

$$(5.2) \quad g_u = A^{-1}(x, \|\nabla u\|^{2r}),$$

where  $A(x, s) = (a_{ij}(x, s))$ .

Consider the pair  $(\bar{\Omega}, g_u)$  as a Riemannian manifold for fixed  $t \in [0, T]$ . Let  $X, Y$  be vector fields on  $\bar{\Omega}$  and  $f$  be a function. Then

$$(5.3) \quad \langle X, Y \rangle_{g_u} = \langle A^{-1}(x, \|\nabla u\|^{2r})X, Y \rangle, \quad \nabla_{g_u} f = A(x, \|\nabla u\|^{2r})\nabla f,$$

where  $\langle \cdot, \cdot \rangle$  and  $\langle \cdot, \cdot \rangle_{g_u}$  are the inner products in the standard metric and the metric  $g_u$ , and  $\nabla$  and  $\nabla_{g_u}$  are the gradients in the standard metric and the metric  $g_u$ , respectively.

Let the metric  $g$  be given as in (1.28). Then under the assumptions (1.27) and (5.1) there are constants  $c_0 > 0$  and  $c_\gamma > 0$  such that

$$(5.4) \quad c_0 |\nabla_g f|_g^2 \leq |\nabla_{g_u} f|_{g_u}^2 = \langle A(x, \|\nabla u\|^{2r})\nabla f, \nabla f \rangle \leq c_\gamma |\nabla_g f|_g^2,$$

for  $t \in [0, T]$ ,  $f \in C^\infty(\Omega)$ .

Let  $D_{g_u}$  and  $D_g$  be the Levi-Civita connections in the Riemannian metrics  $g_u$  and  $g$ , respectively. Let  $H$  be a vector field on  $\bar{\Omega}$ . Denote by  $D_{g_u}H$  and  $D_gH$  the covariant differentials in the metrics  $g_u$  and  $g$ . They are two order tensor fields on  $\bar{\Omega}$ . We define

$$(5.5) \quad \zeta = D_{g_u}H - D_gH.$$

We have the following.

**LEMMA 5.1** (see [37]). *Let  $H$  be a vector field on  $\bar{\Omega}$ . Suppose that the tensor field of order two  $\zeta = \zeta(\cdot, \cdot)$  is given in the formula (5.5). Let  $\gamma > 0$  be given and let  $u$  satisfy the assumption (5.1). Then there exists a constant  $c_\gamma > 0$ , which depends only on  $\gamma$ , such that*

$$(5.6) \quad |\zeta(X, Y)| \leq c_\gamma \|\nabla u\|^{2r} |X| |Y| \quad \forall X, Y \in R_x^n, \quad x \in \bar{\Omega}.$$

We define the energy of order one associated with the problem (1.25) by

$$(5.7) \quad E_1(t) = \|\dot{u}\|_{L^2(\Omega)}^2 + (A(x, \|\nabla u\|^{2r})\nabla u, \nabla u)_{L^2(\Omega)},$$

and define the second order energy by

$$(5.8) \quad E_2(t) = (A(x, \|\nabla u\|^{2r})\nabla \dot{u}, \nabla \dot{u})_{L^2(\Omega)} + \|\operatorname{div}(A(x, \|\nabla u\|^{2r}) \cdot \nabla u)\|_{L^2(\Omega)}^2.$$

We obtain the following, which is similar to Lemma 3 in [8].

**LEMMA 5.2.** *Let  $u$  be a solution of the problem (1.25) and let  $\hat{\Omega} \subseteq \Omega$  be a subset with a boundary  $\partial\hat{\Omega}$ .*

(1) Suppose that  $\mathcal{H}$  is a vector field on  $\hat{\Omega}$ . Then

$$\begin{aligned} & \int_s^t E_1^{\frac{\beta}{2}} \int_{\partial\hat{\Omega}} \left[ \mathcal{H}(u) \frac{\partial u}{\partial \nu_a} + \frac{1}{2} ((\dot{u})^2 - |\nabla_{g_u} u|_{g_u}^2) \langle \mathcal{H}, \nu \rangle \right] d\sigma d\tau \\ &= E_1^{\frac{\beta}{2}} (\dot{u}, \mathcal{H}(u))_{L^2(\hat{\Omega})} \Big|_s^t + \int_s^t E_1^{\frac{\beta}{2}} \int_{\hat{\Omega}} f(x, \dot{u}) \mathcal{H}(u) dx d\tau \\ &\quad - \frac{\beta}{2} \int_s^t E_1^{\frac{\beta-2}{2}} E_1'(\tau) \int_{\hat{\Omega}} \dot{u} \mathcal{H}(u) dx d\tau \\ &\quad + \int_s^t E_1^{\frac{\beta}{2}} \int_{\hat{\Omega}} \left\{ D_{g_u} \mathcal{H}(\nabla_{g_u} u, \nabla_{g_u} u) + \frac{1}{2} (\dot{u}^2 - |\nabla_{g_u} u|_{g_u}^2) \operatorname{div} \mathcal{H} \right\} dx d\tau, \end{aligned}$$

where  $\nu$  is the unit normal of  $\partial\hat{\Omega}$  pointing towards the exterior of  $\hat{\Omega}$ , and

$$\frac{\partial u}{\partial \nu_a} = \sum_{i,j=1}^n a_{ij}(x, \|\nabla u\|^{2r}) \frac{\partial u}{\partial x_j} \nu_i$$

is the conormal derivative.

(2) Let  $h \in C^2(\hat{\Omega})$ . We have

$$\begin{aligned} & \int_s^t E_1^{\frac{\beta}{2}} \int_{\hat{\Omega}} h(\dot{u}^2 - |\nabla_{g_u} u|_{g_u}^2) dx d\tau \\ &= \int_s^t E_1^{\frac{\beta}{2}} \int_{\partial\hat{\Omega}} \left( \frac{1}{2} u^2 \frac{\partial h}{\partial \nu_a} - h u \frac{\partial u}{\partial \nu_a} \right) d\sigma d\tau - \frac{\beta}{2} \int_s^t E_1^{\frac{\beta-2}{2}} E_1'(\tau) \int_{\hat{\Omega}} \dot{u} h(u) dx d\tau \\ &\quad + E_1^{\frac{\beta}{2}}(\tau) (\dot{u}, h u)_{L^2(\hat{\Omega})} \Big|_s^t + \int_s^t E_1^{\frac{\beta}{2}} \int_{\hat{\Omega}} \left( f(x, \dot{u}) h u - \frac{1}{2} u^2 \operatorname{div} \nabla_{g_u} h \right) dx d\tau. \end{aligned}$$

*Proof of Theorem 1.3.* From (1.25), we know that

$$(5.9) \quad (\ddot{u}, \dot{u})_{L^2(\Omega)} + \int_{\Omega} \sum_{i,j=1}^n a_{ij}(x, \|\nabla u\|^{2r}) \dot{u}_{x_i} u_{x_j} + \int_{\Omega} f(x, \dot{u}) \dot{u} = 0,$$

which gives

$$E_1'(t) = -2 \int_{\Omega} f(x, \dot{u}) \dot{u} + 2 \int_{\Omega} \sum_{i,j=1}^n a_{ijs}(x, \|\nabla u\|^{2r}) \|\nabla u\|^{2r-2} (\nabla u, \nabla \dot{u}) u_{x_i} u_{x_j},$$

where  $a_{ijs}$  is the partial differential of  $a_{ij}$  with respect to  $s$ .

There exists a constant  $c_\gamma > 0$  such that

$$(5.10) \quad \left| \sum_{i,j=1}^n a_{ijs}(x, \|\nabla u\|^{2r}) \|\nabla u\|^{2r-2} (\nabla u, \nabla \dot{u}) u_{x_i} u_{x_j} \right| \leq \frac{1}{2} c_\gamma E_1^{r+1/2}(t) E_2^{1/2}(t).$$

Obviously we have

$$(5.11) \quad E_1'(t) - c_\gamma E_1^{r+1/2}(t) E_2^{1/2}(t) \leq -2 \int_{\Omega} f(x, \dot{u}) \dot{u} \leq 0.$$

Notice that

$$(5.12) \quad \int_s^t E_1^{\frac{\beta+2}{2}}(\tau) d\tau = \int_s^t E_1^{\frac{\beta}{2}} \int_{\Omega} (\dot{u}^2 + |\nabla_{g_u} u|_{g_u}^2) dx d\tau.$$

After a procedure similar to that in the proofs of Lemmas 3.3 and 3.4, we have

$$\begin{aligned} \int_s^t E_1^{\frac{\beta+2}{2}}(\tau) d\tau &\leq c_{\gamma} E_1^{\frac{\beta+2}{2}}(s) + c_{\gamma} E_1^{\frac{\beta+2}{2}}(t) + c_{\gamma} E_1(s) - c_{\gamma} E_1(t) \\ &\quad + c_{\gamma} \int_s^t E_1^{\frac{\beta}{2}} \int_G (\dot{u}^2 + f^2(x, \dot{u})) dx d\tau + c_{\gamma} \int_s^t E_1^{r+1/2}(\tau) E_2^{1/2}(\tau) d\tau. \end{aligned}$$

By (1.21) and (5.12) we have

$$\begin{aligned} \int_G (\dot{u}^2 + f^2(x, \dot{u})) dx &\leq c \int_G (\dot{u} f(x, \dot{u}))^{\frac{2}{\beta+2}} dx \leq c \left( \int_G \dot{u} f(x, \dot{u}) dx \right)^{\frac{2}{\beta+2}} \\ &\leq c(c_{\gamma} E_1^{r+1/2} E_2^{1/2} - E_1')^{\frac{2}{\beta+2}}. \end{aligned}$$

Hence, using the Young inequality, for any  $\varepsilon > 0$  we have

$$\begin{aligned} \int_s^t E_1^{\frac{\beta}{2}} \int_G (\dot{u}^2 + f^2(x, \dot{u})) dx d\tau &\leq c \int_s^t E_1^{\frac{\beta}{2}}(\tau) (c_{\gamma} E_1^{r+1/2} E_2^{1/2} - E_1'(\tau))^{\frac{\beta+2}{2}} d\tau \\ &\leq \int_s^t (\varepsilon E_1^{\frac{\beta+2}{2}} + c(\gamma, \varepsilon) E_1^{r+1/2} E_2^{1/2} - c(\varepsilon) E_1') d\tau \\ &\leq \varepsilon \int_s^t E_1^{\frac{\beta+2}{2}} d\tau + c(\gamma, \varepsilon) \int_s^t E_1^{r+1/2}(\tau) E_2^{1/2}(\tau) d\tau + C(\varepsilon) E_1(s) - C(\varepsilon) E_1(t). \end{aligned}$$

Similar to (3.44), we have

$$\begin{aligned} \max \left\{ E_1^{\frac{\beta+2}{2}}(t), E_1^{\frac{\beta+2}{2}}(s) \right\} &\leq \frac{1}{t-s} \int_s^t E_1^{\frac{\beta+2}{2}}(\tau) d\tau + c_{\gamma} \int_s^t E_1^{r+1/2+\beta/2}(\tau) E_2^{1/2}(\tau) d\tau \\ &\quad + c_{\gamma} \int_s^t E_1^{3/2+\beta/2}(\tau) d\tau + \int_s^t E_1^{\frac{\beta}{2}}(\tau) f(x, \dot{u}) \dot{u} dx d\tau, \end{aligned}$$

where the following estimate has been used:

$$-E_1'(t) \leq c E^{3/2}(t) + c_{\gamma} E_1^{r+1/2} E_2^{1/2}(t) + \int_{\Omega} f(x, \dot{u}) \dot{u} dx.$$

Then there exist constants  $c_{\gamma} > 0$  and  $T_{\gamma} > 3 \sup_{x \in \Omega} |H|_g / \alpha$  such that, if  $0 \leq s \leq t \leq T$ ,  $t - s \geq T_{\gamma}$ , then

$$\int_s^t E_1^{\frac{\beta+2}{2}}(\tau) d\tau + c_{\gamma} E_1(t) + c_{\gamma} E_1^{\frac{\beta+2}{2}}(t) \leq c_{\gamma} E_1(s) + c_{\gamma} E_1^{\frac{\beta+2}{2}}(s) + c_{\gamma} \int_s^t \mathcal{L}(\tau) d\tau,$$

where  $\mathcal{L}(t)$  is the high order of the energy defined as

$$\mathcal{L}(\tau) = E_1^{r+1/2+\beta/2}(\tau) E_2^{1/2}(\tau) + E_1^{3/2+\beta/2}(\tau) + E_1^{r+1/2}(\tau) E_2^{1/2}(\tau).$$

After a discussion similar to that in section 4, we obtain the existence of global solutions to (1.25). Furthermore, we have

$$(5.13) \quad E_1(t) + E_1^{\frac{\beta+2}{2}}(t) - E_1(s) - E_1^{\frac{\beta+2}{2}}(s) + w(\eta) \int_s^t E_1^{\frac{\beta+2}{2}}(\tau) d\tau \leq 0$$

for  $0 \leq s \leq t \leq T$ ,  $t - s \geq T_\gamma$ , where

$$w(\eta) > 0$$

for  $\eta > 0$  small. From (5.13) we know that

$$E_1(t) \leq E_1(s), \quad 0 \leq s \leq t \leq T, \quad t - s \geq T_\gamma,$$

which yields

$$(5.14) \quad E_1^{\frac{\beta+2}{2}}(s) - E_1^{\frac{\beta+2}{2}}(t) \leq c(E_1(s) - E_1(t))$$

for  $\eta \leq (\frac{2c}{2+\beta})^{2/\beta}$ .

Combining (5.13) and (5.14), we get

$$E_1(t) - E_1(s) + w(\eta) \int_s^t E_1^{\frac{\beta+2}{2}}(\tau) d\tau \leq 0$$

for  $0 \leq s \leq t \leq T$ ,  $t - s \geq T_\gamma$ , which yields

$$(5.15) \quad E_1(t) \leq E_1(0) \left( \frac{1}{1 + \frac{2}{\beta} w(\eta)(t - T_\gamma) E_1^{\beta/2}(0)} \right)^{2/\beta}, \quad t \geq T_\gamma.$$

We can choose the suitable constant  $c$  such that the estimate (1.23) holds for all  $t > 0$ .

Next, we prove that the second energy is bounded. From the estimate (5.15), the following corollary is immediate.

**COROLLARY 5.1.** *If  $w > \beta/2$ , then*

$$(5.16) \quad \int_0^t E_1^w(s) ds \leq \frac{2w}{2w - \beta} C E_1(0)^{w-\beta/2}, \quad t \geq 0.$$

The equation can be written as

$$(5.17) \quad \ddot{u} - \operatorname{div}(A \cdot \nabla u) + f(x, \dot{u}) = 0.$$

A computation yields

$$\begin{aligned} (5.18) \quad E_2'(t) &= (\dot{A} \cdot \nabla \dot{u}, \nabla \dot{u})_{L^2(\Omega)} + 2(A \cdot \nabla \dot{u}, \nabla \ddot{u})_{L^2(\Omega)} \\ &\quad + (2\operatorname{div}(A \cdot \nabla u), (\operatorname{div}(\dot{A} \cdot \nabla u) + \operatorname{div}(A \cdot \nabla \dot{u})))_{L^2(\Omega)} \\ &= (\dot{A} \cdot \nabla \dot{u}, \nabla \dot{u})_{L^2(\Omega)} - 2(\operatorname{div}(A \cdot \nabla \dot{u}), \ddot{u})_{L^2(\Omega)} \\ &\quad + (2\operatorname{div}(A \cdot \nabla u), \operatorname{div}(\dot{A} \cdot \nabla u)) + (2\operatorname{div}(A \cdot \nabla u), \operatorname{div}(A \cdot \nabla \dot{u}))_{L^2(\Omega)} \\ &= (\dot{A} \cdot \nabla \dot{u}, \nabla \dot{u})_{L^2(\Omega)} + 2(\operatorname{div}(A \cdot \nabla \dot{u}), f)_{L^2(\Omega)} + 2(\operatorname{div}(A \cdot \nabla u), \operatorname{div}(\dot{A} \cdot \nabla u))_{L^2(\Omega)} \\ &\equiv I_1 + I_2 + I_3, \end{aligned}$$

where  $I_2$  can be written as

$$I_2 = 2(\operatorname{div}(A \cdot \nabla \dot{u}), f)_{L^2(\Omega)} = -2 \int_{\Omega} \sum_{i,j=1}^n \{a_{ij} \dot{u}_{x_j} f_{x_i}(x, \dot{u}) + a_{ij} \dot{u}_{x_j} f_s(x, \dot{u}) \dot{u}_{x_i}\}.$$

We need to estimate the term  $E'_2(t)$ . First, it is easily seen that

$$(5.19) \quad I_1(t) \leq CE^{r-1/2}(t)E_2^{3/2}(t),$$

$$I_2(t) \leq CE^{r-1/2}(t)E_2^{1/2}(t),$$

$$I_3(t) \leq CE^{r-1/2}(t)E_2(t),$$

where the condition (1.20) is used.

Combining (5.18) and (5.19), we know that at least one of the following three inequalities is true:

$$(5.20) \quad E'_2(t) \leq cE^{r-1/2}(t)E_2^{3/2}(t),$$

$$(5.21) \quad E'_2(t) \leq CE^{r-1/2}(t)E_2^{1/2}(t),$$

$$(5.22) \quad E'_2(t) \leq CE^{r-1/2}(t)E_2(t).$$

Letting  $\omega = r - 1/2$  in (5.16) yields

$$(5.23) \quad \int_0^t E^{r-1/2}(s)ds \leq \frac{2r-1}{2r-1-\beta} CE(0)^{r-1/2-\beta/2}.$$

The inequalities (5.20)–(5.23) imply that the second energy  $E_2(t)$  is bounded in  $t \in [0, \infty)$ .

**Acknowledgments.** The authors thank the reviewers for their suggestion to include the case (1.21).

## NECESSARY AND SUFFICIENT OPTIMALITY CONDITIONS FOR RELAXED AND STRICT CONTROL PROBLEMS\*

SEID BAHMALI†

**Abstract.** We consider a stochastic control problem where the set of strict (classical) controls is not necessarily convex, and the system is governed by a nonlinear stochastic differential equation, in which the control enters both the drift and the diffusion coefficients. By introducing a new approach, we establish necessary as well as sufficient conditions of optimality for two models. The first concerns the relaxed controls, which are measure-valued processes in which an optimal solution exists. The second is a particular case of the first and relates to strict control problems. These results are given in the form of global stochastic maximum principle by using only the first-order expansion and the associated adjoint equation. This improves all of the previous works on the subject.

**Key words.** stochastic differential equation, strict control, relaxed control, maximum principle, adjoint process, variational inequality

**AMS subject classification.** 93Exx

**DOI.** 10.1137/070681053

**1. Introduction.** We study a stochastic control problem where the system is governed by a nonlinear stochastic differential equation (SDE) of the type

$$\begin{cases} dx_t^v = b(t, x_t^v, v_t) dt + \sigma(t, x_t^v, v_t) dW_t, \\ x_0^v = \xi, \end{cases}$$

where  $b$  and  $\sigma$  are given deterministic functions,  $\xi$  is the initial data, and  $W = (W_t)_{t \geq 0}$  is a standard  $d$ -dimensional Brownian motion, defined on a filtered probability space  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathcal{P})$  satisfying the usual conditions.

The control variable  $v = (v_t)$ , called strict (classical) control, is an  $\mathcal{F}_t$  adapted process with values in some set  $U$  of  $\mathbb{R}^k$ . We denote by  $\mathcal{U}$  the class of all strict controls.

The criteria to be minimized, over the set  $\mathcal{U}$ , has the form

$$J(v) = \mathbb{E} \left[ g(x_T^v) + \int_0^T h(t, x_t^v, v_t) dt \right],$$

where  $g$  and  $h$  are given maps and  $x_t^v$  is the trajectory of the system controlled by  $v$ .

A control  $u \in \mathcal{U}$  is called optimal if it satisfies

$$J(u) = \inf_{v \in \mathcal{U}} J(v).$$

This kind of stochastic control problems have been studied extensively, both by the dynamic programming approach and by the Pontryagin stochastic maximum principle. In this paper, we are concerned with the second approach, whose objective is to establish necessary as well as sufficient conditions for optimality of controls. There are

many works concerning this subject. The first contribution in this direction is made by Kushner [18]. The other fundamental advance was developed by Haussmann [11, 12]. Versions of the stochastic maximum principle in which the diffusion coefficient is allowed to depend explicitly on the control variable were derived by Arkin and Saksonov [1], Bensoussan [5], Elliot [8], Elliot and Kohlmann [9], and Peng [23]. Necessary (as well as sufficient) optimality conditions for linear systems with random coefficients, where no  $L^p$ -bounds are imposed on the controls, are established by Cadellinas and Karatzas [6].

The common fact in most of these works is that an optimal solution in the class of strict controls may fail to exist. Existence of such a strict optimal control follows from the Filippov convexity condition, which is the convexity of the image of the action space  $U$  by the map  $(b(t, x, \cdot), \sigma\sigma^*(t, x, \cdot), h(t, x, \cdot))$ ; see [4], [7], [13], [14], [19]. Without this convexity condition, an optimal strict control does not necessarily exist in  $\mathcal{U}$ . To overcome this problem of existence without imposing the Filippov condition, the idea is then to introduce a bigger new class  $\mathcal{R}$  of processes in which the controller chooses at time  $t$  a probability measure  $q_t(da)$  on the control set  $U$ , rather than an element  $v_t$  of  $U$ . This new class of processes is called relaxed controls and has a richer topological structure, for which the control problem becomes solvable.

In the relaxed model, the system is governed by the SDE

$$\begin{cases} dx_t^q = \int_U b(t, x_t^q, a) q_t(da) dt + \int_U \sigma(t, x_t^q, a) q_t(da) dW_t, \\ x_0^q = \xi. \end{cases}$$

The functional cost to be minimized, over the class  $\mathcal{R}$  of relaxed controls, is defined by

$$J(q) = \mathbb{E} \left[ g(x_T^q) + \int_0^T \int_U h(t, x_t^q, a) q_t(da) dt \right].$$

A relaxed control  $\mu$  is called optimal if it solves

$$J(\mu) = \inf_{q \in \mathcal{R}} J(q).$$

The relaxed control problem finds its interest in two essential points. The first is that an optimal solution exists. Fleming [10] derived an existence result of an optimal relaxed control with uncontrolled diffusion coefficient. The existence of an optimal solution, where the drift and the diffusion coefficients depend explicitly on the relaxed control variable, has been solved by El Karoui, Nguyen, and Piqué [7]. The relaxed optimal control in this general case is shown to be Markovian. See Bahlali, Mezerdi, and Djehiche [2] for an alternative proof for existence of an optimal relaxed control. The second is that it is a generalization of the strict control problem. Indeed, if  $q_t(da) = \delta_{v_t}(da)$  is a Dirac measure concentrated at a single point  $v_t$ , then we get a strict control problem as a particular case of the relaxed one.

Motivated by the existence of an optimal solution, the unique versions of stochastic maximum principle for relaxed controls were established by Mezerdi and Bahlali [22] in the case of uncontrolled diffusion, Bahlali, Mezerdi, and Djehiche [2], where the drift and the diffusion coefficients depend explicitly on the relaxed control variable, and Bahlali, Djehiche, and Mezerdi [3] for the problem of mixed singular-relaxed controls. All these results are obtained by using the previous works on strict controls, Ekeland's variational principle, and some stability properties of the trajectories and adjoint processes with respect to the control variable.

The general stochastic maximum principle for strict controls established by Peng [23] and its extension to the class of measure-valued processes developed by Bahlali, Mezerdi, and Djehiche [2], have been both obtained by using the second-order expansion. Then, these two results are given with two adjoint processes and a variational inequality of the second-order.

Our aim in this paper is to establish necessary as well as sufficient conditions of optimality in the form of global stochastic maximum principle, for relaxed and strict controls, without using the second-order expansion. To achieve this goal, we introduce a new approach and derive these two main results as follows.

First, we give the optimality conditions for relaxed controls. The main idea is to use the fact that the set of relaxed controls is convex. Then, we establish necessary optimality conditions by using the classical way of the convex perturbation method. More precisely, if we denote by  $\mu$  an optimal relaxed control and  $q$  an arbitrary element of  $\mathcal{R}$ , then with a sufficiently small  $\theta > 0$  and for each  $t \in [0, T]$ , we can define a perturbed control as follows:

$$\mu_t^\theta = \mu_t + \theta(q_t - \mu_t).$$

We derive the variational equation from the state equation, and the variational inequality from the inequality

$$0 \leq J(\mu^\theta) - J(\mu).$$

By using the fact that the drift, the diffusion, and the running cost coefficients are linear with respect to the relaxed control variable, necessary optimality conditions are obtained directly in the global form. This result improves significantly that of Bahlali, Mezerdi, and Djehiche [2], in the sense where we use only the first-order expansion with only one adjoint process.

To achieve the first result of this paper, we prove under minimal additional hypothesis, that these necessary optimality conditions for relaxed controls are also sufficient.

The second main result in this paper characterizes the optimality for strict control processes. It is directly derived from the above result by restricting from relaxed to strict controls. The main idea is to replace the relaxed controls by a Dirac measures charging a strict controls. Thus, we reduce the set  $\mathcal{R}$  of relaxed controls and minimize the cost  $J$  over the subset  $\delta(\mathcal{U}) = \{q \in \mathcal{R} / q = \delta_v; \ v \in \mathcal{U}\}$ . Then, we derive necessary optimality conditions by using only the first-order expansion and the associated adjoint equation. Therefore we no longer need the second-order expansion. This result improves considerably the Peng stochastic maximum principle [23]. Moreover, we prove that these necessary conditions becomes sufficient, without imposing either the convexity of  $U$  or that of the Hamiltonian  $H$  in  $v$ .

This paper is organized as follows. In section 2, we formulate the strict and relaxed control problems and give the various assumptions used throughout this paper. Section 3 is devoted to study the relaxed control problems and we establish necessary as well as sufficient conditions of optimality for relaxed controls. In the last section, we derive directly from the results of section 3, the optimality conditions for strict controls.

Throughout this paper, we denote by  $C$  some positive constant and we need the following matrix notations. We denote by  $\mathcal{M}_{n \times d}(\mathbb{R})$  the space of  $n \times d$  real matrices and by  $\mathcal{M}_{n \times n}^d(\mathbb{R})$  the linear space of vectors  $M = (M_1, \dots, M_d)$ , where

$M_i \in \mathcal{M}_{n \times n}(\mathbb{R})$ .

For any  $M, N \in \mathcal{M}_{n \times n}^d(\mathbb{R})$ ,  $L, S \in \mathcal{M}_{n \times d}(\mathbb{R})$ ,  $\alpha, \beta \in \mathbb{R}^n$ , and  $\gamma \in \mathbb{R}^d$ , we use the following notations:

$$\alpha\beta = \sum_{i=1}^n \alpha_i \beta_i \in \mathbb{R} \text{ is the product scalar in } \mathbb{R}^n;$$

$$LS = \sum_{i=1}^d L_i S_i \in \mathbb{R}, \text{ where } L_i \text{ and } S_i \text{ are the } i\text{th columns of } L \text{ and } S;$$

$$ML = \sum_{i=1}^d M_i L_i \in \mathbb{R}^n;$$

$$M\alpha\gamma = \sum_{i=1}^d (M_i \alpha) \gamma_i \in \mathbb{R}^n;$$

$$MN = \sum_{i=1}^d M_i N_i \in \mathcal{M}_{n \times n}(\mathbb{R});$$

$$MLN = \sum_{i=1}^d M_i L N_i \in \mathcal{M}_{n \times n}(\mathbb{R});$$

$$ML\gamma = \sum_{i=1}^d M_i L \gamma_i \in \mathcal{M}_{n \times n}(\mathbb{R}).$$

We denote by  $L^*$  the transpose of the matrix  $L$  and  $M^* = (M_1^*, \dots, M_d^*)$ .

**2. Formulation of the problem.** Let  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathcal{P})$  be a filtered probability space satisfying the usual conditions, on which a  $d$ -dimensional Brownian motion  $W = (W_t)_{t \geq 0}$  is defined. We assume that  $(\mathcal{F}_t)$  is the  $\mathcal{P}$ -augmentation of the natural filtration of  $W$ .

Let  $T$  be a strictly positive real number and  $U$  a nonempty compact set of  $\mathbb{R}^k$ .

### 2.1. The strict control problem.

**DEFINITION 1.** An admissible strict control is an  $\mathcal{F}_t$ -adapted process  $v = (v_t)$  with values in  $U$  such that

$$\mathbb{E} \left[ \sup_{0 \leq t \leq T} |v_t|^2 \right] < \infty.$$

We denote by  $\mathcal{U}$  the set of all admissible strict controls.

For any  $v \in \mathcal{U}$ , we consider the following controlled SDE:

$$(1) \quad \begin{cases} dx_t^v = b(t, x_t^v, v_t) dt + \sigma(t, x_t^v, v_t) dW_t, \\ x_0^v = \xi, \end{cases}$$

where

$$\begin{aligned} b &: [0, T] \times \mathbb{R}^n \times U \longrightarrow \mathbb{R}^n, \\ \sigma &: [0, T] \times \mathbb{R}^n \times U \longrightarrow \mathcal{M}_{n \times d}(\mathbb{R}), \end{aligned}$$

and  $\xi$  is an  $n$ -dimensional  $\mathcal{F}_0$ -measurable random variable such that

$$\mathbb{E} |\xi|^2 < \infty.$$

The expected cost to be minimized is defined from  $\mathcal{U}$  into  $\mathbb{R}$  by

$$(2) \quad J(v) = \mathbb{E} \left[ g(x_T^v) + \int_0^T h(t, x_t^v, v_t) dt \right],$$

where

$$\begin{aligned} g : \mathbb{R}^n &\longrightarrow \mathbb{R}, \\ h : [0, T] \times \mathbb{R}^n \times U &\longrightarrow \mathbb{R}. \end{aligned}$$

A strict control  $u$  is called optimal if it satisfies

$$(3) \quad J(u) = \inf_{v \in \mathcal{U}} J(v).$$

The following assumptions will be in force throughout this paper:

$$(4) \quad b, \sigma, g, h \text{ are continuously differentiable with respect to } x.$$

They and all their derivatives  $b_x, \sigma_x, g_x, h_x$  are continuous in  $(x, v)$ .

$b_x, \sigma_x, g_x, h_x$  are uniformly bounded.  $b, \sigma, g, h$  are bounded by  $C(1 + |x| + |v|)$ .

Under the above assumptions, for every  $v \in \mathcal{U}$ , (1) has a unique strong solution, and the functional cost  $J$  is well defined from  $\mathcal{U}$  into  $\mathbb{R}$ .

**2.2. The relaxed model.** The strict control problem  $\{(1), (2), \text{ and } (3)\}$  formulated in the last subsection may fail to have an optimal solution without the Filippov convexity condition, which is the convexity of the image of the action space  $U$  by the map  $(b(t, x, \cdot), \sigma\sigma^*(t, x, \cdot), h(t, x, \cdot))$ ; see [4], [7], [13], [14], [19]. Let us begin by a deterministic example which shows that even in simple cases, existence of a strict optimal control is not ensured (see Fleming [10] and Yong and Zhou [24] for other examples).

The problem is to minimize, over the set of measurable functions  $v : [0, T] \rightarrow \{-1, 1\}$ , the following functional cost:

$$J(v) = \int_0^T (x_t^v)^2 dt,$$

where  $x_t^v$  denotes the solution of

$$\begin{cases} dx_t^v = v_t dt, \\ x_0^v = 0. \end{cases}$$

We then have

$$\inf_{v \in \mathcal{U}} J(v) = 0.$$

Indeed, consider the following sequence of controls:

$$v_t^n = (-1)^k \quad \text{if} \quad \frac{k}{n}T \leq t \leq \frac{k+1}{n}T, \quad 0 \leq k \leq n-1.$$

Then, clearly

$$\begin{aligned} \left| x_t^{v^n} \right| &\leq \frac{T}{n}, \\ |J(v^n)| &\leq \frac{T^3}{n^2}, \end{aligned}$$

which implies that

$$\inf_{v \in \mathcal{U}} J(v) = 0.$$

There is, however, no control  $v$  such that  $J(v) = 0$ . If this were the case, then for every  $t$ ,  $x_t^v = 0$ . This in turn would imply that  $v_t = 0$ , which is impossible. The problem is that the sequence  $(v^n)$  has no limit in the space of strict controls. This limit, if it exists, will be the natural candidate for optimality. If we identify  $v_t^n$  with the Dirac measure  $\delta_{v_t^n}(da)$  and set  $q_n(dt, dv) = \delta_{v_t^n}(dv) dt$ , then we get a measure on  $[0, 1] \times U$ . Then, the sequence  $(q_n(dt, dv))_n$  converges weakly to  $\frac{1}{2} dt [\delta_{-1} + \delta_1](da)$ .

This suggests that the set  $\mathcal{U}$  of strict controls is too narrow and should be embedded into a wider class with a richer topological structure, for which the control problem becomes solvable.

The idea of relaxed controls is to replace the  $U$ -valued process  $(v_t)$  with  $\mathbb{P}(U)$ -valued process  $(q_t)$ , where  $\mathbb{P}(U)$  is the space of probability measures equipped with the topology of weak convergence.

**DEFINITION 2.** A relaxed control is the term  $q = (\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, P, W_t, q_t, x_t, \xi)$  such that (1)  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, P)$  is a filtered probability space satisfying the usual conditions. (2)  $(q_t)_t$  is a  $\mathbb{P}(\bar{U})$ -valued process, progressively measurable with respect to  $(\mathcal{F}_t)_t$  and such that for each  $t$ ,  $\mathbf{1}_{[0, t]} \cdot q$  is  $\mathcal{F}_t$ -measurable. (3)  $(x_t)_t$  is  $\mathbb{R}^n$ -valued and  $\mathcal{F}_t$ -adapted with continuous paths such that  $x_0 = \xi$  and for each  $f \in C_b^2(\mathbb{R}^n, \mathbb{R})$

$$f(x_t) - f(\xi) - \int_0^t \int_U Lf(s, x_s, a) q_s(\omega, da) ds$$

is a  $P$ -martingale, where  $L$  is the infinitesimal generator associated with (5), acting on a map  $f$  in  $C_b^2(\mathbb{R}^n, \mathbb{R})$ .

By a slight abuse of notation, we will often denote a relaxed control by  $q$  instead of specifying all of the components.

**Remark 3.** The set of strict controls is embedded into the set of relaxed controls by the mapping

$$f : v \mapsto f_v(dt, da) = dt \delta_{v_t}(da),$$

where  $\delta_v$  is the atomic measure concentrated at a single point  $v$ .

For more details on relaxed controls, see [2], [3], [7], [10], [20], [21], [22].

**DEFINITION 4.** An admissible relaxed control is a relaxed control  $q = (q_t)$  such that

$$\mathbb{E} \left[ \sup_{0 \leq t \leq T} |q_t|^2 \right] < \infty.$$

We denote by  $\mathcal{R}$  the set of all admissible relaxed controls.

For any  $q \in \mathcal{R}$ , we consider the following relaxed SDE:

$$(5) \quad \begin{cases} dx_t^q = \int_U b(t, x_t^q, a) q_t(da) dt + \int_U \sigma(t, x_t^q, a) q_t(da) dW_t, \\ x_0^q = \xi. \end{cases}$$

The expected cost to be minimized, in the relaxed model, is defined from  $\mathcal{R}$  into  $\mathbb{R}$  by

$$(6) \quad J(q) = \mathbb{E} \left[ g(x_T^q) + \int_0^T \int_U h(t, x_t^q, a) q_t(da) dt \right].$$

A relaxed control  $\mu$  is called optimal if it solves

$$(7) \quad J(\mu) = \inf_{q \in \mathcal{R}} J(q).$$

Existence of an optimal solution for the problem  $\{(5), (6), (7)\}$  has been solved by El Karoui, Nguyen, and Piqué [7] by using a compactification method. The relaxed optimal control in this general case is shown to be Markovian. See Bahlali, Mezerdi, and Djehiche [2] for an alternative proof for existence of an optimal relaxed control.

*Remark 5.* If we put

$$\begin{aligned} \bar{b}(t, x_t^q, q_t) &= \int_U b(t, x_t^q, a) q_t(da), \\ \bar{\sigma}(t, x_t^q, q_t) &= \int_U \sigma(t, x_t^q, a) q_t(da), \\ \bar{h}(t, x_t^q, q_t) &= \int_U h(t, x_t^q, a) q_t(da), \end{aligned}$$

then (5) becomes

$$(5') \quad \begin{cases} dx_t^q = \bar{b}(t, x_t^q, q_t) dt + \bar{\sigma}(t, x_t^q, q_t) dW_t, \\ x_T^q = \xi, \end{cases}$$

with a functional cost given by

$$J(q) = \mathbb{E} \left[ g(x_T^q) + \int_0^T \bar{h}(t, x_t^q, q_t) dt \right].$$

Hence, by introducing relaxed controls, we have replaced  $U$  by a larger space  $\mathbb{P}(U)$ . We have gained the advantage that  $\mathbb{P}(U)$  is both compact and convex. Furthermore, the new coefficients of (5) and the running cost are linear with respect to the relaxed control variable.

*Remark 6.* The coefficients  $\bar{b}$  and  $\bar{\sigma}$  (defined in the above remark) check, respectively, the same assumptions as  $b$  and  $\sigma$ . Then, under assumptions (4),  $\bar{b}$  and  $\bar{\sigma}$  are uniformly Lipschitz and with linear growth. Then, by classical results on SDEs (the Itô theorem; see Ikeda and Watanabe [15], Karatzas and Shreve [17]), for every  $q \in \mathcal{R}$ , (5') admits a unique strong solution. Consequently, for every  $q \in \mathcal{R}$ , (5) has a unique strong solution. On the other hand, it is easy to see that  $\bar{h}$  checks the same assumptions as  $h$ . Then, the functional cost  $J$  is well defined from  $\mathcal{R}$  into  $\mathbb{R}$ .

*Remark 7.* If  $q_t = \delta_{v_t}$  is an atomic measure concentrated at a single point  $v_t \in U$ , then for each  $t \in [0, T]$  we have

$$\begin{aligned}\int_U b(t, x_t^q, a) q_t(da) &= \int_U b(t, x_t^q, a) \delta_{v_t}(da) = b(t, x_t^q, v_t), \\ \int_U \sigma(t, x_t^q, a) q_t(da) &= \int_U \sigma(t, x_t^q, a) \delta_{v_t}(da) = \sigma(t, x_t^q, v_t), \\ \int_U h(t, x_t^q, a) q_t(da) &= \int_U h(t, x_t^q, a) \delta_{v_t}(da) = h(t, x_t^q, v_t).\end{aligned}$$

In this case  $x^q = x^v$ ,  $J(q) = J(v)$ , and we get a strict control problem. Thus the problem of strict controls  $\{(1), (2), (3)\}$  is a particular case of relaxed control problem  $\{(5), (6), (7)\}$ .

*Remark 8.* We note that the relaxed equation (5) can be expressed in terms of martingale measure (see El Karoui, Nguyen, and Piqué [7] and Bahlali, Mezerdi, and Djehiche [2]). If we follow this formulation, the state equation is governed by a martingale measure and is given by

$$\begin{cases} dx_t^q = \int_U b(t, x_t^q, a) q_t(da) dt + \int_U \sigma(t, x_t^q, a) M(da, dt), \\ x_0^q = \xi. \end{cases}$$

where  $M(da, dt)$  is a martingale measure with intensity the relaxed control  $q_t(da) dt$ .

In our formulation of the relaxed stochastic control problem, the state equation (5) is governed by the Brownian motion  $W$ . This formulation was used by Ma and Yong [20] for a relaxed control problem of forward-backward systems. See Ma and Yong [20] for more details.

### 3. Necessary and sufficient optimality conditions for relaxed controls.

In this section, we study the problem  $\{(5), (6), (7)\}$  and we establish necessary as well as sufficient conditions of optimality for relaxed controls.

**3.1. Preliminary results.** Since the set of relaxed controls  $\mathcal{R}$  is convex, a classical way of treating such a problem is to use the convex perturbation method. More precisely, let  $\mu$  be an optimal relaxed control and  $x_t^\mu$  the solution of (5) controlled by  $\mu$ . Then, we can define a perturbed relaxed control as follows:

$$(8) \quad \mu_t^\theta = \mu_t + \theta(q_t - \mu_t),$$

where  $\theta > 0$  is sufficiently small and  $q$  is an arbitrary element of  $\mathcal{R}$ .

Denote by  $x_t^\theta$  the solution of (5) associated with  $\mu^\theta$ .

From the optimality of  $\mu$ , the variational inequality will be derived from the fact that

$$(9) \quad 0 \leq J(\mu^\theta) - J(\mu).$$

To this end, we need the following classical lemmas.

LEMMA 9. *Under assumptions (4), we have*

$$(10) \quad \lim_{\theta \rightarrow 0} \left[ \sup_{0 \leq t \leq T} \mathbb{E} |x_t^\theta - x_t^\mu|^2 \right] = 0.$$

*Proof.* We have

$$\begin{aligned}
 x_t^\theta - x_t^\mu &= \int_0^t \left[ \int_U b(s, x_s^\theta, a) \mu_s^\theta(da) - \int_U b(s, x_s^\mu, a) \mu_s(da) \right] ds \\
 &\quad + \int_0^t \left[ \int_U \sigma(s, x_s^\theta, a) \mu_s^\theta(da) - \int_U \sigma(s, x_s^\mu, a) \mu_s(da) \right] dW_s \\
 &= \int_0^t \left[ \int_U b(s, x_s^\theta, a) \mu_s^\theta(da) - \int_U b(s, x_s^\mu, a) \mu_s^\theta(da) \right] ds \\
 &\quad + \int_0^t \left[ \int_U b(s, x_s^\mu, a) \mu_s^\theta(da) - \int_U b(s, x_s^\mu, a) \mu_s(da) \right] ds \\
 &\quad + \int_0^t \left[ \int_U \sigma(s, x_s^\theta, a) \mu_s^\theta(da) - \int_U \sigma(s, x_s^\mu, a) \mu_s^\theta(da) \right] dW_s \\
 &\quad + \int_0^t \left[ \int_U \sigma(s, x_s^\mu, a) \mu_s^\theta(da) - \int_U \sigma(s, x_s^\mu, a) \mu_s(da) \right] dW_s.
 \end{aligned}$$

By using the definition of  $\mu_t^\theta$  and taking expectation, we have

$$\begin{aligned}
 \mathbb{E} |x_t^\theta - x_t^\mu|^2 &\leq C \mathbb{E} \int_0^t \left| \int_U b(s, x_s^\theta, a) \mu_s(da) - \int_U b(s, x_s^\mu, a) \mu_s(da) \right|^2 ds \\
 &\quad + C \theta^2 \mathbb{E} \int_0^t \left| \int_U b(s, x_s^\theta, a) q_s(da) - \int_U b(s, x_s^\theta, a) \mu_s(da) \right|^2 ds \\
 &\quad + C \mathbb{E} \int_0^t \left| \int_U \sigma(s, x_s^\theta, a) \mu_s(da) - \int_U \sigma(s, x_s^\mu, a) \mu_s(da) \right|^2 ds \\
 &\quad + C \theta^2 \mathbb{E} \int_0^t \left| \int_U \sigma(s, x_s^\theta, a) q_s(da) - \int_U \sigma(s, x_s^\theta, a) \mu_s(da) \right|^2 ds.
 \end{aligned}$$

By (4),  $b$  and  $\sigma$  are uniformly Lipschitz with respect to  $x$ . Hence

$$\mathbb{E} |x_t^\theta - x_t^\mu|^2 \leq C \mathbb{E} \int_0^t |x_s^\theta - x_s^\mu|^2 ds + C \theta^2.$$

By using Gronwall's lemma and the Buckholder–Davis–Gundy inequality, we obtain the desired result.  $\square$

LEMMA 10. Let  $z_t$  be the solution of the following linear equation (called variational equation):

$$(11) \quad \begin{cases} dz_t = \int_U b_x(t, x_t^\mu, a) \mu_t(da) z_t dt + \int_U \sigma_x(t, x_t^\mu, a) \mu_t(da) z_t dW_t \\ \quad + \left[ \int_U b(t, x_t^\mu, a) \mu_t(da) - \int_U b(t, x_t^\mu, a) q_t(da) \right] dt \\ \quad + \left[ \int_U \sigma(t, x_t^\mu, a) \mu_t(da) - \int_U \sigma(t, x_t^\mu, a) q_t(da) \right] dW_t, \\ z_0 = 0. \end{cases}$$

Then, we have

$$(12) \quad \lim_{\theta \rightarrow 0} \mathbb{E} \left| \frac{x_t^\theta - x_t^\mu}{\theta} - z_t \right|^2 = 0.$$

*Proof.* For simplicity, we put

$$(13) \quad X_t = \frac{x_t^\theta - x_t^\mu}{\theta} - z_t.$$

Then, we have

$$\begin{aligned}
 X_t = & \frac{1}{\theta} \int_0^t \int_U b(s, x_s^\theta, a) \mu_s^\theta(da) - \int_U b(s, x_s^\mu, a) \mu_s^\theta(da) ds \\
 & + \frac{1}{\theta} \int_0^t \left[ \int_U b(s, x_s^\mu, a) \mu_s^\theta(da) - \int_U b(s, x_s^\mu, a) \mu_s(da) \right] ds \\
 & + \frac{1}{\theta} \int_0^t \left[ \int_U \sigma(s, x_s^\theta, a) \mu_s^\theta(da) - \int_U \sigma(s, x_s^\mu, a) \mu_s^\theta(da) \right] dW_s \\
 & + \frac{1}{\theta} \int_0^t \left[ \int_U \sigma(s, x_s^\mu, a) \mu_s^\theta(da) - \int_U \sigma(s, x_s^\mu, a) \mu_s(da) \right] dW_s \\
 & - \int_0^t \int_U b_x(s, x_s^\mu, a) \mu_s(da) z_s ds - \int_0^t \int_U \sigma_x(s, x_s^\mu, a) \mu_s(da) z_s dW_s \\
 & - \int_0^t \left[ \int_U b(s, x_s^\mu, a) \mu_s(da) - \int_U b(s, x_s^\mu, a) q_s(da) \right] ds \\
 & - \int_0^t \left[ \int_U \sigma(s, x_s^\mu, a) \mu_s(da) - \int_U \sigma(s, x_s^\mu, a) q_s(da) \right] dW_s.
 \end{aligned}$$

By using the definition of  $\mu^\theta$  and taking expectation, we get

$$\begin{aligned}
 \mathbb{E} |X_t|^2 \leq & C \mathbb{E} \int_0^t \int_0^1 \int_U |b_x(s, x_s^\mu + \lambda \theta(X_s + z_s), a) X_s|^2 \mu_s(da) d\lambda ds \\
 & + C \mathbb{E} \int_0^t \int_0^1 \int_U |\sigma_x(s, x_s^\mu + \lambda \theta(X_s + z_s), a) X_s|^2 \mu_s(da) d\lambda ds \\
 & + C \mathbb{E} |\alpha_t^\theta|^2,
 \end{aligned}$$

where  $\alpha_t^\theta$  is given by

$$\begin{aligned}
 \alpha_t^\theta = & \int_0^t \int_0^1 \int_U b_x(s, x_s^\mu + \lambda \theta(X_s + z_s), a) (x_s^\theta - x_s^\mu) q_s(da) d\lambda ds \\
 & - \int_0^t \int_0^1 \int_U b_x(s, x_s^\mu + \lambda \theta(X_s + z_s), a) (x_s^\theta - x_s^\mu) \mu_s(da) d\lambda ds \\
 & + \int_0^t \int_0^1 \int_U \sigma_x(s, x_s^\mu + \lambda \theta(X_s + z_s), a) (x_s^\theta - x_s^\mu) q_s(da) d\lambda dW_s \\
 & - \int_0^t \int_0^1 \int_U \sigma_x(s, x_s^\mu + \lambda \theta(X_s + z_s), a) (x_s^\theta - x_s^\mu) \mu_s(da) d\lambda dW_s \\
 & + \int_0^t \int_0^1 \int_U b_x(s, x_s^\mu + \lambda \theta(X_s + z_s), a) z_s \mu_s(da) d\lambda ds \\
 & + \int_0^t \int_0^1 \int_U \sigma_x(s, x_s^\mu + \lambda \theta(X_s + z_s), a) z_s \mu_s(da) d\lambda dW_s \\
 & - \int_0^t \int_U b_x(s, x_s^\mu, a) z_s \mu_s(da) ds - \int_0^t \int_U \sigma_x(s, x_s^\mu, a) z_s \mu_s(da) dW_s.
 \end{aligned}$$

Since  $b_x$  and  $\sigma_x$  are continuous and bounded, then

$$\mathbb{E} |X_t|^2 \leq C \mathbb{E} \int_0^t |X_s|^2 ds + C \mathbb{E} |\alpha_t^\theta|^2,$$

$$\lim_{\theta \rightarrow 0} \mathbb{E} |\alpha_t^\theta|^2 = 0.$$

We conclude by using Gronwall's lemma in the above inequality.  $\square$

LEMMA 11. *Let  $\mu$  be an optimal relaxed control minimizing the cost  $J$  over  $\mathcal{R}$  and  $x_t^\mu$  the associated optimal trajectory. Then, for any  $q \in \mathcal{R}$ , we have*

$$(14) \quad 0 \leq \mathbb{E} [g(x_T^\mu) z_T] + \mathbb{E} \int_0^T \int_U h_x(t, x_t^\mu, a) \mu_t(da) z_t dt \\ + \mathbb{E} \int_0^T \left[ \int_U h(t, x_t^\mu, a) q_t(da) - \int_U h(t, x_t^\mu, a) \mu_t(da) \right] dt.$$

*Proof.* By (9), we have

$$0 \leq \mathbb{E} [g(x_T^\theta) - g(x_T^\mu)] \\ + \mathbb{E} \int_0^T \int_U h(t, x_t^\theta, a) \mu_t^\theta(da) dt - \mathbb{E} \int_0^T \int_U h(t, x_t^\mu, a) \mu_t(da) dt \\ = \mathbb{E} [g(x_T^\theta) - g(x_T^\mu)] \\ + \mathbb{E} \int_0^T \int_U h(t, x_t^\theta, a) \mu_t^\theta(da) dt - \mathbb{E} \int_0^T \int_U h(t, x_t^\mu, a) \mu_t^\theta(da) dt \\ + \mathbb{E} \int_0^T \int_U h(t, x_t^\mu, a) \mu_t^\theta(da) dt - \mathbb{E} \int_0^T \int_U h(t, x_t^\mu, a) \mu_t(da) dt.$$

By using the definition of  $\mu_t^\theta$ , we have

$$0 \leq \mathbb{E} [g(x_T^\theta) - g(x_T^\mu)] \\ + \mathbb{E} \int_0^T \left[ \int_U h(t, x_t^\theta, a) \mu_t(da) - \int_U h(t, x_t^\mu, a) \mu_t(da) \right] dt \\ + \theta \mathbb{E} \int_0^T \left[ \int_U h(t, x_t^\theta, a) q_t(da) - \int_U h(t, x_t^\theta, a) \mu_t(da) \right] dt.$$

Hence,

$$0 \leq \mathbb{E} \int_0^1 g_x(x_T^\mu + \lambda \theta (X_T + z_T)) z_T d\lambda \\ + \mathbb{E} \int_0^T \int_U \int_0^1 h_x(t, x_t^\mu + \lambda \theta (X_t + z_t), a) \mu_t(da) z_t d\lambda dt \\ + \mathbb{E} \int_0^T \left[ \int_U h(t, x_t^\mu, a) q_t(da) - \int_U h(t, x_t^\mu, a) \mu_t(da) \right] dt \\ + \rho_t^\theta,$$

where  $X$  is defined in (13) and  $\rho_t^\theta$  is given by

$$\rho_t^\theta = \mathbb{E} \int_0^1 g_x(x_T^\mu + \lambda \theta (X_T + z_T)) X_T d\lambda \\ + \mathbb{E} \int_0^T \int_U \int_0^1 h_x(t, x_t^\mu + \lambda \theta (X_t + z_t), a) \mu_t(da) X_t d\lambda dt.$$

Using the Cauchy–Schwartz inequality, Lemma 10, and the fact that  $g_x$  and  $h_x$  are continuous and bounded, we get

$$\lim_{\theta \rightarrow 0} \rho_t^\theta = 0.$$

The proof is completed by letting  $\theta$  go to 0 in the above inequality.  $\square$

**3.2. Variational inequality and adjoint equation.** In this subsection, we introduce the adjoint process. With this process, we derive the variational inequality from (14). The linear terms in (11) may be treated in the following way (see Bensoussan [5]). Let  $\Phi$  be the fundamental solution of the linear equation

$$(15) \quad \begin{cases} d\Phi_t = \int_U b_x(t, x_t^\mu, a) \mu_t(da) \Phi_t dt + \int_U \sigma_x(t, x_t^\mu, a) \mu_t(da) \Phi_t dW_t, \\ \Phi_0 = I_d. \end{cases}$$

This equation is linear with bounded coefficients. Hence, it admits a unique strong solution which is invertible, and its inverse  $\Psi_t$  is the unique solution of

$$(16) \quad \begin{cases} d\Psi_t = \left[ \int_U \sigma_x(t, x_t^\mu, a) \mu_t(da) \Psi_t \int_U \sigma_x^*(t, x_t^\mu, a) \mu_t(da) \right] dt \\ \quad - \int_U b_x(t, x_t^\mu, a) \mu_t(da) \Psi_t dt - \int_U \sigma_x(t, x_t^\mu, a) \mu_t(da) \Psi_t dW_t, \\ \Psi_0 = I_d. \end{cases}$$

Moreover,  $\Phi$  and  $\Psi$  satisfy

$$(17) \quad \mathbb{E} \left[ \sup_{0 \leq t \leq T} |\Phi_t|^2 \right] + \mathbb{E} \left[ \sup_{0 \leq t \leq T} |\Psi_t|^2 \right] < \infty.$$

We introduce the following processes:

$$(18) \quad \alpha_t = \Psi_t z_t,$$

$$(19) \quad X = \Phi_T^* g_x(x_T^\mu) + \int_0^T \left[ \Phi_t^* \int_U h_x(t, x_t^\mu, a) \mu_t(da) \right] dt,$$

$$(20) \quad Y_t = \mathbb{E}[X / \mathcal{F}_t] - \int_0^t \left[ \Phi_s^* \int_U h_x(s, x_s^\mu, a) \mu_s(da) \right] ds.$$

We remark from (18), (19), (20) that

$$(21) \quad \mathbb{E}[\alpha_T Y_T] = \mathbb{E}[g_x(x_T^\mu) z_T].$$

Since  $g_x$  and  $h_x$  are bounded, then by (17),  $X$  is square integrable. Hence, the process  $(\mathbb{E}[X / \mathcal{F}_t])_{t \geq 0}$  is a square integrable martingale with respect to the natural filtration of the Brownian motion  $W$ . Then, by Itô's representation theorem we have

$$Y_t = \mathbb{E}[X] + \int_0^t Q_s dW_s - \int_0^t \int_U \Phi_s^* h_x(s, x_s^\mu, a) \mu_s(da) ds,$$

where  $Q$  is an adapted process such that  $\mathbb{E} \int_0^T |Q_s|^2 ds < \infty$ .

By applying Itô's formula to  $\alpha_t$ , then with  $\alpha_t Y_t$  and using (21), the variational inequality (14) becomes

$$(22) \quad 0 \leq \mathbb{E} \int_0^T [\mathcal{H}(t, x_t^\mu, q_t, p_t^\mu, P_t^\mu) - \mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu)] dt,$$

where the Hamiltonian  $\mathcal{H}$  is defined from  $[0, T] \times \mathbb{R}^n \times \mathbb{P}(U) \times \mathbb{R}^n \times \mathcal{M}_{n \times d}(\mathbb{R})$  into  $\mathbb{R}$  by

$$\mathcal{H}(t, x, q, p, P) = \int_U h(t, x, a) q(da) + \int_U b(t, x, a) q(da) p + \int_U \sigma(t, x, a) q(da) P,$$

$(p^\mu, P^\mu)$  is a pair of adapted processes given by

$$(23) \quad p_t^\mu = \Psi_t^* Y_t; \quad p^\mu \in \mathcal{L}^2([0, T]; \mathbb{R}^n),$$

$$(24) \quad P_t^\mu = \Psi_t^* Q_t - \int_U \sigma_x^*(t, x_t^\mu, a) \mu_t(da) p_t^\mu; \quad P^\mu \in \mathcal{L}^2([0, T]; \mathbb{R}^{n \times d}),$$

and the process  $Q$  satisfies

$$(25) \quad \int_0^t Q_s dW_s = \mathbb{E} \left[ \Phi_T^* g_x(x_T^\mu) + \int_0^T \Phi_t^* \int_U h_x(t, x_t^\mu, a) \mu_t(da) dt / \mathcal{F}_t \right] \\ - \mathbb{E} \left[ \Phi_T^* g_x(x_T^\mu) + \int_0^T \Phi_t^* \int_U h_x(t, x_t^\mu, a) \mu_t(da) dt \right].$$

The process  $p^\mu$  is called the adjoint process and from (19), (20), (23), it is given explicitly by

$$p_t^\mu = \mathbb{E} \left[ \Psi_t^* \Phi_T^* g_x(x_T^\mu) + \Psi_t^* \int_t^T \Phi_s^* \int_U h_x(s, x_s^\mu, a) \mu_s(da) ds / \mathcal{F}_t \right].$$

By applying Itô's formula to the adjoint processes  $p^\mu$  in (23), we obtain the adjoint equation, which is a linear backward stochastic differential equation, given by

$$(26) \quad \begin{cases} -dp_t^\mu = \mathcal{H}_x(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) dt - P_t^\mu dW_t, \\ p_T^\mu = g_x(x_T^\mu). \end{cases}$$

**3.3. Necessary optimality conditions for relaxed controls.** Starting from the variational inequality (22), we can now state the necessary optimality conditions, for the relaxed control problem  $\{(5), (6), (7)\}$ , in the global form.

**THEOREM 12** (necessary optimality conditions for relaxed controls in global form). *Let  $\mu$  be an optimal relaxed control minimizing the cost  $J$  over  $\mathcal{R}$  and let  $x^\mu$  denote the corresponding optimal trajectory. Then, there exists a unique pair of adapted processes*

$$(p^\mu, P^\mu) \in \mathcal{L}^2([0, T]; \mathbb{R}^n) \times \mathcal{L}^2([0, T]; \mathbb{R}^{n \times d}),$$

which are solution of the backward stochastic differential equations (26) such that

$$(27) \quad \mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) = \inf_{q_t \in \mathbb{P}(U)} \mathcal{H}(t, x_t^\mu, q_t, p_t^\mu, P_t^\mu); \quad a.e., \quad a.s.$$

*Proof.* The result follows immediately from (22).  $\square$

**Remark 13.** Bahlali, Mezerdi, and Djehiche [2] established necessary optimality conditions for relaxed controls of the second-order with two adjoint processes. The result of the above theorem improves that of [2], in the sense where we consider the same relaxed control problem, in which the control variable enters both the drift and the diffusion coefficients, and we establish necessary optimality conditions of the first-order with only one adjoint process.

**3.4. Sufficient optimality conditions for relaxed controls.** In this subsection, we study when the necessary optimality conditions (27) become sufficient. We recall assumptions (4) and the adjoint equation (26). For any  $q \in \mathcal{R}$ , we denote by  $x^q$  the solution of (5) controlled by  $q$ .

**THEOREM 14** (sufficient optimality conditions for relaxed controls). *If we assume that the functions  $g$  and  $x \mapsto \mathcal{H}(t, x, q, p, P)$  are convex, then  $\mu$  is an optimal solution of the problem  $\{(5), (6), (7)\}$  if it satisfies (27).*

*Proof.* We know that the set of relaxed controls  $\mathcal{R}$  is convex and the Hamiltonian  $\mathcal{H}$  is linear in  $q$ . Let  $\mu$  be an arbitrary element of  $\mathcal{R}$  (candidate to be optimal). For any  $q \in \mathcal{R}$ , we have

$$\begin{aligned} J(\mu) - J(q) &= \mathbb{E}[g(x_T^\mu) - g(x_T^q)] \\ &\quad + \mathbb{E} \int_0^T \left[ \int_U h(t, x_t^\mu, a) \mu_t(da) - \int_U h(t, x_t^q, a) q_t(da) \right] dt. \end{aligned}$$

Since  $g$  is convex, we get

$$g(x_T^q) - g(x_T^\mu) \geq g_x(x_T^\mu)(x_T^q - x_T^\mu).$$

Thus,

$$g(x_T^\mu) - g(x_T^q) \leq g_x(x_T^\mu)(x_T^\mu - x_T^q).$$

Hence,

$$\begin{aligned} J(\mu) - J(q) &\leq \mathbb{E}[g_x(x_T^\mu)(x_T^\mu - x_T^q)] \\ &\quad + \mathbb{E} \int_0^T \left[ \int_U h(t, x_t^\mu, a) \mu_t(da) - \int_U h(t, x_t^q, a) q_t(da) \right] dt. \end{aligned}$$

We remark that  $p_T^\mu = g_x(x_T^\mu)$ ; then we have

$$\begin{aligned} J(\mu) - J(q) &\leq \mathbb{E}[p_T^\mu(x_T^\mu - x_T^q)] \\ &\quad + \mathbb{E} \int_0^T \left[ \int_U h(t, x_t^\mu, a) \mu_t(da) - \int_U h(t, x_t^q, a) q_t(da) \right] dt. \end{aligned}$$

Applying Itô's formula to  $p_t^\mu(x_t^\mu - x_t^q)$  and taking expectation, we obtain

$$\begin{aligned} (28) \quad J(\mu) - J(q) &\leq \mathbb{E} \int_0^T [\mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) - \mathcal{H}(t, x_t^q, q_t, p_t^\mu, P_t^\mu)] dt \\ &\quad - \mathbb{E} \int_0^T \mathcal{H}_x(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu)(x_t^\mu - x_t^q) dt. \end{aligned}$$

Since  $\mathcal{H}$  is convex in  $x$  and linear in  $\mu$ , then by using the Clarke generalized gradient of  $\mathcal{H}$  evaluated at  $(x_t, \mu_t)$  and the necessary optimality conditions (27), it follows by [25, Lemmas 2.2 and 2.3] that

$$\mathcal{H}(t, x_t^q, q_t, p_t^\mu, P_t^\mu) - \mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) \geq \mathcal{H}_x(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu)(x_t^q - x_t^\mu),$$

or equivalently

$$0 \geq \mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) - \mathcal{H}(t, x_t^q, q_t, p_t^\mu, P_t^\mu) - \mathcal{H}_x(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu)(x_t^\mu - x_t^q).$$

By the above inequality and (28), we have

$$J(\mu) - J(q) \leq 0.$$

The theorem is then proved.  $\square$

**4. Necessary and sufficient optimality conditions for strict controls.** In this section, we study the strict control problem  $\{(1), (2), (3)\}$ , and from the results of section 3, we derive the optimality conditions for strict controls. To this end, consider the following subset of  $\mathcal{R}$ :

$$(29) \quad \delta(\mathcal{U}) = \{q \in \mathcal{R} \mid q = \delta_v; \ v \in \mathcal{U}\}.$$

The set  $\delta(\mathcal{U})$  is the collection of all relaxed controls in the form of Dirac measure charging a strict control.

Denote by  $\delta(U)$  the action set of all relaxed controls in  $\delta(\mathcal{U})$ .

If  $q \in \delta(\mathcal{U})$ , then  $q = \delta_v$  with  $v \in \mathcal{U}$ . In this case we have for each  $t$ ,  $q_t \in \delta(U)$  and  $q_t = \delta_{v_t}$ .

*Remark 15.* The necessary and sufficient optimality conditions for relaxed controls, respectively Theorems 12 and 14, hold if we replace  $\mathcal{R}$  by  $\delta(\mathcal{U})$  and  $\mathbb{P}(U)$  by  $\delta(U)$ .

**LEMMA 16.** *The relaxed control  $\mu = \delta_u$  minimizes  $J$  over  $\delta(\mathcal{U})$  if and only if the strict control  $u$  minimizes  $J$  over  $\mathcal{U}$ .*

*Proof.* Let  $\mu = \delta_u$  be an optimal relaxed control minimizing the cost  $J$  over  $\delta(\mathcal{U})$ ; we then have

$$(30) \quad J(\mu) \leq J(q) \quad \forall q \in \delta(\mathcal{U}).$$

Since  $q \in \delta(\mathcal{U})$ , then there exists  $v \in \mathcal{U}$  such that  $q = \delta_v$ . It is easy to see that

$$(31) \quad \begin{cases} x^\mu = x^u, \\ x^q = x^v, \\ J(\mu) = J(u), \\ J(q) = J(v). \end{cases}$$

By (30), we get

$$J(u) \leq J(v) \quad \forall v \in \mathcal{U}.$$

Conversely, let  $u$  be a strict control minimizing the cost  $J$  over  $\mathcal{U}$ . Then

$$J(u) \leq J(v) \quad \forall v \in \mathcal{U}.$$

Since the controls  $u, v \in \mathcal{U}$ , then there exist  $\mu, q \in \delta(\mathcal{U})$  such that

$$\mu = \delta_u, \quad q = \delta_v.$$

This implies that relations (31) hold. Consequently, we get

$$J(\mu) \leq J(q) \quad \forall q \in \delta(\mathcal{U}).$$

The proof is completed.  $\square$

*Remark 17.* (1) The relaxed optimal control  $\mu$  exists, but it is not necessarily an element of  $\delta(\mathcal{U})$ . A strict optimal control  $u$  does not necessarily exist.

(2) If the relaxed optimal control  $\mu \in \delta(\mathcal{U})$ , then we get existence of a strict optimal control. In this case, if we reduce the class of relaxed controls  $\mathcal{R}$  to the set  $\delta(\mathcal{U})$ , then the relaxed control problem simply becomes a strict control problem in which an optimal solution exists.

(3) We know that existence of an optimal solution of strict control problem is ensured by the Filippov condition. It is interesting to see that if we have the Filippov condition, then the relaxed optimal control is an element of  $\delta(\mathcal{U})$ .

**4.1. Necessary optimality conditions for strict controls.** Define the Hamiltonian in the strict case from  $[0, T] \times \mathbb{R}^n \times U \times \mathbb{R}^n \times \mathcal{M}_{n \times d}(\mathbb{R})$  into  $\mathbb{R}$  by

$$H(t, x, v, p, P) = h(t, x, v) + b(t, x, v)p + \sigma(t, x, v)P.$$

**THEOREM 18** (necessary optimality conditions for strict controls in global form). *Suppose that  $u$  is an optimal strict control minimizing the cost  $J$  over  $\mathcal{U}$  and  $x^u$  denotes the solution of (1) controlled by  $u$ . Then, there exists a unique pair of adapted processes*

$$(p^u, P^u) \in \mathcal{L}^2([0, T]; \mathbb{R}^n) \times \mathcal{L}^2([0, T]; \mathbb{R}^{n \times d}),$$

which is a solution of the following backward stochastic differential equation:

$$(32) \quad \begin{cases} -dp_t^u = H_x(t, x_t^u, u_t, p_t^u, P_t^u) dt - P_t^u dW_t, \\ p_T^u = g_x(x_T^u), \end{cases}$$

such that

$$(33) \quad H(t, x_t^u, u_t, p_t^u, P_t^u) = \inf_{v_t \in U} H(t, x_t^u, v_t, p_t^u, P_t^u); \quad a.e., \quad a.s.$$

*Proof.* Let  $u$  be an optimal solution of the strict control problem  $\{(1), (2), (3)\}$  and  $v$  be an arbitrary element of  $\mathcal{U}$ . Then, there exist  $\mu, q \in \delta(\mathcal{U})$  such that

$$(34) \quad \mu = \delta_u, \quad q = \delta_v.$$

Since  $u$  minimizes the cost  $J$  over  $\mathcal{U}$ , then by Lemma 16,  $\mu$  minimizes  $J$  over  $\delta(\mathcal{U})$ . Hence, by the necessary optimality conditions for relaxed controls (Theorem 12), there exists a unique pair of adapted processes  $(p_t^\mu, P_t^\mu)$ , which is a solution of (26) such that

$$\mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) = \inf_{q_t \in \delta(U)} \mathcal{H}(t, x_t^\mu, q_t, p_t^\mu, P_t^\mu); \quad a.e., \quad a.s.$$

By (34) we can easily see that

$$\begin{aligned} x^\mu &= x^u, \\ \mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) &= H(t, x_t^u, u_t, p_t^u, P_t^u), \\ \mathcal{H}(t, x_t^\mu, q_t, p_t^\mu, P_t^\mu) &= H(t, x_t^u, v_t, p_t^u, P_t^u), \end{aligned}$$

where the pair  $(p^u, P^u)$  is the unique solution of (32). The theorem is then proved.  $\square$

*Remark 19.* Peng [23] established necessary optimality conditions for strict controls of the second-order with two adjoint processes. The result of the above theorem improves that of Peng, in the sense where we consider the same strict control problem, with nonconvex control domain and a general state equation in which the control variable enters both the drift and the diffusion coefficients, and we establish necessary optimality conditions of the first-order with only one adjoint process.

**4.2. Sufficient optimality conditions for strict controls.** We recall assumptions (4) and the adjoint equation (32).

**THEOREM 20** (sufficient optimality conditions for strict controls). *If we assume that  $g$  and the map  $x \mapsto H(t, x, v, p, P)$  are convex, then  $u$  is an optimal solution of the problem  $\{(1), (2), (3)\}$ , if it satisfies (33).*

*Proof.* Let  $u$  be a strict control (candidate to be optimal) such that the necessary optimality conditions for strict controls (33) hold. Then, we have

$$H(t, x_t^u, u_t, p_t^u, P_t^u) = \inf_{v_t \in U} H(t, x_t^u, v_t, p_t^u, P_t^u); \quad a.e., \quad a.s.$$

The controls  $u, v$  are elements of  $\mathcal{U}$ ; then there exist  $\mu, q \in \delta(\mathcal{U})$  such that

$$\mu = \delta_u, \quad q = \delta_v.$$

This implies that

$$\begin{aligned} x^\mu &= x^u, \\ \mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) &= H(t, x_t^u, u_t, p_t^u, P_t^u), \\ \mathcal{H}(t, x_t^\mu, q_t, p_t^\mu, P_t^\mu) &= H(t, x_t^u, v_t, p_t^u, P_t^u). \end{aligned}$$

By the above equalities and the necessary optimality conditions for strict controls (33), we deduce that

$$\mathcal{H}(t, x_t^\mu, \mu_t, p_t^\mu, P_t^\mu) = \inf_{q_t \in \delta(U)} \mathcal{H}(t, x_t^\mu, q_t, p_t^\mu, P_t^\mu); \quad a.e., \quad a.s.$$

Since  $H$  is convex in  $x$ , it is easy to see that  $\mathcal{H}$  is convex in  $x$ , and since  $g$  is convex, then from the sufficient optimality conditions for relaxed controls (Theorem 14),  $\mu$  minimizes the cost  $J$  over  $\delta(\mathcal{U})$ . By Lemma 16, we deduce that  $u$  minimizes the cost  $J$  over  $\mathcal{U}$ . The theorem is then proved.  $\square$

*Remark 21.* The sufficient optimality conditions for strict controls are proved without assuming either the convexity of  $U$  or that of  $H$  in  $v$ .

**Acknowledgment.** The author thanks the referee who offered many useful remarks and suggestions that improved the first version of this paper.

## A PROXIMAL-PROJECTION METHOD FOR FINDING ZEROS OF SET-VALUED OPERATORS\*

DAN BUTNARIU<sup>†</sup> AND GÁBOR KASSAY<sup>‡</sup>

**Abstract.** In this paper we study the convergence of an iterative algorithm for finding zeros with constraints for not necessarily monotone set-valued operators in a reflexive Banach space. This algorithm, which we call the proximal-projection method is, essentially, a fixed point procedure, and our convergence results are based on new generalizations of the Browder's demiclosedness principle. We show how the proximal-projection method can be applied for solving ill-posed variational inequalities and convex optimization problems with data given or computable by approximations only. The convergence properties of the proximal-projection method we establish also allow us to prove that the proximal point method (with Bregman distances), whose convergence was known to occur for maximal monotone operators, still converges when the operator involved in it is monotone with sequentially weakly closed graph.

**Key words.** Bregman distance, Bregman projection,  $D_f$ -antiresolvent,  $D_f$ -nonexpansivity pole,  $D_f$ -inverse strongly monotone operator,  $D_f$ -firm operator,  $D_f$ -nonexpansive operator,  $D_f$ -resolvent, firmly nonexpansive operator, Legendre function, maximal monotone operator, monotone operator, nonexpansive operator, proximal mapping, proximal point method, proximal projection method, relative projection, sequentially consistent function, projected subgradient method, Tikhonov–Browder regularization, strongly monotone operator, uniformly convex function, variational inequality

**DOI.** 10.1137/070682071

**1. Introduction.** In what follows,  $X$  denotes a real reflexive Banach space with norm  $\|\cdot\|$ , and  $X^*$  denotes the (topological) dual of  $X$  with the dual norm  $\|\cdot\|_*$ . Let  $f : X \rightarrow (-\infty, +\infty]$  be a proper, lower semicontinuous convex function with domain  $\text{dom } f$ . Then, the Fenchel conjugate  $f^* : X^* \rightarrow (-\infty, +\infty]$  is also a proper lower semicontinuous convex function and  $f^{**} := (f^*)^* = f$ . We assume that  $f$  is a Legendre function in the sense given to this term in [20, Definition 5.2]; that is,  $f$  is essentially smooth and essentially strictly convex. Then, according to [20, Theorem 5.4], the function  $f^*$  is a Legendre function too. Moreover, by [20, Theorems 5.6 and 5.10], both functions  $f$  and  $f^*$  have domains with nonempty interior, are (Gâteaux) differentiable on the interiors of their respective domains,

$$(1.1) \quad \text{ran } \nabla f = \text{dom } \nabla f^* = \text{int dom } f^* = \text{dom } \partial f^*,$$

$$(1.2) \quad \text{ran } \nabla f^* = \text{dom } \nabla f = \text{int dom } f = \text{dom } \partial f,$$

and

$$(1.3) \quad \nabla f = (\nabla f^*)^{-1}.$$

With the function  $f$  we associate the function  $W_f : X^* \times X \rightarrow (-\infty, +\infty]$  defined by

$$(1.4) \quad W_f(\xi, x) = f(x) - \langle \xi, x \rangle + f^*(\xi).$$

By the Young–Fenchel inequality the function  $W_f$  is nonnegative and  $\text{dom } W_f = (\text{dom } f^*) \times (\text{dom } f)$ . It is known (see [1], [2], [19], [38] and see also section 2 below) that, for any nonempty closed convex set  $E$  contained in  $X$  such that  $E \cap \text{int dom } f \neq \emptyset$ , the function  $\text{Proj}_E^f : \text{int dom } f^* \rightarrow X$ , given by

$$(1.5) \quad \text{Proj}_E^f \xi = \arg \min \{W_f(\xi, x) : x \in E\},$$

is well defined and its range is contained in  $E \cap \text{int dom } f$ . In fact, this function is a particular proximal projection, in the sense given to this term in [21], and in [38] is called the projection onto  $E$  relative to  $f$  because, in the particular case when  $X$  is a Hilbert space and  $f(x) = \frac{1}{2} \|x\|^2$ , the vector  $\text{Proj}_E^f \xi$  coincides with the usual (metric) projection of  $\xi$  onto  $E$ .

In this paper we are interested in the following problem.

**PROBLEM 1.1.** *Given an operator  $A : X \rightarrow 2^{X^*}$  and a nonempty closed subset  $C$  of  $X$  such that*

$$(1.6) \quad \emptyset \neq C \cap \text{dom } A \subseteq \text{int dom } f,$$

*find  $x \in C$  such that  $0^* \in Ax$ , where  $0^*$  denotes the null vector in  $X^*$ .*

Our purpose is to discover sufficient conditions for the following iterative procedure, which we call *the proximal-projection method*:

$$(1.7) \quad \begin{aligned} x^0 &\in C_0 \cap \text{dom } A \cap \text{int dom } f \quad \text{and} \\ x^{k+1} &\in \text{Proj}_{C_{k+1} \cap \text{dom } A}^f (\nabla f(x^k) - Ax^k) \quad \forall k \in \mathbb{N}, \end{aligned}$$

to generate approximations of solutions to Problem 1.1 when  $\{C_k\}_{k \in \mathbb{N}}$  is a sequence of closed convex subsets of  $X$  approximating weakly (see Definition 4.5) the set  $C$  under the following conditions of compatibility of  $f$  and  $C_k$  with the data of Problem 1.1.

**ASSUMPTION 1.2.** *For each  $k \in \mathbb{N}$ , the set  $C_k \cap \text{dom } A$  is convex, closed, and satisfies*

$$(1.8) \quad C \subseteq C_k \quad \text{and} \quad (\nabla f - A)(C_k) \subseteq \text{int dom } f^*.$$

In this paper (1.6) and Assumption 1.2 are standing assumptions, even if not explicitly mentioned, whenever we refer to Problem 1.1 or to the proximal-projection method. In view of (1.6) and (1.8) the sets  $C_k \cap \text{dom } A \cap \text{int dom } f$  are necessarily nonempty and, consequently,  $(\nabla f - A)(C_k)$  is nonempty too. This fact, Assumption 1.2, and Lemma 2.1, which ensures that

$$\text{dom Proj}_{C_k \cap \text{dom } A}^f = \text{int dom } f^* \quad \text{and} \quad \text{ran Proj}_{C_k \cap \text{dom } A}^f \subseteq C_k \cap \text{dom } A \cap \text{int dom } f,$$

taken together guarantee that the procedure of generating sequences in (1.7) is well defined.

The proximal-projection method described above is a natural generalization of Landweber's method of finding zeros of linear operators [53], of Shor's [75] (see also [76]) and Ermoliev's [46] "gradient descent" methods for finding unconstrained minima of convex functions, and of Polyak's "projected-subgradient" method for finding constrained minima of convex functions [66]. These methods inspired the construction of a plethora of algorithms for finding zeros of various operators as well as for other purposes. Among them are the algorithms presented in [1], [3], [4], [6], [7], [8], [9], [10], [11], [12], [13], [14], [17], [21], [30], [37], [38], [67], [74] which, in turn, inspired this research. The main formal differences between the proximal-projection method (1.7) and its classical counterparts developed in the 1950s and 1960s consist of the use of proximal projections, instead of metric projections, and of projecting not on the set  $C$  involved in Problem 1.1 but on some convex approximations  $C_k$  of the set  $C$ . The use of proximal projections instead of metric projections is mostly due to the fact that metric projections in Banach spaces which are not Hilbertian do not have many of those properties (like single valuedness and nonexpansivity) which make them so useful in a Hilbert space setting for establishing convergence of algorithms based on them. As far as we know, the idea of using proximal projections instead of metric projections in projected-subgradient type algorithms goes back to Alber's works [1], [2].

As we make clear in section 3.3, there is an intimate connection between the proximal-projection method and the well-known proximal point method with Bregman distances—see (3.23). The proximal point method with Bregman distances considered in this paper is itself a generalization of the classical proximal point algorithm developed in the 1950s by Krasnoselskii [51]; see also Moreau [59], [60], [61], Yosida [78], Martinet [57], [58], and Rockafellar [70], [71], among others (see [54] for a survey of the literature concerning the classical proximal point method). It emerged from the works of Erlander [45], Eriksson [44], Eggermont [43], and Eckstein [42], who studied various instances of the algorithm in  $\mathbb{R}^n$ . Its convergence analysis in Banach spaces which are not necessarily Hilbertian was initiated in [31], [32], and [50] (see [33] and [31] for related references on this topic). Lemma 3.8 shows that, in our setting, the proximal point method with Bregman distances is a particular instance of the proximal-projection method.

Computing projections, metric or proximal, onto a closed convex set with complicated geometry is, in itself, a challenging problem. It requires (see (1.5)) solving convex nonlinear programming problems with convex constraints. Specific techniques for finding proximal projections are presented in [5], [22], and [34]. It is obvious from these works that it is much easier to find proximal projections onto sets with simple geometry such as, for instance, hyperplanes, half spaces, or finite intersections of such sets. These facts naturally led to the question of whether it is possible, in the process of computing iterates of metric or proximal projections algorithms, to replace the constraint set  $C$  by some approximations  $C_k$  whose geometry is simple enough to allow relatively easy calculation of the required metric or proximal projections at each iterative step  $k$ . That this approach is sound is quite clear from the works of Mosco [62], its subsequent developments due to Attouch [15], Aubin and Frankowska [16], Bonnans and Shapiro [25], Dontchev and Zolezzi [41], and from the studies of Liskovets [55], [56]. Its main difficulty in the case of the proximal-projection method is that the approximations  $C_k$  one uses should converge to  $C$  in a manner that ensures stable convergence of the algorithm to solutions of the problem. For some variants of the proximal-projection method, types of convergence of the sets  $C_k$  to  $C$  which

are sufficiently good for this purpose are presented in [4], [7], [9], [12], [13]. They are mostly relaxed forms of Hausdorff metric convergence. It was shown in [8] that, in some circumstances, fast Mosco convergence of the sets  $C_k$  to  $C$  (see [8, Definition 2.1]), a form of convergence significantly less demanding than Hausdorff convergence, is sufficient to make the proximal-projection method (1.7) applied to variational inequalities converge. As we show below, these convergence requirements in the case of the proximal-projection method (1.7) can be further weakened. In fact, in our convergence theorems for the proximal-projection method we require only weak Mosco convergence of the sets  $C_k$  to  $C$  (see Definition 4.5(a)), and this is significantly less demanding than Hausdorff metric or fast Mosco convergence.

The purpose of this work is to find general conditions which guarantee that the proximal-projection method converges weakly or strongly to solutions of Problem 1.1. Observe that there is no apparent connection between the data of Problem 1.1 and the function  $f$  involved in the definition of the proximal-projection method. Our main question is how the function  $f$  should be chosen in order to ensure (weak or strong) convergence of the proximal-projection method to solutions of Problem 1.1 without excessively conditioning the problem data. The function  $f$  is a parameter of the proximal-projection method whose appropriate choice, as we show below, can make the procedure converge to solutions of Problem 1.1 even if the problem data are quite “bad” in the sense that they do not have properties that are usually difficult to verify in practice, such as maximal monotonicity, strict monotonicity, various forms of nonexpansivity, continuity, or closedness properties of some kind or another. Theorems 4.7 and 5.2 are our responses to the question posed above.

Theorem 4.7 shows that for guaranteeing that the proximal-projection method produces weak approximations of solutions for Problem 1.1, it is sufficient to choose a function  $f$  which, besides the conditions (1.6) and (1.8) which are meant to make the procedure consistent with the problem data, should satisfy some requirements, the majority of which are common features of the powers of the norm  $\|\cdot\|^p$  with  $p > 1$  in uniformly convex and smooth Banach spaces. The only somewhat outstanding condition we require for  $f$  is that the operator  $A$  involved in the problem be  $D_f$ -inverse strongly monotone on  $C$  or, if the set  $C$  is approximated by sets  $C_k$ , that  $D_f$ -inverse strong monotonicity of  $A$  should occur on the union of those sets.  $D_f$ -inverse strong monotonicity, a notion introduced in this paper (see Definition 3.3), is a generalization of the notion of firm nonexpansivity for operators in a Hilbert space (see (4.34)). Although in Hilbert spaces provided with the function  $f = \frac{1}{2} \|\cdot\|^2$  this notion coincides with the notion of firm nonexpansivity and, also, with the notion of  $D_f$ -firmness introduced in [21] (see Definition 3.4 below), outside this particular setting the notions of  $D_f$ -inverse strong monotonicity and  $D_f$ -firmness complement each other (cf. section 3.2). In section 4.3 we present several corollaries of Theorem 4.7 and examples which clearly show that fitting a function  $f$  to the specific data of Problem 1.1 may come naturally in many situations. If  $X$  is a Hilbert space and  $A$  is a firmly nonexpansive operator, then the natural choice is  $f = \frac{1}{2} \|\cdot\|^2$  (see Corollary 4.8). In this case the convergence of the proximal-projection method happens to be strong if the set of solutions of the problem has nonempty interior. If in Problem 1.1 we have  $C = X$ , then the problem is equivalent to that of finding a zero for the operator  $\nabla f - \nabla f \circ A_f$ , where  $A_f$  is the  $D_f$ -resolvent of  $A$  (a notion introduced in [21]—see also (3.19)), and application of the proximal-projection method with  $C_k = X$  to  $\nabla f - \nabla f \circ A_f$  is no more and no less than the proximal point method with Bregman distances mentioned above. The operator  $\nabla f - \nabla f \circ A_f$  is  $D_f$ -inverse strongly

monotone whenever the operator  $A$  is monotone (cf. Lemma 3.7). This leads us to the application of Theorem 4.7 to the operator  $\nabla f - \nabla f \circ A_f$ , which is Corollary 4.9. It shows that the proximal point algorithm with Bregman distances converges subsequentially weakly (and when  $A$  has a single zero, sequentially weakly) for a large class of functions  $f$  whenever  $A$  is monotone and provided that its graph is sequentially weakly closed (as happens, for instance, when graph  $A$  is convex and closed in  $X \times X^*$ ). It seems to us that this is the first time when weak convergence of the proximal point algorithm with Bregman distances is proved without requiring maximal monotonicity of  $A$ . The proximal-projection method is also a tool for solving monotone variational inequalities via their Tikhonov–Browder regularization. This is shown by Corollary 4.10, another consequence of Theorem 4.7. Corollary 4.10 also asks for the monotone operator  $B : X \rightarrow 2^{X^*}$  involved in the variational inequality to be such that  $\nabla f - \nabla f \circ \text{Proj}_C^f \circ [(1 - \alpha)\nabla f - B]$  is  $D_f$ -inverse strongly monotone (or, equivalently, such that  $\text{Proj}_C^f \circ [(1 - \alpha)\nabla f - B]$  is  $D_f$ -firm). This happens in many situations of practical interest. Several such situations are described in Examples 4.2 and 4.11.

A careful analysis of the proof of Theorem 4.7 reveals the fact that the proximal-projection method (1.7) is a procedure of approximating fixed points for the operator  $\text{Proj}_C^f \circ (\nabla f - A)$  by iterating the operator. Among the customary tools of proving convergence of such algorithms are Browder’s demiclosedness principle [29, Theorem 8.4] and, related to it, Opial’s convergence results for orbits of asymptotically regular operators [63, Theorems 1 and 2] and their generalizations. Our Theorem 4.7 is based on Proposition 4.4, a generalization of Browder’s demiclosedness principle, which works in reflexive Banach spaces and which is of interest by itself. If the Banach space  $X$  has finite dimension, Proposition 4.4 can be substantially improved—see Proposition 5.1. Thus, in spaces with finite dimension we can also improve Theorem 4.7 by dropping some of the requirements made on the problem data. This is, in fact, our Theorem 5.2, which guarantees convergence of the proximal-projection method with less demanding conditions than closedness of the graph of  $A$ . Accordingly, in finite-dimensional spaces the conclusions of Corollaries 4.9 and 4.10 can be reached at lesser cost for the operators involved in them, as shown by Corollaries 5.3 and 5.4, respectively.

This paper continues and develops a series of concepts, methods, and techniques initiated in [1], [19], [21], [33], [38], and [50]. In sections 2 and 3 we present in a unified approach the notions, notations, and preliminary results on which our convergence analysis of the proximal-projection method is based. It should be noted that, in section 2, some of the notions and results are presented in a more general setting than strictly needed in the subsequent parts of the material. This is done so because we hope to use the framework created in the current paper as a base for a forthcoming study of methods for solving nonclassical variational inequalities which are only tangentially approached here.

**2. Proximal mappings, relative projections, and variational inequalities.** In this section we present the notions, notations, and results concerning proximal projections and variational inequalities which are essential for the convergence analysis of the proximal-projection method done in what follows.

**2.1. Proximal mappings and relative projections.** Throughout this paper we denote by  $\mathcal{F}_f$  the set of proper, lower semicontinuous, convex functions  $\varphi : X \rightarrow$

$(-\infty, +\infty]$  which satisfy the conditions

$$(2.1) \quad \text{dom } \varphi \cap \text{int dom } f \neq \emptyset$$

and

$$(2.2) \quad \varphi_f := \inf \{ \varphi(x) : x \in \text{dom } \varphi \cap \text{dom } f \} > -\infty.$$

With every  $\varphi \in \mathcal{F}_f$  we associate the function  $\text{Env}_\varphi^f : X^* \rightarrow (-\infty, +\infty]$  given by

$$(2.3) \quad \text{Env}_\varphi^f(\xi) = \inf \{ \varphi(x) + W_f(\xi, x) : x \in X \}.$$

This is a natural generalization of the notion of the *Moreau envelope function* (see [72, Definition 1.22]). By (2.1) and (2.2) it results that the function  $\text{Env}_\varphi^f$  is proper and  $\text{dom } \text{Env}_\varphi^f = \text{dom } f^*$ . Another generalization of the *Moreau envelope function* is the function  $\text{env}_\varphi^f := \text{Env}_\varphi^f \circ \nabla f$  introduced and studied in [23]. Using Fenchel's duality theorem, it is easy to deduce that if  $\varphi \in \mathcal{F}_f$ , then

$$\text{Env}_\varphi^f(\xi) = f^*(\xi) - (\varphi + f)^*(\xi) = f^*(\xi) - (\varphi^* \square f^*)(\xi),$$

where  $\varphi^* \square f^*$  denotes the infimal convolution of  $\varphi^*$  and  $f^*$ .

The next result shows a way of generalizing the notion of Moreau proximal mapping (in the sense given to this term in [72]) whose study was initiated in [59], [60], [61] and further developed in [70], [71]. As we will make clear below, the generalization we propose here slightly differs from the notion of  $D_f$ -proximal mapping introduced and studied in [21]. In fact, most of the next lemma can also be deduced from [21, Propositions 3.22 and 3.23] due to the equality (2.7) established below. We prefer to present it here with a direct proof for the sake of completeness.

**LEMMA 2.1.** *Suppose that  $\varphi \in \mathcal{F}_f$ . For any  $\xi \in \text{int dom } f^*$  there exists a unique global minimizer, denoted  $\text{Prox}_\varphi^f(\xi)$ , of the function  $\varphi(\cdot) + W_f(\xi, \cdot)$ . The vector  $\text{Prox}_\varphi^f(\xi)$  is contained in  $\text{dom } \partial \varphi \cap \text{int dom } f$  and we have*

$$(2.4) \quad \text{Prox}_\varphi^f(\xi) = [\partial(\varphi + f)]^{-1}(\xi) = (\partial \varphi + \nabla f)^{-1}(\xi).$$

*Proof.* Let  $\xi \in \text{int dom } f^*$ . Then  $\text{Env}_\varphi^f(\xi)$  is finite and the function  $f - \langle \xi, \cdot \rangle$  is coercive (see [68, Theorem 7A] or [20, Fact 3.1]); that is, its sublevel sets

$$\text{lev}_{\leq}^f(\alpha) := \{x \in X : f(x) \leq \alpha\}$$

are bounded for all  $\alpha \in \mathbb{R}$ . Consequently, the function  $W_f(\xi, \cdot)$  is coercive too. Let  $\{x^k\}_{k \in \mathbb{N}}$  be a sequence contained in  $\text{dom } \varphi \cap \text{dom } f$  and such that

$$\lim_{k \rightarrow \infty} [\varphi(x^k) + W_f(\xi, x^k)] = \text{Env}_\varphi^f(\xi).$$

The sequence  $\{\varphi(x^k) + W_f(\xi, x^k)\}_{k \in \mathbb{N}}$  being convergent is also bounded. So, for some real number  $M > 0$  we have

$$W_f(\xi, x^k) \leq M - \varphi(x^k) \leq M - \varphi_f,$$

showing that the sequence  $\{x^k\}_{k \in \mathbb{N}}$  is contained in the sublevel set  $\text{lev}_{\leq}^\psi(M - \varphi_f)$  of the function  $\psi := W_f(\xi, \cdot)$ . By the coercivity of  $W_f(\xi, \cdot)$  it follows that the sequence

$\{x^k\}_{k \in \mathbb{N}}$  is bounded. Since the space  $X$  is reflexive, it results that  $\{x^k\}_{k \in \mathbb{N}}$  has a weakly convergent subsequence  $\{x^{i_k}\}_{k \in \mathbb{N}}$ . Let  $\bar{x} = \text{w-lim}_{k \rightarrow \infty} x^{i_k}$ . The functions  $f$  and  $\varphi$  are sequentially weakly lower semicontinuous because they are lower semicontinuous and convex. Hence,  $\varphi(\cdot) + W_f(\xi, \cdot)$  is also sequentially weakly lower semicontinuous and, thus, we have

$$\varphi(\bar{x}) + W_f(\xi, \bar{x}) \leq \liminf_{k \rightarrow \infty} [\varphi(x^{i_k}) + W_f(\xi, x^{i_k})] = \text{Env}_\varphi^f(\xi) < +\infty.$$

This implies that  $\bar{x} \in \text{dom } \varphi \cap \text{dom } f$  and that  $\bar{x}$  is a minimizer of  $\varphi(\cdot) + W_f(\xi, \cdot)$ .

Suppose that  $y$  is any minimizer of  $\varphi(\cdot) + W_f(\xi, \cdot)$ . Then  $y$  is also a minimizer of  $\varphi + f - \xi$ . Therefore, we have that  $0 \in \partial(\varphi + f - \xi)(y)$ , that is,  $\xi \in \partial(\varphi + f)(y)$ . The function  $f$  is continuous on  $\text{int dom } f$  because function  $f$  is convex and lower semicontinuous. This and (2.1) imply (see [69]) that  $\partial(\varphi + f)(y) = \partial\varphi(y) + \nabla f(y)$ . Hence,

$$(2.5) \quad \xi \in \partial\varphi(y) + \nabla f(y).$$

Since  $\text{dom } \nabla f = \text{int dom } f$  (see (1.2)), this implies that

$$y \in \text{dom } \partial\varphi \cap \text{dom } \nabla f = \text{dom } \partial\varphi \cap \text{int dom } f.$$

Hence, all minimizers of  $\varphi(\cdot) + W_f(\xi, \cdot)$  are contained in  $\text{dom } \partial\varphi \cap \text{int dom } f \subseteq \text{dom } \varphi \cap \text{int dom } f$ . The Legendre function  $f$  is strictly convex on the convex subsets of  $\text{dom } \partial f$  and, in particular, on the convex set  $\text{dom } \varphi \cap \text{int dom } f = \text{dom } \varphi \cap \text{dom } \partial f$ . Thus,  $\varphi(\cdot) + W_f(\xi, \cdot)$  is strictly convex on this set too. Consequently, there is at most one minimizer of  $\varphi(\cdot) + W_f(\xi, \cdot)$  on the convex set  $\text{dom } \varphi \cap \text{int dom } f$  and this proves that the minimizer  $\bar{x}$ , whose existence was established above, is unique. Formula (2.4) follows from (2.5) when  $y = \bar{x}$ .  $\square$

Lemma 2.1 ensures the well definedness of the function

$$(2.6) \quad \text{Prox}_\varphi^f : \text{int dom } f^* \rightarrow \text{dom } \partial\varphi \cap \text{int dom } f, \quad \xi \rightarrow \text{Prox}_\varphi^f(\xi)$$

when  $\varphi \in \mathcal{F}_f$ . We call this function *the proximal mapping relative to  $f$  associated to  $\varphi$* . The well definedness of the proximal mappings relative to the Legendre function  $f$  can also be deduced from [21, Theorem 3.18], where the well definedness of the resolvent

$$(2.7) \quad \text{prox}_\varphi^f := \text{Prox}_\varphi^f \circ \nabla f$$

was established. In more particular circumstances for  $f$  and  $\varphi$ , the well definedness of  $\text{Prox}_\varphi^f$  was proved in [1], [32], and [38].

Let  $E$  be a closed convex subset of  $X$  satisfying

$$(2.8) \quad E \cap \text{int dom } f \neq \emptyset.$$

Then the indicator function of the set  $E$ , that is, the function  $\iota_E : X \rightarrow (-\infty, +\infty]$  defined by  $\iota_E(x) = 0$  if  $x \in E$ , and  $\iota_E(x) = +\infty$  otherwise, is contained in  $\mathcal{F}_f$ . The operator  $\text{Prox}_{\iota_E}^f$  is called the *projection onto  $E$  relative to  $f$*  (cf. [38]) and is denoted  $\text{Proj}_E^f$  in what follows. According to Lemma 2.1, we have

$$\text{Proj}_E^f = (N_E + \nabla f)^{-1},$$

where  $N_E$  denotes the normal cone operator associated to the set  $E$ . The operator

$$(2.9) \quad \text{proj}_E^f := \text{prox}_{\iota_E}^f = \text{Proj}_E^f \circ \nabla f$$

is exactly the *Bregman projection onto  $E$  relative to  $f$* , whose importance in convex optimization was first emphasized in [24]. To see that, it is sufficient to recall that the *Bregman distance*  $D_f : X \times \text{int dom } f \rightarrow (-\infty, +\infty]$  is the function defined by

$$(2.10) \quad D_f(y, x) := f(y) - f(x) - \langle \nabla f(x), y - x \rangle = W_f(\nabla f(x), y),$$

with  $\text{dom } D_f = (\text{dom } f) \times (\text{int dom } f)$ .

**2.2. Variational inequalities.** There is an intimate connection between proximal mappings and variational inequalities. It is based on the following result, which extends the variational characterization of  $\text{Proj}_E^f$  given in [38] to a variational characterization of  $\text{Prox}_\varphi^f$ .

LEMMA 2.2. *Suppose that  $\varphi \in \mathcal{F}_f$  and  $\xi \in \text{int dom } f^*$ . If  $\hat{x} \in \text{dom } \partial\varphi \cap \text{int dom } f$ , then the following conditions are equivalent:*

- (a)  $\hat{x} = \text{Prox}_\varphi^f(\xi)$ ;
- (b)  $\hat{x}$  is a solution of the variational inequality

$$(2.11) \quad \langle \xi - \nabla f(x), y - x \rangle \leq \varphi(y) - \varphi(x) \quad \forall y \in \text{dom } \varphi \cap \text{dom } f;$$

- (c)  $\hat{x}$  is a solution of the variational inequality

$$W_f(\xi, x) + W_f(\nabla f(x), y) - W_f(\xi, y) \leq \varphi(y) - \varphi(x) \quad \forall y \in \text{dom } \varphi \cap \text{dom } f.$$

*Proof.* (a)  $\Rightarrow$  (b). Suppose that  $\hat{x} = \text{Prox}_\varphi^f(\xi)$ . Take  $y \in \text{dom } \varphi \cap \text{dom } f$  and  $t \in (0, 1)$ . Then  $(1 - t)\hat{x} + ty \in \text{dom } \varphi \cap \text{dom } f$  and we have

$$\varphi(\hat{x}) + W_f(\xi, \hat{x}) \leq \varphi((1 - t)\hat{x} + ty) + W_f(\xi, (1 - t)\hat{x} + ty),$$

that is,

$$(2.12) \quad \varphi((1 - t)\hat{x} + ty) - \varphi(\hat{x}) \geq W_f(\xi, \hat{x}) - W_f(\xi, (1 - t)\hat{x} + ty).$$

Since  $\hat{x} \in \text{int dom } f$ , there exists  $t_0 \in (0, 1)$  such that for any  $t \in (0, t_0)$  we have that  $(1 - t)\hat{x} + ty \in \text{int dom } f$ . Consequently, for any  $t \in (0, t_0)$  the function  $W_f(\xi, \cdot)$  is differentiable at  $(1 - t)\hat{x} + ty$ . Clearly, we also have

$$\nabla W_f(\xi, \cdot)(u) = \nabla f(u) - \xi \quad \forall u \in \text{int dom } f.$$

Therefore, by the convexity of  $W_f(\xi, \cdot)$  and (2.12), we deduce

$$\begin{aligned} t^{-1} [\varphi((1 - t)\hat{x} + ty) - \varphi(\hat{x})] &\geq \langle \nabla W_f(\xi, \cdot)((1 - t)\hat{x} + ty), \hat{x} - y \rangle \\ &= \langle \nabla f((1 - t)\hat{x} + ty) - \xi, \hat{x} - y \rangle \end{aligned}$$

for any  $t \in (0, t_0)$ . The function  $\nabla f(\cdot)$  is norm-to-weak continuous (see, for instance, [65, Proposition 2.8]). Hence, letting  $t \rightarrow 0^+$  in the last inequality, we get

$$\varphi^\circ(\hat{x}; y - \hat{x}) \geq \langle \nabla f(\hat{x}) - \xi, \hat{x} - y \rangle,$$

where  $\varphi^\circ$  stands for the right-hand side derivative of  $\varphi$ , that is,

$$\varphi^\circ(x; d) = \lim_{s \rightarrow 0^+} \frac{\varphi(x + sd) - \varphi(x)}{s}.$$

Taking into account that

$$\varphi(y) - \varphi(\hat{x}) \geq \varphi^\circ(\hat{x}; y - \hat{x})$$

we obtain (2.11).

(b) $\Rightarrow$ (a). Suppose that

$$\langle \xi - \nabla f(\hat{x}), y - \hat{x} \rangle \leq \varphi(y) - \varphi(\hat{x}) \quad \forall y \in \text{dom } \varphi \cap \text{dom } f.$$

Observe that

$$(2.13) \quad \nabla W_f(\xi, \cdot) = \nabla f(\cdot) - \xi.$$

Then, by the convexity of  $W_f(\xi, \cdot)$  and (2.13), for any  $y \in \text{dom } \varphi \cap \text{dom } f$ , we have that

$$\begin{aligned} W_f(\xi, y) - W_f(\xi, \hat{x}) &\geq \langle \nabla W_f(\xi, \cdot)(\hat{x}), y - \hat{x} \rangle \\ &= \langle \nabla f(\hat{x}) - \xi, y - \hat{x} \rangle \\ &\geq \varphi(\hat{x}) - \varphi(y). \end{aligned}$$

This shows that  $\hat{x} = \text{Prox}_\varphi^f(\xi)$ . The equivalence (b)  $\Leftrightarrow$  (c) results immediately by observing that

$$W_f(\xi, x) + W_f(\nabla f(x), y) - W_f(\xi, y) = \langle \xi - \nabla f(x), y - x \rangle$$

whenever  $y \in \text{dom } f$ ,  $\xi \in \text{int dom } f^*$ , and  $x \in \text{int dom } f$ .  $\square$

A consequence of Lemma 2.2 is the following generalization of the variational characterization of the Bregman projections originally given in [5].

**COROLLARY 2.3.** *Let  $x \in \text{int dom } f$  and let  $E$  be a nonempty, closed, and convex set such that  $E \cap \text{int dom } f \neq \emptyset$ . If  $\hat{x} \in E$ , then the following conditions are equivalent:*

- (i) *The vector  $\hat{x}$  is the Bregman projection of  $x$  onto  $E$  with respect to  $f$ ;*
- (ii) *the vector  $z = \hat{x}$  is the unique solution of the variational inequality*

$$\langle \nabla f(x) - \nabla f(z), z - y \rangle \geq 0 \quad \forall y \in E;$$

- (iii) *the vector  $z = \hat{x}$  is the unique solution of the variational inequality*

$$D_f(y, z) + D_f(z, x) \leq D_f(y, x) \quad \forall y \in E.$$

Now we are in position to establish the connection between the proximal mappings and a class of variational inequalities. It extends similar results known to hold in less general settings (see, for instance, [1] and [47, Proposition 1.5.8]). Here we consider the following variational inequality:

$$(2.14) \quad \text{Find } x \in \text{int dom } f \text{ such that}$$

$$\exists \xi \in Bx : [\langle \xi, y - x \rangle \geq \varphi(x) - \varphi(y) \quad \forall y \in \text{dom } f],$$

where  $\varphi \in \mathcal{F}_f$  and  $B : X \rightarrow 2^{X^*}$  is an operator which satisfies the condition

$$(2.15) \quad \emptyset \neq \text{dom } B \cap \text{dom } \varphi \cap \text{int dom } f \quad \text{and} \quad \text{ran } (\nabla f - B) \subseteq \text{int dom } f^*.$$

Condition (2.15) guarantees that the operator

$$\text{Prox}_\varphi^f(\nabla f - B) := \text{Prox}_\varphi^f \circ (\nabla f - B)$$

is well defined. Therefore, the following statement makes sense.

LEMMA 2.4. *Let  $\varphi \in \mathcal{F}_f$  and  $\hat{x} \in \text{dom } \partial\varphi \cap \text{int dom } f$ . Suppose that  $B : X \rightarrow 2^{X^*}$  is an operator which satisfies (2.15). Then  $\hat{x}$  is a solution of the variational inequality (2.14) if and only if it is a fixed point of the operator  $\text{Prox}_\varphi^f(\nabla f - B)$ .*

*Proof.* Note that  $\hat{x}$  is a solution of (2.14) if and only if there exists  $\xi \in B\hat{x}$  such that

$$(2.16) \quad \langle (\nabla f(\hat{x}) - \xi) - \nabla f(\hat{x}), y - \hat{x} \rangle \leq \varphi(y) - \varphi(\hat{x}) \quad \forall y \in \text{dom } \varphi \cap \text{dom } f.$$

According to Lemma 2.2, this is equivalent to  $\hat{x} = \text{Prox}_\varphi^f(\nabla f(\hat{x}) - \xi)$  for some  $\xi \in B\hat{x}$  which, in turn, is equivalent to  $\hat{x} \in \text{Prox}_\varphi^f(\nabla f(\hat{x}) - B\hat{x})$ , i.e., to the condition that  $\hat{x}$  is a fixed point of  $\text{Prox}_\varphi^f(\nabla f - B)$ .  $\square$

Let  $B : X \rightarrow 2^{X^*}$  be an operator and suppose that the closed convex subset  $C$  of  $X$  satisfies

$$(2.17) \quad \emptyset \neq \text{dom } B \cap C \cap \text{int dom } f \quad \text{and} \quad \text{ran } (\nabla f - B) \subseteq \text{int dom } f^*.$$

Note that if  $\varphi := \iota_C$ , then the variational inequality (2.14) is precisely the following problem, which we call *classical variational inequality*:

$$(2.18) \quad \text{Find } x \in C \cap \text{int dom } f \text{ such that}$$

$$\exists \xi \in Bx : [\langle \xi, y - x \rangle \geq 0 \quad \forall y \in C \cap \text{dom } f].$$

Applying Lemma 2.4 and (1.3) in this case, we rediscover the following known result (cf. [2]).

LEMMA 2.5. *Suppose that the condition (2.17) is satisfied and that  $\hat{x} \in C \cap \text{int dom } f$ . Then the following statements are equivalent:*

- (a) *The vector  $\hat{x}$  is a solution of the classical variational inequality (2.18);*
- (b) *the vector  $\hat{x}$  is a fixed point of the operator  $\text{Proj}_C^f(\nabla f - B)$ ;*
- (c) *the vector  $\hat{x}$  is a zero for the operator  $V[B; C; f] : X \rightarrow 2^{X^*}$  given by*

$$(2.19) \quad V[B; C; f] := \nabla f - \nabla f \circ \text{Proj}_C^f(\nabla f - B).$$

Lemmas 2.4 and 2.5 provided the initial motivation for this research. Observe that Lemma 2.4 reduces the problem of finding a solution for the classical variational inequality (2.18) to the problem of finding a fixed point for the operator  $\text{Proj}_C^f(\nabla f - B)$ . It is well known that, in many instances, by iterating an operator starting from initial points located in its domain, one produces sequences which converge to fixed points of the operator. This suggests that for solving the classical variational inequality (2.18), we would have to produce sequences defined by the iterative rule

$$(2.20) \quad x^{k+1} \in \text{Proj}_C^f(\nabla f(x^k) - Bx^k)$$

in the hope that such sequences will converge to fixed points of  $\text{Proj}_C^f(\nabla f - B)$ . Note that any fixed point of the operator  $\text{Proj}_C^f(\nabla f - B)$  is a zero for the operator  $V[B; C; f]$  given by (2.19), and conversely. According to (2.9), we have that

$$\begin{aligned}
 (2.21) \quad \text{Proj}_C^f(\nabla f - V[B; C; f]) &= \text{Proj}_C^f \circ \nabla f \circ \text{Proj}_C^f \circ (\nabla f - B) \\
 &= \text{proj}_C^f \circ \text{proj}_C^f \circ (\nabla f)^{-1} \circ (\nabla f - B) \\
 &= \text{proj}_C^f \circ \nabla f^* \circ (\nabla f - B) \\
 &= \text{Proj}_C^f(\nabla f - B).
 \end{aligned}$$

Thus, we are naturally led to the question of whether, and in which conditions, the sequences generated according to the rule  $x^{k+1} \in \text{Proj}_C^f(\nabla f(x^k) - V[B; C; f]x^k)$ , which are the same (see (2.21)) as the sequences generated according to rule (2.20), converge to zeros of the operator  $V[B; C; f]$ . This is, in fact, a particular instance of the more general question of whether, and in which conditions, the proximal-projection method (1.7) approximates zeros of an operator  $A$  (in our specific case  $A := V[B; C; f]$ ), provided that such zeros exist. In what follows we present answers to this question. It is interesting to observe that by focusing, in our convergence analysis, on conditions concerning the operator  $V[B; C; f]$  instead of  $B$  we do not mean that computing values of  $\text{Proj}_C^f(\nabla f - V[B; C; f])$  is easier than computing values of the same operator via the formula  $\text{Proj}_C^f(\nabla f - B)$ . However, from a theoretical point of view, the operator  $V[B; C; f]$  associated with  $B$  via formula (2.19) may happen to be better conditioned than  $B$  for a convergence analysis of the proximal-projection method. This aspect can be clearly seen after a careful dissection of the considerations which lead to our main convergence results presented in this paper. It should be taken into account that the operator  $B$  may not have zeros in  $C$  even if the operator  $V[B; C; f]$ , associated to  $B$  by (2.19), does. For example, take  $X = \mathbb{R}$ ,  $f(x) = \frac{1}{2}x^2$ ,  $C = [1, 2]$ , and  $Bx = x$  for all  $x \in X$ . Then  $V[B; C; f]x = x - 1$  vanishes at  $x = 1$ , but  $B$  does not have any zero in  $C$ .

**3.  $D_f$ -nonexpansivity poles,  $D_f$ -inverse strong monotonicity, and  $D_f$ -firmness of operators in Banach spaces.** In this section we introduce the notion of  $D_f$ -inverse strong monotonicity for operators from  $X$  to  $2^{X^*}$ . We clarify how this notion is related to the notions of  $D_f$ -nonexpansivity pole introduced in [33] and  $D_f$ -firm operator introduced in [21]. Using these relations we show that the proximal point method with Bregman distances can be seen as a particular instance of the proximal-projection method applied to a  $D_f$ -inverse strongly monotone operator.

**3.1.  $D_f$ -nonexpansivity poles.** In what follows, we associate with the function  $f$  described in section 1, and with any operator  $A : X \rightarrow 2^{X^*}$ , the operator  $A^f : X \rightarrow 2^X$  given by

$$(3.1) \quad A^f := \nabla f^* \circ (\nabla f - A).$$

We call this operator the  $D_f$ -antiresolvent of  $A$ . Observe that

$$(3.2) \quad \text{dom } A^f \subseteq \text{dom } A \cap \text{int dom } f \quad \text{and} \quad \text{ran } A^f \subseteq \text{int dom } f,$$

and that, if  $x \in \text{int dom } f$ , then  $0^* \in Ax$  if and only if  $x \in \text{Fix } A^f$ , where  $\text{Fix } A^f$  denotes the set of fixed points of  $A^f$ . Therefore, the (possibly empty) set of solutions of Problem 1.1 situated in  $\text{int dom } f$ , denoted  $\mathcal{S}_f(A, C)$ , is exactly

$$(3.3) \quad \mathcal{S}_f(A, C) = C \cap \text{Fix } A^f.$$

We are going to prove that, for operators  $A$  which are  $D_f$ -inverse strongly monotone, the set  $\mathcal{S}_f(A, C)$  is exactly the set of  $D_f$ -nonexpansivity poles of  $A^f$  over the set  $C$ , and this fact will be later used in our convergence analysis of the proximal-projection method. To this end, recall the following notion.

DEFINITION 3.1 (cf. [33]). *Let  $T : X \rightarrow 2^X$  be an operator and let  $Y$  be a subset of  $X$  such that*

$$(3.4) \quad \emptyset \neq T(Y \cap \text{int dom } f) \subseteq \text{int dom } f.$$

*The vector  $z \in X$  is called a  $D_f$ -nonexpansivity pole of  $T$  over  $Y$  if the following conditions are satisfied:*

$$(3.5) \quad z \in Y \cap \text{int dom } f,$$

$$(3.6) \quad (x \in Y \cap \text{int dom } f \quad \text{and} \quad u \in Tx) \Rightarrow \langle \nabla f(x) - \nabla f(u), z - u \rangle \leq 0.$$

*We denote by  $\text{Nexp}_Y^f T$  the set of  $D_f$ -nonexpansivity poles of  $T$  over  $Y$ .*

Operators having  $D_f$ -nonexpansivity poles were termed *totally nonexpansive operators* in [33]. Operators  $T$  such that  $\text{ran } T \subseteq \text{dom } T = \text{int dom } f$  and having  $\text{Nexp}_{\text{int dom } f}^f T \supseteq \text{Fix } T$  were called  *$\mathcal{B}$ -class operators* in [20] and [21].  $\mathcal{B}$ -class operators necessarily have  $\text{Nexp}_{\text{int dom } f}^f T = \text{Fix } T$  (cf. [21, Proposition 3.3]). However, not every operator having  $D_f$ -nonexpansivity poles over some subset  $Y$  of  $X$  is  $\mathcal{B}$ -class. For example, the operator  $Tx = \{x^2\}$  when  $X = \mathbb{R}$ ,  $f = \frac{1}{2}|\cdot|^2$ , and  $Y = \text{int dom } f = \mathbb{R}$  has  $z \in \text{Nexp}_{\text{int dom } f}^f T$  if and only if

$$x(1-x)(z-x^2) \leq 0 \quad \forall x \in \mathbb{R},$$

and this last inequality cannot hold because, irrespective of  $z$ , we have  $\lim_{x \rightarrow \infty} x(1-x)(z-x^2) = \infty$ . Hence,  $\text{Nexp}_{\text{int dom } f}^f T = \emptyset$ . In spite of that,  $\text{Fix } T = \{0, 1\}$  and, if  $Y = [0, 1]$ , then (3.6) holds for  $z = 0$  only, i.e.,  $\text{Nexp}_{[0,1]}^f T = \{0\} \neq \text{Fix } T$ .

The following lemma summarizes several properties of operators having nonexpansivity poles which are used in this work.

LEMMA 3.2. *Let the operator  $T : X \rightarrow 2^X$  and the set  $Y \subseteq X$  be such that condition (3.4) holds. Then the following statements are true:*

(a) *The (possibly empty) set  $\text{Nexp}_Y^f T$  is convex and closed when  $Y \subseteq \text{int dom } f$  is convex and closed;*

(b) *a vector  $z \in Y \cap \text{int dom } f$  is a  $D_f$ -nonexpansivity pole of  $T$  over  $Y$  if and only if*

$$(3.7) \quad (x \in Y \cap \text{int dom } f \quad \text{and} \quad u \in Tx) \Rightarrow D_f(z, u) + D_f(u, x) \leq D_f(z, x).$$

(c)  *$\text{Nexp}_Y^f T \subseteq \text{Fix } T$  and  $T$  is single-valued at any  $D_f$ -nonexpansivity pole.*

*Proof.* Statement (a) results from the fact that the function  $z \rightarrow \langle \nabla f(x) - \nabla f(u), z - u \rangle$  is linear and continuous. Statement (b) follows from (3.6) and (2.10). Now, by taking in (3.7)  $x = z \in \text{Nexp}_Y^f T$ , one gets

$$(3.8) \quad D_f(z, u) = D_f(u, z) = 0 \quad \forall u \in Tx.$$

By (3.4), if  $u \in Tz$ , then  $u \in \text{int dom } f$ . The function  $f$  being essentially strictly convex is strictly convex on  $\text{int dom } f$ . Hence, the equalities in (3.8) cannot hold unless  $u = z$  (cf. [33, Proposition 1.1.4]). In other words, we have the following implication:

$$(3.9) \quad z \in \text{Nexp}_Y^f T \Rightarrow Tz = \{z\}.$$

It shows that  $\text{Nexp}_Y^f T \subseteq \text{Fix } T$  and that  $T$  is single-valued at  $D_f$ -nonexpansivity poles.  $\square$

**3.2.  $D_f$ -inverse strong monotonicity and  $D_f$ -firmness.** The notion of a  $D_f$ -inverse strongly monotone operator, introduced in this section, and the notion of a  $D_f$ -firm operator, originally introduced in [21, Definition 3.4], are generalizations of the notion of firmly nonexpansive operator in a Hilbert space. Recall (cf. [48, pp. 41–42]) that if  $X$  is a Hilbert space (which we always identify with its dual  $X^*$ ), then an operator  $A : X \rightarrow X$  is firmly nonexpansive on a subset  $Y$  of  $X$  if and only if

$$(3.10) \quad \langle Ax - Ay, x - y \rangle \geq \|Ax - Ay\|^2 \quad \forall x, y \in Y.$$

It can be easily seen from the definitions given below that if  $X$  is a Hilbert space and if  $f = \frac{1}{2} \|\cdot\|^2$ , then the operator  $A$  is  $D_f$ -inverse strongly monotone on its domain if and only if it is firmly nonexpansive on its domain, and this happens if and only if  $A$  is  $D_f$ -firm.

It is interesting to note that if, instead of the function  $f = \frac{1}{2} \|\cdot\|^2$ , we provide the Hilbert space  $X$  with the Legendre function  $f_q := \frac{1}{2q} \|\cdot\|^2$  for some positive real number  $q$ , then the inequality (3.12) below with  $f_q$  instead of  $f$  becomes the usual  $q$ -inverse strong monotonicity condition (see [49, p. 256])

$$\langle Ax - Ay, x - y \rangle \geq q \|Ax - Ay\|^2 \quad \forall x, y \in X,$$

a generalization of the firm nonexpansivity which describes operators  $A : X \rightarrow X$  whose inverses  $A^{-1}$  are strongly monotone. This explains why we have chosen the term “ $D_f$ -inverse strongly monotone” in order to designate operators satisfying the requirements of the next definition.

Returning to the general context in which  $X$  and  $f$  are as described in section 1, we introduce the following notion.

**DEFINITION 3.3.** *Let  $Y$  be a subset of the space  $X$ . The operator  $A : X \rightarrow 2^{X^*}$  is called  $D_f$ -inverse strongly monotone on the set  $Y$  if*

$$(3.11) \quad Y \cap (\text{dom } A) \cap (\text{int dom } f) \neq \emptyset$$

and

$$(3.12) \quad \left. \begin{array}{l} x, y \in Y \cap \text{int dom } f \\ \xi \in Ax \text{ and } \eta \in Ay \end{array} \right\} \Rightarrow \langle \xi - \eta, \nabla f^*(\nabla f(x) - \xi) - \nabla f^*(\nabla f(y) - \eta) \rangle \geq 0.$$

Operators satisfying a somewhat less restrictive condition than (3.12) were studied in [38, section 5] under the name of inverse-monotone operators relative to  $f$ .

In our further considerations it is important to keep in mind that, in general, an operator  $A$  (even in a Hilbert space, provided that  $f$  is not the function  $f = \frac{1}{2} \|\cdot\|^2$ ) does not have to satisfy (3.10) in order to be  $D_f$ -inverse strongly monotone on  $Y$ . For instance, if the function  $f$  has a minimizer in  $\text{int dom } f$  (i.e., if the equation

$\nabla f(x) = 0$  has a solution), and if  $\alpha \in (0, 1)$ , then the operator  $A = \alpha \nabla f$  is  $D_f$ -inverse strongly monotone on  $Y = \text{dom } A = \text{int dom } f$  without necessarily satisfying (3.10) on  $Y = \text{int dom } f$ . Indeed, in this case, if  $x \in \text{int dom } f$ , then  $\{\nabla f(x), 0^*\} \subset \text{ran } \nabla f = \text{int dom } f^*$  and, due to the convexity of  $\text{int dom } f^*$ , we have that

$$(1 - \alpha) \nabla f(x) = (1 - \alpha) \nabla f(x) + \alpha 0^* \in \text{int dom } f^* = \text{dom } \nabla f^*,$$

and, consequently, the operator

$$A^f x = \nabla f^*((1 - \alpha) \nabla f(x))$$

has  $\text{dom } A^f = \text{int dom } f$ . If  $x, y \in \text{int dom } f$ , and if  $\beta = 1 - \alpha$ , then, by the monotonicity of  $\nabla f^*$ , we deduce that

$$\langle Ax - Ay, \nabla f^*(\nabla f(x) - Ax) - \nabla f^*(\nabla f(y) - Ay) \rangle$$

$$= \alpha \beta^{-1} \langle \beta \nabla f(x) - \beta \nabla f(y), \nabla f^*(\beta \nabla f(x)) - \nabla f^*(\beta \nabla f(y)) \rangle \geq 0;$$

i.e., the operator  $A = \alpha \nabla f$  is  $D_f$ -inverse strongly monotone on  $\text{int dom } f$ . However, the operator  $A = \alpha \nabla f$  does not have to be firmly nonexpansive on its domain even if  $X$  is a Hilbert space. For example, take the considerations above  $X$  to be any nonzero Hilbert space and  $f = \frac{1}{3} \|\cdot\|^3$ . Then,  $\nabla f(x) = \|x\|x$  and, for  $y = 0$ , (3.10) reduces to  $\|x\| \leq \alpha$ , a relation that does not hold for any  $x \in X$ .

We are going to show that there are strong connections between the  $D_f$ -inverse strong monotonicity of the operator  $A$  and the  $D_f$ -firmness of its  $D_f$ -antiresolvent  $A^f$ . For this purpose we recall the following.

DEFINITION 3.4 (cf. [21, Definition 3.4]). *An operator  $T : X \rightarrow 2^X$  is called  $D_f$ -firm if it satisfies the conditions*

$$(3.13) \quad \emptyset \neq \text{dom } T \cup \text{ran } T \subseteq \text{int dom } f$$

and

$$(3.14) \quad u \in Tx \quad \text{and} \quad v \in Ty \Rightarrow \langle \nabla f(u) - \nabla f(v), u - v \rangle \leq \langle \nabla f(x) - \nabla f(y), u - v \rangle.$$

We start with the following result which summarizes some basic properties of  $D_f$ -inverse strongly monotone operators.

LEMMA 3.5. *Let  $A : X \rightarrow 2^{X^*}$  be an operator and let  $Y$  be a subset of  $X$  which satisfies (3.11). The following statements are true:*

(a) *The operator  $A$  is  $D_f$ -inverse strongly monotone on  $Y$  if and only if it satisfies the following condition for any  $x, y \in Y \cap \text{int dom } f$ :*

$$\left. \begin{array}{l} u \in A^f x \\ v \in A^f y \end{array} \right\} \Rightarrow D_f(u, v) + D_f(v, u) + D_f(u, x) + D_f(v, y) \leq D_f(v, x) + D_f(u, y);$$

(b) *if  $A$  is  $D_f$ -inverse strongly monotone on  $Y$ , then  $A$  is  $D_f$ -inverse strongly monotone on any subset of  $Y$  which intersects  $\text{dom } A \cap \text{int dom } f$ ;*

(c) *the operator  $A$  is  $D_f$ -inverse strongly monotone on its domain if and only if its  $D_f$ -antiresolvent  $A^f$  is  $D_f$ -firm;*

(d) *if  $A$  is  $D_f$ -inverse strongly monotone on its domain, then  $A^f$  is single valued and all its fixed points are  $D_f$ -nonexpansivity poles on  $\text{int dom } f$ .*

*Proof.* Statements (a), (b), and (c) result from (3.1), (3.2), (3.13), (3.14), and (2.10). The single valuedness of  $A^f$  in statement (d) is a consequence of (c) and of [21, Proposition 3.5(iii)]. Letting  $y = z \in \text{Fix } A^f$  in the inequality of (a), and taking into account the single valuedness of  $A^f$ , one obtains that  $z$  satisfies (3.7) for  $T = A^f$ .  $\square$

Whenever the operator  $A$  involved in Problem 1.1 is  $D_f$ -inverse strongly monotone on the domain  $C$  of the problem, we have

$$(3.15) \quad \mathcal{S}_f(A, C) = C \cap \text{Fix } A^f = \text{Nexp}_C^f A^f.$$

This immediately follows from the next result.

LEMMA 3.6. *The following statements are true:*

- (a) *If  $z \in \text{Nexp}_C^f A^f$ , then  $Az = \{0^*\}$ ;*
- (b) *if the operator  $A$  is  $D_f$ -inverse strongly monotone on  $C$  and  $z \in \text{int dom } f$  is a solution of Problem 1.1, then  $z \in \text{Nexp}_C^f A^f$ .*

*Proof.* Statement (a) results from (3.1) and Lemma 3.2(c). In order to prove (b), note that for any  $x \in C \cap \text{int dom } f$  and  $y \in A^f x$ , we have

$$D_f(z, x) - D_f(z, y) = D_f(y, x) - \langle \nabla f(x) - \nabla f(y), z - y \rangle$$

and  $y = \nabla f^*(\nabla f(x) - \xi)$  for some  $\xi \in Ax$ . Thus,  $\nabla f(y) = \nabla f(x) - \xi$  and

$$(3.16) \quad D_f(z, x) - D_f(z, y) = D_f(y, x) + \langle 0^* - \xi, z - y \rangle.$$

If  $z$  is a solution of Problem 1.1, then  $z \in C$ ,  $0^* \in Az$ , and  $z = \nabla f^*(\nabla f(z) - 0^*)$ . As a consequence,

$$(3.17) \quad \langle 0^* - \xi, z - y \rangle = \langle 0^* - \xi, \nabla f^*(\nabla f(z) - 0^*) - \nabla f^*(\nabla f(x) - \xi) \rangle.$$

Since  $A$  is  $D_f$ -inverse strongly monotone on  $C$ , it results that the right-hand side of (3.17) is nonnegative (see (3.12)) for any  $x \in C \cap \text{int dom } f$ . Hence, by (3.16) and (3.17), the inequality in (3.7) results, and it shows that  $z \in \text{Nexp}_C^f A^f$ .  $\square$

The class of operators which are  $D_f$ -inverse strongly monotone contains some meaningful operators. Among them are all operators  $A[T] : X \rightarrow 2^{X^*}$  given by

$$(3.18) \quad A[T] = \nabla f - \nabla f \circ T,$$

where  $T : X \rightarrow 2^X$  is a  $D_f$ -firm operator. In particular,  $A[T]$  is  $D_f$ -inverse strongly monotone when  $T = B_f$ , where  $B_f : X \rightarrow 2^X$  is the  $D_f$ -resolvent (cf. [21]) of a monotone operator  $B : X \rightarrow 2^{X^*}$ , i.e.,

$$(3.19) \quad B_f := (\nabla f + B)^{-1} \circ \nabla f.$$

According to [21, Proposition 3.8], the operator  $T = B_f$  satisfies the condition (3.13). These facts are summarized in the following lemma.

LEMMA 3.7. *Let  $T : X \rightarrow 2^X$  be an operator which satisfies (3.13). Then the following statements are true:*

- (a)  *$\text{dom } A[T] = \text{dom } T$ , and its antiresolvent is  $(A[T])^f = T$ ;*
- (b) *the operator  $T$  is  $D_f$ -firm if and only if the operator  $A[T] : X \rightarrow 2^{X^*}$  defined by (3.18) is  $D_f$ -inverse strongly monotone on its domain;*
- (c) *if  $B : X \rightarrow 2^{X^*}$  is a monotone operator with  $\text{dom } B \cap \text{int dom } f \neq \emptyset$ , then  $B_f$  is  $D_f$ -firm, single-valued on its domain,*

$$(3.20) \quad A[B_f] = \nabla f - \nabla f \circ (\nabla f + B)^{-1} \circ \nabla f,$$

and  $A[B_f]$  is  $D_f$ -inverse strongly monotone on its domain.

*Proof.* Statement (a) results from (3.1) and (3.18). To prove (b), observe that for any  $x, y \in \text{dom } T$ , for any  $\xi \in A[T]x$ , and for any  $\eta \in A[T]y$ , we have

$$(3.21) \quad \xi = \nabla f(x) - \nabla f(u) \quad \text{and} \quad \eta = \nabla f(y) - \nabla f(v)$$

for some  $u \in Tx$  and for some  $v \in Ty$ . Therefore,

$$(3.22) \quad \begin{aligned} &\langle \xi - \eta, \nabla f^*(\nabla f(x) - \xi) - \nabla f^*(\nabla f(y) - \eta) \rangle \\ &= \langle \nabla f(x) - \nabla f(y), u - v \rangle - \langle \nabla f(u) - \nabla f(v), u - v \rangle. \end{aligned}$$

If  $T$  is  $D_f$ -firm, then the right-hand side of (3.22) is nonnegative and this implies that  $A[T]$  is  $D_f$ -inverse strongly monotone on  $\text{dom } T$ . Conversely, suppose that  $A[T]$  is  $D_f$ -inverse strongly monotone on  $\text{dom } T$ . If  $u \in Tx$  and  $v \in Ty$ , then the vectors  $\xi$  and  $\eta$  given by (3.21) satisfy (3.22) and the left-hand side of this equality is nonnegative. Hence,  $T$  is  $D_f$ -firm. This proves (b). In order to prove (c) recall that, since  $B$  is monotone, its resolvent,  $B_f$ , is necessarily  $D_f$ -firm and single-valued on its domain (cf. [21, Proposition 3.8]) and, as noted above, it satisfies (3.13). Thus, according to (b), the operator  $A[B_f]$  is  $D_f$ -inverse strongly monotone on its domain.  $\square$

**3.3. Connection between the proximal-projection method and the proximal point method.** Lemma 3.7 helps to establish a connection between the proximal-projection method and the *proximal point method (with Bregman distances)*. The proximal point method we are referring to in this paper is the iterative procedure which, in our setting, can be described by

$$(3.23) \quad x^0 \in \text{dom } B_f \quad \text{and} \quad x^{k+1} = B_f(x^k) \quad \forall k \in \mathbb{N},$$

where  $B : X \rightarrow 2^{X^*}$  is a monotone operator with  $\text{dom } B \cap \text{int dom } f \neq \emptyset$ . Its well definedness is guaranteed when

$$(3.24) \quad \emptyset \neq \text{ran } B_f \subseteq \text{dom } B_f.$$

To ensure that the inclusion in this condition holds, it is sufficient to make sure that  $\text{dom } B_f = X$ . This implicitly happens when one considers the classical proximal point method (see [70]) where  $X$  is a Hilbert space,  $f = \frac{1}{2} \|\cdot\|^2$ , and  $B$  is presumed to be maximal monotone. Alternative conditions which imply that  $\text{dom } B_f = X$  when  $B$  is maximal monotone are presented in [31] in a more general setting. In particular, those conditions hold if  $X$  is a uniformly convex and uniformly smooth Banach space,  $B$  is maximal monotone, and  $f = \frac{1}{2} \|\cdot\|^2$ .

A reason for which maximal monotonicity of  $B$  is a commonly used condition for ensuring well definedness of the proximal point method is that, if  $B$  is maximal monotone and  $f = \frac{1}{2} \|\cdot\|^2$ , then  $\nabla f + B$  and  $\nabla f^*$  are surjective and, thus,  $\nabla f^* \circ (\nabla f + B)$  is surjective too, that is,  $\text{dom } B_f = \text{ran } [\nabla f^* \circ (\nabla f + B)] = X$ . An important observation, for which we are indebted to a referee, shows that in cases when  $B$  is maximal monotone with  $0^* \in \text{ran } B$  and  $f$  is a Legendre function (as presumed in the setting of this work), condition (3.24) is satisfied whenever we have that (i)  $\text{dom } B \subseteq \text{int dom } f$  or (ii)  $B$  is  $3^*$ -monotone and  $\text{dom } B \cap \text{int dom } f \neq \emptyset$ . That is so because, if (i) or (ii) is true, then, according to [21, Corollary 3.14], the operator  $B_f$  is  $\mathcal{B}$ -class, and this implies that (3.24) holds by the definition of  $\mathcal{B}$ -class operators (see [21, Definition 3.1]).

Well definedness of the proximal point method can be sometimes ensured for operators  $B$  which are monotone without being maximal monotone. In such cases, it is interesting to know whether the proximal point method preserves the convergence properties which make it so useful in applications requiring finding zeros of maximal monotone operators. Here is an example of a monotone operator which is not maximal and for which (3.24) holds (in spite of the fact that  $\nabla f + B$  is not surjective). Take  $X = \mathbb{R}$ ,  $f = \frac{1}{2}|\cdot|^2$  and let  $B : X \rightarrow 2^{X^*}$  be given by  $Bx = \{0\}$  if  $x \leq 0$ , and  $Bx = \emptyset$  if  $x > 0$ . The operator  $B$  is monotone, but it is not maximal monotone since the operator defined by  $B'x = \{0\}$  for all  $x \in X$  is a proper monotone extension of  $B$ . Obviously, in this case  $\nabla f$  is the identity,  $(\nabla f + B)x = \{x\}$  if  $x \leq 0$ ,  $(\nabla f + B)x = \emptyset$  if  $x > 0$ , and, therefore,  $\nabla f + B$  is not surjective. However,  $B_f = (\nabla f + B)^{-1} = \nabla f + B$  and, hence,  $\text{ran } B_f = \text{dom } B_f = (-\infty, 0]$ , showing that (3.24) is satisfied, that is, the proximal point algorithm is well defined.

The next result establishes the connection between the proximal-projection method and the proximal point method. It requires that  $\text{dom } B_f$  should be convex and closed. This necessarily happens if  $\nabla f + B$  is surjective and  $\text{dom } f = X$ . However,  $\text{dom } B_f$  may happen to be convex and closed even if  $\nabla f + B$  is not surjective, as one can see from the example above. Other instances in which  $\text{dom } B_f$  is convex and closed are described in the remarks preceding Corollary 4.9 as well as in the body of that corollary.

**LEMMA 3.8.** *Let  $B : X \rightarrow 2^{X^*}$  be a monotone operator such that  $\text{dom } B_f$  is convex and closed and suppose that (3.24) is satisfied. Then the proximal point method (3.23) is exactly the proximal-projection method applied to the  $D_f$ -inverse strongly monotone operator  $A[B_f]$  with  $C_k = X$  for all  $k \in \mathbb{N}$ .*

*Proof.* Observe that, by (3.20), we have

$$\begin{aligned} \text{Proj}_{\text{dom } B_f}^f (\nabla f - A[B_f]) &= \text{Proj}_{\text{dom } B_f}^f \left[ \nabla f \circ (\nabla f + B)^{-1} \circ \nabla f \right] \\ &= \text{proj}_{\text{dom } B_f}^f \left[ (\nabla f + B)^{-1} \circ \nabla f \right] = B_f, \end{aligned}$$

where the last equality result holds because (3.24) is satisfied. This shows that the proximal point method and the proximal-projection method are overlapping when one takes  $A = A[B_f]$  and  $C_k = X$  for all  $k \in \mathbb{N}$  in (1.7).  $\square$

**4. Convergence analysis of the proximal-projection method.** In this section we present a convergence theorem for the proximal-projection method in reflexive Banach spaces. Our convergence analysis is based on a generalization of Lemma 5.7 in [38] which, in turn, is a generalization of a result also known as the Browder's demiclosedness principle [29, Theorem 8.4]. Throughout this section we assume that the function  $f$  and the Banach space  $X$  are as described in section 1.

**4.1. A generalization of Browder's demiclosedness principle.** The demiclosedness principle of Browder says that if  $X$  is a Banach space and if  $T : Y \rightarrow Y$  is a nonexpansive mapping on the nonempty closed convex subset  $Y$  of  $X$ , then for any sequence  $\{z^k\}_{k \in \mathbb{N}} \subseteq Y$  which is weakly convergent and has  $\lim_{k \rightarrow \infty} \|Tz^k - z^k\| = 0$ , the vector  $z = w - \lim_{k \rightarrow \infty} z^k$  is necessarily a fixed point of  $T$ . In [38, Lemma 5.7] a similar result was shown to hold for operators  $T : X \rightarrow X$  which are nonexpansive relative to  $f$  (in the sense given to this term in [39]), i.e., such that

$$(4.1) \quad D_f(Tx, Ty) \leq D_f(x, y) \quad \forall x, y \in Y,$$

provided that  $\text{dom } f = \text{dom } \nabla f = X$  and that  $f$  is not only Legendre but also totally convex (see [33]) and bounded on bounded sets, while  $T$  satisfies  $\lim_{k \rightarrow \infty} D_f(Tz^k, z^k) = 0$ .

Our current generalization of Browder's demiclosedness principle concerns set-valued operators  $T$  satisfying a somehow less stringent nonexpansivity condition than (4.1) with respect to a function  $f$  subjected to weaker requirements than those involved in [38, Lemma 5.7]. In what follows we use the following notion which generalizes that of a nonexpansive operator relative to  $f$ .

**DEFINITION 4.1.** *The operator  $T : X \rightarrow 2^X$  is said to be  $D_f$ -nonexpansive if it satisfies (3.13) and for any  $x \in \text{dom } T$  there exists  $u \in Tx$  such that*

$$(4.2) \quad (\forall y \in \text{dom } T) : [v \in Ty \Rightarrow D_f(v, u) \leq D_f(y, x)].$$

In what follows (see Theorem 4.7 below) we will be interested in operators whose antiresolvents are simultaneously  $D_f$ -firm and  $D_f$ -nonexpansive. It should be noted that the notions of  $D_f$ -nonexpansivity and  $D_f$ -firmness are not equivalent, although some operators may have both properties. If  $X$  is a Hilbert space provided with  $f = \frac{1}{2} \|\cdot\|^2$ , then it is obvious that any  $D_f$ -firm operator (i.e., any firmly nonexpansive operator) is  $D_f$ -nonexpansive (i.e., nonexpansive). Even in this context, the converse implication does not generally hold. Take, for example, the case where the Hilbert space is  $X = \mathbb{R}$  and  $Ax = 2x$ . Its antiresolvent is  $A^f x = -x$  and it is  $D_f$ -nonexpansive without being  $D_f$ -firm. However, operators whose antiresolvents are simultaneously  $D_f$ -nonexpansive and  $D_f$ -firm are not specific to the setting of Hilbert spaces provided with  $f = \frac{1}{2} \|\cdot\|^2$ . For instance, if  $X = \mathbb{R}$  and  $f(x) = \frac{1}{4}x^4$ , then the antiresolvent  $A^f$  of the operator  $A = \alpha \nabla f$  with  $\alpha \in (0, 1)$  is  $D_f$ -nonexpansive and  $D_f$ -firm at the same time. Indeed, an easy calculation shows that  $f^*(y) = \frac{3}{4}y^{\frac{4}{3}}$ , thus  $\nabla f^*(y) = y^{\frac{1}{3}}$ , and one obtains  $A^f x = (1 - \alpha)^{\frac{1}{3}}x$ . Therefore,

$$D_f(A^f y, A^f x) = (1 - \alpha)^{\frac{4}{3}} D_f(y, x) \leq D_f(y, x) \quad \forall x, y \in X,$$

showing that  $A^f$  is  $D_f$ -nonexpansive. On the other hand, by replacing the data above in relation (3.14) we obtain  $(1 - \alpha)^{\frac{1}{3}} \leq 1$ , which is true since  $\alpha \in (0, 1)$ . This shows that  $A^f$  is also  $D_f$ -firm.

One still may hope that (as happens in the particular situation noted above when  $X$  is a Hilbert space provided with  $f = \frac{1}{2} \|\cdot\|^2$ ) a  $D_f$ -firm operator is always  $D_f$ -nonexpansive. The following example shows that this is not the case.

**Example 4.2** (a  $D_f$ -firm operator which is not  $D_f$ -nonexpansive). Let  $X = \mathbb{R}$  and let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be the Legendre function given by  $f(x) = |x|^{3/2}$ . Take the continuous, single-valued operator  $T : \mathbb{R} \rightarrow \mathbb{R}$  defined by

$$T(x) = \begin{cases} \frac{1}{4} & \text{if } x < \frac{1}{16}, \\ \sqrt{x} & \text{if } x \geq \frac{1}{16}. \end{cases}$$

We first show that  $T$  is  $D_f$ -firm; that is, we verify that for every  $x, y \in \mathbb{R}$  one has

$$(4.3) \quad [f'(T(x)) - f'(T(y))][T(x) - T(y)] \leq [f'(x) - f'(y)][T(x) - T(y)].$$

For symmetry reasons we can assume that  $x > y$ . The case  $x, y < 1/16$  being trivial, we shall consider the following two cases.

*Case 1.*  $x, y \geq 1/16$ . In this case (4.3) reduces to  $[\sqrt[4]{x} - \sqrt[4]{y}][\sqrt{x} - \sqrt{y}] \leq (\sqrt{x} - \sqrt{y})^2$ , which is equivalent to the obviously true inequality  $1 \leq \sqrt[4]{x} + \sqrt[4]{y}$ .

Case 2.  $x \geq 1/16$  and  $y < 1/16$ . In this case we distinguish two subcases as follows:

(i)  $y \geq 0$ . In this situation (4.3) can be rewritten as  $[\sqrt[4]{x} - \sqrt{1/4}][\sqrt{x} - 1/4] \leq [\sqrt{x} - \sqrt{y}][\sqrt{x} - 1/4]$ , which, in turn, is equivalent to  $\sqrt[4]{x} + \sqrt{y} \leq \sqrt{x} + 1/2$ . This last inequality holds since for  $x \geq 1/16$  and  $y < 1/16$  we obviously have  $\sqrt[4]{x} + \sqrt{y} \leq \sqrt[4]{x} + 1/4$ , and it is easy to verify that

$$(4.4) \quad \sqrt[4]{x} + 1/4 \leq \sqrt{x} + 1/2 \quad \forall x \in [0, \infty).$$

(ii)  $y < 0$ . In this case, the inequality (4.3) is equivalent to  $[\sqrt[4]{x} - \sqrt{1/4}][\sqrt{x} - 1/4] \leq [\sqrt{x} + \sqrt{-y}][\sqrt{x} - 1/4]$ , that is, to  $\sqrt[4]{x} - 1/2 \leq \sqrt{x} + \sqrt{-y}$ . This last inequality is true because  $\sqrt{x} + \sqrt{-y} \geq \sqrt{x}$  and, by (4.4), we also have  $\sqrt[4]{x} \leq \sqrt{x} + 1/4 < \sqrt{x} + 1/2$  for every  $x > 0$ .

These show that the operator  $T$  is  $D_f$ -firm. Now we verify that  $T$  is not  $D_f$ -nonexpansive, that is, that there exist two real numbers  $x$  and  $y$  such that

$$(4.5) \quad f(T(y)) - f(T(x)) - f'(T(x))(T(y) - T(x)) > f(y) - f(x) - f'(x)(y - x).$$

Taking  $x = 1/8$  and  $y = 1/16$ , a simple computation shows that the left-hand side of (4.5) equals  $(1/2)^{15/4}[2^{3/4} + 2^{1/2} - 3]$ , while the right-hand side equals  $(1/2)^{13/2}[2^{1/2} + 2 - 3]$ . Therefore, for the given  $x$  and  $y$ , relation (4.5) becomes

$$2^{13/2}[2^{3/4} + 2^{1/2} - 3] > 2^{15/4}[2^{1/2} - 1].$$

Since

$$2^{13/2}[2^{3/4} + 2^{1/2} - 3] \simeq 8.6895$$

and

$$2^{15/4}[2^{1/2} - 1] \simeq 5.5730,$$

we deduce that (4.5) holds.  $\square$

Before proceeding with the presentation of our generalization of Browder's demiclosedness principle, several observations concerning its hypothesis are in order.

*Remark 4.3.* (a) The next result is a proper generalization of Lemma 5.7 in [38] which, in turn, is a proper generalization of Browder's demiclosedness principle. To see this, observe that when the operator  $T : X \rightarrow X$  is  $D_f$ -nonexpansive, it satisfies (4.7) below.

(b) The hypotheses of the next result implicitly require that the space  $X$  should be reflexive. The fact is that a function  $f$  which is lower semicontinuous with  $\text{int dom } f \neq \emptyset$  and uniformly convex on bounded subsets of  $\text{int dom } f$  exists on a Banach space  $X$  only if  $X$  is reflexive (cf. [35, Corollary 4.3] in conjunction with [38, Theorem 2.10(ii)]).

With these facts in mind we now proceed with the presentation of the generalization of Browder's demiclosedness principle.

**PROPOSITION 4.4.** *Suppose that the function  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ . Let  $T : X \rightarrow 2^X$  be an operator satisfying (3.13) and suppose that  $\nabla f$  is bounded on bounded subsets of  $\text{dom } T \cup \text{ran } T$ . If  $\{z^k\}_{k \in \mathbb{N}} \subseteq \text{dom } T$  is a sequence which converges weakly to a vector  $z \in \text{dom } T$  and if, for some sequence  $\{u^k\}_{k \in \mathbb{N}}$  satisfying*

$$(4.6) \quad (\forall k \in \mathbb{N} : u^k \in Tz^k) \quad \text{and} \quad \lim_{k \rightarrow \infty} D_f(u^k, z^k) = 0,$$

there exists  $u \in T(z)$  such that

$$(4.7) \quad \liminf_{k \rightarrow \infty} D_f(u^k, u) \leq \liminf_{k \rightarrow \infty} D_f(z^k, z),$$

then the vector  $z$  is a fixed point of  $T$ .

*Proof.* For any  $x \in \text{int dom } f$ , one has

$$D_f(z^k, x) - D_f(z^k, z) = D_f(z, x) + \langle \nabla f(x) - \nabla f(z), z - z^k \rangle.$$

This implies that

$$(4.8) \quad \liminf_{k \rightarrow \infty} D_f(z^k, x) = D_f(z, x) + \liminf_{k \rightarrow \infty} D_f(z^k, z)$$

because, since  $\{z^k\}_{k \in \mathbb{N}}$  converges weakly to  $z$ , we have

$$\lim_{k \rightarrow \infty} \langle \nabla f(x) - \nabla f(z), z - z^k \rangle = 0.$$

Since the function  $f$  is Legendre, it is strictly convex on  $\text{int dom } f$ . This implies that  $D_f(z, x) > 0$  whenever  $x \neq z$  (cf. [33, Proposition 1.1.4]) and, consequently, by (4.8) we obtain

$$(4.9) \quad x \neq z \Rightarrow \liminf_{k \rightarrow \infty} D_f(z^k, x) > \liminf_{k \rightarrow \infty} D_f(z^k, z).$$

We claim that

$$(4.10) \quad \liminf_{k \rightarrow \infty} D_f(u^k, u) = \liminf_{k \rightarrow \infty} D_f(z^k, u).$$

To prove this claim, observe that

$$(4.11) \quad D_f(u^k, u) = D_f(z^k, u) + [f(u^k) - f(z^k)] - \langle \nabla f(u), u^k - z^k \rangle.$$

The sequence  $\{z^k\}_{k \in \mathbb{N}}$  is bounded because it is weakly convergent. Since the function  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ , it is also sequentially consistent (cf. [38, Theorem 2.10]). Therefore, by (4.6), we deduce that

$$(4.12) \quad \lim_{k \rightarrow \infty} \|u^k - z^k\| = 0.$$

Hence,  $\{u^k\}_{k \in \mathbb{N}}$  is bounded and

$$(4.13) \quad \lim_{k \rightarrow \infty} \langle \nabla f(u), u^k - z^k \rangle = 0.$$

The convexity of  $f$  on  $\text{int dom } f$  implies

$$(4.14) \quad \langle \nabla f(u^k), u^k - z^k \rangle \geq f(u^k) - f(z^k) \geq \langle \nabla f(z^k), u^k - z^k \rangle \quad \forall k \in \mathbb{N}.$$

By hypothesis,  $\nabla f$  is bounded on bounded subsets of  $\text{dom } T \cup \text{ran } T$ . Therefore, the sequences  $\{\nabla f(z^k)\}_{k \in \mathbb{N}}$  and  $\{\nabla f(u^k)\}_{k \in \mathbb{N}}$  are bounded. Thus, by (4.12) and (4.14), we deduce that

$$\lim_{k \rightarrow \infty} [f(u^k) - f(z^k)] = 0.$$

This, combined with (4.11) and (4.13), implies (4.10), and the claim above is proved.

Suppose by contradiction that  $z \notin Tz$ . Then the vector  $u \in Tz$  whose existence is guaranteed by hypothesis has  $u \neq z$  and then, by (4.9), we deduce

$$(4.15) \quad \liminf_{k \rightarrow \infty} D_f(z^k, u) > \liminf_{k \rightarrow \infty} D_f(z^k, z).$$

On the other hand, by (4.7) and (4.10), we have that

$$(4.16) \quad \liminf_{k \rightarrow \infty} D_f(z^k, z) \geq \liminf_{k \rightarrow \infty} D_f(u^k, u) = \liminf_{k \rightarrow \infty} D_f(z^k, u),$$

which contradicts (4.15). This completes the proof.  $\square$

**4.2. A convergence theorem for the proximal-projection algorithm.** At this stage we are in position to consider the question of convergence of the procedure (1.7) towards solutions of Problem 1.1. For this purpose, we recall the following.

**DEFINITION 4.5.** (a) (Cf. [62, p. 519]). *The weak upper limit of the sequence  $\{E_k\}_{k \in \mathbb{N}}$  of subsets of  $X$  is the set denoted  $w\text{-}\overline{\lim}_{k \rightarrow \infty} E_k$  and consisting of all  $x \in X$  such that there exists a subsequence  $\{E_{i_k}\}_{k \in \mathbb{N}}$  of  $\{E_k\}_{k \in \mathbb{N}}$  and a sequence  $\{x^k\}_{k \in \mathbb{N}}$  in  $X$  which converges weakly to  $x$  and has the property that  $x^k \in E_{i_k}$  for each  $k \in \mathbb{N}$ .*

(b) *The operator  $A : X \rightarrow 2^{X^*}$  is sequentially weakly-strongly closed if its graph is sequentially closed in  $X \times X^*$  provided with the (weak)  $\times$  (strong)-topology, that is,*

$$(4.17) \quad \left. \begin{array}{l} \forall k \in \mathbb{N} : \xi^k \in Av^k \\ v^k \rightarrow v \text{ and } \xi^k \rightarrow \xi \end{array} \right\} \Rightarrow \xi \in Av.$$

Among the classes of sequentially weakly-strongly closed operators  $A : X \rightarrow 2^{X^*}$  is the class of maximal monotone operators (see [64]). Also, it is obvious that, if  $X$  has finite dimension, then the class of sequentially weakly-strongly closed operators  $A : X \rightarrow 2^{X^*}$  consists of all operators  $A$  with closed graph. Another class of sequentially weakly-strongly closed operators of special interest in applications (related to Fredholm integral equations; see [52, section 8.6]) is the class of compact linear operators  $A : X \rightarrow X^*$ . Recall (see, for instance, [52, p. 405]) that a linear operator  $T$  between two Banach spaces is called compact if the image through  $T$  of the open unit ball is a relatively compact set. A compact linear operator transforms weakly convergent sequences into strongly convergent sequences (cf. [52, Theorem 8.1.7]). So, if  $A : X \rightarrow X^*$  is a linear compact operator, it is necessarily sequentially weakly-strongly closed.

Before proceeding towards the main result of this paper, the following observations may be of use.

**Remark 4.6.** (a) A question which naturally comes to mind in the process of analyzing our next theorem is whether, given a sequence  $\{E_k\}_{k \in \mathbb{N}}$  of nonempty, closed, convex subsets of  $X$ , the set  $E = w\text{-}\overline{\lim}_{k \rightarrow \infty} E_k$  is necessarily convex. The fact is that, in general, the answer to this question is negative. To see this, take  $X = \mathbb{R}$  and

$$E_k := \begin{cases} \left[ -1 - \frac{1}{k+1}, -1 + \frac{1}{k+1} \right] & \text{if } k \text{ is even,} \\ \left[ 1 - \frac{1}{k+1}, 1 + \frac{1}{k+1} \right] & \text{if } k \text{ is odd.} \end{cases}$$

It is easy to verify that the weak upper limit of this sequence of closed convex sets is the nonconvex set  $\{-1, +1\}$ .

(b) It is meaningful to note that the answer to the question posed above is affirmative when  $E = \overline{\text{w-lim}_{k \rightarrow \infty} E_k}$  is the Mosco limit of  $\{E_k\}_{k \in \mathbb{N}}$ . To make things precise, recall (cf. [62, p. 519]) that a sequence of subsets  $\{E_k\}_{k \in \mathbb{N}}$  of  $X$  is called (Mosco) convergent to  $E \subseteq X$  if

$$\text{s-lim}_{k \rightarrow \infty} \overline{E_k} = E = \overline{\text{w-lim}_{k \rightarrow \infty} E_k},$$

where  $\text{s-lim}_{k \rightarrow \infty} \overline{E_k}$  stands for the collection of limit points of the convergent sequences  $\{v^k\}_{k \in \mathbb{N}}$  in  $X$  such that  $v^k \in E_k$  for all  $k \in \mathbb{N}$ . According to [62, p. 520], if  $E$  is the (Mosco) limit of a sequence  $\{E_k\}_{k \in \mathbb{N}}$  of closed and convex subsets of  $X$ , then  $E$  is necessarily closed and convex too.

(c) An essential part of condition (b) of Theorem 4.7 below is the requirement that the gradient  $\nabla f$  of the Legendre function  $f$  should be bounded on bounded subsets of  $\text{int dom } f$ . It is important to observe that *if the Legendre function  $f$  has this property, then  $\text{dom } f = X$* . Indeed, since  $f$  is essentially smooth, it follows that  $\text{int dom } f \neq \emptyset$  and any sequence  $\{x^k\}_{k \in \mathbb{N}}$  contained in  $\text{int dom } f$  and converging to a point of the boundary of  $\text{int dom } f$  has the property that  $\lim_{k \rightarrow \infty} \|\nabla f(x^k)\|_* = \infty$  (cf. [20, Theorem 5.6]). Now, suppose that  $\{x^k\}_{k \in \mathbb{N}}$  is a convergent sequence contained in  $\text{int dom } f$  and denote by  $x$  its limit. Then the sequence  $\{\nabla f(x^k)\}_{k \in \mathbb{N}}$  is bounded because the sequence  $\{x^k\}_{k \in \mathbb{N}}$  is bounded and  $\nabla f$  is bounded on bounded subsets of  $\text{int dom } f$ . We claim that  $x \in \text{int dom } f$ . Assume by contradiction that  $x \notin \text{int dom } f$ . Then  $x$  belongs to the boundary of  $\text{int dom } f$ . Hence,  $\lim_{k \rightarrow \infty} \|\nabla f(x^k)\|_* = \infty$ , and this contradicts the boundedness of  $\{\nabla f(x^k)\}_{k \in \mathbb{N}}$ . Since  $\text{int dom } f$  contains the limit of any convergent sequence of vectors contained in it, it follows that  $\text{int dom } f$  is, simultaneously, a closed and open set. The space  $X$ , being a Banach space, is necessarily arcways connected and, thus, a connected space (cf. [40, Theorem 10.3.2]). Consequently,  $X$  is the only nonempty subset of  $X$  which is open and closed at the same time (cf. [40, Theorem 10.1.8]), that is,  $\text{int dom } f = X$ .

(d) By remark (c) above, the Legendre function  $f$  has  $\nabla f$  bounded on bounded subsets of  $\text{int dom } f$  only if  $\text{dom } f = X$ . Now, suppose that the Legendre function  $f$  has  $\text{dom } f = X$ . Then, according to [18, Proposition 7.8],  $\nabla f$  is bounded on bounded subsets of  $X$  if and only if  $f$  is bounded on bounded subsets of  $X$ . In the particular case of a space  $X$  of finite dimension, this implies that any Legendre function  $f$  with  $\text{dom } f = X$  has  $\nabla f$  bounded on bounded subsets of  $X$  because, in these circumstances, as being a convex function,  $f$  is continuous on  $X$  and, hence, bounded on bounded subsets of  $X$ . In other words, if  $X$  has finite dimension, then the Legendre function  $f$  has  $\nabla f$  bounded on bounded subsets of  $\text{int dom } f$  if and only if  $\text{dom } f = X$ .

The following theorem establishes the basic convergence properties of the proximal-projection method. It should be observed that, in view of Remark 4.6(d), the hypothesis of point (b) of the theorem implicitly requires that  $\text{dom } f = X$ . It is interesting to note that, in general, this theorem guarantees subsequential weak convergence of the sequences generated by the proximal-projection method to solutions of Problem 1.1. However, the theorem also shows that, in some situations of special practical interest, the proximal-projection method produces sequences which converge weakly to such solutions. This is the case when Problem 1.1 has a unique solution (see (ii1)) and this is the typical situation when one has to solve regularized variational inequalities (as emphasized in Corollary 4.10 below). Problem 1.1 may not have a unique solution, but the sequences generated by the proximal-projection method still may converge weakly to such solutions, provided that the Legendre function  $f$  involved in the procedure has sequentially weak-to-weak continuous gradient  $\nabla f$ —see

(ii2). This condition is obviously satisfied by any Legendre function  $f$  on  $X$  when the space  $X$  has finite dimension. If  $X$  has infinite dimension, then finding Legendre functions with a sequentially weak-to-weak continuous gradient is somehow more challenging. We briefly describe here a class of such functions which is presented in more detail in [36]. To this end, let  $G : X \rightarrow X^*$  be a linear continuous operator and let  $G^*$  be its adjoint, that is, the unique linear continuous operator  $G^* : X(\simeq X^{**}) \rightarrow X^*$  such that  $\langle Gx, y \rangle = \langle G^*y, x \rangle$  for all  $x, y \in X$  (see [73, Theorem 4.10]). Define the function  $f_G : X \rightarrow \mathbb{R}$  by  $f_G(x) = \langle Gx, x \rangle$ . It is easy to see that  $\nabla f_G = G + G^*$ . Consequently,  $\nabla f_G$  is linear and continuous and, therefore, weak-to-weak continuous (and, thus, satisfies (ii2)). If, in addition, the operator  $G$  is positive definite and has the property (which necessarily holds when  $\nabla f_G$  is onto and, in particular, when  $G$  is strongly monotone) that  $\lim_{\|x\| \rightarrow \infty} \|Gx + G^*x\|_* = +\infty$ , then  $f_G$  is a Legendre function and, hence, it is a Legendre function with a sequentially weak-to-weak continuous gradient. The functions  $f_G$  presented here have linear gradients. However, there are Legendre functions whose sequentially weak-to-weak continuous gradient is not linear. For instance, this is the case of the function  $f : \ell^p \rightarrow \mathbb{R}$  defined by  $f(x) = \frac{1}{p} \|x\|^p$  with  $p \in (1, +\infty) \setminus \{2\}$  which has  $\nabla f(x)_j = \|x\|^{p-1} \text{sign}(x_j)$  for all  $j \in \mathbb{N}$ —see [29, Proposition 8.2]. Identifying more classes of Legendre functions with a sequentially weak-to-weak continuous gradient is of interest not only for the implementation of the proximal-projection method, but also for the application of other algorithms (see [33] and the references therein).

**THEOREM 4.7.** *Suppose that the function  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ ,  $\nabla f^*$  is bounded on bounded subsets of  $\nabla f(\text{dom } A)$ , and that, in addition to (1.6) and Assumption 1.2, the subsets  $C_k$  of  $X$  satisfy*

$$(4.18) \quad C = \text{w-}\overline{\lim}_{k \rightarrow \infty} C_k.$$

*If Problem 1.1 has at least one solution, if the operator  $A$  is  $D_f$ -inverse strongly monotone on the set  $Q := \bigcup_{k \in \mathbb{N}} C_k$ , and if at least one of the following two conditions is satisfied:*

(a)  *$\nabla f$  is uniformly continuous on bounded subsets of  $\text{int dom } f$  and  $A$  is sequentially weakly-strongly closed;*

(b)  *$\nabla f$  is bounded on bounded subsets of  $\text{int dom } f$ ,  $A^f$  is  $D_f$ -nonexpansive and  $C \subseteq \text{dom } A$ ,*

*then any sequence  $\{x^k\}_{k \in \mathbb{N}}$  generated by the proximal-projection method (1.7) has the following properties:*

(i) *it is bounded and has weak accumulation points, and any such point is a solution of Problem 1.1;*

(ii) *it converges weakly and its weak limit is solution to Problem 1.1 in each of the following situations;*

(ii1) *if Problem 1.1 has a unique solution;*

(ii2) *if  $\nabla f$  is sequentially weak-to-weak continuous.*

(iii) *If the Banach space  $X$  has finite dimension, then  $\{x^k\}_{k \in \mathbb{N}}$  converges in norm to a solution of Problem 1.1.*

*Proof.* Let  $z \in C$  be a solution of Problem 1.1. Then, clearly  $z \in \text{dom } A$  and, by (1.6), we deduce that  $z \in \text{int dom } f$ . For each  $k \in \mathbb{N}$ , let  $\zeta^k \in Ax^k$  be such that

$$(4.19) \quad x^{k+1} = \text{Proj}_{C_{k+1} \cap \text{dom } A}^f(\nabla f(x^k) - \zeta^k).$$

Denote

$$(4.20) \quad u^k := \nabla f^*(\nabla f(x^k) - \zeta^k).$$

Observe that

$$(4.21) \quad u^k \in A^f x^k \quad \text{and} \quad x^{k+1} = \text{proj}_{C_{k+1} \cap \text{dom } A}^f u^k \quad \forall k \in \mathbb{N}.$$

By hypothesis, the operator  $A$  is  $D_f$ -inverse strongly monotone on the set  $Q$  and  $z$  is a solution of Problem 1.1. Note that, since  $0^* \in Az$  and  $z \in C \subseteq Q$ , Lemma 3.6(b) applies with  $C$  replaced by  $Q$ . It implies that  $z \in \text{Nexp}_Q^f A^f$ . By Lemma 2.1 we have that

$$(4.22) \quad x^k \in C_k \cap \text{dom } A \cap \text{int dom } f \subseteq Q \cap \text{dom } A \cap \text{int dom } f \quad \forall k \in \mathbb{N}.$$

First we prove the following.

*Claim 1.* The sequence  $\{x^k\}_{k \in \mathbb{N}}$  is bounded.

In order to show this, notice that, by applying Lemma 3.2(b) to  $z \in \text{Nexp}_Q^f A^f$  we deduce

$$(4.23) \quad D_f(z, u^k) + D_f(u^k, x^k) \leq D_f(z, x^k) \quad \forall k \in \mathbb{N}.$$

This implies

$$(4.24) \quad D_f(z, u^k) \leq D_f(z, x^k) \quad \forall k \in \mathbb{N}.$$

By Assumption 1.2, we have that  $z \in C \subseteq C_k$  for all  $k \in \mathbb{N}$ . Thus, taking into account (2.10), (4.21), and Lemma 2.2 applied to  $\varphi = \iota_{C_{k+1} \cap \text{dom } A}$ , we obtain that

$$(4.25) \quad D_f(z, x^{k+1}) + D_f(x^{k+1}, u^k) \leq D_f(z, u^k) \quad \forall k \in \mathbb{N}.$$

Combining (4.25) with (4.24) yields

$$(4.26) \quad D_f(z, x^{k+1}) \leq D_f(z, x^k) \quad \forall k \in \mathbb{N},$$

showing that the nonnegative sequence  $\{D_f(z, x^k)\}_{k \in \mathbb{N}}$  is nonincreasing and, therefore, bounded. Let  $\beta$  be an upper bound of  $\{D_f(z, x^k)\}_{k \in \mathbb{N}}$ . According to (1.4), (2.10), and (4.26), we deduce that

$$f^*(\nabla f(x^k)) - \langle \nabla f(x^k), z \rangle + f(z) = W_f(\nabla f(x^k), z) = D_f(z, x^k) \leq \beta \quad \forall k \in \mathbb{N}.$$

This implies that the sequence  $\{\nabla f(x^k)\}_{k \in \mathbb{N}}$  is contained in the sublevel set  $\text{lev}_{\leq}^{\psi}(\beta - f(z))$  of the function  $\psi := f^* - \langle \cdot, z \rangle$ . Since  $z \in \text{int dom } f = \text{int dom } (f^*)^*$ , and since the function  $f^*$  is proper and lower semicontinuous, an application of the Moreau–Rockafellar theorem (see [68, Theorem 7(A)] or [20, Fact 3.1]) shows that  $f^* - \langle \cdot, z \rangle$  is coercive. Consequently, all sublevel sets of  $\psi$  are bounded. Hence, the sequence  $\{\nabla f(x^k)\}_{k \in \mathbb{N}}$  is bounded. By hypothesis,  $\nabla f^*$  is bounded on bounded subsets of  $\nabla f(\text{dom } A)$  and, according to (1.7),  $\{\nabla f(x^k)\}_{k \in \mathbb{N}}$  is contained in  $\nabla f(\text{dom } A)$ . Hence, the sequence  $x^k = \nabla f^*(\nabla f(x^k))$ ,  $k \in \mathbb{N}$ , is bounded. This proves Claim 1.

Now we are going to prove the following.

*Claim 2.* The sequence  $\{x^k\}_{k \in \mathbb{N}}$  has weak accumulation points and any such point is a solution of Problem 1.1.

The space  $X$  being reflexive, there exists a weakly convergent subsequence  $\{x^{i_k}\}_{k \in \mathbb{N}}$  of  $\{x^k\}_{k \in \mathbb{N}}$ . Let  $\bar{x} = \text{w-lim}_{k \rightarrow \infty} x^{i_k}$ . In order to show that  $\bar{x} \in C$ , denote  $y^k = x^{i_k}$  for each  $k \in \mathbb{N}$ . According to (4.22), we have that  $y^k \in C_{i_k}$  for every  $k \in \mathbb{N}$ . By hypothesis,  $\text{w-lim}_{k \rightarrow \infty} C_k = C$ , and this implies that  $\bar{x} \in C$  (see Definition 4.5). It remains to

prove that  $0^* \in A\bar{x}$ . To this end, observe that, according to (2.10), (4.25), and (4.24), we have

$$(4.27) \quad 0 \leq D_f(z, u^k) - D_f(z, x^{k+1}) \leq D_f(z, x^k) - D_f(z, x^{k+1}) \quad \forall k \in \mathbb{N}.$$

As noted above, the sequence  $\{D_f(z, x^k)\}_{k \in \mathbb{N}}$  is nonincreasing and nonnegative and, therefore, it converges. By (4.27), this implies that the sequence  $\{D_f(z, u^k)\}_{k \in \mathbb{N}}$  converges and has the same limit as  $\{D_f(z, x^k)\}_{k \in \mathbb{N}}$ . By (4.23) we also have that

$$(4.28) \quad D_f(u^k, x^k) \leq D_f(z, x^k) - D_f(z, u^k) \quad \forall k \in \mathbb{N},$$

and, thus,

$$(4.29) \quad \lim_{k \rightarrow \infty} D_f(u^k, x^k) = 0.$$

Since  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ , it results that it is sequentially consistent too (cf. [38, Theorem 2.10]). Therefore, the equality (4.29) implies that

$$(4.30) \quad \lim_{k \rightarrow \infty} \|u^k - x^k\| = 0.$$

Now, we distinguish two possible situations. First, suppose that condition (a) is satisfied. Note that, according to (4.20), we have

$$\zeta^k = \nabla f(x^k) - \nabla f(u^k) \quad \forall k \in \mathbb{N}.$$

Since  $\nabla f$  is uniformly continuous on bounded subsets of its domain, we deduce by (4.30) that  $\lim_{k \rightarrow \infty} \zeta^k = 0^*$ . The operator  $A$  being sequentially weakly-strongly closed, this and the fact that  $\{x^{i_k}\}_{k \in \mathbb{N}}$  converges weakly to  $\bar{x}$  imply that  $0^* \in A\bar{x}$ . Hence,  $\bar{x}$  is a solution of Problem 1.1 when condition (a) is satisfied.

Alternatively, suppose that condition (b) is satisfied. Recall that, in this case, we necessarily have  $\text{dom } f = X$  (cf. Remark 4.6(d)). By hypothesis (b), we have that  $C \subseteq \text{dom } A$ . By Assumption 1.2, we have that

$$(\nabla f - A)(C) \subseteq (\nabla f - A)(C_0) \subseteq \text{int dom } f^*,$$

and, as shown above,  $\bar{x} \in C$ . Hence,

$$\emptyset \neq (\nabla f - A)(\bar{x}) \subseteq \text{int dom } f^*,$$

which implies that  $\bar{x} \in \text{dom } A^f$ . From (4.2) written with  $x^{i_k}$  instead of  $y$  and  $u^{i_k}$  instead of  $v$ , we obtain that there exists  $\bar{u} \in A^f \bar{x}$ , such that

$$(4.31) \quad D_f(u^{i_k}, \bar{u}) \leq D_f(x^{i_k}, \bar{x}) \quad \forall k \in \mathbb{N}.$$

This implies

$$(4.32) \quad \liminf_{k \rightarrow \infty} D_f(u^{i_k}, \bar{u}) \leq \liminf_{k \rightarrow \infty} D_f(x^{i_k}, \bar{x}).$$

Proposition 4.4, (4.29), and (4.32) imply that  $\bar{x}$  is a fixed point of  $A^f$ , that is,  $0^* \in A\bar{x}$ . Hence,  $\bar{x}$  is a solution of Problem 1.1 in this case too and Claim 2 is established. Also, this completes the proof of (i).

The fact that if Problem 1.1 has a unique solution, then the sequence  $\{x^k\}_{k \in \mathbb{N}}$  converges weakly to that solution is an immediate consequence of (i). Assume that the function  $f$  has a sequentially weak-to-weak continuous gradient. We show next that, in this case, the sequence  $\{x^k\}_{k \in \mathbb{N}}$  cannot have more than one weak accumulation point. Suppose by contradiction that this is not the case and that  $x'$  and  $x''$  are two different weak accumulation points of  $\{x^k\}_{k \in \mathbb{N}}$ . Let  $\{x^{i_k}\}_{k \in \mathbb{N}}$  and  $\{x^{j_k}\}_{k \in \mathbb{N}}$  be subsequences of  $\{x^k\}_{k \in \mathbb{N}}$  converging weakly to  $x'$  and  $x''$ , respectively. By (i) combined with Lemma 3.6(b) it results that  $\{x', x''\} \subseteq \mathcal{S}_f(A, C) = \text{Nexp}_C^f(A^f)$ . Hence, the inequality (4.26) still holds for any  $z \in \{x', x''\}$ . It implies that the sequences  $\{D_f(x', x^k)\}_{k \in \mathbb{N}}$  and  $\{D_f(x'', x^k)\}_{k \in \mathbb{N}}$  are convergent. Let  $a$  and  $b$  be their respective limits. For any  $k \in \mathbb{N}$  we have

$$D_f(x', x^k) - D_f(x'', x^k) = D_f(x', x'') + \langle \nabla f(x'') - \nabla f(x^k), x' - x'' \rangle$$

because of (2.10). Replacing in this equation  $x^k$  by  $x^{j_k}$  and letting  $k \rightarrow \infty$ , we deduce that

$$(4.33) \quad a - b = D_f(x', x'')$$

because  $\nabla f$  is sequentially weak-to-weak continuous. A similar reasoning with  $x'$  and  $x''$  interchanged shows that

$$b - a = D_f(x'', x').$$

Adding this equality to (4.33) we obtain that  $D_f(x', x'') = 0$ . This cannot happen unless  $x' = x''$  because  $f$ , being a Legendre function, is strictly convex on  $C \cap \text{int dom } f$ . Thus, we reached a contradiction and this completes the proof of (ii). It is clear that (iii) follows from (i) and (ii) since the gradient of any convex function in a finite-dimensional space is continuous on the interior of its domain (see, for instance, [65, Proposition 2.8]). This completes the proof of the theorem.  $\square$

**4.3. Consequences of Theorem 4.7.** If  $X$  is a Hilbert space provided with the function  $f = \frac{1}{2} \|\cdot\|^2$ , then Theorem 4.7 has a somewhat simpler form, and even strong convergence of the sequence generated by the proximal-projection method can sometimes be ensured. Note that in this case the operator  $A : X \rightarrow 2^X$  is  $D_f$ -inverse strongly monotone if and only if it is *firmly nonexpansive* in the sense that

$$(4.34) \quad \left. \begin{array}{l} x, y \in X \\ \xi \in Ax, \eta \in Ay \end{array} \right\} \Rightarrow \langle \xi - \eta, x - y \rangle \geq \|\xi - \eta\|^2.$$

Clearly, if  $A$  has this property, then  $A$  is necessarily single-valued on  $X$ , and the operator  $A^f$  (which is exactly  $I - A$ ) is nonexpansive and, thus,  $D_f$ -nonexpansive. Since in this situation  $\text{Proj}_{C_k}^f$  is exactly the metric projection operator  $\text{Proj}_{C_k}$ , we obtain the following result.

**COROLLARY 4.8.** *Let  $X$  be a Hilbert space. Suppose that  $A : X \rightarrow X$  is a firmly nonexpansive operator (i.e., it satisfies (4.34)). If  $C$  is a nonempty, closed, and convex subset of  $X$ , if  $\{C_k\}_{k \in \mathbb{N}}$  is a sequence of subsets of  $X$  satisfying (4.18) and such that  $C_k \cap \text{dom } A$  is convex and closed and contains  $C$  for each  $k \in \mathbb{N}$ , and if Problem 1.1 has at least one solution, then the sequence  $\{x^k\}_{k \in \mathbb{N}}$  generated according to the rule*

$$(4.35) \quad x^0 \in C_0 \cap \text{dom } A \quad \text{and} \quad x^{k+1} = \text{Proj}_{C_{k+1} \cap \text{dom } A}(x^k - Ax^k)$$

converges weakly to a solution of Problem 1.1. If  $\text{int } \mathcal{S}_f(A, C) \neq \emptyset$ , then  $\{x^k\}_{k \in \mathbb{N}}$  converges strongly.

*Proof.* As noted above, the operator  $A$  satisfying (4.34) is  $D_f$ -inverse strongly monotone and  $D_f$ -nonexpansive. Applying Theorem 4.7(b) to  $f = \frac{1}{2} \|\cdot\|^2$ , which has  $\nabla f = I$  (and, hence, has  $\nabla f$  sequentially weak-to-weak continuous), and taking into account that  $A^f = I - A$ , one deduces that the sequence  $\{x^k\}_{k \in \mathbb{N}}$  converges weakly to a vector in  $\mathcal{S}_f(A, C)$ . The set  $\mathcal{S}_f(A, C) = \text{Nexp}_C^f A^f$  is convex and closed (cf. Lemma 3.2(a)). In the current circumstances, the inequality (4.26) still holds for all  $z \in \mathcal{S}_f(A, C)$ . It is equivalent to the condition

$$\|z - x^{k+1}\| \leq \|z - x^k\| \quad \forall z \in \mathcal{S}_f(A, C), \quad \forall k \in \mathbb{N}.$$

Therefore, one can apply Theorem 2.16(iii) in [18], or Theorem 4.5.10 in [26], in order to deduce that the sequence  $\{x^k\}_{k \in \mathbb{N}}$  converges strongly when  $\text{int } \mathcal{S}_f(A, C) \neq \emptyset$ .  $\square$

It was pointed out in subsection 3.3 that there is a strong connection between the proximal-projection method (1.7) and the proximal point method (3.23)—see Lemma 3.8. As far as we know, convergence of the proximal point method in reflexive Banach spaces was established only for maximal monotone operators. We use the connection between the proximal point method and the proximal-projection method to obtain convergence of the proximal point method for operators which are monotone with sequentially weak-to-weak closed graphs (but are not necessarily maximal monotone). Clearly, in spaces with finite dimension, any monotone operator with a closed graph and, in general, monotone operators with closed convex graphs, have this property. The other requirement of the next corollary that  $\text{dom } B_f$  should be convex is necessarily satisfied if  $\nabla f^*$  and  $\nabla f + B$  are surjective because, in this case,  $\text{dom } B_f = \text{ran } \nabla f^* \circ (\nabla f + B) = X$ . This condition is sufficient without being necessary, as the example preceding Lemma 3.8 shows. It can be easily verified that this also happens whenever  $\text{Graph } B$  is convex and  $\nabla f$  is linear. Since the corollary is based on Theorem 4.7(a), the remarks preceding Theorem 4.7 concerning the implications of the hypothesis on the domains of  $f$  and  $f^*$  still apply here.

**COROLLARY 4.9.** *Suppose that the following conditions are satisfied:*

- (a)  *$f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ ;*
- (b)  *$\nabla f$  is uniformly continuous on bounded subsets of  $\text{int dom } f$  as well as sequentially weak-to-weak continuous;*
- (c)  *$\nabla f^*$  is bounded on bounded subsets of  $\text{int dom } f^*$ .*

*If  $B : X \rightarrow 2^{X^*}$  is a monotone operator with sequentially weakly-closed graph in  $X \times X^*$ , satisfying (3.24) and such that  $\text{dom } B_f$  is convex, if  $B$  has at least one zero in  $\text{int dom } f$ , and if*

- (d)  *$\text{dom } B_f$  is closed in  $X$*

*or*

- (e)  *$\nabla f$  is bounded on bounded subsets of  $\text{int dom } f$ ,*

*then the sequences generated by the proximal point method (3.23) converge weakly to zeros of the operator  $B$ .*

*Proof.* We start by observing that, due to the boundedness on bounded subsets of its domain of  $\nabla f^*$ , we have that  $\text{dom } f^* = X^*$ —see Remark 4.6(c). Our proof is done in two stages. In Stage 1 we prove that the conclusion of the corollary holds under assumption (d), i.e., when  $\text{dom } B_f$  is closed in  $X$ . In Stage 2 we show that, if  $\nabla f$  is bounded on bounded subsets of  $\text{int dom } f$  (that is, if condition (e) holds), then  $\text{dom } B_f$  is necessarily closed in  $X$  and, thus, by the result of Stage 1, the conclusion of the corollary is true in this case too.

*Stage 1.* Assume that  $\text{dom } B_f$  is closed in  $X$ . By Lemma 3.8, the proximal point method is identical to the proximal-projection method applied to the operator  $A := A[B_f]$  given by (3.20) and to the sets  $C_k = X$ . Therefore, for proving the conclusion of the corollary in this case, it is sufficient to show that the operator  $A := A[B_f]$  satisfies the requirements of Theorem 4.7(a). In order to do that it is sufficient to ensure that the operator  $A[B_f]$  is  $D_f$ -inverse strongly monotone on its domain and has a sequentially weakly-strongly closed graph. Observe that, according to Lemma 3.7, the operator  $A[B_f]$  is  $D_f$ -inverse strongly monotone on its domain. It remains to show that  $A[B_f]$  is sequentially weakly-strongly closed. Let  $\{y^k\}_{k \in \mathbb{N}}$  be a weakly convergent sequence contained in  $\text{dom } A[B_f]$  and denote  $\xi^k = A[B_f]y^k$ . Suppose that  $\{\xi^k\}_{k \in \mathbb{N}}$  converges strongly in  $X^*$  to some vector  $\xi$ . Let  $y = \text{w-lim}_{k \rightarrow \infty} y^k$ . By hypothesis (b), the sequence  $\{\nabla f(y^k)\}_{k \in \mathbb{N}}$  converges weakly in  $X^*$  to  $\nabla f(y)$ . Thus, the sequence

$$(4.36) \quad \nabla f(y^k) - \xi^k = \left[ \nabla f \circ (\nabla f + B)^{-1} \circ \nabla f \right] (y^k)$$

converges weakly in  $X^*$  to  $\nabla f(y) - \xi$ . Denote  $u^k := \nabla f^* (\nabla f(y^k) - \xi^k)$  and observe that, by (4.36), we have that

$$(4.37) \quad u^k = \left[ (\nabla f + B)^{-1} \circ \nabla f \right] (y^k) = B_f y^k \quad \forall k \in \mathbb{N}.$$

According to hypothesis (c), the sequence  $\{u^k\}_{k \in \mathbb{N}}$  is bounded because the sequence  $\{\nabla f(y^k) - \xi^k\}_{k \in \mathbb{N}}$  is bounded (as shown above, this sequence is weakly convergent). Let  $\{u^{i_k}\}_{k \in \mathbb{N}}$  be a weakly convergent subsequence of  $\{u^k\}_{k \in \mathbb{N}}$  and let  $u$  be the weak limit of this subsequence. By (4.37) we deduce that  $\nabla f(y^{i_k}) \in (\nabla f + B) u^{i_k}$  for all  $k \in \mathbb{N}$ , and thus we obtain

$$(4.38) \quad \nabla f(y^{i_k}) - \nabla f(u^{i_k}) \in B u^{i_k} \quad \forall k \in \mathbb{N}.$$

By hypothesis (b), we have that

$$(4.39) \quad \text{w-} \lim_{k \rightarrow \infty} [\nabla f(y^{i_k}) - \nabla f(u^{i_k})] = \nabla f(y) - \nabla f(u).$$

Since  $\text{Graph } B$  is sequentially weak-to-weak closed and  $\{u^{i_k}\}_{k \in \mathbb{N}}$  converges weakly to  $u$ , the relations (4.38) and (4.39) imply that  $\nabla f(y) - \nabla f(u) \in Bu$ , i.e.,  $\nabla f(y) \in \nabla f(u) + Bu$ . Consequently, we have that

$$(4.40) \quad u = (\nabla f + B)^{-1} (\nabla f(y)) = B_f y$$

because the operator  $B_f$  is single-valued (cf. Lemma 3.7). On the other hand, by (4.36), (4.37), (4.39), and (4.40), we have that

$$\xi = \nabla f(y) - \text{w-} \lim_{k \rightarrow \infty} \nabla f(u^{i_k}) = \nabla f(y) - \nabla f(u) = \nabla f(y) - (\nabla f \circ B_f) y,$$

showing that  $(y, \xi) \in \text{Graph } A[B_f]$ . Hence,  $A := A[B_f]$  is sequentially weakly-strongly closed and, by Theorem 4.7(a) combined with Lemma 3.8, it results that any sequence generated by the proximal point method converges weakly to a zero of  $A[B_f]$ . Noting that

$$0^* \in A[B_f] \bar{x} \Leftrightarrow \nabla f(\bar{x}) = (\nabla f \circ B_f)(\bar{x}) \Leftrightarrow \bar{x} = B_f \bar{x} \Leftrightarrow 0^* \in B \bar{x},$$

we deduce that any sequence generated by the proximal point method converges weakly to a zero of  $B$ . This completes the proof in Stage 1.

*Stage 2.* Assume that  $\nabla f$  is bounded on bounded subsets of  $\text{int dom } f$ . Then, by Remark 4.6(c),  $\text{dom } f = X$ . We are going to show that, in this case, the set  $\text{dom } B_f$  is closed. To this end, let  $\{z^k\}_{k \in \mathbb{N}}$  be a sequence contained in  $\text{dom } B_f$  and converging in  $X$  to some vector  $\bar{z}$ . Denote  $w^k = B_f z^k$ . We claim that the sequence  $\{w^k\}_{k \in \mathbb{N}}$  is bounded. To show that, note that since the operator  $A := A[B_f]$  is  $D_f$ -inverse strongly monotone (cf. Lemma 3.7(c)), all solutions of Problem 1.1 (in which  $A = A[B_f]$ ) are in the set  $\text{Nexp}_{\text{dom } A[B_f]}^f (A[B_f])^f$  (cf. Lemma 3.6). Taking into account that, by Lemma 3.7(a,b),  $B_f = (A[B_f])^f$  and  $\text{dom } B_f = \text{dom } A[B_f]$ , we deduce that all solutions of Problem 1.1 are contained in  $\text{Nexp}_{\text{dom } B_f}^f B_f$ . Let  $z$  be such a solution. Then, by Lemma 3.2(b), we have

$$D_f(z, w^k) + D_f(w^k, z^k) \leq D_f(z, z^k) \quad \forall k \in \mathbb{N}.$$

According to the definition of the modulus of total convexity of  $f$  on the bounded set  $\{z^k\}_{k \in \mathbb{N}}$  denoted  $\nu_f(\{z^k\}_{k \in \mathbb{N}}, \cdot)$ —see [38]—we obtain

$$(4.41) \quad 0 \leq \nu_f\left(\{z^k\}_{k \in \mathbb{N}}; \|w^k - z^k\|\right) \leq D_f(w^k, z^k) \leq D_f(z, z^k) \quad \forall k \in \mathbb{N}.$$

Since  $\nabla f$  is bounded on bounded subsets of  $X$ , the function  $f$  is also bounded on bounded subsets of  $X$ . Consequently, taking into account (2.10), we deduce that the sequence  $\{D_f(z, z^k)\}_{k \in \mathbb{N}}$  is bounded. Let  $M$  be an upper bound of this sequence. Suppose by contradiction that the sequence  $\{w^k\}_{k \in \mathbb{N}}$  contains a subsequence  $\{w^{j_k}\}_{k \in \mathbb{N}}$  such that  $\lim_{k \rightarrow \infty} \|w^{j_k}\| = \infty$ . Then there exists a positive integer  $k_0$  such that for all integers  $k \geq k_0$  we have  $\|w^{j_k} - z^{j_k}\| \geq 1$ . By [38, Proposition 2.1(ii)] and (4.41), we deduce that for any  $k \geq k_0$  we have

$$(4.42) \quad \|w^{j_k} - z^{j_k}\| \nu_f\left(\{z^k\}_{k \in \mathbb{N}}; 1\right) \leq \nu_f\left(\{z^k\}_{k \in \mathbb{N}}; \|w^{j_k} - z^{j_k}\|\right) \leq M \quad \forall k \in \mathbb{N}.$$

The function  $f$  is, by hypothesis, uniformly convex on bounded subsets of  $\text{int dom } f$  and, consequently, it is also totally convex on bounded subsets of  $\text{int dom } f$ ; cf. [38, Theorem 2.10]. Therefore,  $\nu_f(\{z^k\}_{k \in \mathbb{N}}; 1) > 0$ . Taking this into account together with the fact that  $\{z^{j_k}\}_{k \in \mathbb{N}}$  is bounded (since it is convergent) and letting  $k \rightarrow \infty$  in (4.42), we reach a contradiction. Hence, the sequence  $\{w^k\}_{k \in \mathbb{N}}$  is bounded. Let  $\{w^{s_k}\}_{k \in \mathbb{N}}$  be a weakly convergent subsequence of  $\{w^k\}_{k \in \mathbb{N}}$  and let  $\bar{w}$  be the weak limit of this subsequence. According to (3.19), we have that

$$(4.43) \quad \nabla f(z^k) - \nabla f(w^k) \in Bw^k \quad \forall k \in \mathbb{N}.$$

Since  $\nabla f$  is sequentially weak-to-weak continuous, and since  $B$  has a sequentially weak-to-weak closed graph, the relation (4.43), written with  $s_k$  instead of  $k$ , implies that  $\nabla f(\bar{z}) - \nabla f(\bar{w}) \in B\bar{w}$ . This shows that  $\bar{w} = B_f \bar{z}$ , that is,  $\bar{z} \in \text{dom } B_f$ . Hence,  $\text{dom } B_f$  is closed and the proof of the corollary is complete.  $\square$

Another result which follows from Theorem 4.7 concerns a method of regularizing and solving classical variational inequalities in the form (2.18). Since the problem of solving (2.18) may be ill-posed (in the sense that it may not have solutions or it may have multiple solutions) and, therefore, many algorithms for approximating solutions

may not converge, or may converge only subsequentially, to solutions of the problem, one “regularizes” the original problem by solving an auxiliary problem which has a unique solution and whose solution is in the vicinity of the solution set of the original problem, provided that the latter is not empty. A regularization technique, which originates in the works of Tikhonov [77] and Browder [27], [28], consists of replacing the original variational inequality (2.18) by the following regularized variational inequality:

$$(4.44) \quad \text{Find } x \in C \cap \text{int dom } f \text{ such that}$$

$$\exists \xi \in Bx : [\langle \xi + \alpha \nabla f(x), y - x \rangle \geq 0 \quad \forall y \in C \cap \text{dom } f]$$

for some real number  $\alpha > 0$ . If  $B$  is a monotone operator, then  $B + \alpha \nabla f$  is strictly monotone and, therefore, the variational inequality (4.44) cannot have more than one solution. Moreover, in many practically interesting situations, the variational inequality (4.44) has a solution even if the original variational inequality (2.18) does not and, if  $\alpha$  is sufficiently small, then the solution of (4.44) is close to the solution set of the unperturbed variational inequality (2.18) whenever the latter has solutions. This is, for instance, the case (cf. [7, Theorem 3.2]) when the Banach space  $X$  is simultaneously uniformly convex and uniformly smooth and endowed with the Legendre function  $f := \frac{1}{p} \|\cdot\|^p$  for some  $p > 1$  and  $B$  is maximal monotone. Theorem 4.7 allows us to prove the next corollary which extends the applicability of this regularization technique to reflexive Banach spaces which are not necessarily uniformly convex and uniformly smooth and to produce a weakly convergent algorithm for solving (4.44) in this more general setting, even if  $B$  is not maximal monotone. This is of interest because closeness of the solution of (4.44) with small  $\alpha > 0$  to the (presumed nonempty) solution set of the original variational inequality (2.18) can be guaranteed even if  $B$  is not maximal monotone (cf. [9, Theorem 2.1]).

**COROLLARY 4.10.** *Let  $B : X \rightarrow 2^{X^*}$  be a monotone operator and let  $C$  be a nonempty, convex, and closed subset of  $\text{dom } B \cap \text{int dom } f$ . Suppose that  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ ,  $\nabla f^*$  is bounded on bounded subsets of  $\text{int dom } f^*$ , and that, for some real number  $\alpha > 0$ , we have that*

$$(4.45) \quad \emptyset \neq ((1 - \alpha)\nabla f - B)(C) \subseteq \text{int dom } f^*,$$

*and the operator  $\text{Proj}_C^f [(1 - \alpha)\nabla f - B]$  is  $D_f$ -firm. The iterative procedure defined by*

$$(4.46) \quad x^0 \in C \text{ and } x^{k+1} \in \text{Proj}_C^f [(1 - \alpha)\nabla f(x^k) - Bx^k] \quad \forall k \in \mathbb{N}$$

*is well defined and converges weakly to the necessarily unique solution of the variational inequality (4.44), provided that such a solution exists, if one of the following conditions is satisfied:*

(a)  *$X$  has finite dimension,  $\text{dom } f = X$ ,  $\nabla f$  is uniformly continuous on bounded subsets of  $X$ , and  $B$  has a closed graph and is bounded on bounded subsets of its domain;*

(b)  *$\nabla f$  is bounded on bounded subsets of  $\text{int dom } f$ , and the operator*

$$\text{Proj}_C^f [(1 - \alpha)\nabla f - B]$$

*is  $D_f$ -nonexpansive.*

*Proof.* Well definedness of the procedure results from (4.45). The variational inequality (4.44) cannot have more than one solution since the operator  $B' := B + \alpha \nabla f$  is strictly monotone. According to Lemma 2.5, finding a solution of (4.44) is equivalent to finding a zero for the operator  $V := V[B'; C; f]$  defined by (2.19). Note that

$$(4.47) \quad V = \nabla f - \nabla f \circ \text{Proj}_C^f((1 - \alpha)\nabla f - B)$$

and

$$(4.48) \quad V^f = \text{Proj}_C^f((1 - \alpha)\nabla f - B)$$

and that, by (2.21) applied to  $B'$  instead of  $B$ , we have

$$(4.49) \quad \text{Proj}_C^f(\nabla f - V) = \text{Proj}_C^f((1 - \alpha)\nabla f - B).$$

Therefore, we can equivalently rewrite the procedure (4.46) as

$$(4.50) \quad x^0 \in C \quad \text{and} \quad x^{k+1} \in \text{Proj}_C^f(\nabla f(x^k) - Vx^k) \quad \forall k \in \mathbb{N}.$$

This is exactly (1.7) applied to  $V$  instead of  $A$  with the sequence of sets  $C_k = C$  for all  $k \in \mathbb{N}$ . Now, suppose that condition (a) of our corollary is satisfied. In this case, if we show that the graph of  $V$  is closed in  $X \times X^*$  and that  $V$  is  $D_f$ -inverse strongly monotone, then Theorem 4.7(a) applies and leads to the conclusion of the corollary. Also, Theorem 4.7(b) implies that, if condition (b) of the corollary holds, then the procedure (4.50) is weakly convergent to the unique solution of (4.44), provided that  $V$  is  $D_f$ -inverse strongly monotone.  $D_f$ -inverse strong monotonicity of  $V$  results in both cases from Lemma 3.5 combined with (4.48) and with our hypothesis that  $V^f = \text{Proj}_C^f[(1 - \alpha)\nabla f - B]$  is  $D_f$ -firm. So, it remains to prove that, under assumption (a) of the corollary, the graph of  $V$  is closed. To this end, let  $\{y^k\}_{k \in \mathbb{N}}$  be a sequence in  $\text{dom } V$  and assume that this sequence converges to  $y \in X$ . Let  $\{\xi^k\}_{k \in \mathbb{N}}$  be the sequence

$$\xi^k = \nabla f(y^k) - \nabla f \circ \text{Proj}_C^f((1 - \alpha)\nabla f(y^k) - \zeta^k),$$

where  $\zeta^k \in By^k$  for all  $k \in \mathbb{N}$ . Suppose that  $\lim_{k \rightarrow \infty} \xi^k = \xi$ . Then, by Lemma 2.1, we have

$$\nabla f(y^k) - \xi^k = \left[ \nabla f \circ (\nabla f + N_C)^{-1} \right] ((1 - \alpha)\nabla f(y^k) - \zeta^k).$$

According to the hypothesis,  $\nabla f^*$  is bounded on bounded subsets of  $\text{int dom } f^*$ . This and Remark 4.6(c) combined imply that  $\text{dom } f^* = X^*$ . Therefore, for each  $k \in \mathbb{N}$ , we have that  $\nabla f(y^k) - \xi^k \in X^* = \text{int dom } f^*$  and, thus, from the previous equality we deduce

$$(4.51) \quad (1 - \alpha)\nabla f(y^k) - \zeta^k \in (\nabla f + N_C) [\nabla f^*(\nabla f(y^k) - \xi^k)] \quad \forall k \in \mathbb{N}.$$

Since  $B$  is bounded on the bounded set  $\{y^k\}_{k \in \mathbb{N}}$ , it follows that the sequence  $\{\zeta^k\}_{k \in \mathbb{N}}$  is bounded. Let  $\{\zeta^{i_k}\}_{k \in \mathbb{N}}$  be a convergent subsequence of  $\{\zeta^k\}_{k \in \mathbb{N}}$  and let  $\zeta$  be its limit. Since  $\nabla f$  and  $\nabla f^*$  are continuous on their respective domains,  $\text{dom } f^* = X^*$  (as shown above), and the normality operator  $N_C$  is maximal monotone (and, hence, has a closed graph), (4.51) implies

$$(1 - \alpha)\nabla f(y) - \zeta \in (\nabla f + N_C) [\nabla f^*(\nabla f(y) - \xi)].$$

Hence, we have

$$\nabla f^*(\nabla f(y) - \xi) = \text{Proj}_C^f [(1 - \alpha)\nabla f(y) - \zeta]$$

showing that

$$\xi = \nabla f(y) - \nabla f \circ \text{Proj}_C^f [(1 - \alpha)\nabla f(y) - \zeta] \in Vy.$$

This completes the proof.  $\square$

The requirement made in Corollary 4.10 that the operator  $V^f = \text{Proj}_C^f [(1 - \alpha)\nabla f - B]$  should be  $D_f$ -firm may seem unusual. Here are several examples which show that this condition is quite often satisfied without excessively costly demands on the operator  $B$  or the function  $f$ . The next example shows that Corollary 4.10(b) is applicable to solve variational inequalities in the form (4.44) when  $X$  is any Hilbert space,  $f = \frac{1}{2} \|\cdot\|^2$ ,  $C = \text{dom } B = X$ , and  $B$  is a monotone operator which is either contractive with some constant  $\gamma > 0$  or strongly monotone with some constant  $\delta > 0$  and even in more general conditions (when (4.52) holds for some  $\alpha \in (0, \frac{1}{2})$  and  $\beta > 0$ ). Obviously, in this setting, (2.18) is exactly the problem of finding a zero of  $B$ . To follow the considerations in the examples below one should first note that by replacing in (2.18) the operator  $B$  by  $\beta B$ , where  $\beta$  is a positive constant, one obtains a variational inequality which is equivalent to the original one.

*Example 4.11.* Let  $X$  be a Hilbert space and let  $f = \frac{1}{2} \|\cdot\|^2$ . Suppose that  $C = \text{dom } B = X$ . If  $B$  is contractive with some constant  $\gamma > 0$  or strongly monotone with some constant  $\delta > 0$ , then the operator  $V^f = \text{Proj}_C^f [(1 - \alpha)\nabla f - \beta B]$  is  $D_f$ -firm and  $D_f$ -nonexpansive whenever  $\alpha \in (0, \frac{1}{2})$  with  $\beta = \sqrt{\alpha(1 - \alpha)}\gamma^{-1}$  in the contractive case and  $\beta = (1 - 2\alpha)\delta$  in the strongly monotone case.

In order to prove this observe that, in the current setting,  $\nabla f = \text{Proj}_C^f = I$ . Also, the  $D_f$ -firmness condition (3.14) for  $T = V^f$  is equivalent to (4.34) and this is exactly

$$\begin{aligned} & \langle [(1 - \alpha)x - \beta\xi] - [(1 - \alpha)y - \beta\eta], x - y \rangle \\ & \geq \|[(1 - \alpha)x - \beta\xi] - [(1 - \alpha)y - \beta\eta]\|^2, \end{aligned}$$

which can be equivalently rewritten as

$$(4.52) \quad \alpha(1 - \alpha) \|x - y\|^2 + (1 - 2\alpha)\beta \langle \xi - \eta, x - y \rangle \geq \beta^2 \|\xi - \eta\|^2$$

for all pairs  $(x, \xi), (y, \eta) \in \text{Graph } B$ . Moreover, if  $V^f$  is  $D_f$ -firm, then it is also  $D_f$ -nonexpansive. Due to the monotonicity of  $B$ , the inequality (4.52) holds whenever  $\alpha \in (0, \frac{1}{2})$  and

$$(4.53) \quad \alpha(1 - \alpha) \|x - y\|^2 \geq \beta^2 \|\xi - \eta\|^2 \quad \forall (x, \xi) \in \text{Graph } B, \quad \forall (y, \eta) \in \text{Graph } B.$$

If  $B$  is contractive with constant  $\gamma$ , then we have

$$\gamma \|x - y\| \geq \|\xi - \eta\| \quad \forall (x, \xi) \in \text{Graph } B, \quad \forall (y, \eta) \in \text{Graph } B,$$

and multiplying this inequality by  $\beta = \sqrt{\alpha(1 - \alpha)}\gamma^{-1}$  we deduce that (4.53) holds. Similarly, note that (4.52) is satisfied when

$$(4.54) \quad (1 - 2\alpha) \langle \xi - \eta, x - y \rangle \geq \beta \|\xi - \eta\|^2 \quad \forall (x, \xi) \in \text{Graph } B, \quad \forall (y, \eta) \in \text{Graph } B.$$

If  $B$  is strongly monotone with constant  $\delta$ , then

$$\langle \xi - \eta, x - y \rangle \geq \delta \|\xi - \eta\|^2 \quad \forall (x, \xi) \in \text{Graph} B, \quad \forall (y, \eta) \in \text{Graph} B.$$

Multiplying this inequality by  $(1 - 2\alpha)$  we deduce that (4.54) holds in this case.  $\square$

In situations in which  $X$  is not a Hilbert space, or  $X$  is a Hilbert space but the monotone operator  $B$  does not satisfy (4.52) for some  $\alpha \in (0, \frac{1}{2})$  and  $\beta > 0$ , the question of how to choose the “regularization function”  $f$  and the “regularization parameter”  $\alpha$  in the perturbed variational inequality (4.44) in order to force  $D_f$ -firmness and/or  $D_f$ -nonexpansivity on  $V^f = \text{Proj}_C^f((1 - \alpha)\nabla f - B)$  is relevant. Here are examples of situations when  $V^f$  is  $D_f$ -firm even if  $X$  is not a Hilbert space.

*Example 4.12.* If the monotone operator  $B : X \rightarrow 2^{X^*}$  and the nonempty closed convex subset  $C$  of  $\text{dom } B \cap \text{int dom } f$  have the property (4.45), then  $V^f = \text{Proj}_C^f((1 - \alpha)\nabla f - B)$  is  $D_f$ -firm in any of the following situations:

(a)  $C = X$ ,  $\alpha \in (0, 1)$ , and the operator  $\alpha\nabla f + B$  is  $D_f$ -inverse strongly monotone on its domain;

(b)  $X$  is a Hilbert space,  $C = X$ ,  $f = \frac{1}{2} \|\cdot\|^2$ ,  $\alpha \in (0, \frac{1}{2}]$ , and  $B$  is contractive with constant  $\alpha(1 - \alpha)$ .

In order to show this, observe that in case (a), according to Lemma 2.1, we have  $V^f = (\alpha\nabla f + B)^f$  and, by Lemma 3.5(c), the conclusion follows. In case (b) we have that both  $\nabla f$  and  $\text{Proj}_C^f$  coincide with the identity operator  $I$ . Also,  $B$  is necessarily single-valued because it is contractive. These imply (see section 3) that verification of the  $D_f$ -firmness of  $V^f$  amounts to verifying the firm nonexpansivity of  $(1 - \alpha)I - B$ . Note that  $(1 - \alpha)I - B$  is firmly nonexpansive (see (3.10)) if and only if the operator  $\alpha I + B$  is firmly nonexpansive, that is, if and only if

$$\begin{aligned} & \alpha^2 \|x - y\|^2 + 2\alpha \langle x - y, Bx - By \rangle + \|Bx - By\|^2 \\ & \leq \alpha \|x - y\|^2 + \langle x - y, Bx - By \rangle \quad \forall x, y \in X. \end{aligned}$$

Since  $\alpha \in (0, \frac{1}{2}]$  and  $B$  is monotone, the last inequality holds whenever

$$(4.55) \quad \alpha^2 \|x - y\|^2 + \|Bx - By\|^2 \leq \alpha \|x - y\|^2 \quad \forall x, y \in X.$$

By the contractivity of  $B$  with constant  $\alpha(1 - \alpha)$  we deduce that  $\|Bx - By\|^2 \leq \alpha^2(1 - \alpha)^2 \|x - y\|^2$ , and this shows that (4.55) is obviously satisfied.  $\square$

Example 4.12(a), in conjunction with Corollary 4.10, leads to an algorithm for solving the variational inequality (4.44) whenever it is possible to find a Legendre function  $f$  and a number  $\alpha \in (0, 1)$  such that  $\alpha\nabla f + B$  is  $D_f$ -inverse strongly monotone on its domain. Example 4.12(b) points out a situation in which the assumptions of Corollary 4.10(b) hold and, thus, weak convergence of procedure (4.46) to the (presumed existing) solution of the variational inequality (4.44) is guaranteed.

*Example 4.13.* If the monotone operator  $B : X \rightarrow 2^{X^*}$  and the nonempty closed convex subset  $C$  of  $\text{dom } B \cap \text{int dom } f$  have the property (4.45), and if

$$(4.56) \quad \begin{aligned} & \left\langle [\alpha\nabla f(x) + \xi] - [\alpha\nabla f(y) + \eta], \right. \\ & \left. \text{Proj}_C^f [(1 - \alpha)\nabla f(x) - \xi] - \text{Proj}_C^f [(1 - \alpha)\nabla f(y) - \eta] \right\rangle \geq 0, \end{aligned}$$

for any  $(x, \xi)$  and  $(y, \eta)$  in  $\text{Graph} B$ , then the operator  $V^f = \text{Proj}_C^f[(1 - \alpha)\nabla f - B]$  is  $D_f$ -firm. In particular, this happens in any of the following situations:

- (a)  $B = (\frac{1}{2} - \alpha) \nabla f$  and  $\alpha \in (0, \frac{1}{2})$ ;  
 (b) the operator  $P : X \times X^* \rightarrow 2^{X^* \times X}$ , defined by

$$(4.57) \quad P(z, \zeta) = (0^*, \text{Proj}_C^f((1 - \alpha)\nabla f(z) - \zeta)),$$

for some  $\alpha \in (0, 1)$  is monotone when  $X \times X^*$  is provided with the norm  $\|(z, \zeta)\| = (\|z\|^2 + \|\zeta\|_*^2)^{1/2}$  and with the duality pairing  $\langle (z, \zeta), (\zeta', z') \rangle = \langle \zeta', z \rangle + \langle \zeta, z' \rangle$  (and, therefore, its dual is isometric with  $X^* \times X$ ).

Let  $x, y \in \text{dom } V^f$  and let  $\xi \in Bx$  and  $\eta \in By$ . Denote

$$x' = \text{Proj}_C^f((1 - \alpha)\nabla f(x) - \xi) \text{ and } y' = \text{Proj}_C^f((1 - \alpha)\nabla f(y) - \eta).$$

By Lemma 2.1 we have

$$(1 - \alpha)\nabla f(x) - \xi - \nabla f(x') \in N_C(x') \text{ and } (1 - \alpha)\nabla f(y) - \eta - \nabla f(y') \in N_C(y'),$$

which imply

$$\langle (1 - \alpha)\nabla f(x) - \xi, y' - x' \rangle \leq \langle \nabla f(x'), y' - x' \rangle$$

and, respectively,

$$\langle (1 - \alpha)\nabla f(y) - \eta, x' - y' \rangle \leq \langle \nabla f(y'), x' - y' \rangle.$$

Summing up the last two inequalities, we obtain that

$$(4.58) \quad \begin{aligned} & \langle [(1 - \alpha)\nabla f(x) - \xi] - [(1 - \alpha)\nabla f(y) - \eta], x' - y' \rangle \\ & \geq \langle \nabla f(x') - \nabla f(y'), x' - y' \rangle. \end{aligned}$$

The  $D_f$ -firmness condition (3.14) for the operator  $T = V^f$  is exactly

$$\langle \nabla f(x) - \nabla f(y), x' - y' \rangle \geq \langle \nabla f(x') - \nabla f(y'), x' - y' \rangle.$$

According to (4.58), this is satisfied when

$$\langle \nabla f(x) - \nabla f(y), x' - y' \rangle \geq \langle [(1 - \alpha)\nabla f(x) - \xi] - [(1 - \alpha)\nabla f(y) - \eta], x' - y' \rangle,$$

and this last inequality is equivalent to (4.56). Hence, if (4.56) holds, then the operator  $V^f$  is  $D_f$ -firm. In case (a) we have that  $\alpha \nabla f + B = (1 - \alpha)\nabla f - B$ , and using the monotonicity of  $\text{Proj}_C^f$  (cf. [38, Theorem 4.6]) one deduces that (4.56) holds. Suppose that we are in case (b) and the operator  $P$ , given by (4.57), is monotone. Then observe that

$$\begin{aligned} & \left\langle [\alpha \nabla f(x) + \xi] - [\alpha \nabla f(y) + \eta], \right. \\ & \left. \text{Proj}_C^f[(1 - \alpha)\nabla f(x) - \xi] - \text{Proj}_C^f[(1 - \alpha)\nabla f(y) - \eta] \right\rangle \\ & = \langle (x, \alpha \nabla f(x) + \xi) - (y, \alpha \nabla f(y) + \eta), P(x, \xi) - P(y, \eta) \rangle, \end{aligned}$$

and that the last expression is nonnegative due to the monotonicity of  $P$  (see [38, Proposition 4.7]). Hence, (4.56) holds in this case too.  $\square$

Note that problem (4.44), in which  $B = \beta \nabla f$  for some  $\beta > 0$ , is equivalent to the problem of finding the minimizer of  $f$  over  $C$ . The facts observed in Example 4.13(a), in conjunction with Corollary 4.10, lead to a proximal-projection method of finding that minimizer, provided that  $f$  satisfies the other requirements there. Obviously, the effectiveness of that method, as well as of the other methods discussed in this work, depends on the possibility of computing proximal projections onto  $C$ . Algorithms for computing proximal projections are presented in [5], [22], and [38].

Observe that the definition of the operator  $P$ , given by (4.57), does not involve the operator  $B$  but only the Legendre function  $f$ , the closed and convex set  $C$ , and the real number  $\alpha \in (0, 1)$ . Thus, Example 4.13(b) shows that if  $P$  is monotone, then  $\text{Proj}_C^f [(1 - \alpha) \nabla f - B]$  is  $D_f$ -firm for all monotone operators  $B : X \rightarrow 2^{X^*}$ . In other words, if for the Legendre function  $f$ , the closed and convex set  $C$  and the real number  $\alpha \in (0, 1)$  monotonicity of  $P$  can be ensured, then Corollary 4.10 guarantees solvability of a large class of variational inequalities via the particular variant of proximal-projection method (4.46). Since in the process of solving variational inequalities the set  $C$  is a priori given, one should ask whether on some Banach spaces one can find Legendre functions  $f$  for which monotonicity of  $P$  is ensured for some  $\alpha \in (0, 1)$  no matter how the closed and convex set  $C$  is chosen. We do not have any example to prove or disprove existence of spaces  $X$  on which such a Legendre function  $f$  exists.

**5. Convergence of the proximal-projection method in spaces of finite dimension.** Theorem 4.7 and its corollaries ensure weak and, sometimes, strong convergence of the proximal-projection method to solutions of Problem 1.1 under conditions which, besides the  $D_f$ -inverse strong monotonicity of the operator  $A$ , require sequential weak-strong closedness of the  $\text{Graph} A$  or, alternatively,  $D_f$ -nonexpansivity of  $A^f$ . In this section we show that, when the space  $X$  has finite dimension, some of these requirements can be dropped or weakened. This is possible due to the validity in spaces of finite dimension of another generalization of Browder's demiclosedness principle, which we present below.

**5.1. Another variant of the generalized demiclosedness principle.** The following result applies to operators  $T : X \rightarrow 2^X$  which are not necessarily  $D_f$ -nonexpansive but satisfy condition (5.2) below, which is more general than  $D_f$ -firmness (compare condition (5.2) with Definition 3.4). It is interesting to observe that, if  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$  and if  $T$  has a closed graph, then the conclusion of the next result holds even if the hypothesis that  $u$  satisfies (5.2) is removed. This happens because the equality in (5.1) implies that the sequences  $\{z^k\}_{k \in \mathbb{N}}$  and  $\{u^k\}_{k \in \mathbb{N}}$  converge to the same limit  $z$  and, then, closedness of the graph of  $T$  guarantees that  $z \in Tz$ .

**PROPOSITION 5.1.** *Suppose that the space  $X$  has finite dimension,  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ , and  $T : X \rightarrow 2^X$  is an operator satisfying condition (3.13). Let  $\{z^k\}_{k \in \mathbb{N}}$  be a sequence in  $\text{dom } T$  converging to an element  $z \in \text{dom } T$ . If for some sequence  $\{u^k\}_{k \in \mathbb{N}}$  satisfying*

$$(5.1) \quad (\forall k \in \mathbb{N} : u^k \in Tz^k) \quad \text{and} \quad \lim_{k \rightarrow \infty} D_f(u^k, z^k) = 0,$$

*there exists  $u \in Tz$  such that*

$$(5.2) \quad \liminf_{k \rightarrow \infty} \langle \nabla f(u^k) - \nabla f(u), u^k - u \rangle \leq 0,$$

*then the vector  $z$  is a fixed point of  $T$ .*

*Proof.* Since the function  $f$  is convex and differentiable on  $\text{int dom } f$ , the gradient  $\nabla f$  is continuous on  $\text{int dom } f$ . This fact and the strict convexity of  $f$  on  $\text{int dom } f$  imply that

$$(5.3) \quad \lim_{k \rightarrow \infty} \langle \nabla f(z^k) - \nabla f(x), z^k - x \rangle = \langle \nabla f(z) - \nabla f(x), z - x \rangle > 0$$

whenever  $x \in (\text{int dom } f) \setminus \{z\}$ . Because the function  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ , it is also sequentially consistent (cf. [38, Theorem 2.10]). Therefore, the equality in (5.1) implies that

$$(5.4) \quad \lim_{k \rightarrow \infty} \|z^k - u^k\| = 0.$$

Consequently, the sequences  $\{z^k\}_{k \in \mathbb{N}}$  and  $\{u^k\}_{k \in \mathbb{N}}$  converge to the same limit  $z$ . By condition (3.13), the boundedness of  $\{u^k\}_{k \in \mathbb{N}}$ , and the continuity of  $\nabla f$ , we deduce that

$$(5.5) \quad \lim_{k \rightarrow \infty} \langle \nabla f(z^k) - \nabla f(z), z^k - z \rangle = 0 = \lim_{k \rightarrow \infty} \langle \nabla f(z^k) - \nabla f(z), u^k - u \rangle.$$

Note that

$$(5.6) \quad \begin{aligned} \langle \nabla f(u^k) - \nabla f(u), u^k - u \rangle &= \langle \nabla f(u^k) - \nabla f(u), u^k - z^k \rangle \\ &\quad + \langle \nabla f(u^k) - \nabla f(u), z^k - u \rangle \\ &= \langle \nabla f(u^k) - \nabla f(u), u^k - z^k \rangle \\ &\quad + \langle \nabla f(z^k) - \nabla f(u), z^k - u \rangle \\ &\quad + \langle \nabla f(u^k) - \nabla f(z^k), z^k - u \rangle. \end{aligned}$$

Since the sequence  $\{\nabla f(u^k)\}_{k \in \mathbb{N}}$  is bounded, it follows from (5.4) that the first term of the last sum in (5.6) converges to zero as  $k \rightarrow \infty$ . The continuity of  $\nabla f$  and the fact noted above that the sequences  $\{u^k\}_{k \in \mathbb{N}}$  and  $\{z^k\}_{k \in \mathbb{N}}$  converge to the same limit  $z$  imply that the third term of the last sum converges to zero as  $k \rightarrow \infty$ . Taking the limit as  $k \rightarrow \infty$  on both sides of (5.6), we obtain that

$$(5.7) \quad \lim_{k \rightarrow \infty} \langle \nabla f(u^k) - \nabla f(u), u^k - u \rangle = \lim_{k \rightarrow \infty} \langle \nabla f(z^k) - \nabla f(u), z^k - u \rangle.$$

In order to conclude the proof, suppose by contradiction that  $z \notin T(z)$ . Then,  $u \neq z$  and, therefore, by (5.5), (5.2), (5.7), and (5.3), respectively, we obtain

$$\begin{aligned} 0 &= \lim_{k \rightarrow \infty} \langle \nabla f(z^k) - \nabla f(z), z^k - z \rangle = \lim_{k \rightarrow \infty} \langle \nabla f(z^k) - \nabla f(z), u^k - u \rangle \\ &\geq \lim_{k \rightarrow \infty} \langle \nabla f(u^k) - \nabla f(u), u^k - u \rangle = \lim_{k \rightarrow \infty} \langle \nabla f(z^k) - \nabla f(u), z^k - u \rangle > 0, \end{aligned}$$

which is a contradiction.  $\square$

**5.2. A convergence theorem for the proximal-projection method in spaces of finite dimension.** The following theorem shows that, in finite-dimensional spaces, convergence of the proximal-projection method to solutions of Problem 1.1 can be ensured with lesser requirements on the operator  $A$ , in addition to the  $D_f$ -inverse strong monotonicity, than those involved in Theorem 4.7 and its corollaries.

**THEOREM 5.2.** *Suppose that the space  $X$  has finite dimension,  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ ,  $\nabla f^*$  is bounded on bounded subsets of  $\nabla f(\text{dom } A)$ , that (1.6) and Assumption 1.2 hold, and*

$$(5.8) \quad C \cap \text{dom } A = \text{w-}\overline{\lim}_{k \rightarrow \infty} (C_k \cap \text{dom } A).$$

If Problem 1.1 has at least one solution, if the operator  $A : X \rightarrow 2^{X^*}$  is  $D_f$ -inverse strongly monotone on  $Q = \bigcup_{k=0}^{\infty} C_k$ , and if  $C \cap \text{dom } A$  is closed, then the sequences generated by the proximal-projection method (1.7) are well defined and converge to solutions of Problem 1.1.

*Proof.* Well definedness of the sequences generated by (1.7) follows from (1.6) and Assumption 1.2. Suppose that, for each  $k \in \mathbb{N}$ ,  $\zeta^k$  and  $u^k$  are as in (4.19) and (4.20), respectively. Then, clearly, condition (4.21) holds too. Because the operator  $A$  is  $D_f$ -inverse strongly monotone on its domain, the operator  $A^f$  is  $D_f$ -firm (cf. Lemma 3.5). This means that

$$(5.9) \quad \langle \nabla f(u^k) - \nabla f(u), u^k - u \rangle \leq \langle \nabla f(x^k) - \nabla f(x), u^k - u \rangle$$

for any pair  $(x, u) \in \text{Graph } A^f$  and for any  $k \in \mathbb{N}$ . Now, repeating without change the arguments in the proof of Theorem 4.7, one can see that Claim 1 proved there still holds in our setting and implies that the sequence  $\{x^k\}_{k \in \mathbb{N}}$  is bounded. Let  $\{x^{i_k}\}_{k \in \mathbb{N}}$  be a convergent subsequence of  $\{x^k\}_{k \in \mathbb{N}}$  and let  $\bar{x}$  be its limit. An argument identical to that made in the proof of Theorem 4.7 (Claim 2) for the same purpose shows that  $\bar{x} \in C$  and (4.30) holds. According to (5.8), since  $x^{i_k} \in C_{i_k} \cap \text{dom } A$ , it results that

$$(5.10) \quad \bar{x} \in C \cap \text{dom } A.$$

This and (1.6) imply that  $(\nabla f - A)(\bar{x}) \neq \emptyset$ . So, by Assumption 1.2, we deduce

$$\emptyset \neq (\nabla f - A)(\bar{x}) \subseteq (\nabla f - A)(C) \subseteq (\nabla f - A)(C_k) \subseteq \text{int dom } f^*,$$

which clearly implies that  $\bar{x} \in \text{dom } A^f$ . Now, taking into account that, by (5.10),  $A\bar{x} \neq \emptyset$ , writing (5.9) for  $i_k$  instead of  $k$  and  $\bar{x}$  instead of  $x$ , and for any  $u \in A\bar{x}$ , and letting in the resulting inequality  $k \rightarrow \infty$ , we deduce that

$$(5.11) \quad \liminf_{k \rightarrow \infty} \langle \nabla f(u^{i_k}) - \nabla f(u), u^{i_k} - u \rangle \leq 0$$

because  $\nabla f$  is continuous on  $\text{int dom } f$ . This shows that the sequence  $\{u^{i_k}\}_{k \in \mathbb{N}}$  satisfies (5.2) for  $T = A^f$ ,  $z = \bar{x}$ , and any  $u \in A^f \bar{x}$ . Also, by (4.30) and (5.11), the sequences  $\{x^{i_k}\}_{k \in \mathbb{N}}$  and  $\{u^{i_k}\}_{k \in \mathbb{N}}$  satisfy (5.1). Hence, Proposition 5.1 applies to  $T = A^f$ ,  $z = \bar{x}$ , and  $u \in A^f \bar{x}$ . By consequence, we have that  $\bar{x}$  is a fixed point of  $A^f$  and, hence, a zero of  $A$ . It remains to prove that  $\bar{x}$  is the only accumulation point of the sequence  $\{x^k\}_{k \in \mathbb{N}}$ . The proof in this respect reproduces without modifications the arguments made in the proof of Theorem 4.7 in order to show that the sequence  $\{x^k\}_{k \in \mathbb{N}}$  has a single weak accumulation point when  $\nabla f$  is sequentially weak-to-weak continuous.  $\square$

**5.3. Consequences of Theorem 5.2.** Using Theorem 5.2 instead of Theorem 4.7 we can prove again Corollaries 4.9 and 4.10 in a finite-dimensional setting with different, and less demanding, conditions on  $A$ . Here is the new version of Corollary 4.9.

**COROLLARY 5.3.** *Suppose that the space  $X$  has finite dimension,  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ , and  $\text{dom } f^* = X^*$ . If  $B : X \rightarrow 2^{X^*}$  is a monotone operator satisfying (3.24) and having at least one zero, and if any of the following conditions holds:*

- (a)  $\text{ran } (\nabla f + B)$  is closed in  $X^*$  and  $\nabla f^*(\text{ran } (\nabla f + B))$  is convex;
- (b)  $\text{ran } (\nabla f + B) = X^*$ ,

then the sequences generated by the proximal point method (3.23) converge to zeros of the operator  $B$ .

*Proof.* Recall that in this setting  $\nabla f^*$  is bounded on bounded subsets of  $\text{int dom } f^*$  (cf. Remark 4.6(d)). Observe that, according to Lemma 3.7, we have that

$$\text{dom } A[B_f] = \text{dom } B_f = \nabla f^*(\text{ran } (\nabla f + B)).$$

Therefore, if condition (a) holds, the set  $\text{dom } A[B_f] = \text{dom } B_f$  is closed and convex. Since condition (b) implies (a), this remains true when (b) holds. Again by Lemma 3.7, the operator  $A[B_f]$  is  $D_f$ -inverse strongly monotone on its domain. Consequently, the operator  $A := A[B_f]$  satisfies the requirements of Theorem 5.2 when  $C = C_k = X$  for all  $k \in \mathbb{N}$ . Applying Theorem 5.2 to  $A[B_f]$  and taking into account Lemma 3.8, the conclusion follows.  $\square$

Now we give another variant of Corollary 4.10(a) in which the condition that  $A$  should have a closed graph is replaced by less demanding requirements.

**COROLLARY 5.4.** *Let  $B : X \rightarrow 2^{X^*}$  be a monotone operator. Suppose that the space  $X$  has finite dimension,  $f$  is uniformly convex on bounded subsets of  $\text{int dom } f$ , and  $\text{dom } f^* = X^*$ . If  $C$  is a closed convex subset of  $\text{dom } B \cap \text{int dom } f$  such that, for some real number  $\alpha > 0$ ,*

$$(5.12) \quad \emptyset \neq ((1 - \alpha)\nabla f - B)(C) \subseteq \text{int dom } f^*,$$

*and the operator  $\text{Proj}_C^f \circ [(1 - \alpha)\nabla f - B]$  is  $D_f$ -firm, then the iterative procedure given by (4.46) is well defined and converges to the necessarily unique solution of the variational inequality (4.44), provided that such a solution exists.*

*Proof.* Since (4.48) and (4.49) still hold, the operator  $V$  given by (4.47) is  $D_f$ -inverse strongly monotone on its domain (cf. Lemma 3.7). By (5.12) and by the fact that  $C \subseteq \text{dom } B \cap \text{int dom } f$ , it results that  $C \subseteq \text{dom } V$ . Hence, Theorem 5.2 applies to the operator  $A = V$  and the sets  $C_k = C$ , and the conclusion follows.  $\square$

# ALMOST SURE STABILITY OF DISCRETE-TIME SWITCHED LINEAR SYSTEMS: A TOPOLOGICAL POINT OF VIEW\*

XIONGPING DAI<sup>†</sup>, YU HUANG<sup>‡</sup>, AND MINGQING XIAO<sup>§</sup>

**Abstract.** In this paper, we study the stability of discrete-time switched linear systems via symbolic topology formulation and the multiplicative ergodic theorem. A sufficient and necessary condition for  $\mu_A$ -almost sure stability is derived, where  $\mu_A$  is the Parry measure of the topological Markov chain with a prescribed transition (0,1)-matrix  $A$ . The obtained  $\mu_A$ -almost sure stability is invariant under small perturbations of the system. The topological description of stable processes of switched linear systems in terms of Hausdorff dimension is given, and it is shown that our approach captures the maximal set of stable processes for linear switched systems. The obtained results cover the stochastic Markov jump linear systems, where the measure is the natural Markov measure defined by the transition probability matrix. Two examples are provided to illustrate the theoretical outcomes of the paper.

**Key words.** discrete-time switched linear system, topological Markov chain, almost sure stability, Lyapunov exponent, Hausdorff dimension

## 1. Introduction.

**1.1. Motivation.** A switched linear system consists of a family of linear subsystems and a rule that governs the switching among them. These types of models are found in many practical systems in which switching is necessary and essential as the system dynamics evolve. More specifically, we consider the discrete-time dynamical system in the form of

$$(1.1) \quad x_{\ell+1} = H_{\omega_\ell} x_\ell, \quad \ell \geq 0,$$

where  $x_\ell \in \mathbb{R}^n$  and  $n \geq 2$  is a fixed integer,  $\omega_\ell$  takes a value in a given finite-symbolic set, say  $\mathcal{A} = \{1, \dots, \kappa\}$ , and  $H_i \in \mathbb{R}^{n \times n}$  for  $i \in \mathcal{A}$ . Let us denote the nonnegative integer set by  $\mathbb{Z}_+ = \{0, 1, 2, \dots\}$  and the set of all mappings  $\mathbb{Z}_+ \rightarrow \mathcal{A}$  by

$$(1.2) \quad \Sigma_\kappa = \{\omega: \mathbb{Z}_+ \rightarrow \mathcal{A}\}.$$

Then switching can be classified into two situations: (i) arbitrary switching; i.e., the switching rule is characterized by  $\Sigma_\kappa$  defined by (1.2); (ii) switching is subject to certain constraints; i.e., the switching rule is characterized by a subset of  $\Sigma_\kappa$ .

Stability is the primary concern for switched systems. The analysis of its stability is much more difficult and challenging than that of linear systems. When arbitrary

switching is considered, a switched system is said to be asymptotically stable if *all* its trajectories converge to the origin. This is also called absolute stability, and it requires that all infinite products of matrices taken from  $\{H_1, H_2, \dots, H_\kappa\}$  converge to zero. That is,  $\lim_{\ell \rightarrow \infty} \prod_{j=0}^{\ell-1} H_{\omega_j} = 0$  for any index sequence  $\{\omega_0, \omega_1, \dots\}$  with  $\omega_j \in \mathcal{A}$ . This can be equivalently stated by requiring the joint spectral radius of  $\{H_1, H_2, \dots, H_\kappa\}$  to be strictly less than one [3]. To the best of our knowledge, the study of stability of switched linear systems (1.1) has been focused on absolute stability (for example, see [13, 19, 29, 30, 32, 34, 35] and references therein). Currently available approaches for showing absolute stability of switched systems are essentially based on the search of common Lyapunov functions or variations of the same framework. The existence of a common Lyapunov function for a given switched system is quite restrictive, since an expecting common Lyapunov function has to guarantee that the energy of the overall system decreases to zero along all possible state trajectories governed by switches. Moreover, some critical situations are not able to be addressed by using the Lyapunov function approach. For instance, it is well known that the system (1.1) may not be absolutely stable even if each  $H_i, i \in \mathcal{A}$ , is asymptotically stable (i.e., all eigenvalues of  $H_i$  are inside the unit circle) (e.g., see [9]). A switched system that is not absolutely stable does not imply the end of stability analysis of the system. For example, for the stochastic Markov jump systems, almost sure stability (instead of absolute stability) plays a key role in the study of these types of systems, since it provides important convergence information in an “average” sense (under appropriate probability measures) which has been proved to be very useful and effective in applications (see [5, 6, 15, 16, 17, 20, 21, 23, 22, 26, 24, 27, 31, 37] and references therein). Another situation is when switching is subject to a subset of  $\Sigma_\kappa$  (so-called admissible switching set); in this case, how to identify the stability of (1.1) has not been clearly characterized yet.

The main challenge for the study of switched systems results from the switched paths that are arbitrary, although it may be subject to some constraints. The switched mechanism basically is uncertain, and the stability analysis has to cover all possible switchings (jumps). With such an uncertainty, the condition of absolute stability of switched systems is hardly met as the number of switches increases (i.e.,  $\kappa$  is getting large). Thus, to look for condition(s) of “almost” stability instead of absolute stability becomes more realistic in real applications.

In this paper we apply the ergodic theorem from the topology point of view to discuss the stability of (1.1), an approach that is not available in the current literature. More specifically, we translate the problem (1.1) into a finite state topological Markov chain setting under the framework of symbolic topology formulation. Then we study the dynamics (1.1) by the Lyapunov exponents based on the corresponding topological Markov chain. The main mathematical tool is the multiplicative ergodic theorem, which is a fundamental theory for describing the qualitative behaviors of dynamical systems in terms of the statistical characterization. We derive a necessary and sufficient condition for  $\mu_A$ -almost sure stability of (1.1) in which  $\mu_A$  is the Parry measure, i.e., the unique measure with maximal entropy for the underlying setting. Moreover, we have shown that the almost sure stability is not altered under small linear perturbation of the system (1.1), which is important and critical for real applications. Furthermore, a topological description of stable processes of (1.1) in terms of Hausdorff dimension is given, and this finding illustrates the significance for choosing the measure  $\mu_A$  (the Parry measure). Our obtained results cover the stochastic Markov jump linear systems, where the measure is the natural Markov measure defined by the transition probability matrix. The proposed approach and the

obtained results of this paper provide a fresh point of view for the study of switched systems.

**1.2. Outlines.** The paper is organized as follows. In section 2, we transform the switched system (1.1) to a symbolic dynamical system under the framework of topology. Then system (1.1) with constraints is expressed equivalently as a one-sided topological Markov chain with a prescribed transition  $(0,1)$ -matrix  $A$ . The concept of almost sure stability is introduced, and two preliminary propositions are provided in this section. In section 3, a necessary and sufficient condition for  $\mu_A$ -almost sure stability of (1.1) is presented, and a topological description of stable processes of (1.1) in terms of Hausdorff dimension is given. Section 4 addresses the connection between our obtained results and those for stochastic Markov jump linear systems. Two examples, one for arbitrary switching and another for restricted switching, are provided to illustrate theoretical results of the paper in section 5. The paper ends with concluding remarks.

**1.3. Matrix norms.** Let  $H = (h_{ij})$  be an  $n \times n$  matrix of real numbers. Throughout this paper the *norm*,  $\|H\|$ , of  $H$  can be either  $\|H\|_F$ , or  $\|H\|_1$ , or  $\|H\|_\infty$ , whose definitions are, respectively,

$$\|H\|_F = \sqrt{\sum_{i,j=1}^n |h_{ij}|^2}, \quad \|H\|_1 = \sum_{i,j=1}^n |h_{ij}|, \quad \text{and} \quad \|H\|_\infty = \max_{1 \leq i,j \leq n} |h_{ij}|.$$

It is known that these norms satisfy the following properties:

$$\begin{aligned} (1.3a) \quad & \|H + H'\| \leq \|H\| + \|H'\|, \\ (1.3b) \quad & \|HH'\| \leq \|H\|\|H'\|, \\ (1.3c) \quad & \|Hx\| \leq \|H\|\|x\|, \end{aligned}$$

where  $H'$  is also an  $n \times n$  matrix, and  $x = (x_1, \dots, x_n)^T \in \mathbb{R}^n$  is an  $n$ -dimensional vector. In particular (1.3c) holds for  $\|H\|$  in terms of corresponding induced norms in  $\mathbb{R}^n$  by  $\|x\| = \sqrt{\sum_{i=1}^n |x_i|^2}$ , or  $\sum_{i=1}^n |x_i|$ , or  $\max_{1 \leq i \leq n} |x_i|$ , respectively.

**2. Symbolic topology formulation.** We use a symbolic string  $\omega = (\omega_0 \omega_1 \dots)$  with  $\omega_j \in \mathcal{A} = \{1, \dots, \kappa\}$  to represent a specific switching path of (1.1). The set of all possible switching paths  $\omega = (\omega_0 \omega_1 \dots)$  is the  $\kappa$ -dimensional one-sided symbolic space given by (1.2), that is,

$$\Sigma_\kappa = \{\omega = (\omega_0 \omega_1 \dots) \mid \omega_i \in \mathcal{A} \text{ for } i = 0, 1, 2, \dots\},$$

which is a compact metric space endowed with the usual distance function

$$(2.1a) \quad \text{dist}(\omega, \omega') = \rho^{-n(\omega, \omega')} \quad \forall \omega, \omega' \in \Sigma_\kappa,$$

where  $\rho > 1$  is any prescribed constant and

$$(2.1b) \quad n(\omega, \omega') = \inf\{\ell \in \mathbb{Z}_+ \mid \omega_\ell \neq \omega'_\ell\}.$$

If  $\omega_\ell = \omega'_\ell$  for all nonnegative integers  $\ell$ , then  $n(\omega, \omega') := +\infty$ .

In order to include those cases in which switching constraints exist, let  $A = [a_{ij}]$  be an irreducible  $(0,1)$ -matrix of size  $\kappa \times \kappa$ , which is predefined. That is,  $a_{ij}$  equals

either 0 or 1, and for any pair  $(i, j)$  there is some integer  $n > 0$  such that  $a_{ij}^{(n)} > 0$ , where  $a_{ij}^{(n)}$  is the  $(i, j)$ th element of  $A^n$ . The *admissible set*  $\Sigma_A$  is defined to be

$$\Sigma_A = \{ \omega = (\omega_0 \omega_1 \cdots) \in \Sigma_\kappa \mid a_{\omega_\ell \omega_{\ell+1}} = 1 \text{ for } \ell = 0, 1, \dots \}.$$

Thus it is clear that in general  $\Sigma_A \subset \Sigma_\kappa$ . For the arbitrary switching case where the matrix  $A$  satisfies  $a_{ij} \equiv 1$  for any  $1 \leq i, j \leq \kappa$ , we have  $\Sigma_A = \Sigma_\kappa$ . Clearly the matrix  $A$  contains transition information of all admissible paths, and thus it is usually called a transition matrix.

It is not difficult to see that if  $(\omega_0 \omega_1 \omega_2 \cdots) \in \Sigma_A$ , then we have  $(\omega_1 \omega_2 \cdots) \in \Sigma_A$ . The  $\Sigma_A$ -invariant mapping

$$\sigma_A: \Sigma_A \rightarrow \Sigma_A; \quad (\omega_0 \omega_1 \cdots) \mapsto (\omega_1 \omega_2 \cdots)$$

is called the one-sided shift defined by the transition matrix  $A$ . The dynamical system  $(\Sigma_A, \sigma_A)$  is said to be a *one-sided topological Markov chain* with the transition matrix  $A$ , which is a compact subsystem of the one-sided full-shift dynamical system  $(\Sigma_\kappa, \sigma)$ , where  $\sigma: \Sigma_\kappa \rightarrow \Sigma_\kappa$  is similarly defined by  $(\omega_0 \omega_1 \cdots) \mapsto (\omega_1 \omega_2 \cdots)$  for any  $\omega = (\omega_0 \omega_1 \cdots) \in \Sigma_\kappa$ .

We next define a random matrix over  $\Sigma_A$  associated with the system (1.1) by

$$S: \Sigma_A \rightarrow \{H_1, \dots, H_\kappa\}; \quad \omega \mapsto S(\omega) = H_{\omega_0} \quad \forall \omega = (\omega_0 \omega_1 \cdots) \in \Sigma_A.$$

Let us denote for any  $t \in \mathbb{N}$  and for any  $\omega \in \Sigma_A$

$$(2.2a) \quad \sigma_A^t = \overbrace{\sigma_A \circ \cdots \circ \sigma_A}^{t \text{ times}} \quad \text{and} \quad \sigma_A^0 = id: \Sigma_A \rightarrow \Sigma_A$$

and

$$(2.2b) \quad S(\omega, t) = S(\sigma_A^{t-1} \omega) \cdots S(\omega): \mathbb{R}^n \rightarrow \mathbb{R}^n.$$

Here  $S(\cdot, \cdot)$  is called a *linear cocycle* based on  $(\Sigma_A, \sigma_A)$ . Notice that  $S(\sigma_A^\ell \omega) = H_{\omega_\ell}$  for any  $\omega = (\omega_0 \omega_1 \cdots)$  and  $\ell \in \mathbb{Z}_+$ . Then the system

$$(2.3) \quad x_{\ell+1} = S(\sigma_A^\ell \omega) x_\ell, \quad \text{where } \omega \in \Sigma_A,$$

can be regarded as a hybrid linear system with Markovian switchings. Thus for a specific path  $\omega$  and an initial condition  $x_0$ , according to (2.2), the state of (2.3) can be expressed as

$$(2.4a) \quad x_{\ell+1} = S(\omega, \ell + 1) x_0.$$

In fact  $S(\cdot, \cdot)$  describes the discrete-time linear skew-product flow  $\varphi_{\sigma_A, S}$  based on ergodic system  $(\Sigma_A, \sigma_A)$  in the following sense:

$$(2.4b) \quad \varphi_{\sigma_A, S}: \Sigma_A \times \mathbb{R}^n \times \mathbb{Z}_+ \rightarrow \Sigma_A \times \mathbb{R}^n; \quad (\omega, x, t) \mapsto (\sigma_A^t \omega, S(\omega, t)x).$$

For a given one-sided topological Markov chain  $(\Sigma_A, \sigma_A)$  with a transition matrix  $A$ , one always can define an invariant measure  $\mu$  under the one-sided shift  $\sigma_A$  from the classical Krylov–Bogolioubov theorem [36]. Now we are ready to introduce the definition of  $\mu$ -almost sure stability of (1.1).

DEFINITION 1. Let  $A$  be an irreducible transition matrix and  $\mu$  be an ergodic  $\sigma_A$ -invariant Borel probability measure on  $\Sigma_A$ ; namely,  $\mu(\sigma_A^{-1}B) = \mu(B)$  for any Borel subset  $B$  of  $\Sigma_A$ , and  $\mu(B) = 0$  or  $1$  whenever  $\sigma_A^{-1}B = B$  holds  $\mu$ -mod  $0$ .<sup>1</sup> The switched linear system (1.1) is said to be “ $\mu$ -almost surely stable” with respect to an admissible set  $\Sigma_A$  if (1.1) is exponentially stable for  $\mu$ -almost all switching sequences  $\omega$  in  $\Sigma_A$ . This is equivalent to saying that, for  $\mu$ -a.e. (almost everywhere)  $\omega \in \Sigma_A$ , we have

$$\lim_{\ell \rightarrow \infty} \frac{1}{\ell} \ln \|x_\ell\| = \lim_{\ell \rightarrow \infty} \frac{1}{\ell} \ln \|S(\omega, \ell)x_0\| < 0 \quad \forall x_0 \in \mathbb{R}^n.$$

Since  $\Sigma_A$  is compact under the metric given by (2.1), the set of all  $\sigma_A$ -invariant Borel probability measures on  $\Sigma_A$  is nonempty and is a compact convex set. It contains many elements. The question arises as to which is the most suitable member for the study of almost sure stability. In section 3, we shall show that the Parry measure, which has a strong ergodic property, is what we look for.

In order to introduce the concept of Lyapunov exponent, we need to show that the following proposition holds.

PROPOSITION 1. Let  $S(\cdot, \cdot)$  be the linear cocycle as in (2.2b) based on the ergodic system  $(\Sigma_A, \mu, \sigma_A)$ . Then we have

$$(2.5) \quad \lim_{t \rightarrow \infty} \frac{1}{t} \int_{\Sigma_A} \ln \|S(\omega, t)\| d\mu(\omega) = \inf_{t \in \mathbb{N}} \frac{1}{t} \int_{\Sigma_A} \ln \|S(\omega, t)\| d\mu(\omega).$$

*Proof.* Let us first define

$$f_t = \int_{\Sigma_A} \ln \|S(\omega, t)\| d\mu(\omega).$$

For any  $t_1, t_2 \in \mathbb{Z}_+$ , according to (2.2), for any  $\omega \in \Sigma_A$  one has

$$\begin{aligned} \|S(\omega, t_1 + t_2)\| &= \|S(\sigma_A^{t_1}\omega, t_2)S(\omega, t_1)\| \\ &\leq \|S(\sigma_A^{t_1}\omega, t_2)\| \|S(\omega, t_1)\|. \end{aligned}$$

The property  $\sigma_A$ -invariance of  $\mu$  implies

$$\int_{\Sigma_A} \ln \|S(\sigma_A^{t_1}\omega, t_2)\| d\mu(\omega) = \int_{\Sigma_A} \ln \|S(\omega, t_2)\| d\mu(\omega) = f_{t_2}.$$

Hence we have

$$\begin{aligned} f_{t_1+t_2} &\leq \int_{\Sigma_A} \ln \|S(\sigma_A^{t_1}\omega, t_2)\| d\mu(\omega) + \int_{\Sigma_A} \ln \|S(\omega, t_1)\| d\mu(\omega) \\ &= f_{t_1} + f_{t_2}. \end{aligned}$$

Therefore, the real sequence  $(f_t)_{t=0}^\infty$  is subadditive. From Kingman's subadditive ergodic theorem [36], it follows that

$$\lim_{t \rightarrow \infty} \frac{1}{t} \int_{\Sigma_A} \ln \|S(\omega, t)\| d\mu(\omega) = \inf_{t \in \mathbb{N}} \frac{1}{t} \int_{\Sigma_A} \ln \|S(\omega, t)\| d\mu(\omega),$$

which completes the proof.  $\square$

<sup>1</sup>Two Borel sets “ $B = C$   $\mu$ -mod  $0$ ” means that  $\mu((B \setminus C) \cup (C \setminus B)) = 0$ . In addition, the  $\sigma_A$ -invariance of  $\mu$  is equivalent to  $\int_{\Sigma_A} f d\mu = \int_{\Sigma_A} f \circ \sigma_A d\mu$  for all  $f \in C(\Sigma_A)$ , which we will use in the proof of Proposition 1, where  $C(\Sigma_A)$  denotes the set of all continuous real functions defined on  $\Sigma_A$ .

As a convention, the real number

$$\lambda(\sigma_A, S, \mu) := \lim_{t \rightarrow \infty} \frac{1}{t} \int_{\Sigma_A} \ln \|S(\omega, t)\| d\mu(\omega)$$

is called the *Lyapunov exponent* of the cocycle  $S(\cdot, \cdot)$  based on the ergodic system  $(\Sigma_A, \mu, \sigma_A)$  [18]. According to the *multiplicative ergodic theorem* (see, for example, [33]), for  $\mu$ -a.e.  $\omega \in \Sigma_A$  we know

$$(2.6) \quad \lambda(\sigma_A, S, \mu) = \lim_{t \rightarrow \infty} \frac{1}{t} \ln \|S(\omega, t)\|,$$

where the limit does not depend on the choice of the path  $\omega$ . This leads to a necessary and sufficient condition of  $\mu$ -almost sure stability for system (2.3) (or, equivalently, (1.1) subject to the constraint  $\Sigma_A$ ).

**PROPOSITION 2.** *Let  $\mu$  be an ergodic probability measure with respect to  $(\Sigma_A, \sigma_A)$ . Then the system*

$$x_{\ell+1} = S(\sigma_A^\ell \omega) x_\ell \quad \forall \omega \in \Sigma_A$$

*is  $\mu$ -almost surely stable if and only if*

$$\lambda(\sigma_A, S, \mu) < 0.$$

*Here  $\sigma_A^\ell$  is defined in (2.2a).*

### 3. Stability and topological description of stable processes.

**3.1. Almost sure stability.** Following convention, we now define a *canonical Markov measure* generated by an irreducible  $(0, 1)$ -matrix  $A$  of size  $\kappa \times \kappa$ . Let us denote the spectral radius of the nonnegative matrix  $A$  by  $\rho_A$ . Then from the Perron–Frobenius theorem it follows that there are two positive vectors

$$(3.1a) \quad v = (v_1, \dots, v_\kappa)^T \quad \text{and} \quad u = (u_1, \dots, u_\kappa)$$

in  $\mathbb{R}^\kappa$  such that

$$(3.1b) \quad Av = \rho_A v \quad \text{and} \quad uA = \rho_A u$$

with

$$(3.1c) \quad \sum_{i=1}^{\kappa} u_i v_i = 1.$$

Let

$$(3.2a) \quad p_A = (p_1, \dots, p_\kappa) \quad \text{with} \quad p_i = u_i v_i \quad \text{for} \quad 1 \leq i \leq \kappa$$

and

$$(3.2b) \quad P_A = [p_{ij}], \quad \text{where} \quad p_{ij} = \frac{a_{ij} v_j}{\rho_A v_i} \quad \text{for} \quad 1 \leq i, j \leq \kappa.$$

Then we have  $p_A P_A = p_A$ . The matrix  $P_A = [p_{ij}]$  can be viewed as a transition probability matrix with  $p_{ij} = 0$  if and only if  $a_{ij} = 0$ . The canonical  $\sigma_A$ -invariant Markov measure  $\mu_A$  on  $\Sigma_A$  is derived as follows:

$$(3.3a) \quad \mu_A([i_0 \cdots i_\ell]_A) = p_{i_0} p_{i_0 i_1} \cdots p_{i_{\ell-1} i_\ell},$$

where

$$(3.3b) \quad [i_0 \cdots i_\ell]_A = \{\omega \in \Sigma_A \mid \omega_0 = i_0, \dots, \omega_\ell = i_\ell\}$$

is the *cylinder* defined by the word of length  $\ell + 1$  for  $(i_0 \cdots i_\ell) \in \mathcal{A}^{\ell+1}$  with any  $\ell + 1 \in \mathbb{N}$ . According to [36, Theorem 1.13] we know that

- (1)  $\mu_A$  is supported on  $\Sigma_A$  with  $\text{supp}(\mu_A) = \Sigma_A$ , where  $\text{supp}(\mu_A)$  means the minimal  $\sigma_A$ -invariant closed subset of  $\Sigma_A$  with  $\mu_A$ -measure 1.
- (2)  $\mu_A$  is an ergodic  $\sigma_A$ -invariant Borel probability measure on  $\Sigma_A$ .

*Remark 1.* Compared to the stochastic Markovian, the above formulation is more general since the transition rates (or the generator) of the Markov chain can be arbitrary due to the fact that it is not necessary for the transition matrix  $A$  to be a probability matrix. We now derive the first main result of this paper.

**THEOREM 1.** *Consider the switched linear system (1.1) with the switching sequence belonging to a topological Markov shift  $(\Sigma_A, \sigma_A)$ . For any  $t \in \mathbb{N}$ , write*

$$(3.4) \quad \lambda_{i_0 i_1 \cdots i_{t-1}} = \|H_{i_{t-1}} \cdots H_{i_0}\| \quad \forall (i_0 \cdots i_{t-1}) \in \mathcal{A}^t,$$

where  $\|\cdot\|$  is the matrix norm and where  $\mathcal{A}^t = \overbrace{\mathcal{A} \times \cdots \times \mathcal{A}}^{t \text{ times}}$ . Let  $p_A = (p_1, \dots, p_\kappa)$ ,  $P_A = [p_{ij}]$  and the measure  $\mu_A$  be defined by (3.2) and (3.3), respectively. Then (1.1) is  $\mu_A$ -almost surely stable if and only if there is at least one  $\hat{t} \in \mathbb{N}$  such that

$$(3.5) \quad \prod_{(i_0 \cdots i_{\hat{t}-1}) \in \mathcal{A}^{\hat{t}}} \lambda_{i_0 i_1 \cdots i_{\hat{t}-1}}^{p_{i_0} p_{i_0 i_1} \cdots p_{i_{\hat{t}-2} i_{\hat{t}-1}}} < 1.$$

Moreover, if (1.1) is  $\mu_A$ -almost surely stable, then there exists some  $\varepsilon > 0$  such that every switched linear system

$$(1.1)' \quad x_{\ell+1} = H'_{\omega_\ell} x_\ell, \quad \ell \geq 0,$$

is also  $\mu_A$ -almost surely stable on  $(\Sigma_A, \sigma_A)$  whenever

$$(3.6) \quad \|H_i - H'_i\| \leq \varepsilon, \quad 1 \leq i \leq \kappa.$$

*Proof.* Consider the discrete-time flow generated by system (2.3)

$$\varphi_{\sigma_A, S}: \Sigma_A \times \mathbb{R}^n \times \mathbb{Z}_+ \rightarrow \Sigma_A \times \mathbb{R}^n$$

defined by

$$(\omega, x, t) \mapsto (\sigma_A^t \omega, S(\omega, t)x) = (\sigma_A^t \omega, H_{\omega_{t-1}} \cdots H_{\omega_0} x)$$

for any  $t \in \mathbb{Z}_+$ ,  $x \in \mathbb{R}^n$  and for any  $\omega = (\omega_0 \omega_1 \cdots) \in \Sigma_A$ .

Since (1.1) subject to the constraint  $\Sigma_A$  and (2.3) represent the same systems, by Proposition 2, the  $\mu_A$ -almost sure stability of (1.1) means that the Lyapunov exponent  $\lambda(\sigma_A, S, \mu_A)$  of  $\varphi_{\sigma_A, S}$  associated with  $\mu_A$  is strictly negative.

Assume that  $\lambda(\sigma_A, S, \mu_A) < 0$  holds. Then, it follows from Proposition 1 that there is some  $\hat{t} \in \mathbb{N}$  which is such that

$$\frac{1}{\hat{t}} \int_{\Sigma_A} \ln \|S(\omega, \hat{t})\| d\mu_A(\omega) < 0.$$

Thus, as  $\Sigma_A = \bigcup \{[i_0 \cdots i_{\hat{t}-1}]_A : (i_0 \cdots i_{\hat{t}-1}) \in \mathcal{A}^{\hat{t}}\}$ , where  $[i_0 \cdots i_{\hat{t}-1}]_A$  is defined with respect to  $A$ , and  $[i_0 \cdots i_{\hat{t}-1}]_A$  are disjoint of each other, (3.5) follows from (2.2) and (3.3).

Conversely, let (3.5) hold for some  $\hat{t} \in \mathbb{N}$ . Then we obtain

$$\begin{aligned} 0 &> \sum_{(i_0 \cdots i_{\hat{t}-1}) \in \mathcal{A}^{\hat{t}}} p_{i_0} p_{i_0 i_1} \cdots p_{i_{\hat{t}-2} i_{\hat{t}-1}} \ln \lambda_{i_0 i_1 \cdots i_{\hat{t}-1}} \\ &= \sum_{(i_0 \cdots i_{\hat{t}-1}) \in \mathcal{A}^{\hat{t}}} \int_{[i_0 \cdots i_{\hat{t}-1}]_A} \ln \|S(\omega, \hat{t})\| d\mu_A(\omega) \\ &= \int_{\Sigma_A} \ln \|S(\omega, \hat{t})\| d\mu_A(\omega), \end{aligned}$$

which implies that

$$0 > \frac{1}{\hat{t}} \int_{\Sigma_A} \ln \|S(\omega, \hat{t})\| d\mu_A(\omega) \geq \lambda(\sigma_A, S, \mu_A)$$

holds.

Since  $p_A = (p_1, \dots, p_\kappa)$ ,  $P_A = [p_{ij}]$ , and  $\mu_A$  all are independent of  $\{H_1, \dots, H_\kappa\}$ , and the index

$$\lambda_{i_0 i_1 \cdots i_{\hat{t}-1}} = \|H_{i_{\hat{t}-1}} \cdots H_{i_0}\| \quad \forall (i_0 \cdots i_{\hat{t}-1}) \in \mathcal{A}^{\hat{t}}$$

is continuous with respect to  $(H_1, \dots, H_\kappa)$ , the robustness follows directly from the criterion (3.5). Thus the proof is completed.  $\square$

*Remark 2.* The ergodic  $\sigma_A$ -invariant measure  $\mu_A$  defined by (3.2)–(3.3) is called the “Parry measure” of the topological Markov chain  $(\Sigma_A, \sigma_A)$ . It is a Gibbs measure which has the maximal entropy, namely,  $h_{top}(\sigma_A) = h_{\mu_A}(\sigma_A)$ , and such a property can characterize other measures in a “maximal” way (for more detail see section 3.3 below). The proof of Theorem 1 holds as long as  $\mu_A$  is an ergodic  $\sigma_A$ -invariant Borel probability measure on  $\Sigma_A$  with  $\text{supp}(\mu_A) = \Sigma_A$ .

Theorem 1 gives a necessary and sufficient condition for  $\mu_A$ -almost sure stability of topological Markov jump system (2.3). In particular, in view of (3.5), sufficient condition can be tested by finding  $\hat{t}$  satisfying (3.5).

The following subsections provide a topological description of the set of stable processes.

**3.2. Hausdorff dimension.** Let  $X$  be a compact metric space with a metric  $d(\cdot, \cdot)$ . We denote

$$B(x, r) = \{y \in X \mid d(x, y) \leq r\},$$

which stands for a closed ball centered at  $x \in X$  with radius  $r > 0$ . Recall that for  $s \geq 0$  the  $s$ -Hausdorff measure of  $Y \subseteq X$  for a given metric  $d(\cdot, \cdot)$  is defined as

$$\mathcal{H}_d^s(Y) = \liminf_{\delta \rightarrow 0} \left\{ \sum_i |A_i|^s : \bigcup_i A_i \supseteq Y \text{ and } \sup_i |A_i| < \delta \right\},$$

where  $\{A_i\}$  is a countable cover of  $Y$  and  $|A_i|$  represents the diameter of  $A_i$  in terms of  $d(\cdot, \cdot)$ . Furthermore, the *Hausdorff dimension* of  $Y$  is defined by

$$HD_d(Y) = \inf \{s \in \mathbb{R}_+ : \mathcal{H}_d^s(Y) = 0\}.$$

For a given Borel probability measure  $\mu$  on  $X$ , the *Hausdorff dimension* of  $\mu$  is given by

$$HD_d(\mu) = \inf \{HD_d(Y) : Y \text{ is a Borel subset of } X \text{ with } \mu(Y) = 1\}.$$

The nonnegative number  $HD_d(\cdot)$ , which depends upon the given metric  $d(\cdot, \cdot)$ , in general satisfies only

$$(3.7a) \quad HD_d(\mu) \leq HD_d(\text{supp}(\mu))$$

and

$$(3.7b) \quad HD_d(Y) \leq HD_d(Y') \quad \text{if } Y \subseteq Y';$$

for instance, we refer readers to [14] for more details. Here we state some important facts (see [38]) that will be needed for the proof of our next theorem.

- (a) Let  $\mu$  be a Borel probability measure on  $X$  and  $E$  a Borel subset of  $X$  with  $\mu(E) > 0$ . If  $\underline{\delta} \leq \liminf_{r \rightarrow 0} \frac{\ln \mu(B(x, r))}{\ln r} \leq \limsup_{r \rightarrow 0} \frac{\ln \mu(B(x, r))}{\ln r} \leq \bar{\delta}$  for all  $x \in E$ , then  $\underline{\delta} \leq HD_d(E) \leq \bar{\delta}$ .

For any  $\delta > 0$ , let  $N(X, \delta)$  denote the minimal number of  $\delta$ -ball  $B(x, \delta)$  needed to cover  $X$ . We define the *lower* and *upper box-dimension* of  $X$ , respectively, as

$$\underline{\dim}_B(X) = \liminf_{\delta \rightarrow 0} \frac{\ln N(X, \delta)}{-\ln \delta}$$

and

$$\overline{\dim}_B(X) = \limsup_{\delta \rightarrow 0} \frac{\ln N(X, \delta)}{-\ln \delta}.$$

If  $\underline{\dim}_B(X) = \overline{\dim}_B(X)$ , denoted by  $\dim_B(X)$ , then we call it the *box-dimension* of  $X$  with respect to  $d(\cdot, \cdot)$ . It is well known from [14] that the following holds.

- (b)  $HD_d(X) \leq \underline{\dim}_B(X)$ .

**3.3. Topological entropy.** Let  $f: (X, \mu) \rightarrow (X, \mu)$  be a continuous transformation of a compact metrizable space  $X$  which preserves a Borel probability measure  $\mu$ . The topological dynamical system  $(X, f)$  is said to be *Li-Yorke chaotic* [28, 2] provided that there is an uncountable subset  $X_0$  of  $X$  such that

$$\limsup_{\ell \rightarrow \infty} d(f^\ell x, f^\ell y) > 0 \quad \forall x, y \in X_0, \quad x \neq y,$$

and

$$\liminf_{\ell \rightarrow \infty} d(f^\ell x, f^\ell y) = 0 \quad \forall x, y \in X_0, \ x \neq y.$$

In order to quantitatively measure the uncertainty, randomness, or disorder of the system  $(X, f)$ , in 1958, Kolmogorov [25] introduced the concept of *measure-theoretic entropy*, denoted by  $h_\mu(f)$ , to the measure-preserving system  $(X, \mu, f)$ . In 1965, Adler, Konheim, and McAndrew [1] introduced topological entropy, which is the analogous invariant for topological dynamical systems. It soon turned out that there is a simple relationship between these quantities: maximizing the metric entropy over a suitable class of measures defined on a dynamical system gives its topological entropy (see, for example, [36]). For the convenience of later discussion, we let

$$B_\ell^f(x, \delta) = \{y \in X \mid \text{dist}(f^i x, f^i y) \leq \delta \text{ for } 0 \leq i < \ell\}$$

for any  $x \in X$  and any  $\ell \in \mathbb{N}, \delta > 0$ . Clearly,  $B(x, \delta) = B_1^f(x, \delta)$ . Due to Brin and Katok [8], we know that the following holds.

- (c)  $h_\mu(f, x) := \lim_{\delta \rightarrow 0} \liminf_{\ell \rightarrow \infty} \frac{\ln \mu(B_\ell^f(x, \delta))}{-\ell} = \lim_{\delta \rightarrow 0} \limsup_{\ell \rightarrow \infty} \frac{\ln \mu(B_\ell^f(x, \delta))}{-\ell}$  holds for  $\mu$ -a.e.  $x \in X$ .
- (d)  $h_\mu(f, x)$  is  $f$ -invariant; namely,  $h_\mu(f, x) = h_\mu(f, f^\ell x)$  for all  $\ell > 0$  for  $\mu$ -a.e.  $x \in X$ .
- (e)  $h_\mu(f) = \int_X h_\mu(f, x) d\mu$ .
- (f) In particular, if  $\mu$  is ergodic, then  $h_\mu(f) = h_\mu(f, x)$  for  $\mu$ -a.e.  $x \in X$ .

Next, by  $N(X, \ell, \delta)$  we denote the minimal number of Bowen balls  $B_\ell^f(x, \delta)$  needed to cover  $X$ . Then, the *topological entropy* of  $(X, f)$ , written  $h_{\text{top}}(f)$ , is defined by the following:

$$(g) \quad h_{\text{top}}(f) = \lim_{\delta \rightarrow 0} \limsup_{\ell \rightarrow \infty} \frac{\ln N(X, \ell, \delta)}{\ell}.$$

According to the well-known variational principle of entropy [36], we have the following:

- (h)  $h_{\text{top}}(f) = \sup_\mu h_\mu(f)$ , where  $\mu$  ranges over all  $f$ -invariant ergodic Borel probability measures on  $X$ .

Note that if  $h_{\text{top}}(f) = h_\mu(f)$ ,  $\mu$  is called a *maximal entropy measure*. By virtue of (f) above, the maximal entropy measure  $\mu$  contains almost all complexity information of the system  $(X, f)$ .

Chaos and entropy are characteristics of the complexity of system  $(X, f)$  from two different viewpoints. Chaos is closely related to system behavior, while entropy focuses on “physical principles.” In general, they have the following relationships:

- (i)  $h_{\text{top}}(f) > 0$  implies that  $(X, f)$  is Li–Yorke chaotic [4].
- (j)  $h_{\text{top}}(\sigma_A) > 0$  if and only if  $(\Sigma_A, \sigma_A)$  is Li–Yorke chaotic [39].

**3.4. Stable processes.** Theorem 1 gives only a measure description of the set of stable switching sequences of system (1.1) on  $\Sigma_A$ . The next theorem provides a precisely topological description of the set of stable processes of (1.1), mainly motivated by [10, 11, 12].

**THEOREM 2.** *We consider the topological Markov jump linear system (2.3). Let*

$$\Sigma_{\text{stab}}(S; A) = \{\omega \in \Sigma_A \mid x_{\ell+1} = S(\sigma_A^\ell \omega) x_\ell \text{ is exponentially stable}\}.$$

*If  $\lambda(\sigma_A, S, \mu_A) < 0$ , then we have*

$$(3.8) \quad HD_\rho(\Sigma_{\text{stab}}(S; A)) = HD_\rho(\Sigma_A) = \frac{h_{\text{top}}(\sigma_A)}{\ln \rho}.$$

Here  $HD_{\rho}(\cdot)$  means the Hausdorff dimension under the metric  $\rho(\cdot, \cdot)$  defined by (2.1). Moreover,  $HD_{\rho}(\Sigma_{stab}(S; A)) > 0$  if and only if  $(\Sigma_A, \sigma_A)$  is Li-Yorke chaotic.

*Proof.* First note  $\Sigma_A \supseteq \Sigma_{stab}(S; A)$ . This implies  $HD_{\rho}(\Sigma_A) \geq HD_{\rho}(\Sigma_{stab}(S; A))$  from section 3.2. It follows from Proposition 2 and Definition 1 that  $\Sigma_{stab}(S; A)$  has  $\mu_A$ -measure 1. Hence the definition of  $HD_{\rho}(\mu_A)$  yields  $HD_{\rho}(\Sigma_{stab}(S; A)) \geq HD_{\rho}(\mu_A)$ . We thus obtain

$$(3.9) \quad HD_{\rho}(\Sigma_A) \geq HD_{\rho}(\Sigma_{stab}(S; A)) \geq HD_{\rho}(\mu_A).$$

Since  $\mu_A$  is the Parry measure, this implies  $h_{top}(\sigma_A) = h_{\mu_A}(\sigma_A)$ . In order to finish the proof, it is sufficient to show the following two equalities:

$$(3.10a) \quad HD_{\rho}(\mu_A) = \frac{h_{\mu_A}(\sigma_A)}{\ln \rho}$$

and

$$(3.10b) \quad HD_{\rho}(\Sigma_A) \leq \frac{h_{top}(\sigma_A)}{\ln \rho},$$

where  $h_{top}(\sigma_A)$  and  $h_{\mu_A}(\sigma_A)$  stand for the topological entropy and the measure-theoretic entropy with respect to  $\mu_A$  of the Markov chain  $(\Sigma_A, \sigma_A)$ , respectively.

To prove (3.10a), we first claim that for any ergodic  $\sigma_A$ -invariant Borel probability measure  $\mu$  on  $\Sigma_A$  we have

$$(3.11) \quad HD_{\rho}(\mu) = \frac{h_{\mu}(\sigma_A)}{\ln \rho}.$$

From (2.1a) we see that  $\sigma_A$  possesses the following so called “similarity property”:

$$(3.12) \quad \text{dist}(\sigma_A \omega, \sigma_A \omega') = \rho \text{dist}(\omega, \omega') \quad \text{if } \text{dist}(\omega, \omega') < \rho^{-2}.$$

In fact, given any  $\omega = (\omega_0 \omega_1 \omega_2 \cdots)$ ,  $\omega' = (\omega'_0 \omega'_1 \omega'_2 \cdots) \in \Sigma_A$ . If we have  $\text{dist}(\omega, \omega') < \rho^{-2}$ , then  $n(\omega, \omega') \geq 3$ , which implies  $\omega_0 = \omega'_0$ ,  $\omega_1 = \omega'_1$ , and  $\omega_2 = \omega'_2$ . Thus,  $n(\sigma_A \omega, \sigma_A \omega') = n(\omega, \omega') - 1$ , and thus  $\text{dist}(\sigma_A \omega, \sigma_A \omega') = \rho^{-n(\sigma_A \omega, \sigma_A \omega')} = \rho \rho^{-n(\omega, \omega')} = \rho \text{dist}(\omega, \omega')$ .

Now for given any  $i \geq 3$ , we have

$$(3.13) \quad [\omega_0 \cdots \omega_{i+\ell}]_A = B(\omega, \rho^{-(i+\ell)}) = B_{\ell+1}^{\sigma_A}(\omega, \rho^{-i}) \quad \forall \omega \in \Sigma_A \text{ and } \forall \ell \in \mathbb{N},$$

because of  $B(\sigma_A^j \omega, \rho^{-i}) = [\omega_j \cdots \omega_{j+i}]_A$  and

$$\begin{aligned} B_{\ell+1}^{\sigma_A}(\omega, \rho^{-i}) &= \bigcap_{j=0}^{\ell} \sigma_A^{-j} B(\sigma_A^j \omega, \rho^{-i}) \\ &= \bigcap_{j=0}^{\ell} \sigma_A^{-j} [\omega_j \cdots \omega_{j+i}]_A. \end{aligned}$$

Hence  $\mu(B(\omega, \rho^{-i-\ell})) = \mu(B_{\ell+1}^{\sigma_A}(\omega, \rho^{-i}))$ , and thus we have

$$\begin{aligned} \frac{\ln \mu(B(\omega, \rho^{-i-\ell}))}{\ln \rho^{-i-\ell}} &= \frac{\ln \mu(B_{\ell+1}^{\sigma_A}(\omega, \rho^{-i}))}{\ln \rho^{-i-\ell}} \\ &= \frac{\ln \mu(B_{\ell+1}^{\sigma_A}(\omega, \rho^{-i}))}{-(i+\ell) \ln \rho}, \end{aligned}$$

which implies that

$$\limsup_{\ell \rightarrow \infty} \frac{\ln \mu(B(\omega, \boldsymbol{\rho}^{-i-\ell}))}{\ln \boldsymbol{\rho}^{-i-\ell}} = \frac{1}{\ln \boldsymbol{\rho}} \limsup_{\ell \rightarrow \infty} \frac{\ln \mu(B_{\ell+1}^{\sigma_A}(\omega, \boldsymbol{\rho}^{-i}))}{-\ell}$$

and

$$\liminf_{\ell \rightarrow \infty} \frac{\ln \mu(B(\omega, \boldsymbol{\rho}^{-i-\ell}))}{\ln \boldsymbol{\rho}^{-i-\ell}} = \frac{1}{\ln \boldsymbol{\rho}} \liminf_{\ell \rightarrow \infty} \frac{\ln \mu(B_{\ell+1}^{\sigma_A}(\omega, \boldsymbol{\rho}^{-i}))}{-\ell}.$$

Thus we obtain

$$(3.14a) \quad \limsup_{\delta \rightarrow 0} \frac{\ln \mu(B(\omega, \delta))}{\ln \delta} = \frac{1}{\ln \boldsymbol{\rho}} \limsup_{\ell \rightarrow \infty} \frac{\ln \mu(B_{\ell+1}^{\sigma_A}(\omega, \boldsymbol{\rho}^{-i}))}{-\ell}$$

and

$$(3.14b) \quad \liminf_{\delta \rightarrow 0} \frac{\ln \mu(B(\omega, \delta))}{\ln \delta} = \frac{1}{\ln \boldsymbol{\rho}} \liminf_{\ell \rightarrow \infty} \frac{\ln \mu(B_{\ell+1}^{\sigma_A}(\omega, \boldsymbol{\rho}^{-i}))}{-\ell}.$$

Since  $i \geq 3$  is arbitrary, from statements (c) and (f) in section 3.3 and (3.14), we arrive at

$$(3.15) \quad \begin{aligned} \lim_{\delta \rightarrow 0} \frac{\ln \mu(B(\omega, \delta))}{\ln \delta} &= \frac{1}{\ln \boldsymbol{\rho}} \lim_{i \rightarrow \infty} \liminf_{\ell \rightarrow \infty} \frac{\ln \mu(B_{\ell+1}^{\sigma_A}(\omega, \boldsymbol{\rho}^{-i}))}{-\ell} \\ &= \frac{1}{\ln \boldsymbol{\rho}} \lim_{i \rightarrow \infty} \limsup_{\ell \rightarrow \infty} \frac{\ln \mu(B_{\ell+1}^{\sigma_A}(\omega, \boldsymbol{\rho}^{-i}))}{-\ell} \\ &= \frac{h_\mu(\sigma_A)}{\ln \boldsymbol{\rho}} \quad \mu\text{-a.e. } \omega \in \Sigma_A. \end{aligned}$$

Therefore, (3.11) follows directly from statement (a) in section 3.2.

On the other hand, from (3.13) we see that

$$N(\Sigma_A, \boldsymbol{\rho}^{-i-\ell}) = N(\Sigma_A, \ell + 1, \boldsymbol{\rho}^{-i}) \quad \forall \ell \in \mathbb{N}, i \geq 3.$$

Thus

$$(3.16) \quad \begin{aligned} \limsup_{\delta \rightarrow 0} \frac{\ln N(\Sigma_A, \delta)}{-\ln \delta} &= \limsup_{\ell \rightarrow 0} \frac{\ln N(\Sigma_A, \boldsymbol{\rho}^{-i-\ell})}{-\ln \boldsymbol{\rho}^{-i-\ell}} \\ &= \limsup_{\ell \rightarrow \infty} \frac{\ln N(\Sigma_A, \ell + 1, \boldsymbol{\rho}^{-i})}{(i + \ell) \ln \boldsymbol{\rho}} \\ &= \frac{1}{\ln \boldsymbol{\rho}} \limsup_{\ell \rightarrow \infty} \frac{\ln N(\Sigma_A, \ell + 1, \boldsymbol{\rho}^{-i})}{\ell}. \end{aligned}$$

For arbitrary  $i$ , according to statement (g) in section 3.3, (3.16) yields

$$(3.17) \quad \begin{aligned} \limsup_{\delta \rightarrow 0} \frac{\ln N(\Sigma_A, \delta)}{-\ln \delta} &= \frac{1}{\ln \boldsymbol{\rho}} \lim_{i \rightarrow \infty} \limsup_{\ell \rightarrow \infty} \frac{\ln N(\Sigma_A, \ell + 1, \boldsymbol{\rho}^{-i})}{\ell} \\ &= \frac{h_{top}(\sigma_A)}{\ln \boldsymbol{\rho}}, \end{aligned}$$

which implies that (3.10b) holds from statement (b) in section 3.2. Therefore, (3.10) holds.

Finally, from (3.8) and statement (j) in section 3.3, it follows directly that the Hausdorff dimension  $HD_{\rho}(\Sigma_{stab}(S; A))$  is strictly positive if and only if  $(\Sigma_A, \sigma_A)$  is Li–Yorke chaotic.

Thus, the proof is completed.  $\square$

*Remark 3.* Identity (3.8) implies that the  $\mu_A$ -measure defined in (3.3) (which is the Parry measure of  $(\Sigma_A, \sigma_A)$ ) is a desirable measure from the topological point of view since the “size” of the set of all stable paths is the same as the set of all admissible paths in the sense of Hausdorff dimension.

*Remark 4.* Suppose that there are two Parry measures of  $(\Sigma_{\kappa}, \sigma)$  such that system (1.1) is  $\mu_{A'}$ - and  $\mu_A$ -almost surely stable with respect to two admissible sets  $\Sigma_{A'}$  and  $\Sigma_A$ , respectively. Assume that  $h_{top}(\sigma_A) \geq h_{top}(\sigma_{A'})$ . Then according to Theorem 2, we have

$$(3.18) \quad HD_{\rho}(\Sigma_{stab}(S; A)) = \frac{h_{top}(\sigma_A)}{\ln \rho} \geq \frac{h_{top}(\sigma_{A'})}{\ln \rho} = HD_{\rho}(\Sigma_{stab}(S; A')).$$

Hence, larger topological entropy of  $\sigma_A$  results in a larger set of stable paths of (1.1).

*Remark 5.* According to [39], if the underlying setting  $(\Sigma_A, \sigma_A)$  is Li–Yorke chaotic, then it has positive entropy. Thus the more Li–Yorke chaotic  $(\Sigma_A, \sigma_A)$  behaves, the larger the set of  $\mu_A$ -almost surely stable paths the switched linear system (1.1) has.

The largest topological entropy of  $(\Sigma_A, \sigma_A)$  is attained when  $\Sigma_A = \Sigma_{\kappa}$  and  $\sigma_A = \sigma$ . We thus consider the switched system (1.1) with the switching paths allowed to be the whole symbol space  $\Sigma_{\kappa}$ . The corresponding transition matrix  $A = [a_{ij}]$  satisfies  $a_{ij} = 1$  for all  $1 \leq i, j \leq \kappa$ . In this case, the unique maximal entropy measure  $\mu_A$  is the  $(\frac{1}{\kappa}, \dots, \frac{1}{\kappa})$ -product measure  $\mu_{\kappa}$  with  $h_{top}(\sigma) = \ln \kappa$  (Theorem 8.9 in [36]). The following corollary characterizes the  $\mu_{\kappa}$ -almost sure stability of (1.1) without constraints.

**COROLLARY 1.** *Let us consider the switched linear system (1.1) with the switching sequences belonging to the whole symbol space  $\Sigma_{\kappa}$ . Then we have the following.*

- (1) *The system is  $\mu_{\kappa}$ -almost stable if and only if there is at least one  $\hat{t} \in \mathbb{N}$  such that*

$$\prod_{(i_0 \dots i_{\hat{t}-1}) \in \mathcal{A}^{\hat{t}}} \lambda_{i_0 i_1 \dots i_{\hat{t}-1}} < 1,$$

where  $\lambda_{i_0 i_1 \dots i_{\hat{t}-1}}$  is defined by (3.4).

- (2) *Let  $\Sigma_{stab}(S; \Sigma_{\kappa}) = \{\omega \in \Sigma_{\kappa} \mid x_{\ell+1} = S(\sigma^{\ell} \omega) x_{\ell} \text{ is exponentially stable}\}$ . Then we have*

$$HD_{\rho}(\Sigma_{stab}(S; \Sigma_{\kappa})) = HD_{\rho}(\Sigma_{\kappa}) = \frac{\ln \kappa}{\ln \rho},$$

provided that the system (1.1) is  $\mu_{\kappa}$ -almost stable.

*Proof.* The proof is straightforward based on Theorems 1 and 2. Note that (3.5) is equivalent to

$$\left[ \prod_{(i_0 \dots i_{\hat{t}-1}) \in \mathcal{A}^{\hat{t}}} \lambda_{i_0 i_1 \dots i_{\hat{t}-1}} \right]^{(\frac{1}{\kappa})^{\hat{t}}} < 1,$$

which is equivalent to

$$\prod_{(i_0 \cdots i_{t-1}) \in \mathcal{A}^t} \lambda_{i_0 i_1 \cdots i_{t-1}} < 1. \quad \square$$

**COROLLARY 2.** *Suppose that  $\|H_i\| \leq 1$  for  $i = 1, 2, \dots, \kappa$  and that there is at least  $j$  with  $1 \leq j \leq \kappa$  such that  $\|H_j\| < 1$ . Then the system (1.1) is  $\mu_\kappa$ -almost surely stable.*

The next corollary describes the “strongest”  $\mu$ -almost surely stable case.

**COROLLARY 3.** *Suppose that  $\|H_i\| < 1$  for  $i = 1, 2, \dots, \kappa$ . Then the system (1.1) is  $\mu$ -almost stable for any  $\sigma$ -invariant probability measure  $\mu$ , and, consequently, (1.1) is absolutely stable.*

**4. Stochastic Markov jump linear systems.** In this section, we consider the discrete-time system (1.1), where  $\omega_k$  is a discrete-time Markovian stochastic process taking value in  $\mathcal{A} = \{1, \dots, \kappa\}$ , with transition probabilities  $p_{ij} = \Pr\{\omega_{k+1} = j | \omega_k = i\}$ . The matrix  $P = [p_{ij}]$  is called the transition probability distribution. Now the switched system given by

$$(4.1) \quad x_{\ell+1} = H_{\omega_\ell} x_\ell, \quad \ell \geq 0,$$

is a standard stochastic Markov jump linear system where  $\omega_\ell$  is a random variable. The almost sure stability of this type of system has been discussed by many authors. Recently a new necessary and sufficient condition for almost sure stability by the approach of using a so-called lifted version of the system was proposed [5, Proposition 3.4]. We shall show that our results obtained in the previous section can cover such a case.

Assume that the transition probability matrix  $P$  is irreducible. According to the Perron–Frobenius theorem [7], there exists a unique (invariant) distribution  $p = (p_1, \dots, p_\kappa)$  such that

- (a)  $0 < p_i < 1$ ,  $\sum_{i=1}^\kappa p_i = 1$ ;
- (b) (invariance)  $p \cdot P = p$ .

Now a natural Markov measure  $\mu_{p,P}$  on  $\Sigma_\kappa$  defined by  $(p, P)$  can be obtained as follows:

$$(4.2) \quad \mu_{p,P}([i_0 \cdots i_\ell]) = p_{i_0} p_{i_0 i_1} \cdots p_{i_{\ell-1} i_\ell}.$$

Next, we define an irreducible  $(0, 1)$ -matrix  $A_P = [a_{ij}]_{\kappa \times \kappa}$  associated with  $P$  as follows:

$$(4.3) \quad a_{ij} = \begin{cases} 1 & \text{if } p_{ij} > 0, \\ 0 & \text{if } p_{ij} = 0. \end{cases}$$

Let  $(\Sigma_{A_P}, \sigma_{A_P})$  be the one-sided Markov shift defined by the transition matrix  $A_P$ .

One can verify directly that

- $\mu_{p,P}$  is supported on  $\Sigma_{A_P}$  with  $\text{supp}(\mu_{p,P}) = \Sigma_{A_P}$ ;
- $\mu_{p,P}$  is an ergodic  $\sigma_{A_P}$ -invariant Borel probability measure on  $\Sigma_{A_P}$  [36, Theorem 1.13].

Thus, according to the proofs of Theorems 1 and 2, we immediately have the following corollary.

**COROLLARY 4.** *Consider the stochastic Markov jump linear system (4.1) with the probability transition matrix  $P$ . Let the corresponding ergodic  $\sigma_{A_P}$ -invariant Borel*

probability measure  $\mu_{p,P}$  be defined as (4.2). Then the system is  $\mu_{p,P}$ -almost surely stable if and only if there is at least one  $\hat{t} \in \mathbb{N}$  such that

$$(4.4) \quad \prod_{(i_0 \dots i_{\hat{t}-1}) \in \mathcal{A}^{\hat{t}}} \lambda_{i_0 i_1 \dots i_{\hat{t}-1}}^{p_{i_0} p_{i_0 i_1} \dots p_{i_{\hat{t}-2} i_{\hat{t}-1}}} < 1,$$

where  $\lambda_{i_0 i_1 \dots i_{\hat{t}-1}}$  is given by (3.4). Moreover, if (4.1) is  $\mu_{p,P}$ -almost surely stable, then there exists some  $\varepsilon > 0$  such that every switched linear system

$$(1.1)' \quad x_{\ell+1} = H'_{\omega_\ell} x_\ell, \quad \ell \geq 0,$$

is also  $\mu_{p,P}$ -almost surely stable based on  $(\Sigma_{A_P}, \sigma_{A_P})$  whenever

$$\|H_i - H'_i\| \leq \varepsilon, \quad 1 \leq i \leq \kappa.$$

COROLLARY 5. Over a  $(p, P)$ -Markov shift  $(\Sigma_{A_P}, \sigma_{A_P})$ , write

$$\Sigma_{stab}(p, P) = \left\{ \omega \in \Sigma_{A_P} \mid x_{\ell+1} = S(\sigma_{A_P}^\ell \omega) x_\ell \text{ with } \lim_{\ell \rightarrow \infty} \frac{1}{\ell} \ln \|x_\ell\| < 0 \ \forall x_0 \in \mathbb{R}^n \right\}.$$

If (4.4) holds for some  $\hat{t} \in \mathbb{N}$ , then

$$(4.5) \quad HD_\rho(\Sigma_{A_P}) \geq HD_\rho(\Sigma_{stab}(p, P)) \geq HD_\rho(\mu_{p,P}).$$

Remark 6. For the natural Markov measure defined above, in general, we have only

$$HD_\rho(\Sigma_{A_P}) \geq HD_\rho(\Sigma_{stab}(\mu_{p,P})),$$

since  $\mu_{p,P}$  usually is not the Parry measure, and

$$HD_\rho(\mu_{p,P}) = \frac{h_{\mu_{p,P}}(\sigma_{A_P})}{\ln \rho} \neq HD_\rho(\Sigma_{A_P}).$$

This is mainly due to  $\mu_{p,P}$  not needing to be a maximal entropy. Hence the “size” of the set of all stable paths is possibly smaller than that of the admissible set  $\Sigma_{A_P}$ .

We close this section with two more remarks.

Remark 7. Criterion (4.4) for almost sure stability is an extension of the Fang–Loparo–Feng criterion [15]. In fact, if  $\hat{t} = 1$ , then we have

$$\prod_{i \in \mathcal{A}} \|S_i\|^{p_i} < 1,$$

which coincides with the Fang–Loparo–Feng sufficient criterion.

Remark 8. Compared with the Bolzern–Colaneri–Nicolao criterion [5], our approach in getting (4.4) does not involve any lifting of the system (4.1). For an  $m$ -lifting of the system, one easily obtains from a corresponding  $\kappa^m$ -dimensional  $(\tilde{p}, \tilde{P})$ -Markov shift  $(\Sigma_{\tilde{A}_{\tilde{P}}}, \sigma_{\tilde{A}_{\tilde{P}}})$  [5, Propositions 3.1 and 3.2], and thus it can be included in our framework.

**5. Illustrative examples.** In this section, we give two examples (with  $\kappa = 2$ ) to show how to apply the criteria obtained in this paper. In what follows, we denote by  $\mu_2$  the Parry measure of the full shift system  $(\Sigma_2, \sigma)$ , and  $\|\cdot\|$  stands for  $\|\cdot\|_F$ , which is defined in section 1.3.

*Example 1.* Consider the switched system (1.1) with  $\mathcal{A} = \{1, 2\}$ , and

$$H_1 = \begin{bmatrix} 0.2 & 1 \\ 0 & 0.2 \end{bmatrix}, \quad H_2 = \begin{bmatrix} 0.9 & 0.4 \\ 0.5 & 0.2 \end{bmatrix}.$$

It is obvious that this system is not stable for all switching sequences  $\omega \in \Sigma_2$  since the spectral radius of  $H_2$  is greater than 1. However, it is  $\mu_2$ -almost surely stable, where  $\mu_2$  is the maximal entropy measure of  $(\Sigma_2, \sigma)$ , since

$$\begin{aligned} \lambda_{11} &= \|H_1 H_1\| = 0.4040, \quad \lambda_{12} = \|H_1 H_2\| = 0.7432, \\ \lambda_{21} &= \|H_2 H_1\| = 1.1377, \quad \lambda_{22} = \|H_2 H_2\| = 1.2545, \\ \prod_{(i_0 i_1) \in \{1,2\} \times \{1,2\}} \lambda_{i_0 i_1} &= 0.4285 < 1. \end{aligned}$$

Hence, this demonstrates that the system is  $\mu_2$ -almost surely stable and the Hausdorff dimension of the set of all stable sequences  $\omega \in \Sigma_2$  equals 1 (under the metric constant  $\rho = 2$ ) by Corollary 1.

In [5], the system with stochastic Markov chains was considered, where the transition probability distribution was

$$P = \begin{bmatrix} 0.6 & 0.4 \\ 0.1 & 0.9 \end{bmatrix}.$$

The unique invariant distribution in this case is  $p = (0.2, 0.8)$ . It is not difficult to see that condition (4.4) holds true for  $\hat{t} = 3$ . Hence, the system is  $\mu_{p,P}$ -almost surely stable by Corollary 4. However, one can directly verify that the Hausdorff dimension of the set of all stable sequences in the sense of  $\mu_{p,P}$ -almost sure stability is strictly less than 1.

We have known that the system is both  $\mu_2$ -almost surely stable and  $\mu_{p,P}$ -almost surely stable. Nevertheless, to check  $\mu_{p,P}$ -almost surely stable, one needs to use Corollary 4 since it requires the information of transition probability distribution. It is possible for a stochastic Markov jump system to be  $\mu_{p,P}$ -almost surely stable but not to be  $\mu_2$ -almost surely stable since the maximal entropy measure  $\mu_2$  and the ergodic invariant measure  $\mu_{p,P}$  are mutually singular.

According to Theorem 1, we know that the almost sure stability of (1.1) is robust; that is, there exists  $\varepsilon > 0$  such that whenever  $\|H'_i - H_i\| \leq \varepsilon$ ,  $i = 1, 2$ , the switched system

$$(5.1) \quad x_{\ell+1} = H'_{\omega_\ell} x_\ell, \quad \omega_\ell \in \{1, 2\},$$

is also  $\mu_2$ -almost surely stable and the Hausdorff dimension of the set of all stable sequences  $\omega \in \Sigma_2$  equals 1, too. Now as an example we estimate the upper bound of admissible perturbation constant  $\varepsilon$ . Let

$$\lambda_{ij} = \|H_i H_j\| \quad \forall i, j \in \{1, 2\}.$$

We first solve the inequality

$$\begin{aligned}
 & (\lambda_{11} + \delta)(\lambda_{12} + \delta)(\lambda_{21} + \delta)(\lambda_{22} + \delta) \\
 & \leq \lambda_{11}\lambda_{12}\lambda_{21}\lambda_{22} + |\delta|(\lambda_{11}\lambda_{12}\lambda_{21} + \lambda_{11}\lambda_{12}\lambda_{22} + \lambda_{11}\lambda_{21}\lambda_{22} + \lambda_{12}\lambda_{21}\lambda_{22}) \\
 & \quad + \delta^2(\lambda_{11}\lambda_{12} + \lambda_{11}\lambda_{21} + \lambda_{11}\lambda_{22} + \lambda_{12}\lambda_{21} + \lambda_{12}\lambda_{22} + \lambda_{21}\lambda_{22}) \\
 & \quad + |\delta|^3(\lambda_{11} + \lambda_{12} + \lambda_{21} + \lambda_{22}) + \delta^4 \\
 & < 1.
 \end{aligned}$$

Substituting the values of  $\lambda_{ij}$  into the above inequality, one can get approximately

$$|\delta| < 0.1542.$$

Next, we denote  $G_i = H'_i - H_i$ ,  $i = 1, 2$ . A sufficient condition for the  $\mu_2$ -almost sure stability of the perturbation system (5.1) is

$$\begin{aligned}
 & \prod_{(i_0 i_1) \in \{1,2\} \times \{1,2\}} \|(H_{i_0} + G_{i_0})(H_{i_1} + G_{i_1})\| \\
 & \leq [\|H_1 H_1\| + 2\varepsilon\|H_1\| + \varepsilon^2] [\|H_1 H_2\| + \varepsilon(\|H_1\| + \|H_2\|) + \varepsilon^2] \\
 & \quad [\|H_2 H_1\| + \varepsilon(\|H_1\| + \|H_2\|) + \varepsilon^2] [\|H_2 H_2\| + 2\varepsilon\|H_2\| + \varepsilon^2] \\
 & < 1,
 \end{aligned}$$

where

$$\varepsilon = \max\{\|G_1\|, \|G_2\|\}.$$

Since

$$\|H_1\| = 1.0392, \quad \|H_2\| = 1.1225,$$

it follows that a sufficient condition for the inequality

$$\prod_{(i_0 i_1) \in \{1,2\}^2} \|(H_{i_0} + G_{i_0})(H_{i_1} + G_{i_1})\| \leq \prod_{(i_0 i_1) \in \{1,2\}^2} (\lambda_{i_0 i_1} + 2.245\varepsilon + \varepsilon^2) < 1$$

to hold is

$$2.245\varepsilon + \varepsilon^2 = \delta < 0.1542,$$

which yields

$$\varepsilon < 0.0667.$$

*Example 2.* Let us consider the system given in Example 1 with the switching sequences  $\omega$  belonging to the topological Markov chain  $(\Sigma_A, \sigma_A)$  with the topological transition matrix  $A$  as

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}.$$

This means that during the switching process the subsystem  $H_2$  cannot be allowed to follow itself.

Direct computations show that the spectral radius of  $A$  is given by

$$\rho_A = \frac{1 + \sqrt{5}}{2},$$

and the Perron vectors are

$$v^T = u = \left( \frac{1 + \sqrt{5}}{\sqrt{10 + 2\sqrt{5}}}, \sqrt{\frac{2}{5 + \sqrt{5}}} \right).$$

Thus the Parry distribution is

$$p_A = (0.7236, 0.2764),$$

and the transition probability matrix is given by

$$P_A = \begin{bmatrix} \frac{2}{1+\sqrt{5}} & \frac{2}{3+\sqrt{5}} \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} 0.6180 & 0.3820 \\ 1 & 0 \end{bmatrix}.$$

So we have

$$\prod_{(i_0 i_1) \in \{1,2\}^2} \lambda_{i_0 i_1}^{p_{i_0 p_{i_0 i_1}}} = 0.6366 < 1.$$

This verifies that condition (3.5) holds for  $\hat{t} = 2$ . The system thus is  $\mu_A$ -almost surely stable, where  $\mu_A$  is the Parry measure of  $(\Sigma_A, \sigma_A)$ , and

$$HD_{\boldsymbol{\rho}}(\Sigma_{stab}(S; A)) = HD_{\boldsymbol{\rho}}(\Sigma_A) = \frac{\ln(1 + \sqrt{5})}{\ln 2} - 1 > 0,$$

where  $\boldsymbol{\rho} = 2$  (see (2.1a)).

**6. Concluding remarks.** By viewing switching sequences as the elements in symbolic topology space, we have established a necessary and sufficient condition for almost sure stability of discrete-time switched linear systems by using the multiplicative ergodic theorem. Among all ergodic probability measures, Parry measure has been shown to be able to capture the maximal set of stable processes for linear switched systems in the sense of Hausdorff dimension. The  $\mu_A$ -almost sure stability is unchanged under small linear perturbations of the system. Furthermore, a connection between the switched system (1.1) and its corresponding symbolic dynamical system  $(\Sigma_A, \sigma_A)$  is identified; that is, the more Li–Yorke chaotic  $(\Sigma_A, \sigma_A)$  behaves, the larger the set of  $\mu_A$ -almost surely stable paths (1.1) has. Some recent results for the stochastic Markov jump linear systems can be adopted in our framework. Future research will be concentrated on the continuous-time case as well as on nonlinear switched systems.

**Acknowledgment.** The authors would like to thank the anonymous reviewers for their suggestions which have been very helpful in the improvement of the paper.

## HAMILTON–JACOBI EQUATIONS ARISING FROM BOUNDARY CONTROL PROBLEMS WITH STATE CONSTRAINTS\*

SILVIA FAGGIAN†

**Abstract.** The analysis of a class of infinite-dimensional Hamilton–Jacobi–Bellman (HJB) equations is undertaken related to linear convex boundary control problems for PDEs with constraints on the state. A definition of generalized solution (namely, weak solution) of the HJB equation is provided (weak is the limit of strong, while strong is the limit of classical, as defined in [S. Faggian, *Appl. Math. Optim.*, 51 (2005), pp. 123–162]). Consequently an existence and uniqueness result is provided for weak solutions of the HJB equation, as well as existence of an optimal control, being the limit of optimal controls of approximating problems. The study then describes an economic application to optimal investment with vintage capital, having positivity constraints on the capital.

**Key words.** linear convex control, boundary control, state constraints, age-structured systems, vintage models

**1. Introduction.** The present paper is devoted to the analysis of the Hamilton–Jacobi–Bellman (HJB) equation as related to linear convex boundary control in Hilbert spaces with constraints on the state. More precisely, we let  $H$  and  $U$  be separable real Hilbert spaces with scalar products  $(\cdot|\cdot)_H$  and  $(\cdot|\cdot)_U$ , respectively, and consider a dynamical system of the type

$$(1.1) \quad \begin{cases} y'(\tau) = A_0 y(\tau) + B u(\tau), & \tau \in [t, T], \\ y(t) = x \in H, \end{cases}$$

where  $H$  is the state space,  $y : [t, T] \rightarrow H$  is the trajectory,  $U$  is the control space and  $u : [t, T] \rightarrow U$  is the control,  $A_0 : D(A_0) \subset H \rightarrow H$  is the infinitesimal generator of a strongly continuous semigroup of linear operators  $\{e^{\tau A_0}\}_{\tau \geq 0}$  on  $H$ , and the control operator  $B$  is linear and *unbounded*, say  $B : U \rightarrow [D(A_0^*)]'$ . In addition, we consider a cost functional given by

$$(1.2) \quad J(t, x, u) = \int_t^T [g_0(\tau, y(\tau)) + h(\tau, u(\tau))] d\tau + \varphi_0(y(T)),$$

where the functions  $\varphi_0$  and, for all fixed  $\tau$  in  $[0, T]$ ,  $g_0(\tau, \cdot)$  and  $h(\tau, \cdot)$  are lower semi-continuous (l.s.c.) and convex, and possibly infinite valued, as explained later. Our problem is that of minimizing  $J(t, x, u)$  with respect to  $u$  over a suitable subset of  $L^p(t, T; U)$ ,  $p > 1$ , of admissible controls.

More precisely we are interested in deriving an existence and uniqueness result for the HJB equation associated to the problem, that is,

$$(1.3) \quad \begin{cases} \phi_t(t, x) + \mathcal{H}(T - t, -B^* \phi_x(t, x)) - (A_0 x | \phi_x(t, x))_H = g_0(T - t, x), \\ \phi(0, x) = \varphi_0(x) \end{cases}$$

\*Received by the editors February 26, 2007; accepted for publication (in revised form) March 8, 2008; published electronically July 23, 2008.

†LUM “Jean Monnet,” Casamassima, Bari, I-70010, Italy (faggian@lum.it).

for all  $x \in H$  and  $t \in [0, T]$ , where

$$\mathcal{H}(t, u) = \sup_{v \in U} \{ (u|v)_U - h(t, v) \}.$$

The treatment of such a problem with not necessarily continuous  $g_0$  and  $\varphi_0$  costs allows us to study a rather general class of problems with state constraints. Indeed one may show that if the set of admissible controls is of the type

$$\mathcal{U}(t, x) := \{ u \in L^p(t, T; U) : y(\tau; t, x, u) \in \mathcal{C} \ \forall \tau \in [t, T] \},$$

where we denoted by  $y(\tau; t, x, u)$  the trajectory of the system at time  $\tau$  which started in  $x$  at time  $t$ , and is driven by the control  $u$ , and where

$$(1.4) \quad \mathcal{C} \subset H \text{ is a closed convex set}$$

possibly having an empty interior, then the problem is equivalent to a problem with modified costs  $g$  and  $\varphi$  (set equal to  $+\infty$  outside  $\mathcal{C}$ ), and with no constraints on the state variable.

After recalling the results for the unconstrained problem contained in [33] and [34], we discuss in sections 4 and 5 existence and uniqueness of a *weak* solution of the HJB equation, that is, the pointwise limit of regular *strong* (as defined in [33]) solutions of approximating equations. Moreover we show that the value function  $W$  defined by

$$W(t, x) := \inf_{u \in \mathcal{U}(t, x)} J(t, x, u)$$

is the unique weak solution of the backward HJB equation, and it can be used in some applied cases to provide a feedback formula for optimal controls.

It is well known that control problems with unbounded control operator  $B$  arise when we rephrase into abstract terms some boundary control problem for PDEs (or, more generally, problems with control on a subdomain). Indeed, our framework with the application to the economic problem of optimal investment with vintage capital is motivated by that of Barucci and Gozzi [13, 12], which we describe in detail in section 6. Similar problems with an unbounded control operator have been discussed in a series of papers by this author and others. The unconstrained case has been studied for both finite and infinite horizons [33, 34, 36], while [35] contains the finite horizon case with constrained controls. Then the important novelty of this paper is that the (finite horizon) case with both *boundary control* and *state constraints* are undertaken. In particular the paper extends to the case of boundary control the results of existence and uniqueness for HJB equation contained in the paper by Cannarsa and Di Blasio [17] for distributed control and with different assumptions. Moreover, our model also takes into account the case of unconstrained problems as those in [33, 34], but with merely l.s.c. data  $\varphi_0$  and  $g_0$  rather than differentiable ones, as in [33, 34].

In our opinion this paper contributes to the study of a subject, that of optimal control problems in infinite dimensions with boundary control and/or state constraints, which is difficult to treat and whose literature is rather poor. Indeed, for the linear convex problem with *state constraints* but bounded  $B$ , we mention again the work by Cannarsa and Di Blasio [17]; for the case of viscosity solutions (with both bounded  $B$  and  $A$ ) we mention the papers by Gozzi, Cannarsa, and Soner [18] and Kocan and Soravia [47]. Finally we mention the book by Fattorini [37] on maximum principle.

Some further references on *boundary control* in infinite dimensions follow. We recall that such problems have been studied in the framework of classical/strong solutions and in that of viscosity solutions. Regarding dynamic programming in the classical/strong framework, the available results mainly regard the case of linear systems and quadratic costs (where the HJB equation reduces to the operator Riccati equation). The reader is then referred, e.g., to the books by Lasiecka and Triggiani [48, 49], to the book by Bensoussan et al. [14], and, for the case of nonautonomous systems, to the papers by Acquistapace, Flandoli, and Terreni [1] and Acquistapace and Terreni [2, 3, 4]. For the case of a linear system and a general convex cost, we mention the papers by this author [31, 32, 33, 34]. On the Pontryagin maximum principle for boundary control problems, see the book by Barbu and Precupanu (Chapter 4 in [11]).

For viscosity solutions and HJB equations in infinite dimensions we mention the series of papers by Crandall and Lions [21, 22, 23, 24, 25, 26, 27], where also some boundary control problem arises. Moreover, for boundary control we mention Gozzi, Cannarsa, and Soner [19] and the paper by Cannarsa, and Tessitore [20] on existence and uniqueness of viscosity solutions of the HJB equation. We note also that a verification theorem in the case of viscosity solutions has been proved in some finite-dimensional case in the book by Yong and Zhou [55]. We finally mention the paper by Fabbri [30], where the author derives an existence and uniqueness result for the viscosity solution of the HJB equation associated to optimal investment with vintage capital (with infinite horizon and without constraints), which is the application of section 6 of the present paper, and some continuity property of the value function,<sup>1</sup> obtaining the results by making use of the specific properties of the state equation, while no result is provided there for the general problem.<sup>2</sup>

We mention also some fundamental papers and books on the case of *distributed control* in the classical/strong framework, such as the works by Barbu and Da Prato [7, 8, 9] for some linear convex problems, Di Blasio [28, 29] for the case of constrained control, Cannarsa and Di Blasio [17] for the case of state constraints, and Barbu, Da Prato, and Popa [10] and Gozzi [42, 44, 43] for semilinear systems.

Regarding applications, on control on a subdomain (boundary or point control) we refer the reader to the many examples contained in the books by Lasiecka and Triggiani [48, 49] and by Bensoussan et al. [14, 15]. Moreover, for economic models with vintage capital the reader may see the papers by Barucci and Gozzi [13, 12] Feichtinger et al. [41, 38, 39, 40], and for population dynamic the book by Iannelli [46], the paper by Anița et al. [6], and the papers by Almeder et al. [5] and the references therein.

The paper is organized as follows. In section 2 we recall the definition of strong solutions and the results on existence and uniqueness strong solutions with unconstrained state. In section 3 we formulate the problem with state constraints, and in sections 4 and 5 we discuss existence and uniqueness for weak solutions of the HJB equation associated to the optimal control problem; finally in section 6 we apply the theory to optimal investment with vintage capital and positivity constraints.

**2. Preliminaries: The unconstrained case.** We recall here all the relevant results in the *unconstrained* case that are needed in what follows. According to the notation in [33], if  $X$  and  $Y$  are Banach spaces, we denote by  $|\cdot|_X$  the norm on  $X$ ,

<sup>1</sup>More precisely, the author proves Lipschitz  $B$ -continuity, where  $B = (A^* - \lambda I)^{-1}(A - \lambda I)^{-1}$ .

<sup>2</sup>No comparison between strong and viscosity solutions is yet available for the unconstrained problem, even for optimal investment with vintage capital.

by  $|\cdot|$  the euclidean norm in  $\mathbb{R}$ , and we set

$$\begin{aligned} Lip(X; Y) &= \left\{ f : X \rightarrow Y : [f]_L := \sup_{x, y \in X, x \neq y} \frac{|f(x) - f(y)|_Y}{|x - y|_X} < +\infty \right\}, \\ C_{Lip}^1(X) &:= \{f \in C^1(X) : [f']_L < +\infty\}, \\ \mathcal{B}_r(X, Y) &:= \left\{ f : X \rightarrow Y : |f|_{\mathcal{B}_r} := \sup_{x \in X} \frac{|f(x)|_Y}{1 + |x|_X^r} < +\infty \right\}, \quad \mathcal{B}_r(X) := \mathcal{B}_r(X, \mathbb{R}). \end{aligned}$$

Moreover we set

$$\Sigma_0(X) := \{w \in \mathcal{B}_2(X) : w \text{ is convex, } w \in C_{Lip}^1(X)\}$$

and, for  $T > 0$ ,

$$\begin{aligned} \mathcal{Y}([0, T] \times X) &= \{w : [0, T] \times X \rightarrow \mathbb{R} : w \in C([0, T], \mathcal{B}_2(X)), \\ &\quad w(t, \cdot) \in \Sigma_0(X) \ \forall t \in [0, T], \ w_x \in C([0, T], \mathcal{B}_1(X, X'))\}. \end{aligned}$$

All the spatial derivatives above have to be intended as Fréchet differentials.

Then we consider two Hilbert spaces  $V, V'$ , being dual spaces, which we do not identify for reasons stated in Remark 2.2, and we denote the duality pairing by  $\langle \cdot, \cdot \rangle$ . We set  $V'$  as the state space of the problem and denote by  $U$  the control space, with  $U$  being another Hilbert space.

Given an initial time  $t \geq 0$ , an initial state  $x \in V'$ , a finite horizon  $T > t$ , a number  $p \geq 2$ , and a control  $u \in L^p(t, T; U)$ , we consider a state equation of type

$$(2.1) \quad \begin{cases} y'(\tau) = Ay(\tau) + Bu(\tau), & \tau \in ]t, \tau[, \\ y(t) = x \end{cases}$$

and an objective functional of type

$$(2.2) \quad J_T(t, x, u) = \int_t^T [g(\tau, y(\tau)) + h(\tau, u(\tau))] d\tau + \varphi(y(T)).$$

We deal with the problem of minimizing  $J_T(t, x, \cdot)$  over all  $u \in L^p(t, T; U)$ , taking the following set of assumptions on the data.

*Assumptions 2.1.*

1.  $A : D(A) \subset V' \rightarrow V'$  is the infinitesimal generator of a strongly continuous semigroup  $\{e^{\tau A}\}_{\tau \geq 0}$  on  $V'$ ;
2. there exists  $\omega \geq 0$  such that  $|e^{\tau A}x|_{V'} \leq e^{\omega\tau}|x|_{V'}$  for all  $\tau \geq 0$ ;
3.  $g \in \mathcal{Y}([0, T] \times V')$ ,  $t \mapsto [g_x(t, \cdot)]_L \in L^1(0, T)$ ;
4.  $\varphi \in \Sigma_0(V')$ ;
5.  $B \in L(U, V')$ ;
6.  $h(t, \cdot)$  is convex and l.s.c.;  $\partial_u h(t, \cdot)$  is injective for all  $t \in [0, T]$ ;
7. if is set  $\mathcal{H}(t, u) := [h(\tau, \cdot)]^*(u)$ , then we assume  $\mathcal{H} \in \mathcal{Y}([0, T] \times U)$ ,  $\mathcal{H}(t, 0) = 0$ , and  $\sup_{t \in [0, T]} [\mathcal{H}_u(t, \cdot)]_L < +\infty$ .

We will often refer to the trajectory as to the mild solution of (2.1), that is,

$$(2.3) \quad y(\tau) = e^{(\tau-t)A}x + \int_t^\tau e^{(\tau-\sigma)A}Bu(\sigma)d\sigma, \quad \tau \in [t, T].$$

*Remark 2.2.* We do not identify  $V$  and  $V'$ , for in the applications the problem is naturally set in a Hilbert space  $H$ , such that  $V \subset H \equiv H' \subset V'$  (with all bounded inclusions). Indeed, in order to avoid the discontinuities due to the presence of  $B$ , as they appear in (1.1)–(1.2), we work in the extended state space  $V'$  related to  $H$  in the following way:  $V$  is the Hilbert space  $D(A_0^*)$  endowed with the scalar product  $(v|w)_V := (v|w)_H + (A_0^*v|A_0^*w)_H$ , and  $V'$  is the dual space of  $V$  endowed with the operator norm. Then assume that  $B \in L(U, V')$  and extend the semigroup  $\{e^{tA_0}\}_{t \geq 0}$  on  $H$  to a semigroup  $\{e^{tA}\}_{t \geq 0}$  on the space  $V'$ , having infinitesimal generator  $A$ , a proper extension of  $A_0$ . The reader is referred to [34] for a detailed treatment. The coefficient  $\omega$  could be any real number, but is assumed positive in order to avoid double proofs for positive and negative signs.

*Remark 2.3.* Note that  $g$  and  $\varphi$  arising from applications are, as functions of the  $x$  variable, often naturally defined in  $H$ , not on the larger space  $V'$ , and belong to the class  $C^1(H)$ . Then we need to *assume* here that they can be extended to functions in  $C^1(V')$ , which is a nontrivial issue. We refer the reader to section 6 to see how such an extension is obtained in the specific case of the economic example, and to [33] and [34] for a thorough discussion of this issue.

*Remark 2.4.* In Assumption 2.1(7), we assumed  $\mathcal{H}(t, 0) = 0$ . Such an assumption is not restrictive since  $\mathcal{H}(t, 0) = -\inf_{v \in U} h(t, v)$ , and if this value is not 0, we may reduce to this case simply setting  $\bar{g} = g + \inf_{v \in U} h(t, v)$  and  $\bar{h} = h - \inf_{v \in U} h(t, v)$  and treating the problem with  $\bar{g}$  and  $\bar{h}$  in place of  $g$  and  $h$ . Note also that the assumption  $\partial h(t, \cdot)$  injective is intended to yield a good definition for  $\mathcal{H}_u$  as it is, roughly speaking,  $\mathcal{H}_u = (\partial h)^{-1}$ . Note also that once one has the datum  $h$ , its convex conjugate  $\mathcal{H}$  is very often explicitly computed. Then the assumptions on  $\mathcal{H}$  are essentially assumptions on its convex conjugate  $h$ , but more conveniently stated to ensure  $\mathcal{H}$  has the desired properties.

Such optimal control problems can be associated by means of dynamic programming to the HJB equation

$$(2.4) \quad \begin{cases} v_t(t, x) - \mathcal{H}(t, -B^*v_x(t, x)) + \langle Ax|v_x(t, x) \rangle + g(t, x) = 0, & (t, x) \in [0, T] \times V', \\ v(T, x) = \varphi(x), \end{cases}$$

which can be written, by the change of variable  $v(t, x) = \phi(T - t, x)$ , as

$$(2.5) \quad \begin{cases} \phi_t(t, x) + \mathcal{H}(T - t, -B^*\phi_x(t, x)) - \langle Ax, \phi_x(t, x) \rangle = g(T - t, x), & (t, x) \in [0, T] \times V', \\ \phi(0, x) = \varphi(x). \end{cases}$$

Finally, the value function of the problem is defined as

$$(2.6) \quad W_T(t, x) = \inf_{u \in L^p(t, T; U)} J_T(t, x, u).$$

Indeed in [33] Faggian proved existence and uniqueness of *strong* solutions, as defined in Definition 2.5 below, for a class of more general HJB equations, that is,

$$(2.7) \quad \begin{cases} \phi_t(t, x) + F(t, \phi_x(t, x)) - \langle Ax, \phi_x(t, x) \rangle = g(T - t, x), & (t, x) \in [0, T] \times V', \\ \phi(0, x) = \varphi(x), \end{cases}$$

where  $F$  satisfies

$$(2.8) \quad F \in \mathcal{Y}([0, T] \times V), \quad F(t, 0) = 0, \quad \sup_{t \in [0, T]} [F_p(t, \cdot)]_L < +\infty.$$

Note indeed that if we set

$$F(t, p) := \mathcal{H}(t, -B^*p) = \sup_{u \in U} \{|u| - B^*p\}_U - h(t, u),$$

then  $F$  satisfies (2.8) and it is well defined for  $p$  in  $V$ , to which  $\phi_x(t, x)$  belongs.

DEFINITION 2.5. *Let Assumptions 2.1(1–4) and (2.8) be satisfied. We say that  $\phi \in C([0, T], \mathcal{B}_2(V'))$  is a strong solution of (2.7) if there exists a family  $\{\phi^\varepsilon\}_\varepsilon \subset C([0, T], \mathcal{B}_2(V'))$  such that*

- (i)  $\phi^\varepsilon(t, \cdot) \in C_{Lip}^1(V')$  and  $\phi^\varepsilon(t, \cdot)$  is convex for all  $t \in [0, T]$ ;  $\phi^\varepsilon(0, x) = \varphi(x)$  for all  $x \in V'$ ;
- (ii) there exist constants  $\Gamma_1, \Gamma_2 > 0$  such that

$$\sup_{t \in [0, T]} [\phi_x^\varepsilon(t, \cdot)]_L \leq \Gamma_1, \quad \sup_{t \in [0, T]} |\phi_x^\varepsilon(t, 0)|_V \leq \Gamma_2 \quad \forall \varepsilon > 0;$$

- (iii) for all  $x \in D(A)$ ,  $t \mapsto \phi^\varepsilon(t, x)$  is continuously differentiable;
- (iv)  $\phi^\varepsilon \rightarrow \phi$ , as  $\varepsilon \rightarrow 0+$ , in  $C([0, T], \mathcal{B}_2(V'))$ ;
- (v) there exists  $g_\varepsilon \in C([0, T]; \mathcal{B}_2(V'))$  such that, for all  $t \in [0, T]$  and  $x \in D(A)$ ,

$$\phi_t^\varepsilon(t, x) + F(t, \phi_x^\varepsilon(t, x)) - \langle Ax, \phi_x^\varepsilon(t, x) \rangle = g_\varepsilon(T - t, x),$$

with  $g_\varepsilon(t, x) \rightarrow g(t, x)$  pointwise, and  $\int_0^T |g_\varepsilon(s, \cdot) - g(s, \cdot)|_{\mathcal{B}_2} ds \rightarrow 0$ , as  $\varepsilon \rightarrow 0+$ .

The main result contained in [33] is as follows.

THEOREM 2.6. *Let Assumptions 2.1(1–4) and (2.8) be satisfied. There exists a unique strong solution  $\phi$  of (2.7) in the class  $C([0, T], \mathcal{B}_2(V'))$  with the following properties:*

- (i) for all  $x \in D(A)$ ,  $\phi(\cdot, x)$  is Lipschitz continuous;
- (ii)  $\phi \in \mathcal{Y}([0, T] \times V')$ ; moreover the following estimate is satisfied for all  $t \in [0, T]$ :

$$(2.9) \quad [\phi_x(t)]_L \leq e^{2\omega t} [\varphi']_L + \int_0^t e^{2\omega(t-s)} [g_x(T-s, \cdot)]_L ds.$$

Regarding applications to the optimal control problem, in [34] we were able to prove the following theorem.

THEOREM 2.7. *Let Assumptions 2.1(1–7) be satisfied, and let  $\phi$  be the strong solution of (2.5) described in Theorem 2.6. Then*

$$W_T(t, x) = \phi(T - t, x) \quad \forall t \in [0, T], \quad \forall x \in V',$$

that is, the value function  $W_T$  of the optimal control problem is the unique strong solution of the backward HJB equation (2.4).

Finally, we recall the result on optimal control in feedback form.

THEOREM 2.8. *Under Assumptions 2.1, the unique optimal control for problem*

$$\inf \left\{ J(t, x, u) : u \in L^p(t, T; U), \quad y(\tau) := e^{(\tau-t)A}x + \int_t^\tau e^{(\tau-\sigma)A}Bu(\sigma)d\sigma \right\}$$

is given by

$$u^*(\tau) = \mathcal{H}_u(\tau, -B^*W_x(\tau, y^*(\tau))),$$

where  $y^*$  is the unique solution of the closed loop equation

$$y^*(\tau) := e^{(\tau-t)A}x + \int_t^s e^{(\tau-\sigma)A}B\mathcal{H}_u(\sigma, -B^*W_x(\sigma, y^*(\sigma)))d\sigma.$$

**3. Setting of the optimal control problem with state constraints.** Next we want to perform dynamic programming for a problem in  $V'$  that contains, as a subclass, the problem set in  $H$  through (1.1)–(1.3), in the spirit of the previous section.

Then if  $K$  is a convex closed subset of  $V'$ , we consider the general problem

$$\inf\{J(t, x, u) : u \in L^p(t, T; U)\}, \quad p > 1,$$

for any  $(t, x) \in [0, T] \times K$ , where the trajectory is given by (2.3), the cost functional by (2.2), but with no regularity assumptions on  $g$  and  $\varphi$ , which are assumed merely l.s.c. and convex in the  $x$  variable.

More precisely, we make the following assumptions on the data.

*Assumptions 3.1.* We define

$$\Sigma_K \equiv \Sigma_K(V') := \{\phi : V' \rightarrow (-\infty, +\infty] : \phi \text{ is convex and l.s.c., } K \subset D(\phi)\},$$

where  $D(\phi) = \{x \in V' : \phi(x) < +\infty\}$ , and assume the following:

1.  $A : D(A) \subset V' \rightarrow V'$  is the infinitesimal generator of a strongly continuous semigroup  $\{e^{\tau A}\}_{\tau \geq 0}$  on  $V'$ ;
2. there exists  $\omega \geq 0$  such that  $|e^{\tau A}x|_{V'} \leq e^{\omega\tau}|x|_{V'}$  for all  $\tau \geq 0$ ;
3.  $B \in L(U, V')$ ;
4.  $g(t, \cdot) \in \Sigma_K$  for all  $t \in [0, T]$ ;  $g(\cdot, x)$  is l.s.c. and  $L^1(0, T)$  for all  $x \in V'$ ;
5.  $\varphi \in \Sigma_K$ ;
6.  $h(t, \cdot)$  is convex and l.s.c.;  $\partial_u h(t, \cdot)$  is injective for all  $t \in [0, T]$ ; moreover  $h(t, u) \geq a(t)|u|_U^p + b(t)$ , with  $a(t) \geq \alpha_T > 0$ ,  $b \in L^1(0, T; \mathbb{R})$ ,  $p > 1$ ;
7. if it is set  $\mathcal{H}(t, u) := \sup_{v \in U} \{(u|v)_U - h(t, v)\}$ , then we assume  $\mathcal{H} \in \mathcal{Y}([0, T] \times U)$ ,  $\mathcal{H}(t, 0) = 0$ , and  $\sup_{t \in [0, T]} [\mathcal{H}_u(t, \cdot)]_L < +\infty$ .

The functional  $J(t, x, u)$  has to be minimized with respect to  $u$  over the set of admissible controls given by

$$\mathcal{U}(t, x) = \{u \in L^p(t, T; U) : J(t, x, u) < +\infty\}.$$

The value function defined as

$$W(t, x) := \inf_{u \in \mathcal{U}(t, x)} J(t, x, u)$$

is the candidate solution to the HJB equation given by (2.4).

*Remark 3.2.* Again, Assumptions 3.1(6–7) imply that if we set  $F(t, p) = \mathcal{H}(t, -B^*p)$ , then  $F$  satisfies (2.8).

We end this section by explaining to which extent such a framework applies to both the unconstrained problem (i.e., the case  $K = V'$ ) with l.s.c. data and the case with state constraints ( $K$  a proper subset of  $V'$ ). Indeed, not all problems such as (1.1), (1.2), (1.3) are going to fit into this framework.

We need to assume that  $g_0$  and  $\varphi_0$  appearing in (1.2) admit l.s.c. extensions to  $V'$ , as shown more precisely in the following.

*Assumptions 3.3.* Let  $K = cl_{V'}(C)$ , the smallest closed convex set containing  $C$ , with respect to the topology of  $V'$ . We assume there exist l.s.c. functions  $g : [0, T] \times V' \rightarrow \mathbb{R}$  and  $\varphi : V' \rightarrow \mathbb{R}$ , finite on  $[0, T] \times K$ , such that  $g(t, x) = g_0(t, x)$ , and  $\varphi(x) = \varphi_0(x)$  for all  $t$  in  $[0, T]$  and for all  $x$  in  $C$ .

Consequently, we make the following remarks.

*Remark 3.4.* (a) If  $K$  is any closed convex subset of  $V'$  and  $g$  and  $\varphi$  are l.s.c. functions of  $x$  in  $V'$ , then the functions

$$\tilde{g}(t, x) = \begin{cases} g(t, x), & x \in K, \\ +\infty, & x \in V' \setminus K, \end{cases}$$

and

$$\tilde{\varphi}(x) = \begin{cases} \varphi(x), & x \in K, \\ +\infty, & x \in V' \setminus K, \end{cases}$$

are still l.s.c. in the  $x$  variable. Moreover, with such a choice, we have

$$D(\tilde{g}(t, \cdot)) = D(\tilde{\varphi}) = K \quad \forall t.$$

(b) Let us assume we have a dynamical system in the space  $V'$  with trajectory given by (2.3), and a cost functional of type (2.2), where  $g$  and  $\varphi$  are l.s.c. functions, and that we want to minimize such a functional over  $L^p(t, T; U)$  with respect to the control  $u$ , with the constraint

$$y(\tau) \text{ lies in } K, \text{ where } K \text{ is a closed and convex subset of } V',$$

that is, minimize  $J$  over the set of admissible controls

$$(3.1) \quad \mathcal{U}(t, x) := \{u \in L^p(t, T; U) : y(\tau; t, x, u) \in K \quad \forall \tau \in [t, T]\}$$

for any  $(t, x) \in [0, T] \times K$ . Then it is easy to check that such a problem is equivalent to minimizing  $J$  over the whole class  $L^p(t, T; U)$  of controls (no state constraints), with costs  $\tilde{g}$  and  $\tilde{\varphi}$  as defined above, in place of  $g$  and  $\varphi$ .

(c) In the applications, as in the problem set in  $H$ , the constraints on the state are naturally given by means of some convex closed subset  $\mathcal{C}$  of the space  $H$ . Then one may easily show that

$$\mathcal{C} = K \cap H.$$

Then if one knows by dynamic programming that the optimal trajectory  $y^*$  lies in  $K$ , and knows by some other means—as it often happens—that whenever the initial datum  $x$  is in  $H$  also the whole trajectory lies in  $H$ , one may derive that

$$x \in \mathcal{C} \Rightarrow y^*(s) \in \mathcal{C} \quad \forall s \in [t, T],$$

that is, the state constraint is satisfied in the original sense. The reader will find such an application in the last section of the paper.

**4. Weak solutions of the HJB equation.** In order to study the optimal control problem just set and the associated HJB equation (2.4), we need to extend the theory described in the previous section to equations with more general convex coefficients, possibly taking the value  $+\infty$ . We answer this issue by introducing *weak* solutions of the HJB equation in the next section. The definition is given for a wider class of equations that includes the HJB equation of the optimal control problem as a subclass by assuming (2.8), which is implied by Assumptions 3.1.

DEFINITION 4.1. *Let Assumptions 3.1(1–5) and let (2.8) be satisfied. Then  $\phi : [0, T] \times V' \rightarrow (-\infty, +\infty]$  is a weak solution of (2.7) if*

- (i)  $\phi(t, \cdot) \in \Sigma_K$  for all  $t \in [0, T]$ ;
- (ii) *there exist sequences  $\{\varphi_n\}_n \subset \Sigma_0$  and  $\{g_n\} \subset \mathcal{Y}([0, T] \times V')$ , such that*

$$\varphi_n(x) \uparrow \varphi(x), \quad g_n(t, x) \uparrow g(t, x) \quad \forall x \in V', \quad \forall t \in [0, T] \text{ as } n \rightarrow +\infty,$$

*and, moreover, if  $\phi_n$  is the unique strong solution of*

$$\begin{cases} \phi_t(t, x) + F(t, \phi_x(t, x)) - \langle Ax, \phi_x(t, x) \rangle = g_n(T - t, x), & (t, x) \in [0, T] \times V', \\ \phi(0, x) = \varphi_n(x) \end{cases}$$

*in  $C([0, T], \mathcal{B}_2(V'))$ , then*

$$\phi_n(t, x) \uparrow \phi(t, x) \quad \forall (t, x) \in [0, T] \times V'.$$

Remark 4.2. Since strong solutions were proved in [34] to be Lipschitz with respect to the time variable and  $C^1$  with respect to the space variable, and the weak solution  $\phi$  is a sup-envelope of strong solutions  $\phi_n$ , then  $\phi$  is l.s.c. in  $[0, t] \times V'$ . For the same reason  $\phi_n$  convex in the  $x$  variable implies that  $\phi$  is convex in  $x$  as well.

Note also that by (i) in the definition, the weak solution  $\phi$  is finite on  $K$ .

THEOREM 4.3. *Let Assumptions 3.1 be satisfied. Assume that there exists a weak solution  $\phi$  of (2.5). Then, for any  $(t, x) \in [0, T] \times K$ , the following hold:*

- (i) *The solution  $\phi$  satisfies*

$$(4.1) \quad \phi(T - t, x) = \inf_{u(t, x)} J(t, x, u).$$

- (ii) *There exists a pair  $\{u^*, y^*\}$ , optimal at  $(t, x)$ , such that*

$$\phi(T - t, x) = J(t, x, u^*).$$

- (iii) *If  $\varphi_n$  and  $g_n$  are as described in Definition 4.1, then there exists a sequence of pairs  $\{(u_n^*, y_n^*)\}$ , optimal at  $(t, x)$  for the functional*

$$J_n(t, x, u) = \int_t^T [h(\tau, u(\tau)) + g_n(\tau, y(\tau))] d\tau + \varphi_n(y(T)),$$

*such that*

$$u^* = w - \lim_{n \rightarrow +\infty} u_n^* \quad \text{in } L^p(t, T; U)$$

*and*

$$y^*(s) = w - \lim_{n \rightarrow +\infty} y_n^*(s) \quad \text{in } V' \quad \forall s \in [t, T],$$

$$y^* = w - \lim_{n \rightarrow +\infty} y_n^* \quad \text{in } L^p(t, T; V').$$

*Proof.* First we recall that, due to Remark 3.2, weak solutions of (2.5) are well defined. Let  $\phi$  be a weak solution of (2.5) and let  $\{g_n\}$ ,  $\{\varphi_n\}$ , and  $\{\phi_n\}$  be as defined in Definition 4.1. Since  $\phi_n$  are strong solutions of (2.5), then

$$\phi_n(T-t, x) = \inf_{u \in L^p(t, T; U)} J_n(t, x, u),$$

as stated by Theorem 2.7. Moreover,  $g_n \leq g$  and  $\varphi_n \leq \varphi$  so that

$$\phi_n(T-t, x) \leq J_n(t, x, u) \leq J(t, x, u) \quad \forall t, x, u.$$

By taking the limit in the preceding estimate as  $n \rightarrow +\infty$  and then the infimum with respect to the control  $u$ , we obtain

$$(4.2) \quad \phi(T-t, x) \leq \inf_{u \in L^p(t, T; U)} J(t, x, u).$$

The reverse inequality can be proved as follows. Let  $t \in [0, T]$  and  $x \in K$ , and let  $\{u_n^*\}$  be the sequence of (unique) optimal controls for  $J_n(t, x, u)$  as described in Theorem 2.8, so that

$$\phi_n(T-t, x) = J_n(t, x, u_n^*).$$

Also let  $\{y_n^*\}$  be the associated trajectories.

We claim that

$$(4.3) \quad \sup_{n \in \mathbb{N}} \|u_n^*\|_{L^p(t, x; U)} < +\infty.$$

Indeed, note that

$$\|y_n^*\|_{L^\infty(t, T; V')} \leq C_0(|x|_{V'} + \|u_n^*\|_{L^p(t, T; U)}),$$

where

$$C_0 = C_0(T) = \max \left\{ e^{\omega T}, \frac{e^{q\omega T} - 1}{q\omega} \|B\|_{L(U, V')} \right\} \quad \text{with} \quad \frac{1}{p} + \frac{1}{q} = 1.$$

Moreover, since  $g_n$  and  $\varphi_n$  are increasing and  $g_n \in \mathcal{Y}([0, T], V')$ , there exist positive constants  $C_1 = C_1(T)$  and  $C_2$  (independent of  $x$  and  $t$ ) such that

$$g_n(t, x) \geq g_0(t, x) \geq -C_1(1 + |x|_{V'})$$

and

$$\varphi_n(x) \geq \varphi_0(x) \geq -C_2(1 + |x|_{V'}).$$

Recall also that  $h$  satisfies Assumptions 3.1. Then, for all  $n$ ,  $x$ , and  $t$ , we have

$$(4.4) \quad \begin{aligned} J_n(t, x, u_n^*) &\geq -C_1 \int_t^T (1 + |y_n^*(s)|_{V'}) ds + \int_t^T a(s) |u_n^*(s)|^p ds \\ &\quad + \int_t^T b(s) ds - C_2(1 + |y_n^*(T)|_{V'}) \\ &\geq \alpha \|u_n^*\|_{L^p(t, T; U)}^p - C \|u_n^*\|_{L^p(t, T; U)} - D, \end{aligned}$$

with  $\alpha = \alpha_T$  as in Assumptions 3.1, and

$$C := C(T) = C_0(C_2 + C_1T),$$

$$D := D(T, x) = |x|_{V'}(C_1T + C_2) + C_1T + C_2 + \|b\|_{L^1(0,T;\mathbb{R})}.$$

On the other hand, we have

$$(4.5) \quad J_n(t, x, u_n^*) \leq \phi(T - t, x) =: C_3,$$

with  $C_3 = C_3(t, x) < +\infty$  by definition for  $x \in K$ . Then from (4.4) and (4.5) we derive

$$\alpha \|u_n^*\|_{L^p(t,T;U)}^p - C \|u_n^*\|_{L^p(t,T;U)} \leq C_3 + D,$$

which implies (4.3).

Now (4.3) implies that there exists a subsequence  $\{u_{n_k}^*\}$  of  $\{u_n^*\}$  and  $u^* \in L^p(t, T; U)$  such that

$$u_{n_k}^* \rightharpoonup u^* \text{ weakly in } L^p(t, T; U).$$

Consequently, if  $y^*$  is the trajectory associated to the control  $u^*$ ,

$$y_{n_k}^*(s) \rightharpoonup y^*(s) \text{ weakly in } V' \quad \forall s \in [t, T]$$

and

$$y_{n_k}^* \rightharpoonup y^* \text{ in } L^p(t, T; V').$$

The proof of such facts is standard and we omit it.

Next we want to show that

$$(4.6) \quad \liminf_{k \rightarrow +\infty} J_{n_k}(t, x, u_{n_k}^*) \geq J(t, x, u^*).$$

To this purpose, note that  $u \mapsto \int_t^T h(s, u(s))ds$  being a convex function, it is also weakly l.s.c., so that

$$(4.7) \quad \liminf_{k \rightarrow +\infty} \int_t^T h(s, u_{n_k}^*(s))ds \geq \int_t^T h(s, u^*(s))ds.$$

Moreover, let  $m \in \mathbb{N}$  be fixed. Since  $\varphi_n$  is an increasing sequence, we have

$$\varphi_{n_k}(y_{n_k}^*(T)) \geq \varphi_m(y_{n_k}^*(T)) \quad \forall n_k \geq m.$$

Now

$$\liminf_{k \rightarrow +\infty} \varphi_{n_k}(y_{n_k}^*(T)) \geq \liminf_{k \rightarrow +\infty} \varphi_m(y_{n_k}^*(T)) \geq \varphi_m(y^*(T))$$

since  $\varphi_m$  is convex (and then weakly l.s.c.). By letting  $m \rightarrow +\infty$  we then obtain

$$(4.8) \quad \liminf_{k \rightarrow +\infty} \varphi_{n_k}(y_{n_k}^*(T)) \geq \varphi(y^*(T)).$$

In the same way we find

$$\liminf_{k \rightarrow +\infty} g_{n_k}(s, y_{n_k}^*(s)) \geq g(s, y^*(s)) \quad \forall s \in [t, T].$$

Moreover since the sequence  $g_n$  is increasing, then

$$g_{n_k}(s, y_{n_k}^*(s)) \geq g_{n_1}(s, y_{n_k}^*(s)) \geq -C(1 + |y_{n_k}^*(s)|_{V'}^2)$$

for some  $C > 0$ , as  $g_{n_1} \in \mathcal{Y}([0, T] \times V')$ . Since  $y_n \in L^p(t, T; V')$ , by Fatou's lemma we derive

$$(4.9) \quad \liminf_{k \rightarrow +\infty} \int_t^T g_{n_k}(s, y_{n_k}^*(s)) ds \geq \int_t^T g(s, y^*(s)) ds.$$

By means of (4.7)–(4.9) we then obtain (4.6), which implies

$$(4.10) \quad \phi(T - t, x) = \liminf_{k \rightarrow +\infty} J_{n_k}(t, x, u_{n_k}^*) \geq J(t, x, u^*).$$

Then, by means of (4.2), we have also

$$(4.11) \quad \phi(T - t, x) = \lim_{n \rightarrow +\infty} J_n(t, x, u_n^*) = \liminf_{k \rightarrow +\infty} J_{n_k}(t, x, u_{n_k}^*) = J(t, x, u^*).$$

Hence (4.1) holds and  $u^*$  is optimal.  $\square$

The following corollary easily follows.

**COROLLARY 4.4.** *If there exists a weak solution of (2.5), then it is unique.*

*Remark 4.5.* If the function  $h$  is strictly convex in  $u$ , then the optimal control  $u^*$  is unique and the whole sequence of optimal controls  $u_n^*$  converges weakly to  $u^*$  in  $L^p(t, T; U)$ . Moreover, if, for example,  $h(t, u) = h(u) = |u|_U^p$ , then

$$(4.12) \quad u_n^* \rightarrow u^* \text{ strongly in } L^p(t, T; U)$$

and

$$(4.13) \quad y_n^* \rightarrow y^* \text{ in } C([t, T], V').$$

Indeed we have just showed that  $J_n(t, x, u_n^*) \rightarrow J(t, x, u^*)$ , as  $n \rightarrow +\infty$ , so that

$$(4.14) \quad \int_t^T |u_n^*(\tau)|_U^p d\tau = \int_t^T |u^*(\tau)|_U^p d\tau + \int_t^T [g(\tau, y^*(\tau)) - g_n(\tau, y_n^*(\tau))] d\tau \\ + \varphi(y^*(\tau)) - \varphi_n(y_n^*(\tau)) + \sigma(n),$$

with  $\sigma(n) \rightarrow 0$  as  $n \rightarrow 0$ . Hence from (4.8)–(4.9) we obtain

$$\limsup_{k \rightarrow +\infty} \int_t^T |u_{n_k}^*(\tau)|_U^p d\tau \leq \int_t^T |u^*(\tau)|_U^p d\tau,$$

along a subsequence, which together with (4.7) implies  $u_{n_k}^* \rightarrow u^*$  strongly in  $L^p(t, T; U)$  as  $k \rightarrow +\infty$ . To show that the whole sequence of optimal controls  $u_n^*$  converges strongly in  $L^p$ , one assumes by contradiction that there exist an  $\varepsilon > 0$  and a subsequence  $\{u_{n_l}^*\}$  such that  $\|u_{n_l}^* - u^*\|_p \geq \varepsilon$  for all  $l \in \mathbb{N}$ . Then such a subsequence is itself bounded and has a subsequence converging weakly and, possibly passing to a further subsequence, strongly to some optimal control  $v^*$ . But as the optimal control is unique, this yields a contradiction. The proof of (4.13) is a straightforward consequence of the Lebesgue theorem.

*Remark 4.6.* Besides existence and uniqueness for the HJB equation, Cannarsa and Di Blasio [17] provide optimal feedback maps in the case when  $B$  is (bounded and) invertible—which is not true in the case of the economic application of section 6. Nevertheless, we show in an example how one can derive feedback controls when dealing with explicitly given data  $B$  and  $h$ .

**5. An existence result.** We may prove also existence of weak solutions when  $g$  has a particular dependence on the time variable, as stated and proved in the theorem below. To this extent we first prove the following lemma.

LEMMA 5.1. *If  $\phi_1$  and  $\phi_2$  are strong solutions of (2.5) associated to data  $\varphi_1 \leq \varphi_2$  and  $g_1 \leq g_2$ , respectively, then  $\phi_1 \leq \phi_2$ .*

*Proof.* Note that according to the properties of strong solutions proved in [33], for  $i = 1, 2$  we have

$$\phi_i(T - t, x) = \inf_{L^p(t, T; U)} J_i(t, x, u),$$

where

$$J_i(t, x, u) = \int_t^T [h(\tau, u(\tau)) + g_i(\tau, y(\tau))] d\tau + \varphi_i(y(T)).$$

Since the assumptions on the data imply

$$J_1(t, x, u) \leq J_2(t, x, u) \quad \forall u \in L^p(t, T; U),$$

by taking the infimum over  $L^p(t, T; U)$ , we get the desired inequality.  $\square$

THEOREM 5.2. *Assume that Assumptions 3.1 are satisfied, with  $g$  of the following type:*

$$(5.1) \quad g(t, x) = \gamma(x)\eta(t), \quad \gamma \in \Sigma_K, \quad \eta \in C([0, T], \mathbb{R}).$$

*Assume also that for each  $(t, x) \in [0, T] \times V'$  there exists an admissible control. Then there exists a weak solution of (2.5).*

*Proof.* We construct a sequence such as that in Definition 4.1 by using Yosida approximations. For given  $\lambda > 0$ , we define

$$(5.2) \quad \begin{aligned} \varphi_\lambda(x) &:= \inf_{y \in V'} \left\{ \varphi(y) + \frac{|x - y|_{V'}^2}{2\lambda} \right\}, \quad x \in V', \\ \gamma_\lambda(x) &:= \inf_{y \in V'} \left\{ \gamma(y) + \frac{|x - y|_{V'}^2}{2\lambda} \right\}, \quad x \in V'. \end{aligned}$$

It is well known (see, for instance, [11, Chap. 2]) that  $\varphi_\lambda, \gamma_\lambda$  are in  $\Sigma_0$ , with  $[\varphi'_\lambda]_L \leq \frac{1}{\lambda}$  and  $[\gamma'_\lambda]_L \leq \frac{1}{\lambda}$ . Moreover

$$\varphi_\lambda(x) \uparrow \varphi(x), \quad \gamma_\lambda(x) \uparrow \gamma(x) \quad \forall x \in V', \quad \forall t \in [0, T] \text{ as } \lambda \downarrow 0^+.$$

Then both  $\varphi_\lambda$  and  $\gamma_\lambda(\cdot)\eta(\cdot)$  satisfy Assumptions 3.1, so that there exists a unique strong solution  $\phi_\lambda$  of equation

$$\begin{cases} \phi_t(t, x) + \mathcal{H}(T - t, \phi_x(t, x)) - \langle Ax, \phi_x(t, x) \rangle = \gamma_\lambda(x)\eta(T - t), & (t, x) \in [0, T] \times V', \\ \phi(0, x) = \varphi_\lambda(x). \end{cases}$$

Moreover,  $\phi_\lambda$  satisfies

$$(5.3) \quad \phi_\lambda(T - t, x) = \inf_{L^p(t, T; U)} J_\lambda(t, x, u),$$

where

$$J_\lambda(t, x, u) = \int_t^T [h(\tau, u(\tau)) + g_\lambda(y(\tau))\eta(\tau)]d\tau + \varphi_\lambda(y(T)).$$

Since  $\varphi_\lambda(x) \uparrow \varphi(x)$  and  $\gamma_\lambda(x) \uparrow \gamma(x)$ , by Lemma 5.1 we have that for all  $x$  and  $t$  the sequence  $\{\phi_\lambda(t, x)\}_\lambda$  is increasing. We then set

$$\phi(t, x) := \sup_{\lambda > 0} \phi_\lambda(t, x) = \lim_{\lambda \rightarrow 0^+} \phi_\lambda(t, x).$$

By definition, the function  $\phi$  is l.s.c. in  $(t, x)$  and convex in  $x$  for all fixed  $t$ . It is then left to show that  $K \subset D(\phi(t, \cdot))$  for all fixed  $t \in [0, T]$ . Let  $x \in K$ ,  $t \in [0, T]$ , and let  $\bar{u}$  be an admissible control for the problem starting at  $(t, x)$ . Then

$$\phi_\lambda(T - t, x) \leq J_\lambda(t, x, \bar{u}) \leq J(t, x, \bar{u}) < +\infty,$$

and so

$$\phi(T - t, x) \leq J(t, x, \bar{u}) < +\infty. \quad \square$$

*Remark 5.3.* If  $g$  depends on time, one may set

$$g_\lambda(t, x) := \inf_{y \in V'} \left\{ g(t, y) + \frac{|x - y|_{V'}^2}{2\lambda} \right\}, \quad x \in V'.$$

Note that if  $x_0 \in D(g(t, \cdot))$ , then

$$g_\lambda(t, x) \leq g(t, x_0) + \frac{|x - x_0|_{V'}^2}{2\lambda},$$

so that  $g_\lambda(t, \cdot) \in \mathcal{B}_2(V')$  for all  $t$ . If one is able to show that

$$g_\lambda \in C([0, T], \mathcal{B}_2(V')) \quad \text{and} \quad (g_\lambda)_x \in C([0, T], \mathcal{B}_1(V')),$$

then the proof above may be performed as before, as both  $\varphi_\lambda$  and  $g_\lambda$  satisfy the assumptions in Theorem 2.6 (see also Remark 5.2 in [33]).

Theorems 5.2 and 4.3 imply the following result.

**COROLLARY 5.4.** *Let Assumptions 3.1 be satisfied, with  $g$  as in (5.1). Then the following properties are equivalent:*

- (i) *there exists a unique weak solution of (2.5);*
  - (ii) *at each  $(t, x) \in [0, T] \times K$  there exists an admissible control.*
- Moreover if (i) or (ii) holds, there exists an optimal pair  $(u^*, y^*)$  and*

$$\phi(T - t, x) = J(t, x, u^*).$$

**6. Applications to vintage capital problems with state constraints.** We here describe our motivating example: the problem of optimal investment with vintage capital in the setting introduced by Barucci and Gozzi [13, 12], and later reprised and generalized by Feichtinger et al. [41, 38, 39] and Faggian [33, 34].

The capital accumulation is described by the system

$$(6.1) \quad \begin{cases} \frac{\partial y(\tau, s)}{\partial \tau} + \frac{\partial y(\tau, s)}{\partial s} + \mu y(\tau, s) = u_1(\tau, s), & (\tau, s) \in ]t, T[ \times ]0, \bar{s}], \\ y(\tau, 0) = u_0(\tau), & \tau \in ]t, T[, \\ y(t, s) = x(s), & s \in [0, \bar{s}], \end{cases}$$

with  $t > 0$  the initial time,  $\bar{s} \in [0, +\infty[$  the maximal allowed age, and  $\tau \in [0, T[$  with horizon  $T < +\infty$ . The unknown  $y(\tau, s)$  represents the amount of capital goods of age  $s$  accumulated at time  $\tau$ , the initial datum is a function  $x \in L^2(0, \bar{s})$ , and  $\mu > 0$  is a depreciation factor. Moreover,  $u_0 : [t, T[ \rightarrow \mathbb{R}$  is the investment in new capital goods ( $u_0$  is the boundary control) while  $u_1 : [t, T[ \times [0, \bar{s}] \rightarrow \mathbb{R}$  is the investment at time  $\tau$  in capital goods of age  $s$  (hence, the distributed control). Investments are jointly referred to as the control  $u = (u_0, u_1)$ . Note that such problems are known as *vintage capital* problems, for the capital goods depend jointly on time  $\tau$  and on age  $s$ , which is equivalent to their dependence on time and vintage  $\tau - s$ .

In addition, we consider the firm profits represented by the functional

$$I(t, x; u_0, u_1) = \int_t^T e^{-\lambda\tau} [R(Q(\tau)) - c(u(\tau))] d\tau + e^{-\lambda T} R_0(Q(T)),$$

where, for some given measurable coefficient  $\alpha$ , we have that

$$Q(\tau) = \int_0^{\bar{s}} \alpha(s) y(\tau, s) ds$$

is the output rate (linear in  $y(\tau)$ ), and  $R, R_0$  are concave revenues from the output  $Q$ . Moreover we set

$$c(u_0, u_1) = \beta_0 |u_0|^p + \gamma_0 u_0 + \beta_1 |u_1|_H^p + (u_1 | \gamma_1)_H, \quad (u_0, u_1) \in \mathbb{R} \times L^2(0, \bar{s}),$$

with  $\beta_1 |u_1|_H^p + (u_1 | \gamma_1)_H$  indicating the running investment cost for technologies of age greater than 0, and with  $\beta_0 |u_0|^p + \gamma_0 u_0$  the investment cost in new technologies, including adjustment innovation.

The entrepreneur's problem is that of maximizing  $I(t, x; u_0, u_1)$  over all controls  $(u_0, u_1)$  chosen in a set such that the corresponding trajectories are positive, that is, such that the following constraint on the state is satisfied:

$$(6.2) \quad y(\tau, s; t, x, u_0, u_1) \geq 0 \quad \forall \tau, s.$$

When rephrased in an infinite-dimensional setting, with  $H := L^2(0, \bar{s})$  as state space, the state equation (6.1) can be reformulated as a linear control system with an unbounded control operator, that is,

$$(6.3) \quad \begin{cases} y'(\tau) = A_0 y(\tau) + B u(\tau), & \tau \in ]t, T[, \\ y(t) = x, \end{cases}$$

where  $y : [t, T] \rightarrow H$ ,  $x \in H$ ,  $A_0 : D(A_0) \subset H \rightarrow H$  is the infinitesimal generator of a strongly continuous semigroup  $\{e^{A_0 t}\}_{t \geq 0}$  on  $H$  with domain  $D(A_0) = \{f \in H^1(0, \bar{s}) : f(0) = 0\}$  and defined as  $A_0 f(s) = -f'(s) - \mu f(s)$ , the control space is  $U = \mathbb{R} \times H$ , the control function is a couple  $u \equiv (u_0, u_1) : [t, T] \rightarrow \mathbb{R} \times H$ , and the control operator is given by  $Bu \equiv B(u_0, u_1) = u_1 + u_0 \delta_0$  for all  $(u_0, u_1) \in \mathbb{R} \times H$ ,  $\delta_0$  being the Dirac delta at the point 0. Although  $B \notin L(U, H)$ , note that  $B \in L(U, D(A_0^*))$ .

Following Remark 2.2, we then set

$$V = D(A_0^*) = \{f \in H^1(0, \bar{s}) : f(\bar{s}) = 0\}$$

and  $V' = D(A_0^*)'$ . Such abstract rephrasing is discussed in detail in [34], to which the reader is referred.

Regarding the target functional, we set

$$J_T(t, x; u) := -I(t, x; u_0, u_1),$$

where

- $g_0 : [0, T] \times H \rightarrow \mathbb{R}$ ,  $g(\tau, x) = -e^{-\lambda\tau} R((\alpha|x)_H)$ ;
- $h : [0, T] \times U \rightarrow \mathbb{R}$ ,  $h(t, u_0, u_1) = e^{-\lambda t} [\beta_0 |u_0|^p + \gamma_0 u_0 + \beta_1 |u_1|_H^p + (u_1|\gamma_1)_H]$ ;
- $\phi_0 : H \rightarrow \mathbb{R}$ ,  $\phi_0(x) = -e^{-\lambda T} R_0((\alpha|x)_H)$ .

Moreover

$$\mathcal{C} := \{x \in L^2(0, \bar{s}) : x(s) \geq 0 \text{ for a.e. } s \in [0, \bar{s}]\},$$

and, for any  $(t, x) \in [0, T] \times \mathcal{C}$ , the control  $u$  is chosen in the set of admissible controls

$$\mathcal{U}(t, x) := \{u \in L^p(0, T; U) : y(\tau; t, x, u) \in \mathcal{C}\}.$$

Note that  $\mathcal{C}$  is a convex closed subset of  $H$ , whose closure in  $V'$  is

$$K = cl_{V'}(\mathcal{C}) = \{z \in V' : \langle z, v \rangle \geq 0 \ \forall v \in V, v \geq 0\}.$$

*Remark 6.1.* Note that  $K$  is invariant with respect to the semigroup, that is,

$$e^{\tau A}(K) \subset K \ \forall \tau \in [t, T].$$

Indeed  $\langle e^{(\tau-t)A}x, v \rangle = \langle x, e^{(\tau-t)A^*}v \rangle \geq 0$ , as (see [34]) we have

$$[e^{(\tau-t)A^*}v](s) = e^{-\mu(\tau-t)}v(s + \tau - t)\chi_{[0, \bar{s}-\tau+t]}(s) \geq 0 \ \forall s \in [0, \bar{s}], \ \forall v \in V.$$

*Remark 6.2.* If we want to ensure Assumptions 3.1 are satisfied, we need to better specify the properties of the cost and the revenue functions. For instance, if we assume  $\alpha$  to be more regular, say  $\alpha \in V$ , and  $R$  and  $R_0$  concave in  $\mathbb{R}$  (hence continuous), then Assumptions 3.3 are satisfied by setting  $g(\tau, x) = -e^{-\lambda\tau} R(\langle a, x \rangle)$  when  $x \in K$  and  $g(\tau, x) = +\infty$  elsewhere, and similarly  $\varphi(x) = -e^{-\lambda T} R_0(\langle a, x \rangle)$  when  $x \in K$  and  $\varphi(x) = +\infty$  elsewhere. Assumptions 3.1(4–7) are then also satisfied.

Then the following existence and uniqueness result for the problem holds.

**THEOREM 6.3.** *Assume that the data of the problem described above satisfy Assumptions 3.1, with  $p \geq 2$ . Assume also  $R$  bounded on bounded subsets, and  $\alpha \in V'$ . Let  $t \in [0, T]$  and  $x \in K$ . Then*

- (i) *there exists a unique weak solution  $\phi$  to (2.5);*
- (ii) *for every  $t$  in  $[0, T]$  and every  $x$  in  $K$ , there exists  $(u^*, y^*)$  optimal at  $(t, x)$  for the optimal control problem, with  $y^*(\tau) \in K$  for every  $\tau$  in  $[t, T]$ ;*
- (iii)  $J(t, x, u^*) = \phi(T - t, x)$ .

*Proof.* For all  $t$  and  $x$  in  $K$  the null control is admissible. Indeed

$$|J(t, x, 0)| = \left| \int_t^T e^{-\lambda\tau} R(\langle \alpha, e^{(\tau-t)A}x \rangle) d\tau \right| \leq M \frac{e^{-\lambda t} - e^{-\lambda T}}{\lambda} < +\infty,$$

where  $M = \sup\{|R(y)| : |y| \leq |\alpha|_V e^{\omega T} |x|_{V'}\}$ . The proof is then a straightforward application of Corollary 5.4.  $\square$

Once the problem is solved in the extended state space  $V'$ , one has to go back to the original problem set in  $H$ . In order to do so we recall that whenever the initial datum  $x$  is in  $H$ , the whole trajectory lies in  $H$ , as Barucci and Gozzi prove in their paper [13].

THEOREM 6.4. *Given any initial datum  $x \in H$  and control  $u \in L^p(t, T; U)$ , the mild solution of (6.3)*

$$y(s) = e^{(s-t)A}x + \int_t^s e^{(s-\tau)A}Bu(\tau)d\tau$$

*belongs to  $C([t, T]; H)$ .*

More precisely, it is shown in [34] that whenever  $x$  is in  $H$ , we may write the solution also as

$$(6.4) \quad y(\tau) = e^{-(\tau-t)A_0}x + \int_t^\tau e^{-(\tau-r)A_0}u_1(r)dr - A_0 \int_t^\tau e^{-(\tau-r)A_0}w(r)dr,$$

where  $w(r)(s) = e^{-\mu s}u_0(r)$ , or even more explicitly as

$$(6.5) \quad \begin{aligned} y(\tau, s) &= e^{-\mu(\tau-t)}x(s-\tau+t)\chi_{[\tau-t, \bar{s}]}(s) \\ &+ u_0(\tau-s)e^{-\mu s}\chi_{[0, (\tau-t) \wedge \bar{s}]}(s) + \int_0^{(\tau-t) \wedge s} e^{-\mu q}u_1(\tau-q, s-q)dq. \end{aligned}$$

Then by means of the preceding theorem and Remark 3.4(c), we may infer that the state constraints are satisfied by the optimal trajectory any time the initial datum lies in  $\mathcal{C}$ , as stated next.

THEOREM 6.5. *Let  $(t, x) \in [0, T] \times K$  and let  $(u^*, y^*)$  be optimal at  $(t, x)$ . Then*

$$y^*(\tau) \in \mathcal{C} \quad \forall \tau \in [t, T].$$

**6.1. Feedback controls.** We intend to show here that once the running cost (or profit, as in the economic example) is explicitly given as in the example we are treating, one may expect to derive a more meaningful feedback formula for optimal controls than the one obtained by the limiting procedure in Theorem 4.3.

After some easy but tedious computations, one obtains

$$(6.6) \quad \mathcal{H}(t, u_0, u_1) = (q-1)^{q-1}q^{-q}e^{-\lambda t}[\beta_0|e^{\lambda t}u_0 - \gamma_0|^q + \beta_1|e^{\lambda t}u_1 - \gamma_1|_H^q],$$

where  $q = p/(p-1)$ . Note that as  $h$  is strictly convex, the optimal control is unique, as we remarked in section 4. Moreover it is easily shown that  $\mathcal{H}$  satisfies Assumptions 3.1(7).

LEMMA 6.6. *Let the assumptions of Theorem 6.3 be satisfied, and let  $p \geq 2$ . Let  $(u^*, y^*)$  be the unique optimal couple at  $(t, x)$ , and let  $(u_n^*, y_n^*)$  be the associated sequence of optimal couples of the approximating problems. Then*

- (i)  $u_{0n}^* \rightarrow u_0^*$  strongly in  $L^p(t, T)$ ,<sup>3</sup> and  $u_{1n}^* \rightarrow u_1^*$  strongly in  $L^p(t, T; H)$ ;
- (ii) if  $x \in \mathcal{C}$ , then  $y_n^*(\tau) \rightarrow y^*(\tau)$  strongly in  $H$  for all  $\tau \in [t, T]$ .

*Proof.* By making use of the fact that the optimal control is unique and  $J_n(u_n^*) \rightarrow J(u^*)$  as  $n \rightarrow +\infty$ , by weak convergence of both  $u_{0n}^*$  and  $u_{1n}^*$  to  $u_0^*$  and  $u_1^*$ , respectively, and proceeding as in Remark 4.5, one may show that along a subsequence

$$(6.7) \quad \begin{aligned} \limsup_{k \rightarrow +\infty} \int_t^T e^{-\lambda \tau} [\beta_0|u_{0n_k}^*(\tau)|^p + \beta_1|u_{1n_k}^*(\tau)|_H^p] d\tau \\ \leq \int_t^T e^{-\lambda \tau} [\beta_0|u_0^*(\tau)|^p + \beta_1|u_1^*(\tau)|_H^p] d\tau. \end{aligned}$$

<sup>3</sup> $L^p(t, T) \equiv L^p(t, T; \mathbb{R})$ .

Since also

$$(6.8) \quad \begin{aligned} \liminf_{n \rightarrow +\infty} \int_t^T e^{-\lambda\tau} [\beta_0 |u_{0n}^*(\tau)|^p + \beta_1 |u_{1n}^*(\tau)|_H^p] d\tau \\ \geq \int_t^T e^{-\lambda\tau} [\beta_0 |u_0^*(\tau)|^p + \beta_1 |u_1^*(\tau)|_H^p] d\tau, \end{aligned}$$

then the limit exists along the subsequence  $\{u_{n_k}^*\}$  and coincides with the right-hand side. Again as in Remark 4.5, one shows that the same assertion yields for the whole sequence  $\{u_n^*\}$ , that is,

$$(6.9) \quad \lim_{n \rightarrow +\infty} \int_t^T e^{-\lambda\tau} [\beta_0 |u_{0n}^*(\tau)|^p + \beta_1 |u_{1n}^*(\tau)|_H^p] d\tau = \int_t^T e^{-\lambda\tau} [\beta_0 |u_0^*(\tau)|^p + \beta_1 |u_1^*(\tau)|_H^p] d\tau.$$

Note that (6.9) and the weak convergence of  $u_n^*$  to  $u_0^*$  imply

$$\begin{aligned} \liminf_{n \rightarrow \infty} \int_t^T \beta_0 e^{-\lambda\tau} |u_{0n}^*(\tau)|^p d\tau &= \int_t^T \beta_0 e^{-\lambda\tau} |u_0^*(\tau)|^p d\tau, \\ \liminf_{n \rightarrow \infty} \int_t^T \beta_1 e^{-\lambda\tau} |u_{1n}^*(\tau)|_H^p d\tau &= \int_t^T \beta_1 e^{-\lambda\tau} |u_1^*(\tau)|_H^p d\tau, \end{aligned}$$

so that one derives that (i) is satisfied at least along a subsequence and, by a standard argument, along the whole sequence. The proof of (ii) is performed by making use of the particular structure of the solution of the economic problem, given by (6.4) and (6.5). Then

$$(6.10) \quad \begin{aligned} &|y_n^*(\tau) - y^*(\tau)|_H \\ &\leq \int_t^\tau e^{(\tau-r)A_0} |u_{1n}^*(r) - u_1^*(r)|_H dr + \left| A_0 \int_t^\tau e^{-(\tau-r)A_0} (w_n(r) - w(r)) dr \right|_H \\ &\equiv I_1^n(\tau) + I_2^n(\tau), \end{aligned}$$

with  $w_n(\tau)(s) = e^{-\mu s} u_{0n}^*(\tau)$ . Now

$$I_1^n(\tau) \leq C \|u_{1n}^* - u_1^*\|_{L^1(t, T; H)} \leq C_1 \|u_{1n}^* - u_1^*\|_{L^p(t, T; H)}$$

for suitable positive constants  $C$  and  $C_1$ , while by means of (6.5) we have

$$(6.11) \quad \begin{aligned} I_2^n(\tau)^2 &\leq \int_0^{\bar{s} \wedge (\tau-t)} e^{-2\mu s} |(u_{0n}^* - u^*)(\tau-s)|^2 ds \\ &\leq \|u_{0n}^* - u^*\|_{L^2(t, T)}^2 \leq C \|u_{0n}^* - u^*\|_{L^p(t, T)}^2, \end{aligned}$$

which together yields (ii).  $\square$

**THEOREM 6.7.** *In the assumptions of Theorem 6.3, let  $\psi$  be the restriction of  $\phi$  to the set  $[0, T] \times H$ , that is,*

$$\psi : [0, T] \times H \rightarrow \mathbb{R}, \quad \psi(t, x) := \phi(t, x),$$

and let

$$\partial_x \psi(t, x) = \{h \in H : \psi(t, y) - \psi(t, x) \geq (h|y - x)_H \quad \forall y \in H\}$$

be its spatial subgradient. Also let  $(u^*, y^*)$  be the optimal couple at  $(t, x) \in [t, T] \times H$ , and  $\tau \in [t, T]$ . Then

(i)  $u_0^*(\tau) = \lim_{n \rightarrow +\infty} u_{0n}^*(\tau)$ , where

$$u_{0n}^*(\tau) = -\beta_0 p^{1-q} |e^{\lambda\tau} \phi_x^n(T - \tau, y_n^*(\tau))(0) + \gamma_0|^{q-2} (e^{\lambda\tau} \phi_x^n(T - \tau, y_n^*(\tau))(0) + \gamma_0);$$

(ii) there exists a selection  $\xi(\tau) \in \partial_x \psi(T - \tau, y^*(\tau))$  such that

$$u_1^*(\tau) = -\beta_1 p^{1-q} |e^{\lambda\tau} \xi(\tau) + \gamma_1|_H^{q-2} (e^{\lambda\tau} \xi(\tau) + \gamma_1).$$

*Proof.* Let  $(t, x)$  be fixed in  $[0, T] \times K$ , and let  $u_n^*$  be the sequence of controls, optimal at  $(t, x)$ , of the approximating problems, as in Theorem 4.3. It is easy to show that the operator  $B : U \rightarrow V'$ ,  $Bu = u_1 + \delta_0 u_0$  has adjoint

$$B^* : V \rightarrow U, \quad B^*v := (v(0), v) \in \mathbb{R} \times V,$$

so that by means of the feedback formula in Theorem 2.8 applied to optimal controls  $u_n^*$ , one has

(6.12)

$$u_{0n}^*(\tau) = -\beta_0 p^{1-q} |e^{\lambda\tau} \phi_x^n(T - \tau, y_n^*(\tau))(0) + \gamma_0|^{q-2} (e^{\lambda\tau} \phi_x^n(T - \tau, y_n^*(\tau))(0) + \gamma_0),$$

which proves the first assertion in the statement of the theorem, while

$$(6.13) \quad u_{1n}^*(\tau) = -\beta_1 p^{1-q} |e^{\lambda\tau} \phi_x^n(T - \tau, y_n^*(\tau)) + \gamma_1|_H^{q-2} (e^{\lambda\tau} \phi_x^n(T - \tau, y_n^*(\tau)) + \gamma_1).$$

By reversing (6.13) one obtains

$$(6.14) \quad \phi_x^n(T - \tau, y_n^*(\tau)) = -\beta_1^{1-p} p e^{-\lambda\tau} |u_{1n}^*(\tau)|_H^{p-2} u_{1n}^*(\tau) + e^{-\lambda\tau} \gamma_1,$$

so that by Lemma 6.6(i) there exists  $k \mapsto n_k$  such that for almost every  $\tau$  in  $[t, T]$  one has

$$(6.15) \quad \xi(\tau) := H - \lim_{k \rightarrow \infty} \phi_x^{n_k}(T - \tau, y_{n_k}^*(\tau)) = -\beta_1^{1-p} p e^{-\lambda\tau} |u_1^*(\tau)|_H^{p-2} u_1^*(\tau) + e^{-\lambda\tau} \gamma_1.$$

From

$$\phi^{n_k}(T - \tau, y) - \phi^{n_k}(T - \tau, y_{n_k}^*(\tau)) \geq \langle \phi_x^{n_k}(T - \tau, y_{n_k}^*(\tau)), y - y_{n_k}^*(\tau) \rangle_{V, V'} \quad \forall y \in V',$$

and recalling that when  $x$  is in  $H$  the whole trajectory  $y_{n_k}^*(\tau)$  lies in  $H$  for all  $\tau$ , we derive

$$(6.16) \quad \phi^{n_k}(T - \tau, y) - \phi^{n_k}(T - \tau, y_{n_k}^*(\tau)) \geq (\phi_x^{n_k}(T - \tau, y_{n_k}^*(\tau)) | y - y_{n_k}^*(\tau))_H \quad \forall y \in H.$$

We now would like to derive from the preceding inequality the following estimate:

$$(6.17) \quad \psi(T - \tau, y) - \psi(T - \tau, y^*(\tau)) \geq (\xi(\tau) | y - y^*(\tau))_H \quad \forall y \in H \text{ for a.e. } \tau \in [t, T].$$

Indeed, by means of the same argument that led to (4.8), we get

$$\phi(T - \tau, y) - \phi(T - \tau, y^*(\tau)) \geq \limsup_{k \rightarrow \infty} (\phi^{n_k}(T - \tau, y) - \phi^{n_k}(T - \tau, y_{n_k}^*(\tau))).$$

On the other hand, for almost every  $\tau$  in  $[t, T]$ ,  $\phi_x^{n_k}(T - \tau, y_n^*(\tau))$  converges to  $\xi(\tau)$  in  $H$ , and  $y_n^*(\tau)$  converges to  $y^*(\tau)$ , both strongly in  $H$  (Lemma 6.6(ii)), so that

$$(\phi_x^{n_k}(T - \tau, y_n^*(\tau)) \mid y - y_n^*(\tau))_H \rightarrow (\xi(\tau) \mid y - y^*(\tau))_H \text{ for a.e. } \tau \in [t, T].$$

Hence,

$$\xi(\tau) \in \partial_x \psi(T - \tau, y^*(\tau)) \text{ for a.e. } \tau \in [t, T],$$

and passing to limits in (6.13),

$$u_1^*(\tau) = -\beta_1 p^{1-q} |e^{\lambda\tau} \xi(\tau) + \gamma_1|_H^{q-2} (e^{\lambda\tau} \xi(\tau) + \gamma_1). \quad \square$$

# CONTROLLABILITY PROBLEMS FOR THE STRING EQUATION ON A HALF-AXIS WITH A BOUNDARY CONTROL BOUNDED BY A HARD CONSTANT\*

L. V. FARDIGOLA<sup>†</sup>

**Abstract.** In this paper necessary and sufficient conditions for null-controllability and approximate null-controllability are obtained for the control system  $w_{tt} = w_{xx} - q^2 w$ ,  $w_x(0, t) = u(t)$ ,  $x > 0$ ,  $t \in (0, T)$ , where  $q \geq 0$ ,  $T > 0$ , and  $u$  is a control bounded by a hard constant. These problems are considered in the Sobolev spaces. Controls solving these problems are found explicitly. Bang-bang controls solving the approximate null-controllability problem are found by means of the solutions of the Markov power moment problem. Continuous controls solving this problem are constructed with the aid of the Cesàro means of a Fourier series generated by the data of the control system.

**Key words.** wave equation, half-axis, controllability problem, control bounded by a hard constant, Neumann control, Fourier transform, Sobolev space, Cesàro mean

**1. Introduction.** Controllability problems for hyperbolic partial differential equations were investigated in a number of papers (see, e.g., the references in [10]).

One of the most generally accepted ways to study control systems with distributed parameters is their interpretation in the form

$$(1.1) \quad \frac{dW}{dt} = \mathbf{A}W + \mathbf{B}u, \quad t \in (0, T),$$

where  $T > 0$ ,  $W : (0, T) \rightarrow \mathcal{H}$  is an unknown function,  $u : (0, T) \rightarrow H$  is a control,  $\mathcal{H}$ ,  $H$  are Banach spaces,  $A$  is an infinitesimal operator in  $\mathcal{H}$ , and  $B : H \rightarrow \mathcal{H}$  is a linear bounded operator. An important advantage of this approach is the possibility of employing ideas and techniques of semigroup operator theory. At the same time it should be noticed that the most substantial results on operator semigroups that are the most important for applications deal with the case when the semigroup generator  $A$  has a discrete spectrum or a compact resolvent and therefore the semigroup may be treated by means of eigenelements of  $A$ . These assumptions correspond to differential equations in bounded domains only.

In this paper we consider the wave equation on a half-axis. We should note that most of the papers investigating controllability of the wave equation deal with bounded domains and consider  $L^2$ -controllability or, more generally,  $L^p$ -controllability ( $2 \leq p < +\infty$ ); see [1], [4], [5], [6], [7], [11], and many others. But only  $L^\infty$ -controls can be realized practically. Moreover, such controls should be bounded by a hard constant (like in restriction (1.4)) for practical purposes. Furthermore, classical control theory started precisely from this point of view as switching controls are the ones realized in a concrete system. That is why we construct bang-bang controls solving the approximate null-controllability problem in this paper. However, sometimes to control a system

---

arising in nature and technology we do not necessarily have to stress the system and drive it to a desired state immediately and directly. We often need to control a system by letting it fluctuate while trying to drive it to a desired state without forcing it too much. Therefore we construct continuous controls solving the approximate null-controllability problem and satisfying (1.4).

Consider the wave equation on a half-axis,

$$(1.2) \quad w_{tt} = w_{xx} - q^2 w, \quad x > 0, \quad t \in (0, T),$$

controlled by the Neumann boundary condition

$$(1.3) \quad w_x(0, t) = u(t), \quad t \in (0, T),$$

where  $T > 0$ ,  $q \geq 0$  is a real number. We also assume that the control  $u$  satisfies the restriction

$$(1.4) \quad u \in \mathcal{B}^U(0, T) = \{v \in L^2(0, T) \mid |v(t)| \leq U \text{ a.e. on } (0, T)\},$$

where  $U > 0$  is given.

Controllability problems for the wave equation on a half-axis in the context of controls bounded by a hard constant were investigated in [14], [15]. In these papers the wave equation on a half-axis controlled by the Dirichlet boundary condition was studied for  $q = 0$ . In the present paper most of the results of [14], [15] are extended on the case of the Neumann control for  $q \geq 0$ . If  $q = 0$ , the cases of the Dirichlet control and the Neumann control are rather similar. If  $q > 0$ , investigation of the null-controllability problem for (1.2) is essentially more complicated and requires additional methods. In the present paper the operator  $\Phi$  describing the influence of a control on a target state is introduced and studied in the Sobolev spaces  $H_0^s$ ,  $s \leq 1$ . In fact, application of  $\Phi$  is the most essential new point of the paper. In addition, continuous controls  $u \in \mathcal{B}^U(0, T)$  solving the approximate null-controllability problem are constructed in the present paper. They are not considered in [14], [15].

In section 3 we obtain necessary and sufficient conditions for null-controllability and approximate null-controllability of system (1.2), (1.3) with restrictions (1.4) on the control. Controls solving the problems of null-controllability and approximate null-controllability are found explicitly. If  $q = 0$ , they coincide with the initial states, and if  $q > 0$ , they are given in the form of an integral transform of the initial state such that its kernel is a modified Bessel function. In both cases these controls may be of a rather complicated form.

Construction of bang-bang controls that solve the approximate null-controllability problem is the main goal of the section 4. We show that this problem can be reduced to a system of the Markov power moment problems. They may be solved by the algorithm given in [14]. Further we prove that solutions of the Markov power moment problems give us solutions of the approximate null-controllability problem for  $s < 1/2$ .

Bang-bang controls are the simplest by their structure, but they do not allow us to solve the approximate null-controllability problem for  $s \geq 1/2$ . Moreover, in some cases we should avoid to stress of the control system and drive it to a desired state in a continuous way. That is why we construct continuous controls that solve the approximate null-controllability problem for  $s \leq 1$  and satisfy (1.4) in section 5. They are obtained with the aid of the Cesàro means for a Fourier series determined by the data of the considered system. These controls generate a continuous steering state if an initial state is continuous. The problem of steering a finite string from a continuous

initial state with a continuous control function that is at  $t = 0$  compatible with the initial state to the zero state such that the generated system state is continuous has been considered in [4].

In the appendix (section 6) some auxiliary statements are proved. In particular, the operators describing the influence of a control on a target state of the considered control system are constructed and investigated. The results of this section are applied in sections 3–5.

If we replace  $q$  by  $iq$  in (1.2), i.e., consider the equation

$$(1.2') \quad w_{tt} = w_{xx} + q^2 w, \quad x > 0, \quad t \in (0, T),$$

instead of (1.2), then replacing  $q$  by  $iq$  throughout this paper gives us results analogous to ones obtained in sections 3–6 for the control system (1.2'), (1.3).

**2. Notation.** Let us give definitions of the spaces used in the work. Let  $\mathcal{S}$  be the Schwartz space [12], [13]

$$\mathcal{S} = \left\{ \varphi \in C^\infty(\mathbb{R}) \mid \forall m \in \mathbb{N} \right. \\ \left. \forall l \in \mathbb{N} \sup \left\{ \left| D^m \varphi(x) \right| (1 + |x|^2)^l \mid x \in \mathbb{R} \right\} < +\infty \right\},$$

and let  $\mathcal{S}'$  be the dual space, where  $D = -i\partial/\partial x$  and  $|\cdot|$  is the Euclidean norm.

Denote by  $H_l^s$  ( $s, l \in \mathbb{R}$ ) the following Sobolev spaces:

$$H_l^s = \left\{ \varphi \in \mathcal{S}' \mid (1 + |x|^2)^{l/2} (1 + |D|^2)^{s/2} \varphi \in L^2(\mathbb{R}) \right\}, \\ \|\varphi\|_l^s = \left( \int_{-\infty}^{\infty} \left| (1 + |x|^2)^{l/2} (1 + |D|^2)^{s/2} \varphi(x) \right|^2 dx \right)^{1/2}.$$

Let  $\mathcal{F} : \mathcal{S}' \longrightarrow \mathcal{S}'$  be the Fourier transform operator. For  $\varphi \in \mathcal{S}$  we have

$$(\mathcal{F}\varphi)(\sigma) = (2\pi)^{-1/2} \int_{-\infty}^{\infty} e^{-ix\sigma} \varphi(x) dx$$

and  $(\mathcal{F}f, \psi) = (f, \mathcal{F}^{-1}\psi)$  for  $f \in \mathcal{S}'$ ,  $\psi \in \mathcal{S}$ . It is well known [3, Chapter 1] that  $\mathcal{F}H_0^s = H_s^0$  and  $\|\varphi\|_0^s = \|\mathcal{F}\varphi\|_s^0$  if  $\varphi \in H_0^s$ .

A distribution  $f \in \mathcal{S}'$  is said to be *odd* if  $(f, \varphi(\xi)) = -(f, \varphi(-\xi))$ ,  $\varphi \in \mathcal{S}$ . A distribution  $f \in \mathcal{S}'$  is said to be *even* if  $(f, \varphi(\xi)) = (f, \varphi(-\xi))$ ,  $\varphi \in \mathcal{S}$ .

Let  $\Omega$  be the odd extension operator,  $\Omega : \mathcal{S}' \longrightarrow \mathcal{S}'$ ,  $(\Omega f)(x) = f(x) - f(-x)$ ,  $f \in \mathcal{S}'$ , and let  $\Xi$  be the even extension operator,  $\Xi : \mathcal{S}' \longrightarrow \mathcal{S}'$ ,  $(\Xi f)(x) = f(x) + f(-x)$ ,  $f \in \mathcal{S}'$ .

Further, we use the spaces

$$\mathcal{H}^s = \left\{ \varphi \in \mathcal{S}' \times \mathcal{S}' \mid \text{supp } \varphi \subset [0, +\infty) \text{ and } \Xi\varphi \in H_0^s \times H_0^{s-1} \right\}, \\ \tilde{H}^s = \left\{ \varphi \in H_0^s \times H_0^{s-1} \mid \varphi \text{ is even} \right\}$$

with the norm  $\|\varphi\|^s = ((\|\varphi_0\|_0^s)^2 + (\|\varphi_1\|_0^{s-1})^2)^{1/2}$ ,  $\varphi = (\varphi_0^s)$ , and also the space

$$\hat{H}_s = \left\{ \varphi \in H_s^0 \times H_{s-1}^0 \mid \varphi \text{ is even} \right\}$$

with the norm  $\|\varphi\|_s = ((\|\varphi_0\|_s^0)^2 + (\|\varphi_1\|_{s-1}^0)^2)^{1/2}$ ,  $\varphi = (\varphi_0)$ . We consider control system (1.2), (1.3) in the spaces  $H_0^s$ ,  $s \in \mathbb{R}$ .

Applying the even extension operator to system (1.2), (1.3) we reduce it to the form (1.1), where

$$(2.1) \quad \mathbf{A} = \begin{pmatrix} 0 & 1 \\ \left(\left(\frac{d}{dx}\right)^2 - q^2\right) & 0 \end{pmatrix}, \quad \mathbf{A} : \tilde{H}^{s-2} \longrightarrow \tilde{H}^{s-2}, \quad D(\mathbf{A}) = \tilde{H}^s,$$

$$(2.2) \quad \mathbf{B} = \begin{pmatrix} 0 \\ -2\delta(x) \end{pmatrix}, \quad \mathbf{B} : \mathbb{R} \longrightarrow \tilde{H}^{s-2}, \quad D(\mathbf{B}) = \mathbb{R}.$$

Here  $\delta$  is the Dirac distribution,  $\delta = H'$ ,  $H$  is the Heaviside function  $H(\xi) = 1$  if  $\xi > 0$ , and  $H(\xi) = 0$  otherwise.

**3. Conditions for (approximate) null-controllability.** Consider control system (1.2), (1.3) with the initial conditions

$$(3.1) \quad \begin{cases} w(x, 0) = w_0^0(x), \\ w_t(x, 0) = w_1^0(x), \end{cases} \quad x > 0,$$

where  $w^0 = \begin{pmatrix} w_0^0 \\ w_1^0 \end{pmatrix} \in \mathcal{H}^s$ . We assume throughout this section that  $s \leq 1$ .

Let  $W^0 = \Xi w^0$ ,  $W(\cdot, t) = \Xi \begin{pmatrix} w(\cdot, t) \\ \partial w(\cdot, t) / \partial t \end{pmatrix}$ . Evidently,  $W^0 \in \tilde{H}^s$ ,  $W(\cdot, t) \in \tilde{H}^s$  ( $t \in (0, T)$ ). It is easy to see that control problem (1.2), (1.3), (3.1) is equivalent to the Cauchy problem

$$(3.2) \quad \frac{dW}{dt} = \begin{pmatrix} 0 & 1 \\ \left(\left(\frac{d}{dx}\right)^2 - q^2\right) & 0 \end{pmatrix} W - \begin{pmatrix} 0 \\ 2\delta(x) \end{pmatrix} u, \quad t \in (0, T),$$

$$(3.3) \quad W(x, 0) = W^0,$$

where  $W(\cdot, t) \in \tilde{H}^s$ ,  $t \in [0, T]$ ,  $W^0 \in \tilde{H}^s$ ,  $u \in \mathcal{B}^U(0, T)$ .

Thus control problem (1.2), (1.3), (3.1) can be reduced to the Cauchy problem with initial condition (3.3) for a system of the form (1.1) with the parameter (control)  $u$ .

Consider for (3.2), (3.3) the steering condition

$$(3.4) \quad W(\cdot, T) = W^T,$$

where  $W^T \in \tilde{H}^s$ .

For given  $T > 0$ ,  $w^0 \in \mathcal{H}^s$  denote by  $\mathcal{R}_T^U(w^0)$  the set of the states  $W^T \in \tilde{H}^s$  for which there exists a control  $u \in \mathcal{B}^U(0, T)$  such that problem (3.2)–(3.4) has a unique solution.

**DEFINITION 3.1.** A state  $w^0 \in \mathcal{H}^s$  is called *null-controllable at a given time  $T > 0$  if 0 belongs to  $\mathcal{R}_T^U(w^0)$*  and *approximately null-controllable at a given time  $T > 0$  if 0 belongs to the closure of  $\mathcal{R}_T^U(w^0)$  in  $\tilde{H}^s$* .

Let  $\Phi : \mathcal{S}' \longrightarrow \mathcal{S}'$  with  $D(\Phi) = \{g \in \mathcal{S}' \mid g \text{ is odd and } \text{supp } g \subset [-T, T]\}$  such that

$$(\Phi g)(x) = \mathcal{F}_{\sigma \rightarrow x}^{-1} \left( \frac{-i}{\sqrt{\sigma^2 + q^2}} (\mathcal{F}g) \left( \sqrt{\sigma^2 + q^2} \right) \right) (x), \quad g \in D(\Phi).$$

In the appendix it is proved that  $\Phi$  is invertible,  $\Phi^{-1} : \mathcal{S}' \longrightarrow \mathcal{S}'$ ,  $D(\Phi^{-1}) = R(\Phi) = \{g \in \mathcal{S}' \mid g \text{ is even and } \text{supp } g \subset [-T, T]\}$  (Lemma 6.3). Moreover,  $\Phi$  is bounded from  $H_0^{s-1}$  to  $H_0^s$  (Lemma 6.1) and  $\Phi^{-1}$  is bounded from  $H_0^s$  to  $H_0^{s-1}$  (Lemma 6.3).

PROPOSITION 3.2. *Let  $W^0 \in \mathcal{S}' \times \mathcal{S}'$ ,  $u \in \mathcal{B}^U(0, T)$ . Then*

$$(3.5) \quad W(x, T) = E(x, T) * \left[ W^0(x) - \Phi \begin{pmatrix} \Omega \mathcal{U} \\ \Omega \mathcal{U}' \end{pmatrix} (x) \right], \quad t \in [0, T],$$

where  $\mathcal{U}(t) = u(t)(H(t) - H(t - T))$ ,  $W$  is a unique solution of (3.2)–(3.3),  $*$  is the convolution with respect to  $x$ , and

$$(3.6) \quad E(x, t) = \frac{1}{2} \begin{pmatrix} \partial/\partial t & 1 \\ (\partial/\partial t)^2 & \partial/\partial t \end{pmatrix} \left( J_0 \left( q\sqrt{t^2 - |x|^2} \right) (\text{sgn } t) H(t^2 - x^2) \right).$$

In particular, if  $W^0 \in \tilde{H}^p$ ,  $\Omega \mathcal{U} \in H^{p-1}$ , and  $\Xi \mathcal{U} \in H^{p-1}$ , then  $W(\cdot, T) \in \tilde{H}^p$ ,  $p \in \mathbb{R}$ .

*Proof.* Applying the Fourier transform with respect to  $x$  to problem (3.2)–(3.4) we obtain the following problem in  $\mathcal{S}' \times \mathcal{S}'$ :

$$(3.7) \quad \frac{dV}{dt} = \begin{pmatrix} 0 & 1 \\ -(\sigma^2 + q^2) & 0 \end{pmatrix} V - \sqrt{\frac{2}{\pi}} \begin{pmatrix} 0 \\ 1 \end{pmatrix} u, \quad t \in (0, T),$$

$$(3.8) \quad V(\cdot, 0) = V^0,$$

$$(3.9) \quad V(\cdot, T) = V^T,$$

where  $V(\cdot, t) = \mathcal{F}W(\cdot, t)$ ,  $t \in [0, T]$ ,  $V^0 = \mathcal{F}W^0$ ,  $V^T = \mathcal{F}W^T$ . Then the function

$$(3.10) \quad V(\sigma, t) = \Sigma(\sigma, t) \left( V^0(\sigma) - \sqrt{\frac{2}{\pi}} \int_0^t \Sigma(\sigma, -\tau) \begin{pmatrix} 0 \\ 1 \end{pmatrix} u(\tau) d\tau \right), \quad t \in [0, T],$$

is a unique solution of (3.7)–(3.8) in  $\mathcal{S}' \times \mathcal{S}'$ . Here

$$\Sigma(\sigma, t) \equiv \begin{pmatrix} \cos(\rho t) & \frac{\sin(\rho t)}{\rho} \\ -\rho \sin(\rho t) & \cos(\rho t) \end{pmatrix} \Big|_{\sqrt{\sigma^2 + q^2}} \equiv \begin{pmatrix} \partial/\partial t & 1 \\ (\partial/\partial t)^2 & \partial/\partial t \end{pmatrix} \frac{\sin \left( t\sqrt{\sigma^2 + q^2} \right)}{\sqrt{\sigma^2 + q^2}}.$$

Put  $E(x, t) = \mathcal{F}_{\sigma \rightarrow x}^{-1} \Sigma(\sigma, t) / \sqrt{2\pi}$ . Let us prove that

$$(3.11) \quad \mathcal{F}_{\sigma \rightarrow x}^{-1} \left( \frac{\sin \left( t\sqrt{\sigma^2 + q^2} \right)}{\sqrt{\sigma^2 + q^2}} \right) (x) = \sqrt{\frac{\pi}{2}} J_0 \left( q\sqrt{t^2 - x^2} \right) H(t^2 - x^2) \text{sgn } t,$$

where  $J_\nu(\xi) = \sum_{m=0}^{\infty} \frac{(-1)^m}{\Gamma(m+1)\Gamma(m+\nu+1)} \left(\frac{\xi}{2}\right)^{2m+\nu}$  is the Bessel function ( $\nu \in \mathbb{R}$ ) and  $\Gamma$  is the Euler gamma function. It is well known that

$$(3.12) \quad \left( F_{(\sigma, q) \rightarrow (x, y)}^{-1} \frac{\sin \left( t\sqrt{\sigma^2 + q^2} \right)}{\sqrt{\sigma^2 + q^2}} \right) (x) = \frac{\text{sgn } t H(t^2 - x^2 - y^2)}{\sqrt{t^2 - x^2 - y^2}}.$$

Since  $\mathcal{F}_{y \rightarrow q}^{-1} \frac{H(a^2 - y^2)}{\sqrt{a^2 - y^2}} = \sqrt{\frac{\pi}{2}} J_0(qa)$  then (3.11) follows from (3.12). Hence  $E$  is of the form (3.6). It follows from (3.10) that

$$(3.13) \quad W(x, T) = E(x, T) * \left[ W^0(x) - \sqrt{\frac{2}{\pi}} \mathcal{F}^{-1} \int_0^\infty \left( -\frac{\sin(t\sqrt{\sigma^2 + q^2})}{\sqrt{\sigma^2 + q^2}} \right) \mathcal{U}(t) dt \right].$$

Therefore (3.5) holds. With regard to Lemmas 6.1 and 6.7 we conclude that if  $W^0 \in \tilde{H}^p$ ,  $\Omega \mathcal{U} \in H^{p-1}$ , and  $\Xi \mathcal{U} \in H^{p-1}$ , then  $W(\cdot, T) \in \tilde{H}^p$ ,  $p \in \mathbb{R}$ . The proposition is proved.

Thus we have

$$(3.14) \quad \mathcal{R}_T^U(w^0) = \left\{ E(x, T) * \left[ \Xi w^0(x) - \Phi \left( \frac{\Omega \mathcal{U}}{\Omega \mathcal{U}'} \right) (x) \right] \mid u \in \mathcal{B}^U(0, T) \right\}.$$

The following theorem gives us sufficient conditions for (approximate) null-controllability.

**THEOREM 3.3.** *For a state  $w^0 \in \mathcal{H}^s$  and a given time  $T > 0$  assume that*

$$(3.15) \quad \text{supp } w_0^0 \subset [0, T];$$

$$(3.16) \quad \Xi w_0^0 \in H_0^1 \text{ and } |(\Phi^{-1} \Xi w_0^0)(\xi)| \leq U \text{ a.e. on } [0, T];$$

$$(3.17) \quad \Xi w_1^0 = \Phi \left( \frac{d}{d\xi} (\text{sgn } \xi (\Phi^{-1} \Xi w_0^0)) \right).$$

*Then the state  $w^0$  is null-controllable at the time  $T$ . Moreover, the solution of the null-controllability problem (the control  $u$ ) is unique and*

$$\begin{aligned} u(t) &= -\frac{d}{dt} \int_t^T I_0(q\sqrt{x^2 - t^2}) w_0^{0'}(x) dx \\ &= w_0^{0'}(t) + \int_t^T \frac{qt I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} w_0^{0'}(x) dx \\ (3.18) \quad &= w_1^0(t) + \int_t^T \frac{qx I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} w_1^0(x) dx \quad \text{a.e. on } (0, T). \end{aligned}$$

Here  $I_\nu(\xi) = i^{-\nu} J_\nu(i\xi)$  is the modified Bessel function. Under conditions (3.15)–(3.17)  $T_* = \max \text{supp } w_0^0$  is the optimal time and  $u$  of the form (3.18) (for  $T = T_*$ ) is the time-optimal control for the null-controllability problem.

*Proof.* Put

$$(3.19) \quad \widehat{\mathcal{U}} = \Phi^{-1} \Xi w_0^0.$$

It follows from Lemma 6.3 and (3.16) that  $\widehat{\mathcal{U}}$  is odd and  $\widehat{\mathcal{U}} \in L^\infty(\mathbb{R})$ . Put  $\mathcal{U}(t) = H(t)\widehat{\mathcal{U}}(t)$  and denote by  $u(t)$  its restriction on  $[0, T]$ . Then  $\widehat{\mathcal{U}}(t) = (\Omega \mathcal{U})(t)$ ,  $\mathcal{U}(t) = u(t)(H(t) - H(t - T))$ . Using again Lemma 6.4 we conclude that  $u \in \mathcal{B}^U(0, T)$  and the first part of assertion (3.18) is true for it. Taking into account (3.17), (3.19) we

get

$$\begin{aligned} W_1^0 &= \Xi w_1^0 = \Phi \left( \frac{d}{dt} (\operatorname{sgn} t (\Phi^{-1} \Xi w_0^0)) \right) \\ (3.20) \quad &= \Phi \left( \frac{d}{dt} (\operatorname{sgn} t (\Phi^{-1} \Phi \Omega \mathcal{U})) \right) = \Phi \left( \frac{d}{dt} (\operatorname{sgn} t \Omega \mathcal{U}) \right) = \Phi \Omega \mathcal{U}'. \end{aligned}$$

With regard to (3.19), (3.20) we have from (3.5) that  $W(\cdot, T) = 0$ . Here  $W$  is the solution of (3.2), (3.3). Thus  $w_0^0$  is null-controllable.

It follows from (3.20) and Lemma 6.5 that  $(\Xi \mathcal{U})' = \widetilde{W}_1^{0'}$ , where  $\widetilde{W}_1^0 \in H_0^0$  is even,  $\operatorname{supp} \widetilde{W}_1^0 \subset [-T, T]$ , and  $\widetilde{W}_1^0(t) = W_1^0(t) + \int_{|t|}^T \frac{qxI_1(q\sqrt{x^2-t^2})}{\sqrt{x^2-t^2}} W_1^0(x) dx$ . Since  $\Xi \mathcal{U}$  and  $\widetilde{W}_1^0$  have compact supports, then  $\Xi \mathcal{U} = \widetilde{W}_1^0$ . Therefore the second part of (3.18) is true.

Put  $T_* = \max \operatorname{supp} w_0^0$ . With regard to (3.5) we conclude that  $T = T_*$  is the optimal time and  $u$  of the form (3.18) (for  $T = T_*$ ) is the time-optimal control for null-controllability problem. The theorem is proved.

The following theorem asserts that conditions (3.15)–(3.17) are not only sufficient but also necessary for (approximate) null-controllability.

**THEOREM 3.4.** *If a state  $w^0 \in \mathcal{H}^s$  is approximately null-controllable at a given time  $T > 0$ , then assertions (3.15)–(3.17) are valid.*

*Proof.* For each  $n \in \mathbb{N}$  there exists a state  $W^n \in \mathcal{R}_T^U(w^0)$  such that  $\|W^n\|^s < 1/n$ . With regard to (3.14) we have

$$E(x, -T) * W^n(x) = W^0(x) - \Phi \begin{pmatrix} \Omega \mathcal{U}_n \\ \Omega \mathcal{U}_n' \end{pmatrix} (x)$$

for some  $u_n \in \mathcal{B}^U(0, T)$ , where  $\mathcal{U}_n(t) = u_n(t)(H(t) - H(t - T))$ . Using Lemma 6.7 we get

$$(3.21) \quad \Phi \begin{pmatrix} \Omega \mathcal{U}_n \\ \Omega \mathcal{U}_n' \end{pmatrix} \longrightarrow W^0 \quad \text{as } n \longrightarrow \infty \text{ in } \widetilde{H}^s.$$

According to Lemma 6.1  $\operatorname{supp} W_0^0 \subset [0, T]$ . Applying Lemma 6.3 we have

$$(3.22) \quad \begin{pmatrix} \Omega \mathcal{U}_n \\ \Omega \mathcal{U}_n' \end{pmatrix} \longrightarrow \Phi^{-1} W^0 \quad \text{as } n \longrightarrow \infty \text{ in } H_{s-1}^0 \times H_{s-2}^0.$$

Put  $\widehat{\mathcal{U}} = \Phi^{-1} W_0^0$ . With regard to Lemma 6.3 we get  $\operatorname{supp} \widehat{\mathcal{U}} \subset [-T, T]$ ,  $\widehat{\mathcal{U}}$  is odd. Let us prove that

$$(3.23) \quad |\widehat{\mathcal{U}}(t)| \leq U \quad \text{a.e. on } [-T, T].$$

Since  $\Omega \mathcal{U}_n \longrightarrow \widehat{\mathcal{U}}$  as  $n \longrightarrow \infty$  in  $H_0^{s-1}$  then the sequence  $\{\Omega \mathcal{U}_n\}_{n=1}^\infty$  converges to  $\widehat{\mathcal{U}}$  as  $n \longrightarrow \infty$  in  $\mathcal{S}'$  and consequently in  $(L^2(\mathbb{R}))'$  because  $\{\Omega \mathcal{U}_n\}_{n=1}^\infty$  is uniformly bounded on  $\mathbb{R}$  and  $\mathcal{S}$  is dense in  $L^2(\mathbb{R})$ . By the Riesz theorem  $\widehat{\mathcal{U}} \in L^2(\mathbb{R})$ . Since  $u_n \in \mathcal{B}^U(0, T)$  then (3.23) holds. With regard to Lemma 6.1 we obtain from here that (3.15), (3.16) are true. Setting  $\mathcal{U}(t) = H(t)\widehat{\mathcal{U}}(t)$  and taking into account (3.22) we obtain

$$\begin{pmatrix} \Omega \mathcal{U}_n \\ \Omega \mathcal{U}_n' \end{pmatrix} \longrightarrow \begin{pmatrix} \Omega \mathcal{U} \\ \Omega \mathcal{U}' \end{pmatrix} = \Phi^{-1} W^0 \quad \text{as } n \longrightarrow \infty \text{ in } H_{s-1}^0 \times H_{s-2}^0.$$

Hence (3.17) holds. The theorem is proved.

*Remark 3.1.* According to Lemma 6.5 condition (3.16),

$$\Xi w_0^0 \in H_0^1 \quad \text{and} \quad \left| w_0^{0'}(t) + \int_t^T \frac{qt I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} w_0^{0'}(x) dx \right| \leq U \quad \text{a.e. on } [0, T],$$

is equivalent to

$$(3.16') \quad w_1^0 \in H_0^0 \quad \text{and} \quad \left| w_1^0(t) + \int_t^T \frac{qx I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} w_1^0(x) dx \right| \leq U \quad \text{a.e. on } [0, T]$$

if (3.15) and (3.17) hold.

*Remark 3.2.* It follows from the proof of Theorem 3.3 that condition (3.17) is equivalent to

$$(3.17') \quad w_0^{0'}(x) - w_1^0(x) + \int_x^\infty \frac{q I_1(q\sqrt{\xi^2 - x^2})}{\sqrt{\xi^2 - x^2}} (x w_0^{0'}(\xi) - \xi w_1^0(\xi)) d\xi = 0, \quad x > 0.$$

And according to Lemma 6.6 condition (3.17) is equivalent to

$$(3.17'') \quad w_1^0(x) = w_0^{0'}(x) + q \int_x^\infty w_0^0(\xi) \frac{I_1(q(\xi - x))}{\xi - x} d\xi, \quad x > 0.$$

Other conditions equivalent to (3.17) are given below in Remarks 4.1 and 5.2.

*Remark 3.3.* Let  $q = 0$ . Then (3.17) is of the form  $w_1^0 = w_0^{0'}$  and (3.18) is of the form  $u(t) = w_0^{0'}(t) = w_1^0(t)$  a.e. on  $[0, T]$ .

*Remark 3.4.* With regard to Lemma 6.5

$$(3.24) \quad w_1^0 \in H_0^0 \quad \text{and} \quad |w_1^0(x)| \leq \frac{U}{I_0(qT)} \quad \text{a.e. on } [0, T]$$

is sufficient for (3.16') (and (3.16)) and

$$(3.25) \quad w_1^0 \in H_0^0 \quad \text{and} \quad |w_1^0(x)| \leq U(1 + qT) \quad \text{a.e. on } [0, T]$$

is necessary for (3.16') (and (3.16)). If  $q = 0$ , we obtain from here that (3.16') and (3.16) are equivalent to

$$(3.26) \quad w_1^0 \in H_0^0 \quad \text{and} \quad |w_1^0(x)| \leq U \quad \text{a.e. on } [0, T].$$

It follows from Example 3.1 (see below) that (3.24) is not necessary and (3.25) is not sufficient for (3.16') (and (3.16)) in the case  $q > 0$  for each  $T > 0$ .

*Example 3.1.* Let  $q > 0$ ,  $T > 0$ ,  $\alpha > 0$ . Put  $f(x) = \alpha(H(x + T) - H(x - T))$ ,  $h(x) = f(x) - \int_{|x|}^\infty \frac{qt J_1(\sqrt{t^2 - x^2})}{\sqrt{t^2 - x^2}} f(t) dt = \alpha J_0(\sqrt{T^2 - x^2})(H(x + T) - H(x - T))$ . With regard to Lemma 6.5 we obtain that  $f(t) = h(t) + \int_{|t|}^\infty \frac{qx I_1(\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} h(x) dx$ . Evidently,  $\sup\{|f(x)| \mid x \in (-T, T)\} = \sup\{|h(t)| \mid t \in (-T, T)\} = \alpha$ . Setting  $\alpha = U$  we conclude that (3.24) is not necessary for (3.16') (and (3.16)) for each  $T > 0$ . Setting  $\alpha = (1 + qT)U$  we conclude that (3.25) is not sufficient for (3.16') (and (3.16)) for each  $T > 0$ .

**4. Bang-bang controls.** The solution found in section 3 for the null-controllability problem (i.e., the control) may be too complicated for practical purposes. In this section we find bang-bang controls solving the approximate null-controllability problem. We consider a system of the Markov power moment problems and show that their bang-bang solutions are solutions of the approximate null-controllability problem if  $s < 1/2$ .

Consider control system (3.2), (3.3) and assume that for  $T > 0$  and  $w^0 \in \mathcal{H}^s$ ,  $s \leq 1$ , conditions (3.15)–(3.17) hold. According to Theorem 3.3 there exists  $\tilde{u} \in \mathcal{B}^U(0, T)$  such that  $W^0 = \Xi w^0 = \Phi\left(\frac{\Omega \tilde{\mathcal{U}}}{\Omega \mathcal{U}'}\right)$ , where  $\tilde{\mathcal{U}}(t) = \tilde{u}(t)[H(t) - H(t - T)]$ . With regard to (3.5) we obtain

$$(4.1) \quad W(x, T) = E(x, T) * \Phi \begin{pmatrix} \Omega(\tilde{\mathcal{U}} - \mathcal{U}) \\ \Omega(\tilde{\mathcal{U}}' - \mathcal{U}') \end{pmatrix}$$

for a given  $u \in \mathcal{B}^U(0, T)$ , where  $\mathcal{U}(t) = u(t)[H(t) - H(t - T)]$  and  $W$  is the solution of (3.2), (3.3).

Let  $n \in \mathbb{N}$ . Taking into account (3.18) we conclude that

$$(4.2) \quad \begin{aligned} \int_0^T t^n \tilde{u}(t) dt &= - \int_0^\infty t^n \frac{d}{dt} \int_t^T I_0(q\sqrt{x^2 - t^2}) w_0^{0'}(x) dx dt \\ &= -n \int_0^T t^{n-1} \left( w_0^0(t) + \int_t^\infty \frac{qx I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} w_0^0(x) dx \right) dt. \end{aligned}$$

For  $f \in \mathcal{H}^s$  and  $m \in \mathbb{N}$  we have

$$\begin{aligned} \int_0^\infty t^m \left( f(t) + \int_t^\infty \frac{qx I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} f(x) dx \right) dt \\ = \int_0^\infty x^m f(x) dx + \int_0^\infty x f(x) \int_0^x \frac{qt^m I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} dt dx. \end{aligned}$$

Since

$$\int_0^x t^m (x^2 - t^2)^k dt = \frac{x^{2k+m+1}}{2} \int_0^1 \xi^{(m-1)/2} (1-\xi)^k d\xi = \frac{x^{2k+m+1}}{2} \frac{\Gamma(\frac{m+1}{2}) \Gamma(k+1)}{\Gamma(k + \frac{m+1}{2} + 1)}$$

then

$$\begin{aligned} \int_0^\infty \frac{qt^m I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} dt &= \Gamma\left(\frac{m+1}{2}\right) \sum_{k=0}^\infty \frac{x^{2k+m+1}}{(k+1)! \Gamma(k + \frac{m+1}{2} + 1)} \left(\frac{q}{2}\right)^{2k+2} \\ &= -x^{m-1} + \Gamma\left(\frac{m+1}{2}\right) \left(\frac{2}{q}\right)^{(m-1)/2} x^{(m-1)/2} I_{(m-1)/2}(qx). \end{aligned}$$

Hence

$$(4.3) \quad \begin{aligned} \int_0^\infty t^m \left( f(t) + \int_t^\infty \frac{qx I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} f(x) dx \right) dt \\ = \Gamma\left(\frac{m+1}{2}\right) \left(\frac{2}{q}\right)^{(m-1)/2} \int_0^\infty x^{(m+1)/2} I_{(m-1)/2}(qx) f(x) dx \end{aligned}$$

for  $f \in \mathcal{H}^s$  and  $m \in \mathbb{N}$ . For  $n = \overline{0, \infty}$  and  $j = 0, 1$  put

$$(4.4) \quad \omega_j^n = -n\Gamma\left(\frac{n}{2}\right)\left(\frac{2}{q}\right)^{(n-2)/2} \int_0^\infty x^{n/2} I_{(n-2)/2}(qx) w_j^0(x) dx.$$

In particular, if  $q = 0$ , then  $\omega_j^n = -n \int_0^\infty x^{n-1} w_j^0(x) dx$ ,  $n = \overline{0, \infty}$ . Then

$$(4.5) \quad \int_0^T t^n \tilde{u}(t) dt = \omega_0^n, \quad n = \overline{0, \infty}.$$

Taking into account (3.17), (3.18), and (4.3) we get

$$\int_0^T t^n \tilde{u}(t) dt = \int_0^T t^n \left( w_1^0(x) + \int_t^\infty \frac{qx I_1(q\sqrt{x^2 - t^2})}{\sqrt{x^2 - t^2}} w_1^0(x) dx \right) dt = -\frac{\omega_1^{n+1}}{n+1}$$

for  $n = \overline{0, \infty}$ . Summarizing we get the following.

*Remark 4.1.* Condition (3.17) is equivalent to  $\omega_1^n + n\omega_0^{n-1} = 0$ ,  $n = \overline{1, \infty}$ .

**DEFINITION 4.1.** *The problem of determination of a function  $u \in \mathcal{B}^U(0, T)$  such that*

$$(4.6) \quad \int_0^T t^n u(t) dt = \omega_0^n, \quad n = \overline{0, \infty},$$

*for a given  $\{\omega_0^n\}_{n=0}^\infty$  and  $T > 0$  is called the Markov power moment problem on  $(0, T)$  for the infinite sequence  $\{\omega_0^n\}_{n=0}^\infty$ .*

With regard to (4.1) we obtain  $W(x, T) \equiv 0 \Leftrightarrow \Omega \tilde{\mathcal{U}}(t) \equiv \Omega \mathcal{U}(t)$ . Due to the Paley–Wiener theorem we get that  $\tilde{\nu} = \mathcal{F}\Omega \tilde{\mathcal{U}}$  and  $\nu = \mathcal{F}\Omega \mathcal{U}$  are entire functions. Therefore  $W(x, T) \equiv 0 \Leftrightarrow [\tilde{\nu}^{(m)}(0) = \nu^{(m)}(0)]$ ,  $m = \overline{0, \infty}$ . Taking into account (4.5) and

$$\tilde{\nu}^{(m)}(0) = (-i)^m \sqrt{\frac{2}{\pi}} \int_0^T t^m \tilde{u}(t) dt, \quad \nu^{(m)}(0) = (-i)^m \sqrt{\frac{2}{\pi}} \int_0^T t^m u(t) dt, \quad m = \overline{0, \infty},$$

we conclude that  $u \in \mathcal{B}^U(0, T)$  is a solution of the Markov power moment problem (4.6) for  $\{\omega_0^n\}_{n=0}^\infty$  given by (4.4) iff it is a solution of the null-controllability problem for (3.2), (3.3).

With regard to Theorem 3.3 this gives us the following.

**THEOREM 4.2.** *Assume that  $T > 0$  and for a state  $w^0 \in \mathcal{H}^s$  conditions (3.15)–(3.17) hold. Assume also that  $\{\omega_0^n\}_{n=0}^\infty$  is defined by (4.4). Then the Markov power moment problem (4.6) has a unique solution on  $(0, T)$  for  $\{\omega_0^n\}_{n=0}^\infty$ . Moreover, this solution is the solution of the null-controllability problem for  $w^0$  at the time  $T$  and is of the form (3.18).*

Consider (4.6) for a finite set of  $n$ :

$$(4.7) \quad \int_0^T t^n u(t) dt = \omega_0^n, \quad n = \overline{0, N},$$

where  $N \in \mathbb{N}$ .

**DEFINITION 4.3.** *The problem of determination of a function  $u \in \mathcal{B}^U(0, T)$  satisfying condition (4.7) for a given  $\{\omega_0^n\}_{n=0}^N$  and  $T > 0$  is called the Markov power moment problem on  $(0, T)$  for the finite sequence  $\{\omega_0^n\}_{n=0}^N$ .*

Obviously,  $u$  of the form (3.18) is a solution of this problem for  $\{\omega_0^n\}_{n=0}^\infty$  given by (4.4), but it is not unique.

Let us show that solutions of moment problem (4.7) for various  $N$  give us controls solving the approximate null-controllability problem.

**THEOREM 4.4.** *Let  $T > 0$ ,  $w^0 \in \mathcal{H}^s$ ,  $s < 1/2$ . Also, let conditions (3.15)–(3.17) be fulfilled and  $\{\omega_0^n\}_{n=0}^\infty$  be defined by (4.4). Then for all  $\varepsilon > 0$  there exists  $N > 0$  such that for each solution  $u \in \mathcal{B}^U(0, T)$  of moment problem (4.7) the corresponding solution  $W$  of control system (3.2), (3.3) satisfies  $\|W(\cdot, T)\|^s < \varepsilon$ .*

*Proof.* Taking into account (4.5) we have

$$\begin{aligned} \left( \mathcal{F}(\tilde{u} - u) \right)(\sigma) &= \frac{1}{\sqrt{2\pi}} \sum_{n=0}^{\infty} \frac{(-i\sigma)^n}{n!} \int_0^T t^n (\tilde{u}(t) - u(t)) dt \\ &= \frac{1}{\sqrt{2\pi}} \sum_{n=0}^{\infty} \frac{(-i\sigma)^n}{n!} \left( \omega_0^n - \int_0^T t^n u(t) dt \right). \end{aligned}$$

Let  $N \in \mathbb{N}$  be fixed and also let  $u \in \mathcal{B}^U(0, T)$  be a solution of (4.7). Then

$$(4.8) \quad \left( \mathcal{F}(\tilde{u} - u) \right)(\sigma) = \frac{1}{\sqrt{2\pi}} \sum_{n=N+1}^{\infty} \frac{(-i\sigma)^n}{n!} \left( \omega_0^n - \int_0^T t^n u(t) dt \right).$$

Since

$$\begin{aligned} \left| \left( \frac{\partial}{\partial \sigma} \right)^m \left( \mathcal{F}(\tilde{u} - u) \right)(\sigma) \right| &= \frac{1}{\sqrt{2\pi}} \left| \int_0^T (ix)^m e^{-i\sigma x} (\tilde{u}(t) - u(t)) dt \right| \\ &\leq \frac{2UT^{m+1}}{\sqrt{2\pi}(m+1)!}, \quad \sigma \in \mathbb{R}, \quad m = \overline{0, \infty}, \end{aligned}$$

then

$$(4.9) \quad \left| \left( \mathcal{F}(\tilde{u} - u) \right)(\sigma) \right| \leq \frac{2UT^{N+2}a^{N+1}}{\sqrt{2\pi}(N+2)!}, \quad |\sigma| \leq a,$$

$$(4.10) \quad \left| \left( \mathcal{F}(\tilde{u} - u) \right)(\sigma) \right| \leq \frac{2UT}{\sqrt{2\pi}}, \quad \sigma \in \mathbb{R},$$

where  $a > 0$ . Therefore

$$\begin{aligned} \left( \left\| \mathcal{F}(\tilde{u} - u) \right\|_{s-1}^0 \right)^2 &= \int_{-\infty}^{\infty} (1 + \sigma^2)^{s-1} \left| \left( \mathcal{F}(\tilde{u} - u) \right)(\sigma) \right|^2 d\sigma \\ &\leq \frac{4U^2(Ta)^{2(N+2)}}{\pi a((N+2)!)^2} + \frac{4(UT)^2}{\pi} \int_a^{\infty} (1 + \sigma^2)^{s-1} d\sigma \\ &\leq \frac{4U^2(Ta)^{2(N+2)}}{\pi a((N+2)!)^2} - \frac{4(UT)^2}{\pi} \frac{a^{2s-1}}{2s-1}. \end{aligned}$$

Applying the Stirling formula we have

$$\frac{(Ta)^{N+2}}{(N+2)!} \leq \left( \frac{Tae}{N+2} \right)^{N+2} \frac{1}{\sqrt{2\pi(N+2)}}.$$

Setting  $a = (N + 2)/(2Te)$  we get

$$\left(\|\tilde{u} - u\|_0^{s-1}\right)^2 = \left(\|\mathcal{F}(\tilde{u} - u)\|_{s-1}^0\right)^2 \leq \frac{U^2Te}{\pi^2(N+2)^22^{2N+2}} - \frac{(N+2)^{2s-1}}{\pi(2s-1)(2Te)^{2s-1}}.$$

Applying Proposition 3.2 and Lemmas 6.7 and 6.1 we conclude that

$$(4.11) \quad |||W(\cdot, T)|||^p \leq M_q^T L_q^p \left\| \begin{pmatrix} \Omega(\tilde{u} - u) \\ \Omega(\tilde{u}' - u') \end{pmatrix} \right\|^{p-1} \leq 2M_q^T L_q^p \|\tilde{u} - u\|_0^{p-1},$$

since  $\|f'\|_0^{p-1} \leq \|f\|_0^p$ ,  $f \in H_0^p$ ,  $p \leq 1$ . Therefore

$$(4.12) \quad |||W(\cdot, T)|||^s \leq 2M_q^T L_q^s \left(\|\tilde{u} - u\|_0^{s-1}\right)^2 \leq 2M_q^T L_q^s \left(\frac{U^2Te}{\pi^2(N+2)^22^{2N+2}} - \frac{(N+2)^{2s-1}}{\pi(2s-1)(2Te)^{2s-1}}\right)^{1/2} \longrightarrow 0 \quad \text{as } N \longrightarrow \infty.$$

The theorem is proved.

Denote

$$\begin{aligned} \mathcal{B}_N^U(0, T) = \{u \in \mathcal{B}^U(0, T) \mid \exists T_* \in (0, T) (|u(t)| = U \text{ a.e. on } (0, T_*)) \\ \wedge (u(t) = 0 \text{ a.e. on } (T_*, T)) \\ \wedge (u \text{ has no more than } N \text{ discontinuities on } (0, T_*))\}. \end{aligned}$$

It is well known [8, 9] that if the Markov power moment problem (4.7) is solvable, then there exists its solution  $u \in \mathcal{B}_N^U(0, T)$ . Taking into account Theorem 4.4 we conclude that under the conditions of this theorem we can find a solution  $u_N \in \mathcal{B}_N^U(0, T)$  of the Markov power moment problem (4.7) for  $N \in \mathbb{N}$ , and such solutions  $\{u_N\}_{N=1}^\infty$  give us bang-bang controls solving the approximate null-controllability problem (see also (4.12)).

Thus the following theorem is true.

**THEOREM 4.5.** *Let  $T > 0$ ,  $w^0 \in \mathcal{H}^s$ ,  $s < 1/2$ . Also, let conditions (3.15)–(3.17) be fulfilled and  $\{\omega_0^n\}_{n=0}^\infty$  be defined by (4.4). Then for all  $N \in \mathbb{N}$  there exists a solution  $u_N \in \mathcal{B}_N^U(0, T)$  of moment problem (4.7). Moreover, for this  $u_N$  the corresponding solution  $W^N$  of control system (3.2), (3.3) satisfies the estimate*

$$\begin{aligned} & |||W^N(\cdot, T)|||^s \\ & \leq 2M_q^T L_q^s \left(\frac{U^2Te}{\pi^2(N+2)^22^{2N+2}} - \frac{(N+2)^{2s-1}}{\pi(2s-1)(2Te)^{2s-1}}\right)^{1/2} \longrightarrow 0 \quad \text{as } N \longrightarrow \infty. \end{aligned}$$

Bang-bang controls solving the approximate null-controllability problem; i.e., solutions (4.7) ( $N \in \mathbb{N}$ ) can be found by the algorithm given in [14].

Let us show that the condition  $s < 1/2$  of Theorems 4.4 and 4.5 is essential. Precisely, if  $s = 1$ , then  $\exists w^0 \in \mathcal{H}^s \forall u \in \cup_{N \in \mathbb{N}} \mathcal{B}_N^U(0, T) \exists \varepsilon_0 > 0$  such that for the solution  $W$  of (3.2), (3.3) corresponding to the control  $u$  we have  $|||W(\cdot, T)|||^s \geq \varepsilon_0$ . Thus the state  $w^0$  is not approximately null-controllable at the time  $T$  by bang-bang controls if  $s = 1$ .

*Example 4.1.* Let  $s = 1$ ,  $T > 0$ . Also, let  $\tilde{\mathcal{U}}(t) = \frac{U}{2} [H(t) - H(t - T)]$ ,  $w^0 = H(x)(\Phi(\frac{\Omega \tilde{\mathcal{U}}}{\Omega \tilde{\mathcal{U}}'}))(x)$ . Evidently,  $w^0 \in \mathcal{H}^s$  and (3.15)–(3.17) hold for it. Let  $N \in \mathbb{N}$ ,  $u \in \mathcal{B}_N^U(0, T)$ . Hence  $u(t) = \alpha \sum_{k=0}^N (-1)^k [H(t - t_k) - H(t - t_{k+1})]$ , where  $\alpha = \pm U$ ,  $0 = t_0 < t_1 < t_2 < \dots < t_{N+1} = T_* \leq T$ ,  $\mathcal{U}(t) = (H(t) - H(t - T))$ . Let  $W$  be a solution of (3.2), (3.3) corresponding to the control  $u$ . Taking into account (4.1) and Lemmas 6.7 and 6.3 we get

$$\| \| W(\cdot, T) \| \| \geq \frac{1}{M_q^T K_q^0} \left\| \left( \begin{array}{c} \Omega(\tilde{\mathcal{U}} - \mathcal{U}) \\ \Omega(\tilde{\mathcal{U}} - \mathcal{U})' \end{array} \right) \right\| \geq \frac{1}{M_q^T K_q^0} \left\| \Omega(\tilde{\mathcal{U}} - \mathcal{U}) \right\|_0^0.$$

Since  $\| \Omega(\tilde{\mathcal{U}} - \mathcal{U}) \|_0^0 \geq (\int_{-T}^T |\Omega(\tilde{\mathcal{U}} - \mathcal{U})(t)|^2 dt) \geq U \sqrt{\frac{T}{2}}$  then  $\| \| W(\cdot, T) \| \| \geq \frac{U \sqrt{T}}{\sqrt{2} M_q^T K_q^0} = \varepsilon_0$ . That was to be proved.

**5. Continuous controls.** Note again that the solution of the null-controllability problem (i.e., the control) found in section 3 may be too complicated for practical purposes. That is why bang-bang controls solving the approximate null-controllability problem have been constructed in section 4. They also solve the Markov power moment problem. Bang-bang controls are the simplest by their structure. But, first, they do not allow us to solve approximate null-controllability problem for  $s \geq 1/2$ , and second, the algorithm for solving the Markov power moment problems (and constructing bang-bang controls) is rather sensitive to computational errors. Moreover, in some cases we need to avoid straining the control system and drive it to a desired state in a continuous way. That is why we construct continuous controls that solve the approximate null-controllability problem for  $s \leq 1$  and satisfy restriction (1.4). They are obtained with the help of the Cesàro means for a Fourier series determined by the data of the considered system. These controls generate a continuous steering state if an initial state is continuous. The problem of steering a finite string from a continuous initial state with a continuous control function that is at  $t = 0$  compatible with the initial state to the zero state such that the generated system state is continuous was considered in [4].

Consider control system (3.2), (3.3) and assume that for  $s \leq 1$ ,  $T > 0$ , and  $w^0 \in \mathcal{H}^s$  conditions (3.15)–(3.17) hold. Set

$$(5.1) \quad \tilde{\mathcal{U}}(t) = H(t) (\Phi^{-1} \Xi w_0^0)(t)$$

and denote by  $\tilde{u}$  the restriction of  $\tilde{\mathcal{U}}$  on  $[0, T]$ . By Theorem 3.3  $\tilde{u} \in \mathcal{B}^U(0, T)$ . Put

$$\nu_n = \frac{2}{T} \int_0^T \tilde{u}(t) \sin \frac{\pi n t}{T} dt, \quad n = \overline{0, \infty}.$$

Taking into account (5.1), (6.4), and Lemma 6.3 we get

$$(5.2) \quad \nu_n = \frac{\sqrt{2\pi i}}{T} (\mathcal{F} \Omega \tilde{\mathcal{U}}) \left( \frac{\pi n}{T} \right) = \frac{2\pi n}{T^2} \int_0^T \cos \left( x \sqrt{(\pi n/T)^2 - q^2} \right) w_0^0(x) dx.$$

Put

$$(5.3) \quad u_n(t) = \frac{1}{n+1} \sum_{k=0}^n \sum_{l=0}^k \nu_l \sin \frac{\pi l t}{T} = \sum_{l=0}^n \frac{n+1-l}{n+1} \nu_l \sin \frac{\pi l t}{T}, \quad n = \overline{0, \infty}.$$

Evidently,  $u_n$  is a Cesàro mean for the Fourier series  $\sum_{l=0}^{\infty} \nu_l \sin \frac{\pi l t}{T}$ ,  $n = \overline{0, \infty}$ . Set  $\nu(t) = \sum_{k=-\infty}^{\infty} (\Omega \tilde{\mathcal{U}})(t - 2Tk)$ . It is well known [16, Chapter 3, section 3] that  $u_n(t) = \frac{1}{T} \int_{-T}^T \nu(t + \xi) F_n(\xi) d\xi$ , where  $F_n(\xi) = \frac{1}{2(n+1)} \left( \frac{\sin((n+1)\pi\xi/T)}{\sin(\pi\xi/T)} \right)^2$  is the Fejér kernel and  $\frac{1}{T} \int_{-T}^T F_n(\xi) d\xi = 1$ . Hence  $|u_n(t)| \leq \left| \frac{1}{T} \int_{-T}^T \nu(t + \xi) F_n(\xi) d\xi \right| \leq \frac{U}{T} \int_{-T}^T F_n(\xi) d\xi = U$  since  $F_n(\xi) \geq 0$ ,  $\xi \in \mathbb{R}$ . Therefore

$$(5.4) \quad u_n \in \mathcal{B}^U(0, T).$$

For  $\mathcal{U}_l^0(t) = \sin \frac{\pi l t}{T} (H(t) - H(t - T))$ ,  $l = \overline{1, \infty}$ , we have

$$(\mathcal{F}\mathcal{U}_l^0)(\sigma) = \frac{i}{\sqrt{2\pi}} \left( \frac{\sin[T(\sigma + \frac{\pi l}{T})]}{\sigma + \frac{\pi l}{T}} - \frac{\sin[T(\sigma - \frac{\pi l}{T})]}{\sigma - \frac{\pi l}{T}} \right) = \sqrt{\frac{2}{\pi}} \frac{(-1)^{l+1} \frac{\pi l}{T} i \sin(\sigma T)}{\sigma^2 - (\frac{\pi l}{T})^2}.$$

Hence  $\mathcal{F}\mathcal{U}_l^0 \in H_p^0$ ,  $p < 3/2$ ,  $l = \overline{1, \infty}$ . Therefore

$$(5.5) \quad \mathcal{U}_n \in H_0^p, \quad p < 3/2, \quad n = \overline{0, \infty},$$

where  $\mathcal{U}_n(t) = u_n(t) (H(t) - H(t - T))$ .

Let us prove that

$$(5.6) \quad u_n \longrightarrow \tilde{u} \quad \text{as } n \longrightarrow \infty \text{ in } L^2(0, T).$$

Since  $\tilde{u} \in \mathcal{B}^U(0, T) \subset L^2(0, T)$  then

$$(5.7) \quad \frac{T}{2} \sum_{l=0}^{\infty} \nu_l^2 = \left( \|\tilde{u}\|_{L^2(0, T)} \right)^2.$$

Taking this into account we have from [16, Chapter 3, section 1] that the first and the second Cesàro means tend to  $\|\tilde{u}\|_{L^2(0, T)}$  as  $n \rightarrow \infty$ , i.e.,

$$(5.8) \quad \sum_{l=0}^n \frac{n+1-l}{n+1} \nu_l^2 \longrightarrow \frac{T}{2} \sum_{l=0}^{\infty} \nu_l^2 \quad \text{as } n \longrightarrow \infty,$$

$$(5.9) \quad \sum_{l=0}^n \frac{(n+1-l)(n+2-l)}{(n+1)(n+2)} \nu_l^2 \longrightarrow \frac{T}{2} \sum_{l=0}^{\infty} \nu_l^2 \quad \text{as } n \longrightarrow \infty.$$

Since (5.8) implies  $\sum_{l=0}^n \frac{l}{n+1} \nu_l^2 \rightarrow 0$  as  $n \rightarrow \infty$  then (5.9) yields  $\sum_{l=0}^n \frac{l^2}{(n+1)^2} \nu_l^2 \rightarrow 0$  as  $n \rightarrow \infty$ . Summarizing, we obtain

$$(5.10) \quad \begin{aligned} \|\tilde{u} - u_n\|_{L^2(0, T)} &= \left\| \sum_{l=0}^{\infty} \nu_l \sin \frac{\pi l t}{T} - \sum_{l=0}^n \frac{n+1-l}{n+1} \nu_l \sin \frac{\pi l t}{T} \right\|_{L^2(0, T)} \\ &= \sqrt{\frac{T}{2}} \left( \sum_{l=n+1}^{\infty} \nu_l^2 + \sum_{l=0}^n \frac{l^2}{(n+1)^2} \nu_l^2 \right)^{1/2} \longrightarrow 0 \quad \text{as } n \longrightarrow \infty, \end{aligned}$$

and hence (5.6) holds.

Taking into account (4.11), (5.4), and (5.10) we get the following.

**THEOREM 5.1.** *Let  $T > 0$ ,  $w^0 \in \mathcal{H}^s$ ,  $s \leq 1$ . Also, let conditions (3.15)–(3.17) be fulfilled,  $\{\nu_n\}_{n=0}^\infty$  and  $\{u_n\}_{n=0}^\infty$  be defined by (5.2), (5.3), respectively. Then  $u_n \in \mathcal{B}^U(0, T)$ ,  $n = \overline{0, \infty}$ , and*

$$\|W^n(\cdot, T)\|^s \leq \sqrt{2T} M_q^T L_q^s \left( \sum_{l=n+1}^\infty \nu_l^2 + \sum_{l=0}^n \frac{l^2}{(n+1)^2} \nu_l^2 \right)^{1/2} \longrightarrow 0 \text{ as } n \longrightarrow \infty,$$

where  $W^n$  is the solution of (3.2), (3.3) corresponding to the control  $u_n$ . Moreover,  $u_n \in C^\infty(0, T)$  and  $\mathcal{U}_n \in H_0^p$ ,  $p < 3/2$ ,  $n = \overline{0, \infty}$ , where  $\mathcal{U}_n(t) = u_n(t)(H(t) - H(t - T))$ .

Thus the continuous controls  $u_n$ ,  $n = \overline{0, \infty}$ , defined by (5.3) are solutions of the approximate null-controllability problem.

*Remark 5.1.* It follows from Proposition 3.2 and (5.5) that  $W^n(\cdot, T) \in H_0^p$  if  $\Xi w_0^0 \in H_0^p$  and  $p < 5/2$ . It is well known [3, Chapter 1] that  $\tilde{H}^p \subset C^1(\mathbb{R}) \times C(\mathbb{R})$  if  $p > 3/2$ . Thus  $W^n(\cdot, T) \in C^1(\mathbb{R}) \times C(\mathbb{R})$  if  $\Xi w_0^0 \in H_0^p$ ,  $3/2 < p < 5/2$ .

For  $n \in \mathbb{N}$  denote  $\lambda_n = \sqrt{(\pi n/T)^2 - q^2}$ ,

$$\tilde{\omega}_j^n = \sqrt{\frac{\pi}{2}} (\mathcal{F} \Xi w_0^0)(\lambda_n), \quad j = 1, 2.$$

Then  $\nu_n = \frac{2i}{T} \sqrt{\frac{\pi}{2}} (\mathcal{F} \tilde{\mathcal{U}}) \left( \frac{\pi n}{T} \right) = \frac{2i}{T} \sqrt{\frac{\pi}{2}} (\mathcal{F} (\Phi^{-1} \Xi w_0^0)) \left( \frac{\pi n}{T} \right) = -\frac{2\pi n}{T^2} \tilde{\omega}_0^n$ . Condition (3.17) is equivalent to  $\Omega w_1^0 = \Phi \tilde{\mathcal{U}}'$ , where  $\tilde{\mathcal{U}}$  is given by (5.1). Therefore

$$\begin{aligned} \tilde{\omega}_1^n &= \frac{Ti}{\pi n} \sqrt{\frac{\pi}{2}} \left( \mathcal{F} (\Xi \tilde{\mathcal{U}})' \right) \left( \frac{\pi n}{T} \right) = - \int_0^T \cos \frac{\pi n t}{T} \tilde{u}(t) dt \\ &= - \sum_{l=0}^\infty \nu_l \int_0^T \cos \frac{\pi n t}{T} \sin \frac{\pi l t}{T} dt = \frac{2}{T} \sum_{l=0}^\infty ((-1)^{l+n} - 1) \frac{l^2}{l^2 - n^2} \tilde{\omega}_0^l, \quad n = \overline{0, \infty}. \end{aligned}$$

Thus the following assertion is true.

*Remark 5.2.* Condition (3.17) is equivalent to

$$\tilde{\omega}_1^n = \frac{2}{T} \sum_{l=0}^\infty ((-1)^{l+n} - 1) \frac{l^2}{l^2 - n^2} \tilde{\omega}_0^l, \quad n = \overline{0, \infty}.$$

*Example 5.1.* Let  $s \leq 1$ ,  $q \geq 0$ ,  $T > 0$ ,  $w_0^0(x) = \frac{1}{2} (x^2 - T^2) (H(x) - H(x - T))$ ,  $w_1^0(x) = (\Phi \frac{d}{dt} (\operatorname{sgn} t \Phi^{-1} \Xi w_0^0)) (x)$ . Evidently,  $w^0 \in \mathcal{H}^s$ . With regard to Lemma 6.4 we get  $(\Phi^{-1} \Xi w_0^0)(t) = t I_0 (q \sqrt{T^2 - t^2}) (H(t + T) - H(t - T))$ .

By Theorem 3.3 the state  $w^0$  is null-controllable (and hence approximately null-controllable) if  $U \geq \sup \{ |t I_0 (q \sqrt{T^2 - t^2})| \mid t \in [0, T] \}$ .

Let us find the continuous controls  $u_n$ ,  $n = \overline{1, \infty}$ , of the form (5.3) that solve approximate null-controllability problem and estimate  $\|W^n(\cdot, T)\|^s$ , where  $W^n$  is the solution of (3.2), (3.3) corresponding to  $u_n$ .

For  $l \in \mathbb{N}$  we have  $\nu_n = -\frac{2\pi n}{T^2} \tilde{\omega}_0^n$ ,

$$\begin{aligned} \tilde{\omega}_0^l &= \frac{1}{2} \int_0^T \cos(\lambda_l x) (x^2 - T^2) dx = \frac{1}{\lambda_l^2} \left( T \cos(\lambda_l T) - \frac{\sin(\lambda_l T)}{\lambda_l} \right), \\ \nu_l &= \frac{2\pi l}{T^2 \lambda_l^2} \left( \frac{\sin(\lambda_l T)}{\lambda_l} - T \cos(\lambda_l T) \right), \end{aligned}$$

and

$$u_n(t) = \frac{2\pi}{T^2} \sum_{l=1}^n \frac{(n+1-l)l}{(n+1)\lambda_l^2} \left( \frac{\sin(\lambda_l T)}{\lambda_l} - T \cos(\lambda_l T) \right) \sin \frac{\pi l t}{T}, \quad t \in [0, T].$$

We have  $|\lambda_l| \leq q \Leftrightarrow 1 \leq l \leq \sqrt{2}Tq/\pi$ . Set  $n_0 \in \mathbb{N}$  such that  $n_0 \leq \sqrt{2}Tq/\pi$  and  $n_0 + 1 > \sqrt{2}Tq/\pi$ . Therefore

$$|\nu_l| \leq \frac{8\pi T l \sinh^2(Tq/2)}{(Tq)^2} \quad \text{if } 1 \leq l \leq n_0,$$

$$|\nu_l| \leq \frac{8T}{\pi l} \quad \text{if } l \geq n_0 + 1.$$

Let  $n > n_0$ . With regard to (5.10) we obtain

$$\begin{aligned} & \sqrt{2T} \left( \sum_{l=n+1}^{\infty} \nu_l^2 + \sum_{l=1}^n \frac{l^2}{(n+1)^2} \nu_l^2 \right)^{1/2} \\ & \leq 4(2T)^{3/2} \left( \frac{1}{\pi^2} \sum_{l=n+1}^{\infty} \frac{1}{l^2} + \frac{1}{\pi^2(n+1)^2} \sum_{l=n_0+1}^n 1 + \frac{\pi^2 \sinh^4(Tq/2)}{(Tq)^4(n+1)^2} \sum_{l=1}^{n_0} l^4 \right)^{1/2} \\ & \leq 4(2T)^{3/2} \left( \frac{2}{\pi^2 n} + (1 - \delta_{0,n_0}) \frac{\pi^2 \sinh^4(Tq/2)}{5(Tq)^4} \frac{(n_0+1)^5}{(n+1)^2} \right) = \varepsilon_n, \end{aligned}$$

where  $\delta_{km}$  is the Kronecker delta  $\delta_{km} = 1$  if  $k = m$ , and  $\delta_{km} = 0$  otherwise. According to Theorem 5.1  $\|W^n(\cdot, T)\|^s \leq M_q^T L_q^s \varepsilon_n$ . For example, for various  $q \geq 0$  and  $T > 0$  we have

$$\begin{aligned} q = 0, \quad T > 0, \quad n_0 = 0, \quad \varepsilon_n &= \frac{8(2T)^{3/2}}{\pi\sqrt{n}}, \\ q > 0, \quad Tq = 1, \quad n_0 = 0, \quad \varepsilon_n &= \frac{8(2T)^{3/2}}{\pi\sqrt{n}}, \\ q > 0, \quad Tq = 4, \quad n_0 = 1, \quad \varepsilon_n &= 4(2T)^{3/2} \sqrt{\frac{2}{\pi^2 n} + \frac{\pi^2 \sinh^4 2}{40(n+1)^2}}, \\ q > 0, \quad Tq = 6, \quad n_0 = 2, \quad \varepsilon_n &= 4(2T)^{3/2} \sqrt{\frac{2}{\pi^2 n} + \frac{3\pi^2 \sinh^4 3}{80(n+1)^2}}, \\ q > 0, \quad Tq = 8, \quad n_0 = 3, \quad \varepsilon_n &= 4(2T)^{3/2} \sqrt{\frac{2}{\pi^2 n} + \frac{\pi^2 \sinh^4 4}{20(n+1)^2}}, \\ q > 0, \quad Tq = 10, \quad n_0 = 4, \quad \varepsilon_n &= 4(2T)^{3/2} \sqrt{\frac{2}{\pi^2 n} + \frac{\pi^2 \sinh^4 5}{16(n+1)^2}}. \end{aligned}$$

**6. Appendix.** We assume throughout this section that  $p \in \mathbb{R}$ .

Denote  $\partial : \mathcal{S}' \longrightarrow \mathcal{S}'$  with  $D(\partial) = \{f \in \mathcal{S}' \mid f \text{ is even and } \text{supp } f \subset [-T, T]\}$  such that  $\partial f = f'$ ,  $f \in D(\partial)$ . Evidently,  $R(\partial) = \{g \in \mathcal{S}' \mid f \text{ is odd and } \text{supp } g \subset [-T, T]\}$ . Then

$$(6.1) \quad \|\partial f\|_0^{p-1} = \|i\sigma \mathcal{F}f\|_{p-1}^0 \leq \|\mathcal{F}f\|_p^0 = \|f\|_0^p, \quad f \in D(\partial) \cap H_0^p;$$

i.e.,  $\partial$  is bounded linear operator from  $H_0^p$  to  $H_0^{p-1}$ . Due to the Paley–Wiener theorem we obtain that  $\partial$  is invertible and  $D(\partial^{-1}) = R(\partial)$ . According to the inverse operator theorem we conclude that  $\exists N^p > 0$  such that

$$(6.2) \quad \|\partial^{-1}g\|_0^p \leq N^p \|g\|_0^{p-1}, \quad g \in R(\partial) \cap H_0^{p-1} = D(\partial^{-1}) \cap H_0^{p-1}.$$

LEMMA 6.1. *Let  $g \in D(\Phi)$ ,  $f = \Phi g$ . Then*

- (i)  $\text{supp } f \subset [-T, T]$ ;
- (ii)  $f$  is even;
- (iii)  $\|f\|_0^p \leq L_q^p \|g\|_0^{p-1}$ ,  $g \in D(\Phi) \cap H_0^p$ , where  $L_q^p > 0$ ;
- (iv) if  $q = 0$ , then  $\Phi = \partial^{-1}$ .

*Proof.* Taking into account the generalized Paley–Wiener theorem [2, Chapter 3] we conclude that (1)  $G = \mathcal{F}g$  is a regular functional; (2)  $G$  is of a polynomial growth on  $\mathbb{R}$ ; and (3)  $G$  can be extended to an entire function of the order  $\leq 1$  and the type  $\leq T$ . Evidently,  $G$  is odd. Therefore  $\frac{1}{\sqrt{\sigma^2 + q^2}} G(\sqrt{\sigma^2 + q^2})$  is an even entire function of the order  $\leq 1$  and the type  $\leq T$  with a polynomial growth on  $\mathbb{R}$ . Using again the generalized Paley–Wiener theorem we obtain that  $f \in \mathcal{S}'$  and (i), (ii) are true. Let us prove (iii). Since  $\|G\|_{p-1}^0 = \|g\|_0^{p-1}$  we then have

$$\begin{aligned} (\|f'\|_0^{p-1})^2 &= \left( \left\| \frac{\sigma G(\sqrt{\sigma^2 + q^2})}{\sqrt{\sigma^2 + q^2}} \right\|_{p-1}^0 \right)^2 \\ &= 2 \int_0^\infty (1 + \sigma^2)^{p-1} \left| \frac{G(\sqrt{\sigma^2 + q^2})}{\sqrt{\sigma^2 + q^2}} \right|^2 \sigma^2 d\sigma \\ &= 2 \int_q^\infty (1 - q^2 + \mu^2)^{p-1} |G(\mu)|^2 \sqrt{1 - \frac{q^2}{\mu^2}} d\mu \leq (\tilde{L}_q^p)^2 (\|g\|_0^{p-1})^2, \end{aligned}$$

where  $\tilde{L}_q^p = (1 + q^2)^{-(p-1)/2}$  if  $p \leq 1$ , and  $\tilde{L}_q^p = 1$  otherwise. With regard to (6.2) we obtain  $\|f\|_0^p \leq N^p \|f'\|_0^{p-1} \leq L_q^p \|g\|_0^{p-1}$ , where  $L_q^p = N^p \tilde{L}_q^p$ . Therefore (iii) holds. If  $q = 0$ , then  $f = \Phi g = \mathcal{F}^{-1} \left( \frac{(\mathcal{F}g)(\sigma)}{(i\sigma)} \right) = \partial^{-1}g$ ; i.e., (iv) is true. The lemma is proved.

LEMMA 6.2. *Let  $g \in D(\Phi) \cap H_0^0$ ,  $f = \Phi g$ . Then*

$$(6.3) \quad f(x) = - \int_{|x|}^\infty J_0(q\sqrt{t^2 - x^2}) g(t) dt.$$

*Proof.* From the definition of  $\Phi$  we get

$$f = -i\mathcal{F}_{\sigma \rightarrow x}^{-1} \left( \frac{(\mathcal{F}g)(\sqrt{\sigma^2 + q^2})}{\sqrt{\sigma^2 + q^2}} \right) = -\frac{1}{\sqrt{2\pi}} \int_{-\infty}^\infty g(t) \mathcal{F}_{\sigma \rightarrow x}^{-1} \left( \frac{\sin(t\sqrt{\sigma^2 + q^2})}{\sqrt{\sigma^2 + q^2}} \right) dt.$$

With regard to (3.11) we conclude that

$$f(x) = -\frac{1}{2} \int_{-\infty}^\infty g(t) J_0(q\sqrt{t^2 - x^2}) H(t^2 - x^2) \text{sgn } t dt.$$

Therefore 6.3 is true. The lemma is proved.

Denote  $\Psi : \mathcal{S}' \longrightarrow \mathcal{S}'$  with  $D(\Psi) = \{f \in \mathcal{S}' \mid f \text{ is even and } \text{supp } g \subset [-T, T]\}$  such that

$$(6.4) \quad (\Psi f)(t) = \mathcal{F}_{\mu \rightarrow t}^{-1} \left( i\mu \left( \mathcal{F}f \right) \left( \sqrt{\mu^2 - q^2} \right) \right) (t), \quad f \in D(\Psi).$$

LEMMA 6.3. *Let  $f \in D(\Psi)$ ,  $g = \Psi f$ . Then*

- (i)  $\text{supp } g \subset [-T, T]$ ;
- (ii)  $g$  is odd;
- (iii)  $\|g\|_0^{p-1} \leq K_q^{p-1} \|f\|_0^p$ ,  $f \in D(\Psi) \cap H_0^p$ , where  $K_q^p > 0$ ;
- (iv) if  $q = 0$ , then  $\Psi = \partial$ .

In addition,  $R(\Psi) = D(\Phi)$ ,  $D(\Psi) = R(\Phi)$ , and  $\Psi = \Phi^{-1}$ .

*Proof.* Reasoning as in the proof of Lemma 6.1 we conclude that  $f \in \mathcal{S}'$  and (i), (ii) are true. Hence  $R(\Psi) \subset D(\Phi)$ . Let us prove (iii). We have  $R(\Phi) \subset D(\Psi)$  and

$$(6.5) \quad \Psi \Phi g = \mathcal{F}_{\mu \rightarrow t}^{-1} \left( i\mu \left( \mathcal{F}_{x \rightarrow \xi} (\Phi g)(x) \right) (\xi) \Big|_{\xi = \sqrt{\mu^2 - q^2}} \right) = \mathcal{F}_{\mu \rightarrow t}^{-1} \left( \frac{\mu}{\mu} (\mathcal{F}g)(\mu) \right) = g;$$

i.e.,  $\Phi : D(\Phi) \longrightarrow R(\Phi)$  is invertible and  $\Phi^{-1} = \Psi$ .

Denote by  $\Phi_p$  the restriction of  $\Phi$  on  $H_0^{p-1}$ :  $\Phi_p : D(\Phi) \cap H_0^{p-1} \longrightarrow R(\Phi) \cap H_0^p$ . According to Lemma 6.1  $\Phi_p$  is bounded. It follows from (6.5) that  $\Phi_p$  is invertible and  $\Phi_p^{-1} = \Psi_{p-1}$ , where  $\Psi_{p-1}$  is the restriction of  $\Psi$  on  $H_0^p$ :  $\Psi_p : D(\Psi) \cap H_0^p \longrightarrow R(\Psi) \cap H_0^{p-1}$ . Applying the inverse operator theorem we conclude that  $\Psi_{p-1}$  is bounded, i.e., (iii) holds. If  $q = 0$ , then  $g = \Phi f = \frac{d}{dt} \mathcal{F}^{-1}((\mathcal{F}g)(\sigma)) = \partial g$ , i.e., (iv) is true. The lemma is proved.

LEMMA 6.4. *Let  $f \in D(\Phi^{-1}) \cap H_0^1$ ,  $g = \Phi^{-1}f$ . Then*

$$(6.6) \quad g(t) = -\frac{d}{dt} \int_{|t|}^{\infty} I_0 \left( q\sqrt{x^2 - t^2} \right) f'(x) dx = f'(t) + qt \int_{|t|}^{\infty} \frac{I_1 \left( q\sqrt{x^2 - t^2} \right)}{\sqrt{x^2 - t^2}} f'(x) dx.$$

*Proof.* We have  $g(t) = \frac{d}{dt} \mathcal{F}_{\mu \rightarrow t}^{-1} \left( \frac{-i}{\sqrt{\mu^2 - q^2}} (\mathcal{F}f')(\sqrt{\mu^2 - q^2}) \right)$ . Since  $\frac{\sin(t\sqrt{\sigma^2 + q^2})}{\sqrt{\sigma^2 + q^2}}$  is an entire function with respect to  $(\sigma, q)$ , then replacing  $q$  by  $iq$  we get from (3.11)

$$(6.7) \quad \mathcal{F}_{\sigma \rightarrow x}^{-1} \left( \frac{\sin \left( t\sqrt{\sigma^2 - q^2} \right)}{\sqrt{\sigma^2 - q^2}} \right) (x) = \sqrt{\frac{\pi}{2}} I_0 \left( q\sqrt{t^2 - x^2} \right) H(t^2 - x^2) \text{sgn } t.$$

Reasoning as in the proof of Lemma 6.2 and using (6.7) instead of (3.11) we conclude that (6.6) holds. The lemma is proved.

LEMMA 6.5. *Let  $f \in D(\Phi^{-1}) \cap H_0^0$ . Then*

$$(6.8) \quad \Phi^{-1}f = \tilde{g}',$$

where  $\tilde{g} \in H_0^0$  is even,  $\text{supp } \tilde{g} \subset [-T, T]$ , and

$$(6.9) \quad \tilde{g}(t) = f(t) + \int_{|t|}^{\infty} \frac{qx I_1 \left( q\sqrt{x^2 - t^2} \right)}{\sqrt{x^2 - t^2}} f(x) dx,$$

$$(6.10) \quad f(x) = \tilde{g}(x) - \int_{|x|}^{\infty} \frac{qt J_1 \left( q\sqrt{t^2 - x^2} \right)}{\sqrt{t^2 - x^2}} \tilde{g}(t) dt.$$

Moreover,

- (i) if  $|f(x)| \leq \mathcal{F}$  a.e. on  $[-T, T]$ , then  $|\tilde{g}(t)| \leq \mathcal{F}I_0(qT)$  a.e. on  $[-T, T]$ ;
- (ii) if  $|\tilde{g}(t)| \leq \mathcal{G}$  a.e. on  $[-T, T]$ , then  $|f(x)| \leq \mathcal{G}(1 + qT)$  a.e. on  $[-T, T]$ .

*Proof.* It follows from Lemma 6.4 that

$$\tilde{g}(t) = - \int_{|t|}^{\infty} I_0 \left( q\sqrt{x^2 - t^2} \right) f'(x) dx + C.$$

Evidently  $\text{supp } \tilde{g} \subset [-T, T]$  iff  $C = 0$ . Hence (6.9) is true. It follows from (6.8) and Lemma 6.2 that (6.10) is also true. It remains to prove (i) and (ii). If  $|f(x)| \leq \mathcal{F}$  a.e. on  $[-T, T]$ , then  $|\tilde{g}(t)| \leq \mathcal{F} \int_{|t|}^T \left| \frac{\partial}{\partial x} I_0 \left( q\sqrt{x^2 - t^2} \right) \right| dx \leq \mathcal{F}I_0(qT)$ . If  $|\tilde{g}(t)| \leq \mathcal{G}$  a.e. on  $[-T, T]$ , then  $|f(x)| \leq \mathcal{G} + \mathcal{G} \int_{|x|}^T \frac{qt}{\sqrt{t^2 - x^2}} dt \leq \mathcal{G}(1 + qT)$ . Thus (i) and (ii) hold and the lemma is proved.

LEMMA 6.6. Let  $f \in H_0^1$  be even,  $\text{supp } f \subset [-T, T]$ ,  $h = \Phi \frac{d}{dt} (\text{sgn } t \Phi^{-1} f)$ . Then

$$(6.11) \quad h(x) = \text{sgn } x f'(x) + q \int_{|x|}^{\infty} f(\xi) \frac{I_1(q(\xi - |x|))}{\xi - |x|} d\xi.$$

*Proof.* Put  $F = \mathcal{F}f$ . Denote  $G(\xi) = \frac{1}{i\xi} \mathcal{F}_{t \rightarrow \xi} \left( \frac{d}{dt} (\text{sgn } t (\Phi^{-1} f)(t)) \right) (\xi)$ . Then

$$\begin{aligned} G &= (\mathcal{F}_{t \rightarrow \xi} (\text{sgn } t (\Phi^{-1} f)(t))) = \frac{1}{\pi} \mathcal{P} \frac{1}{\xi} * \xi F \left( \sqrt{\xi^2 - q^2} \right) \\ &= \frac{2}{\pi} \text{V.p.} \int_0^{\infty} \frac{1}{\xi^2 - \mu^2} \mu^2 F \left( \sqrt{\mu^2 - q^2} \right) d\mu. \end{aligned}$$

Therefore  $h = -\Delta_q \mathcal{F}_{\sigma \rightarrow x} \frac{G(\sqrt{\sigma^2 + q^2})}{\sigma^2 + q^2} = -\frac{1}{2} \Delta_q \left( \frac{e^{-q|x|}}{q} * (\mathcal{F}_{\sigma \rightarrow x} G(\sqrt{\sigma^2 + q^2})) \right)$ , where  $\Delta_q = \left( \frac{d}{dx} \right)^2 - q^2$ . Hence

$$\begin{aligned} h &= \frac{1}{2} \sqrt{\frac{2}{\pi}} \Delta_q \int_0^{\infty} \left( \left( \frac{e^{-q|x|}}{q} * \frac{\sin(|x|\sqrt{\mu^2 - q^2})}{\sqrt{\mu^2 - q^2}} \right) H(\mu^2 - q^2) \right. \\ &\quad \left. - \left( \frac{e^{-q|x|}}{q} * \frac{e^{|x|\sqrt{q^2 - \mu^2}}}{\sqrt{q^2 - \mu^2}} \right) H(q^2 - \mu^2) \right) \mu^2 F \left( \sqrt{\mu^2 - q^2} \right) d\mu \\ &= \frac{2}{\pi} \Delta_q \left( -\frac{e^{-q|x|}}{q} \int_0^{\infty} f'(\nu) \int_0^{\infty} \frac{\sin(\nu\sqrt{\mu^2 - q^2})}{\sqrt{\mu^2 - q^2}} d\mu d\nu \right. \\ &\quad \left. + \int_0^{\infty} f(\nu) \int_0^{\infty} \frac{\cos(\nu\sqrt{\mu^2 - q^2}) \sin(|x|\sqrt{\mu^2 - q^2})}{\sqrt{\mu^2 - q^2}} d\mu d\nu \right. \\ &\quad \left. - \int_0^{\infty} f(\nu) \int_0^q \frac{\cosh(\nu\sqrt{q^2 - \mu^2}) \cosh(x\sqrt{q^2 - \mu^2})}{\sqrt{q^2 - \mu^2}} d\mu d\nu \right). \end{aligned}$$

Taking into account (6.7) and  $\frac{2}{\pi} \int_0^1 \frac{\cosh(\xi t)}{\sqrt{1-t^2}} dt = I_0(\xi)$  we obtain

$$\begin{aligned} h(x) &= \frac{1}{2} \Delta_q \left( (f'(x) * (I_0(qx) \operatorname{sgn} x)) \Big|_{x=0} \frac{e^{-q|x|}}{q} \right. \\ &\quad \left. + \operatorname{sgn} x (f(x) * (I_0(qx) \operatorname{sgn} x)) - f(x) * I_0(qx) \right) \\ &= \frac{1}{2} (\operatorname{sgn} x \Delta_q (f(x) * (\operatorname{sgn} x I_0(qx))) - \Delta_q (f(x) * I_0(qx))) \\ &= \operatorname{sgn} x f'(x) + \frac{1}{2} \operatorname{sgn} x (f(x) * (\operatorname{sgn} x (\Delta_q I_0(qx)))) - \frac{1}{2} f(x) * (\Delta_q I_0(qx)) \\ &= \operatorname{sgn} x f'(x) - \int_0^\infty f(\xi + |x|) (\Delta_q I_0(q\xi)) d\xi. \end{aligned}$$

Since  $\Delta_q I_0(q\xi) = (q^2/2) (I_2(q\xi) - I_0(q\xi)) = -qI_1(q\xi)/\xi$ , we conclude that (6.11) holds and the lemma is proved.

LEMMA 6.7. *If  $f \in H_0^p \times H_0^{p-1}$  and  $g = \mathcal{F}f$ , then*

$$(6.12) \quad \|E(x, t) * f\|^p = \|\Sigma(|\sigma|, t)g\|_p^p \leq M_q^T \|g\|_p^p = M_q^T \|f\|^p, \quad t \in \mathbb{R},$$

where  $M_q^T = \sqrt{(2t^2 + 6)(1 + q^2)}$ .

*Proof.* For all  $t \in \mathbb{R}$  we have

$$\begin{aligned} \|E(x, t) * f\|^p &= \|\Sigma(\sigma, t)g\|_p^p \\ &\leq \left\| \begin{pmatrix} \cos(t\sqrt{\sigma^2 + q^2}) \\ -\sqrt{\sigma^2 + q^2} \sin(t\sqrt{\sigma^2 + q^2}) \end{pmatrix} g_0 \right\|_p^p + \left\| \begin{pmatrix} \sin(t\sqrt{\sigma^2 + q^2}) \\ \sqrt{\sigma^2 + q^2} \cos(t\sqrt{\sigma^2 + q^2}) \end{pmatrix} g_1 \right\|_p^p \\ &\leq \sqrt{2}\sqrt{1 + q^2} \|g_0\|_p^0 + \left( \left( \left\| \frac{\sin(t\sqrt{\sigma^2 + q^2})}{\sqrt{\sigma^2 + q^2}} g_1 \right\|_p^0 \right)^2 + \left( \|g_1\|_{p-1}^0 \right)^2 \right)^{1/2}. \end{aligned}$$

Since  $(1 + |\sigma|^2) \left| \frac{\sin(t\sqrt{\sigma^2 + q^2})}{\sqrt{\sigma^2 + q^2}} \right|^2 \leq t^2 + 2$  we obtain (6.12). The lemma is proved.

# OPTIMAL DIVIDEND PAYMENTS AND REINVESTMENTS OF DIFFUSION PROCESSES WITH BOTH FIXED AND PROPORTIONAL COSTS\*

JOSTEIN PAULSEN†

**Abstract.** Assets are assumed to follow a diffusion process subject to some conditions. The owners can pay dividends at their discretion, but whenever assets reach zero, they have to reinvest money so that assets never go negative. With each dividend payment there is a fixed and a proportional cost, and so with reinvestments. The goal is to maximize the expected value of discounted net cash flow, i.e., dividends paid minus reinvestments. It is shown that there can be two different solutions depending on the model parameters and the costs as follows. (1) Whenever assets reach a barrier  $y^*$  they are reduced to  $y^* - \delta^*$  through a dividend payment, and whenever they reach 0 they are increased to  $\gamma^* \leq y^* - \delta^*$  by a reinvestment. (2) There is no optimal policy, but the value function is approximated by policies of the form described in (1) for increasing barriers. We provide criteria to decide whether an optimal solution exists, and when it does not, we show how to calculate the value function. We discuss how the problem can be solved numerically and give numerical examples.

**Key words.** optimal dividends, diffusion models, impulse control, barrier strategy

**1. Introduction and model formulation.** In this paper the value of a company is defined as the expected present value of dividends paid to the owners minus reinvestments made. Assuming no transaction costs and other market imperfections, the Modigliani–Miller theorem says that the value of the company is independent of its dividend and reinvestment policy. However, this assumption is not likely to hold in practice. Transactions such as dividend payments and reinvestments are not likely to be free of costs. There may be tax differences between dividends received and asset appreciations, and these can be formulated as costs. Investment of the company's assets may be expensive, which is an issue we review in section 3. When transaction costs are taken into account, dividend and reinvestment policies do matter, and the valuation problem becomes more complex. A justification for our valuation method in the presence of transaction costs can be found in Sethi and Taksar [11].

In addition to finding the value of the company, it is of course also useful to find the optimal dividend as well as reinvestment policies, when they exist, and to know when there are no such optimal policies. These problems are addressed in this paper for a rather general diffusion model when transaction costs consist of a constant part and a part that is proportional to the amount transacted.

To get the mathematical formalism right, let  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, P)$  be a probability space satisfying the usual conditions; i.e., the filtration  $(\mathcal{F}_t)_{t \geq 0}$  is right continuous and  $P$ -complete. The income process without dividends is assumed to follow the dynamics

$$dX_t = \mu(X_t)dt + \sigma(X_t)dW_t,$$

where  $W$  is a Brownian motion on the probability space.

---

†Department of Mathematics, University of Bergen, Johs. Brunsgt. 12, 5008 Bergen, Norway (jostein@math.uib.no).

From this income process dividends can be paid out to the owners, but at a cost. Total dividends paid out until time  $t$  are denoted by  $D_t$ . The costs incurred up to time  $t$  from paying out  $D_t$  are denoted by  $\bar{D}_t$ .

In addition, whenever the income process reaches zero, the owners are under the obligation to reinvest in order to prevent it from going negative. Total reinvestments until time  $t$  are denoted by  $C_t$ . Again costs are incurred with reinvestments, and the costs incurred up to time  $t$  from reinvesting  $C_t$  are denoted by  $\bar{C}_t$ .

If the processes  $C$ ,  $D$ ,  $\bar{C}$ , and  $\bar{D}$  are nondecreasing, adapted, and right continuous, we say they are admissible.

After dividends and reinvestments, the capital  $Y$  retained in the company has the dynamics

$$(1.1) \quad dY_t = \mu(Y_t)dt + \sigma(Y_t)dW_t + dC_t - dD_t - d\bar{C}_t - d\bar{D}_t,$$

with  $Y_{0-} = y$ .

Let  $\mathcal{D}$  be the set of all admissible dividend and reinvestment policies. For  $(C, D) \in \mathcal{D}$ , let  $\nu_n = \inf\{t : C_t \vee D_t > n\}$  and define

$$V_{C,D}(y) = \limsup_{n \rightarrow \infty} E^y \left[ \int_{0-}^{\nu_n-} e^{-rt} dA_t \right],$$

where  $A_t = D_t - C_t$  is net payout. Here  $r$  is a properly chosen discount factor and  $E^y$  is expectation with  $Y_{0-} = y$ . The reason for introducing the stopping times  $\{\nu_n\}$  is that both  $C_t$  and  $D_t$  can go to infinity as  $t$  goes to infinity, and therefore  $\lim_{t \rightarrow \infty} A_t$  may not exist, and we are a priori not guaranteed that  $\lim_{t \rightarrow \infty} e^{-rt} A_t$  exists. Therefore the somewhat complicated definition of  $V_{C,D}(y)$  is required.

Our task is to find

$$(1.2) \quad V^*(y) = \sup_{\mathcal{D}} V_{C,D}(y).$$

Furthermore, if it exists, we also want to find the optimal policy  $(C^*, D^*) \in \mathcal{D}$ .

In this paper it is assumed that with each dividend payment there is a fixed cost  $d_0$ , independent of the size of the payment, plus a part that is proportional to the size of the payment. Similarly, with each reinvestment there is a fixed cost  $c_0$  plus a proportional part. Because of the fixed costs, there can be only a finite number of payments on each finite time interval, so we can write

$$(1.3) \quad \begin{aligned} \bar{C}_t &= c_0 \sum_{s \leq t} 1_{\{\Delta C_s > 0\}} + c_1 C_t, \quad 0 \leq c_1 < 1, \\ \bar{D}_t &= d_0 \sum_{s \leq t} 1_{\{\Delta D_s > 0\}} + d_1 D_t, \end{aligned}$$

where  $c_1$  and  $d_1$  are the proportionality factors, assumed nonnegative. We shall call such costs linear costs. Note that  $c_1 \geq 1$  is meaningless since, in that case, the net effect of a reinvestment is zero or negative. Clearly  $\bar{C}$  and  $\bar{D}$  are admissible whenever  $C$  and  $D$  are. From (1.1) and (1.3) we easily get

$$(1.4) \quad \begin{aligned} \Delta C_t &= \frac{\Delta Y_t + c_0}{1 - c_1} 1_{\{\Delta C_t > 0\}}, \quad 0 \leq c_1 < 1, \\ \Delta D_t &= -\frac{\Delta Y_t + d_0}{1 + d_1} 1_{\{\Delta D_t > 0\}}. \end{aligned}$$

Richard [10], Constantinides and Richard [3], and Harrison, Sellke, and Taylor [4] considered optimality of a storage system where, in addition to linear costs connected with increasing or decreasing the storage, there is also a holding cost. In all these papers the underlying process  $X$  is a Brownian motion with drift; i.e.,  $\mu$  and  $\sigma$  are constants. When holding costs are proportional, it was shown in [4] that for the linear Brownian motion this storage problem is equivalent to the dividend and reinvestment problem studied here. For more general diffusions, this equivalence no longer holds. Although the object of [4] was the storage problem, using this equivalence, those authors studied the dividend and reinvestment problem instead. They showed that the optimal policy is such that when assets reach a barrier  $y^*$ , reduce them to  $y^* - \delta^*$ , and when they are at zero, increase them to  $\gamma^*$ , where  $y^*$ ,  $\delta^*$ , and  $\gamma^*$  are uniquely given. This is an impulse control problem since payments are in lumps. We extend these results to the more general diffusion model given in section 2 and review the Brownian motion with drift in Example 2.1. This process has the advantage that an optimal solution always exists, but we shall see that this is not always the case for more general processes.

In Porteus [9] the optimal dividend and reinvestment problem is analyzed in a discrete time setting. This paper is also interesting as a general background and motivation of the problem.

The case with  $c_0 = d_0 = 0$  has been studied in several papers. Under the assumptions given in section 2, the problem was solved in Shreve, Lehoczky, and Gaver [12]. In this case both the optimal dividend process and the optimal reinvestment process, if they exist, are singular processes. Under somewhat different assumptions on the diffusion coefficients, the problem was solved in [11]. Avram, Palmowski, and Pistorius [1] solved the same problem, but with  $X$  as a spectrally negative Lévy process. All these papers assume that  $d_1 = 0$ , but letting  $d_1 > 0$  causes no extra problem.

Most of the attention in the optimal dividend literature has been on the case where activity stops whenever  $Y$  reaches zero; i.e., the task is to maximize

$$(1.5) \quad V_0^*(y) = \sup_{\mathcal{D}_0} E^y \left[ \int_{0-}^{\tau_y} e^{-rt} dD_t \right],$$

where  $\tau_y = \inf\{t : Y_t < 0\}$  with  $\tau_y = \infty$  if  $Y_t \geq 0$  for all  $t$  is the time of ruin. Here  $\mathcal{D}_0$  is the set of all admissible dividend policies (there are no reinvestments in this case). When  $d_0 > 0$ , this problem was first studied by Jeanblanc-Picqué and Shiryaev [5] for a Brownian motion with drift. Cadenillas, Sarkar, and Zapatero [2] worked with a different model, and also a more general utility function for payouts. Under the assumptions of the present paper, a complete solution to this problem is given in Paulsen [8], where it is shown that the optimal dividend process, if it exists, is a jump process, where an amount  $\delta_0^*$  is paid in dividends when the capital reaches a barrier  $y_0^*$ . Under the same assumptions, but with  $d_0 = 0$ , this problem was solved in [12] (at even some higher level of generality).

It may well be that when  $Y$  reaches zero the owners can choose between investing new money or terminating the business. In this case we can calculate  $V^*(y)$  and  $V_0^*(y)$ , and the one that is largest determines whether termination or reinvestment is optimal.

## 2. Results. We start with a list of assumptions.

- A1.  $|\mu(y)| + |\sigma(y)| \leq K(1 + y)$  for all  $y \geq 0$  and some  $K > 0$ .
- A2.  $\mu$  and  $\sigma$  are continuously differentiable and the derivatives  $\mu'$  and  $\sigma'$  are Lipschitz continuous for all  $y \geq 0$ .
- A3.  $\sigma^2(y) > 0$  for all  $y \geq 0$ .

A4.  $\mu'(y) \leq r$  for all  $y \geq 0$ .

The operator  $L$  is defined as

$$Lf(y) = \frac{1}{2}\sigma^2(y)f''(y) + \mu(y)f'(y) - rf(y)$$

for  $f \in C^2(0, \infty)$ . Note that under A2 and A3, any solution of  $Lf(y) = 0$  has  $f \in C^3[0, \infty)$  and  $f'''(y)$  is Lipschitz continuous (see, e.g., Krylov [7, Theorem 6.5.3]).

*Remark 2.1.* Assumption A4 may seem a bit unnatural and restrictive. To give an intuitive idea of what it means, we consider the special case

$$dX_t = (\mu_0 + \mu_1 X_t)dt + \sigma(X_t)dW_t, \quad X_0 = x.$$

Here  $\mu'(x) = \mu_1$ , and furthermore,

$$E^x[e^{-rt}X_t] = \left(x + \frac{\mu_0}{\mu_1}\right)e^{(\mu_1-r)t} - \frac{\mu_0}{\mu_1}e^{-rt}.$$

If  $\mu_1 \leq r$ , then this stabilizes, but if  $\mu_1 > r$ , it grows to infinity and this indicates that it is better to wait. The right quantities to compare are therefore  $\mu'(x)$  and  $r$ , one representing the geometric growth rate and the other the geometric discounting rate. The condition  $\mu'(x) \leq r$  just says that in no state should growth rate exceed discounting rate. Relaxing condition A4 by allowing for  $\mu'(x) > r$  for  $x$  in some subset of the positive real line is clearly possible, but it does complicate matters and is therefore a topic for future research.  $\square$

Before we continue let us briefly recapitulate the general solution when  $d_0 = 0$ , given in [12, Theorem 4.4]. According to this result we should look for a solution of  $LV(y) = 0$ ,  $y > 0$ , and  $y^*$  which satisfy

$$(2.1) \quad V'(0) = \frac{1}{1-c_1}, \quad V'(y^*) = \frac{1}{1+d_1}, \quad \text{and} \quad V''(y^*) = 0.$$

On  $y > y^*$ , set

$$V(y) = V(y^*) + \frac{y - y^*}{1 + d_1}.$$

The optimal solution is singular control at barrier  $y^*$ , and  $V = V^*$  is the value function.

Furthermore, if (2.1) has no solution, then there is no optimal control, but the value function is the limit of singular controls at barrier  $\bar{y}$  for increasing  $\bar{y}$ .

The next definition is connected with (1.4).

**DEFINITION 2.1.** *A lump sum reinvestment strategy with jump-size  $\gamma$  satisfies*

$$\Delta C_t = \frac{\gamma + c_0}{1 - c_1} 1_{\{Y_{t-}=0\}}.$$

*A lump sum dividend barrier strategy at  $\bar{y}$  with jump-size  $\delta \in (0, \bar{y}]$  satisfies for  $Y_{0-} = y$ ,*

$$\begin{aligned} \Delta D_0 &= \frac{y - (\bar{y} - \delta) - d_0}{1 + d_1} 1_{\{y \geq \bar{y}\}}, \\ \Delta D_t &= \frac{\delta - d_0}{1 + d_1} 1_{\{Y_{t-} = \bar{y}\}}. \end{aligned}$$

The corresponding value function is denoted by  $V_{\bar{y},\gamma,\delta}(y)$ . Also we set  $V_{\bar{y},\gamma(\bar{y}),\delta(\bar{y})}(y) = \sup_{\gamma,\delta \in (0,\bar{y})} V_{\bar{y},\gamma,\delta}(y)$ .

PROPOSITION 2.2. Assume A1–A4 and that the process  $Y$  is a strong solution of (1.1) with  $\bar{C}$  and  $\bar{D}$  as in (1.3). Assume that  $0 < c_0 < 1$  and  $d_0 > 0$ , and for fixed  $\bar{y}$ , consider the variational problem for unknown  $V$ ,  $\bar{\gamma} \in (0, \bar{y})$ , and  $\bar{\delta} \in (0, \bar{y})$ ,

$$\begin{aligned}
 (2.2) \quad & LV(y) = 0, \quad 0 < y < \bar{y}, \\
 & V(\bar{\gamma}) = V(0) + \frac{\bar{\gamma} + c_0}{1 - c_1}, \\
 & V'(\bar{\gamma}) = \frac{1}{1 - c_1}, \\
 & V(\bar{y}) = V(\bar{y} - \bar{\delta}) + \frac{\bar{\delta} - d_0}{1 + d_1}, \\
 & V'(\bar{y} - \bar{\delta}) = \frac{1}{1 + d_1}, \\
 & V(y) = V(\bar{y}) + \frac{y - \bar{y}}{1 + d_1}, \quad y > \bar{y}.
 \end{aligned}$$

This problem has a unique solution with  $0 < \bar{\gamma} \leq \bar{y} - \bar{\delta} < \bar{y}$ . Furthermore  $V(y) = V_{\bar{y},\gamma(\bar{y}),\delta(\bar{y})}(y)$  for all  $y \geq 0$ , and so  $\bar{\gamma} = \gamma(\bar{y})$  and  $\bar{\delta} = \delta(\bar{y})$ .

Here the equation  $V(\bar{\gamma}) = V(0) + (\bar{\gamma} + c_0)/(1 - c_1)$  is just an accounting equality; the value after raising the capital from 0 to  $\bar{\gamma}$  equals the value when capital is 0 plus the capital needed, including costs, for the raise. The equation  $V'(\bar{\gamma}) = 1/(1 - c_1)$  says that at  $\bar{\gamma}$  the marginal increase of the value of the company by raising capital by one unit equals the marginal cost of that raise. Hence when capital is raised to  $\bar{\gamma}$ , the owners are indifferent to a further marginal raise. The next two equations have a similar interpretation, while the last equation in (2.2) is only a definition of  $V(y)$  for  $y > \bar{y}$ .

From an intuitive and economic point of view, Proposition 2.2 is very reasonable. Since termination is not an option, for any given  $\bar{y}$  there must necessarily be some strategy that is better than, or not as bad as, any other. A mathematical (and rather long and technical) proof is given in the appendix.

Proposition 2.2 gives optimality for a barrier strategy at a fixed barrier  $\bar{y}$ . The general optimality problem is more complicated, but here is the solution.

THEOREM 2.3. Assume A1–A4 and that the process  $Y$  is a strong solution of (1.1) with  $\bar{C}$  and  $\bar{D}$  as in (1.3). Assume that  $0 < c_0 < 1$  and  $d_0 > 0$ , and consider the following variational problem for unknown  $V$ ,  $y^*$ ,  $\gamma^* \in (0, y^*)$ , and  $\delta^* \in (0, y^*)$ :

$$\begin{aligned}
 (2.3) \quad & LV(y) = 0, \quad 0 < y < y^*, \\
 & V(\gamma^*) = V(0) + \frac{\gamma^* + c_0}{1 - c_1}, \\
 & V'(\gamma^*) = \frac{1}{1 - c_1}, \\
 & V(y^*) = V(y^* - \delta^*) + \frac{\delta^* - d_0}{1 + d_1}, \\
 & V'(y^* - \delta^*) = \frac{1}{1 + d_1}, \\
 & V'(y^*) = \frac{1}{1 + d_1},
 \end{aligned}$$

$$V(y) = V(y^*) + \frac{y - y^*}{1 + d_1}, \quad y > y^*.$$

(a) If (2.3) has a solution, then this solution is unique and

$$V(y) = V_{y^*, \gamma(y^*), \delta(y^*)}(y) = V^*(y), \quad y \geq 0.$$

Therefore  $\gamma^* = \gamma(y^*)$  and  $\delta^* = \delta(y^*)$ .

(b) If (2.3) has no solution, then there is no optimal policy, but

$$V^*(y) = \lim_{\bar{y} \rightarrow \infty} V_{\bar{y}, \gamma(\bar{y}), \delta(\bar{y})}(y)$$

and this limit exists and is finite for every  $y \geq 0$ .

The proof is given in the appendix.

Note that (2.3) is essentially the same as (2.2) with the addition of the “smooth fit” condition at  $y^*$ ,  $V'(y^*) = (1 + d_1)^{-1}$ . This is necessary for finding the optimal  $y^*$ , if it exists. The economic interpretation is that at  $y^*$  the marginal value of keeping money in the company equals the marginal value of paying money out as dividends.

Theorem 2.3 shows that if an optimal strategy exists, then it is a lump sum dividend barrier strategy at some  $y^*$  with jump-size  $\delta^* = \delta(y^*)$  in conjunction with a lump sum reinvestment strategy with jump-size  $\gamma^* = \gamma(y^*)$ . If no optimal strategy exists, then the value function is finite and can be approximated by barrier strategies of the form described in Proposition 2.2 for increasing barriers  $\bar{y}$ .

*Remark 2.2.* A natural question is whether there is an  $x^* > 0$  so that, instead of waiting until assets reach zero, it would be better to reinvest at  $x^*$ . An intuitive economic argument that this is not the case can be drawn directly from assumption A4, since the growth rate of assets is never higher than the discounting rate, so there is no reason to reinvest money before it is necessary. Therefore, letting reinvestments take place only when assets hit zero represents no loss of generality. A more mathematical argument is that if there is such an  $x^*$ , then the equation

$$V(\gamma^*) = V(0) + \frac{\gamma^* + c_0}{1 - c_1}$$

in (2.3) must be replaced by the two equations

$$\begin{aligned} V(x^* + \gamma^*) &= V(x^*) + \frac{\gamma^* + c_0}{1 - c_1}, \\ V'(x^*) &= \frac{1}{1 - c_1}. \end{aligned}$$

But then a solution of this new system would have (at least) two distinct points  $y_{c,i}$ ,  $i = 1, 2$ , where  $V''(y_{c,i}) = 0$ , which is impossible by Lemma A.1.

The following result is useful for deciding whether (2.3) has a solution. Note that, except for the rather mild extra condition in (b), parts (a) and (b) yield an equivalence relation.

**PROPOSITION 2.4.** *Given the same assumptions as in Theorem 2.3, the following hold:*

(a) *Assume that (2.3) has no solution. Then there exists a solution  $g_2$  of  $Lg = 0$  so that*

$$\lim_{y \rightarrow \infty} g_2(y) = \lim_{y \rightarrow \infty} g'_2(y) = 0.$$

Furthermore, for any other independent solution  $g_1$ ,

$$\lim_{y \rightarrow \infty} g'_1(y) = \lim_{y \rightarrow \infty} \frac{g_1(y)}{y} = g'_1$$

for some positive and finite  $g'_1$ .

(b) Assume that there are two solutions  $g_1$  and  $g_2$  of  $Lg = 0$  so that

$$\begin{aligned} \lim_{y \rightarrow \infty} g'_1(y) &= g'_1, \\ \lim_{y \rightarrow \infty} g_2(y) &= 0, \end{aligned}$$

where  $g'_1$  is finite and nonzero. Assume in addition that

$$\lim_{y \rightarrow \infty} \left( \frac{g_1(y)}{g'_1} - y \right) > \frac{\mu(0)}{r} - d_0.$$

Then (2.3) has no solution.

(c) Assume there is a solution  $g$  of  $Lg = 0$  so that

$$\lim_{y \rightarrow \infty} \frac{g(y)}{y} = \infty$$

or equivalently,

$$\lim_{y \rightarrow \infty} g'(y) = \infty.$$

Then (2.3) has a solution.

*Example 2.1.* Let the income process without dividends follow

$$dX_t = \mu dt + \sigma dW_t,$$

with costs as in (1.3). This is a linear Brownian motion, and it is easy to verify that  $Lg(y) = 0$  has the independent solutions  $g_i(y) = e^{\theta_i y}$ ,  $i = 1, 2$ , where

$$\theta_1 = \frac{1}{\sigma^2} \left( \sqrt{\mu^2 + 2r\sigma^2} - \mu \right) \quad \text{and} \quad \theta_2 = -\frac{1}{\sigma^2} \left( \sqrt{\mu^2 + 2r\sigma^2} + \mu \right).$$

Clearly  $\theta_1 > 0$ , and hence an optimal solution exists by Proposition 2.4(c). This is the main result of [4]. To find a numerical solution, the general method of Example 3.1 can be used.

Here is another result that, in conjunction with Proposition 2.4, may be helpful in deciding whether (2.3) has a solution. A proof can be found in [8].

LEMMA 2.5. Assume A2 and A3 and let  $f_i(y)$ ,  $i = 1, 2$ , solve

$$\frac{1}{2}\sigma^2(y)f''_i(y) + \mu_i(y)f'_i(y) - rf_i(y) = 0, \quad y \geq 0,$$

where  $\mu_1(y) > \mu_2(y)$  for all  $y \geq 0$  and

$$f_i(0) = f_0 \quad \text{and} \quad f'_i(0) = f_1 \geq 0, \quad i = 1, 2.$$

Then  $f'_1(y) < f'_2(y)$  for all  $y > 0$ , which in turn implies that  $f_1(y) < f_2(y)$  for all  $y > 0$ .

The following result can be used to find the value function when (2.3) has no solution.

PROPOSITION 2.6. *Given the same assumptions as in Theorem 2.3, assume that (2.3) has no solution, and let  $V$  be the value function. Consider the set of equations (in  $\bar{\gamma}$ )*

$$(2.4) \quad \begin{aligned} V'(\bar{\gamma}) &= \frac{1}{1-c_1}, \\ V(\bar{\gamma}) &= V(0) + \frac{\bar{\gamma} + c_0}{1-c_1}. \end{aligned}$$

Furthermore, with  $g_1$  and  $g_2$  as in Proposition 2.4(a), write

$$V(y) = a_1 g_1(y) + a_2 g_2(y).$$

(a) We have

$$\lim_{y \rightarrow \infty} V'(y) = \frac{1}{1+d_1}.$$

(b) If  $c_1 + d_1 > 0$ , then (2.4) has a unique solution. Furthermore

$$\begin{aligned} a_1 &= \frac{1}{1+d_1} \frac{1}{g'_1}, \\ a_2 &= \frac{1}{1-c_1} \frac{1}{g'_2(\bar{\gamma})} - \frac{1}{1+d_1} \frac{1}{g'_1} \frac{g'_1(\bar{\gamma})}{g'_2(\bar{\gamma})}. \end{aligned}$$

Here  $g'_1 = \lim_{y \rightarrow \infty} g'_1(y)$  and  $\bar{\gamma}$  is the solution of

$$\frac{1-c_1}{1+d_1} \frac{1}{g'_1} (g_1(y) - g_1(0)) + \left( \frac{1}{g'_2(y)} - \frac{1-c_1}{1+d_1} \frac{1}{g'_1} \frac{g'_1(y)}{g'_2(y)} \right) (g_2(y) - g_2(0)) - y = c_0.$$

(c) If  $c_1 = d_1 = 0$  there are two possibilities as follows:

- (i) The equations in (2.4) have a unique solution, and then  $a_1$ ,  $a_2$ , and  $\bar{\gamma}$  are in (b) above. Also, denoting the barriers in (2.2) as  $\bar{y}_n$  and the corresponding reinvestment levels as  $\gamma_n$ , we then have  $\gamma_n \rightarrow \bar{\gamma}$  as  $\bar{y}_n \rightarrow \infty$ .
- (ii) The equations in (2.4) have no solution, but

$$\begin{aligned} a_1 &= \frac{1}{g'_1}, \\ a_2 &= \frac{\lim_{y \rightarrow \infty} \left( \frac{g_1(y)}{g'_1} - y \right) - \frac{g'_1(0)}{g'_1} - c_0}{g_2(0)}. \end{aligned}$$

**3. A financial example.** Assume that the income process without dividends is a linear Brownian motion with drift  $\mu$  and diffusion  $\sigma$ , but that money can be invested in risk-free assets with return  $r$ . Assume in addition that there are investment costs incurred with intensity  $\alpha(Y_t)$ . The dynamics (1.1) then becomes

$$(3.1) \quad \begin{aligned} dY_t &= (\mu + (r - \alpha(Y_t))Y_t)dt + \sigma dW_t + (1 - c_1)\Delta C_t - (1 + d_1)\Delta D_t \\ &\quad - c_0 1_{\{\Delta C_t > 0\}} - d_0 1_{\{\Delta D_t > 0\}}, \quad Y_{0-} = y. \end{aligned}$$

For this model  $\mu(y) = \mu + (r - \alpha(y))y$ , and so  $\mu'(y) \leq r$  for all  $y \geq 0$  if and only if

$$(3.2) \quad \alpha(y) + \alpha'(y)y \geq 0, \quad y \geq 0.$$

The total cost of investment intensity is  $\alpha(Y_t)Y_t$ , and a reasonable assumption is that this consists of a fixed part  $\alpha_0$  and a part that is proportional to the amount invested,  $\alpha_1$ , i.e.,

$$(3.3) \quad \alpha(y) = \frac{\alpha_0}{y} + \alpha_1.$$

Clearly (3.2) is satisfied, and (3.1) becomes

$$(3.4) \quad \begin{aligned} dY_t &= (\mu_0 + (r - \alpha_1)Y_t)dt + \sigma dW_t + (1 - c_1)\Delta C_t - (1 + d_1)\Delta D_t \\ &\quad - c_0 1_{\{\Delta C_t > 0\}} - d_0 1_{\{\Delta D_t > 0\}}, \quad Y_{0-} = y, \end{aligned}$$

where  $\mu_0 = \mu - \alpha_0$ . We shall assume that  $\mu_0 > 0$  and  $0 \leq \alpha_1 < r$ . When  $\alpha_1 = r$ , this is the linear Brownian motion analyzed in Example 2.1.

We need to solve

$$(3.5) \quad Lg(y) = \frac{1}{2}\sigma^2 g''(y) + (\mu_0 + (r - \alpha_1)y)g'(y) - rg(y) = 0.$$

Substituting  $z = -k(y)$  and  $f(z) = g(y)$  with

$$k(y) = \frac{r - \alpha_1}{\sigma^2} \left( y + \frac{\mu_0}{r - \alpha_1} \right)^2$$

brings it into the confluent hypergeometric form

$$zf''(z) + \left( \frac{1}{2} - z \right) f'(z) + \frac{r}{2(r - \alpha_1)} f(z) = 0.$$

Using the forms  $y_3$  and  $y_5$  from [13, p. 5] gives

$$\begin{aligned} g_1(y) &= e^{-k(y)} F(a, b, k(y)), \\ g_2(y) &= e^{-k(y)} U(a, b, k(y)), \end{aligned}$$

where

$$a = \frac{1}{2} + \frac{r}{2(r - \alpha_1)}, \quad b = \frac{1}{2},$$

and  $F$  and  $U$  are the first and second forms of Kummer's solution.

Consider first the case with  $\alpha_1 = 0$ , i.e., investment costs are constant. Then  $a = 1$ , and instead of the  $g_1$  above we can use the simpler  $g_1(y) = ry + \mu_0$ . By [13, p. 60] asymptotically as  $y \rightarrow \infty$ ,

$$e^{-k(y)} U(a, b, k(y)) \sim e^{-k(y)} (k(y))^{-a},$$

and hence  $\lim_{y \rightarrow \infty} g_2(y) = 0$ . Furthermore,  $g'_1(y) = r$  and

$$\lim_{y \rightarrow \infty} \left( \frac{g_1(y)}{r} - y \right) = \frac{\mu_0}{r} = \frac{\mu(0)}{r}.$$

Therefore the conditions of Proposition 2.4(b) are satisfied, and consequently there is no optimal control. The value function is, by Proposition 2.6(b),

$$V^*(y) = \frac{1}{1+d_1} \left( y + \frac{\mu_0}{r} \right) - a_2 e^{-k(y)} U(a, b, k(y)).$$

Here the first term is the value if money could be reinvested without costs when reaching zero, and the second term is a reduction in this value due to reinvestment costs. For this reason,  $a_2 > 0$ . A straightforward differentiation gives that

$$V^{*''}(y) = a_2 e^{-k(y)} [(k''(y) - (k'(y))^2)(U(a, b, k(y)) - U'(a, b, k(y))) + (k'(y))^2(U'(a, b, k(y)) - U''(a, b, k(y)))].$$

Trivially for the  $m$ th derivative,  $\text{sgn}(U^{(m)}(a, b, k(y))) = (-1)^m$ , and for all  $y$  sufficiently large,  $(k'(y)^2) > k''(y)$ , and hence  $g''(y) < 0$  for all  $y$  sufficiently large. But then it follows from Lemma A.1(f) that  $V^*$  is concave. If  $c_1 + d_1 > 0$ ,  $a_2$  can be calculated as in Proposition 2.6(b), and we find that  $\bar{\gamma}$  solves

$$(y + c_0)(1 + d_1) - (c_1 + d_1) \frac{g_2(y) - g_2(0)}{g_2'(y)} = (1 - c_1)r,$$

and then

$$a_2 = \left( \frac{1}{1+d_1} - \frac{1}{1-c_1} \right) \frac{1}{g_2'(\bar{\gamma})}.$$

When  $c_1 = d_1 = 0$ , concavity brings us into Proposition 2.6(c), case (ii), and we get

$$V^*(y) = y + \frac{\mu_0}{r} - \frac{c_0}{U(a, b, k(0))} e^{-(k(y)-k(0))} U(a, b, k(y)).$$

Assume now that  $0 < \alpha_1 < r$ . By [13, p. 60], asymptotically as  $y \rightarrow \infty$ ,

$$(3.6) \quad e^{-k(y)} F(a, b, k(y)) \sim \frac{\Gamma(b)}{\Gamma(a)} \left( \frac{r - \alpha_1}{r} \right)^{\frac{r}{2(r-\alpha_1)}} \left( y + \frac{\mu_0}{r - \alpha_1} \right)^{\frac{r}{r-\alpha_1}}.$$

Therefore, Proposition 2.4(c) applies, and an optimal solution exists.

As a byproduct let us comment on a paper by Cadenillas, Sarkar, and Zapatero [2]. In their paper the income process without dividends follows the mean reverting cash reservoir model

$$dX_t = (\alpha(\rho - X_t) - \beta)dt + \sigma dW_t, \quad \alpha, \beta, \rho \geq 0,$$

with costs as in (1.3). Although in the above it was assumed that  $\mu_0 > 0$ , an easy application of Lemma 2.5, as in the proof of Proposition 3.1 below, shows that an optimal solution exists for this problem as well.

When  $\alpha(y)$  has a more complex structure, there will be no analytical solution of  $Lg(y) = 0$ , but a numerical solution can readily be found. This is outlined in Example 3.1, but before attempting to use this procedure it is useful to know if an optimal strategy exists. To this end, the following result may be helpful.

**PROPOSITION 3.1.** *In addition to the assumptions in Theorem 2.3 let  $\alpha(y)$  satisfy (3.2). Furthermore, assume that  $\alpha(y) \geq \alpha_1$  for all  $y \geq 0$ , where  $\alpha_1 > 0$ . Then (2.3) has a solution.*

TABLE 1

Values of  $y^*$ ,  $\gamma^*$ ,  $y^* - \delta^*$  and values of  $V^*(y)$  for various  $y$  as a function of  $c_0$  when  $\sigma^2 = \mu_0 = 1$ ,  $d_0 = 0.1$ ,  $c_1 = d_1 = 0.05$ ,  $r = 0.1$ , and  $\alpha_1 = 0.02$ .

$c_0$	0	0.1	0.5	1	3	5	7.763	10
$y^*$	4.50	5.14	5.63	5.89	6.33	6.54	6.73	6.84
$\gamma^*$	0	0.61	1.06	1.31	1.72	1.92	3.10	2.20
$y^* - \delta^*$	0.47	1.06	1.51	1.75	2.15	2.35	2.52	2.62
$V^*(0)$	8.81	8.52	7.96	7.36	5.13	2.96	0	-2.39
$V^*(0.2)$	9.02	8.80	8.41	8.01	6.55	5.14	3.21	1.67
$V^*(1)$	9.77	9.66	9.54	9.44	9.15	8.90	8.56	8.29
$V^*(5)$	13.50	13.38	13.28	13.23	13.16	13.11	13.08	13.07

*Proof.* Let  $f_1(y)$  and  $f_2(y)$  satisfy  $L_i f_i(y) = 0$  together with  $f_i(0) = f_0$  and  $f'_i(0) = f_1 \geq 0$ , where

$$L_i f(y) = \frac{1}{2} \sigma^2(y) f''(y) + \mu_i(y) f'(y) - r f(y), \quad i = 1, 2,$$

and

$$\mu_1(y) = \mu_1 + (r - \alpha_1)y \quad \text{and} \quad \mu_2(y) = \mu + (r - \alpha(y))y,$$

where  $\mu_1$  is chosen large enough so that  $\mu_1(y) > \mu_2(y)$  for all  $y \geq 0$ . By Lemma 2.5,  $f_1(y) < f_2(y)$  for all  $y \geq 0$ , and by (3.6) asymptotically,

$$f_1(y) \sim C \left( y + \frac{\mu_1}{r - \alpha_1} \right)^{\frac{r}{r - \alpha_1}}$$

for some  $C > 0$ . Therefore, a solution of (2.3) exists by Proposition 2.4(c).  $\square$

*Example 3.1.* In this example,  $Y$  is given by (3.4) with  $\mu_0 = 1$ ,  $\sigma = 1$ ,  $c_1 = 0.05$ ,  $d_0 = 0.1$ ,  $d_1 = 0.05$ ,  $r = 0.1$ , and  $\alpha_1 = 0.02$ . Two independent solutions  $g_1$  and  $g_2$  with  $g_1(0) = 0$ ,  $g'_1(0) = 1$  and  $g_2(0) = 1$ ,  $g'_2(0) = 0$  were found using the Runge–Kutta method with stepsize  $h = 0.01$  and linear interpolation between the grid points. The function `fsolve` in MATLAB was used to solve (2.3) and this worked well, provided the initial values were not too far away from the true values. Some results are given in Table 1 for varying  $c_0$ . With  $c_0 = 7.763$ ,  $V^*(0) = 0$ , and then  $V^*(y) = V_0^*(y)$  due to uniqueness. Here  $V_0^*$  is the value function when there is absorption at zero; see (1.3). Hence  $c_0 = 7.763$  is the break-even point, where the owners are indifferent to investing new money or letting the company go bankrupt.

One notable observation from Table 1 is that  $V^*(5)$  decreases very little in  $c_0$ ; the reason for this must be that the probability of hitting zero when restarting at  $\eta^* = y^* - \delta^*$  must decrease rather rapidly with  $\eta^*$ .

The limiting case  $c_0 = 0$  is actually not covered here, but since this means that there is no lump sum cost at 0, the optimal policy at 0 is singular, and hence  $\gamma^* = 0$  in this case. In fact, the values when  $c_0 = 0$  were obtained by solving and

$$V'(0) = \frac{1}{1 - c_1}, \quad V(y^*) - V(y^* - \delta^*) = \frac{\delta^* - d_0}{1 + d_1}, \quad \text{and} \quad V'(y^* - \delta^*) = V'(y^*) = \frac{1}{1 + d_1}.$$

Table 2 is similar to Table 1, but with the difference that in Table 2  $d_0$  varies while  $c_0 = 0.1$  is fixed. Comparing the two tables, we see that the effects of varying  $c_0$  and  $d_0$  are very different. For example,  $V^*(0)$  is most sensitive to a decrease in  $c_0$ ,

TABLE 2

Values of  $y^*$ ,  $\gamma^*$ ,  $y^* - \delta^*$  and values of  $V^*(y)$  for various  $y$  as a function of  $d_0$  when  $\sigma^2 = \mu_0 = 1$ ,  $c_0 = 0.1$ ,  $c_1 = d_1 = 0.05$ ,  $r = 0.1$ , and  $\alpha_1 = 0.02$ .

$d_0$	0	0.1	0.5	1	3	5	10	20
$y^*$	1.94	5.14	10.22	14.83	29.28	41.80	70.53	124.46
$\gamma^*$	0.67	0.61	0.54	0.50	0.45	0.43	0.40	0.38
$y^* - \delta^*$	1.94	1.06	0.83	0.73	0.61	0.57	0.52	0.48
$V^*(0)$	8.95	8.52	7.93	7.53	6.67	6.19	5.48	4.73
$V^*(0.2)$	9.22	8.80	8.21	7.81	6.96	6.48	5.77	5.02
$V^*(1)$	10.10	9.66	9.05	8.64	7.75	7.26	6.51	5.74
$V^*(5)$	13.92	13.38	12.55	11.98	10.76	10.08	9.06	8.99

TABLE 3

Values of  $y^*$ ,  $\gamma^*$ ,  $y^* - \delta^*$  and values of  $V^*(y)$  for various  $y$  as a function of  $c_0 = d_0$  when  $\sigma^2 = \mu_0 = 1$ ,  $c_1 = d_1 = 0.05$ ,  $r = 0.1$ , and  $\alpha_1 = 0.02$ .

$c_0 = d_0$	0	0.1	0.5	1	3	5	5.416	10
$y^*$	1.30	5.14	10.75	15.68	30.84	43.80	46.71	73.28
$\gamma^*$	0	0.61	0.97	1.15	1.45	1.60	1.62	1.80
$y^* - \delta^*$	1.30	1.06	1.25	1.37	1.60	1.73	1.75	1.91
$V^*(0)$	9.24	8.52	7.37	6.35	3.22	0.53	0	-5.61
$V^*(0.2)$	9.45	8.80	7.83	7.03	4.70	2.80	2.43	-1.42
$V^*(1)$	10.22	9.66	8.95	8.45	7.32	6.59	6.46	5.28
$V^*(5)$	14.04	13.38	12.47	11.88	10.66	10.00	9.88	8.99

while the opposite is the case with  $V^*(5)$ . Here the case with  $d_0 = 0$  gives singular control at  $y^*$ , and the values when  $d_0 = 0$  were found by solving

$$V(\gamma^*) - V(0) = \frac{\gamma^* + c_0}{1 - c_0}, \quad V'(\gamma^*) = \frac{1}{1 - c_1}, \quad V'(y^*) = \frac{1}{1 + d_1}, \quad \text{and} \quad V''(y^*) = 0.$$

In Table 3 we let  $c_0 = d_0$  increase, while the other parameters are as before. Comparing with Tables 1 and 2, we see that for small  $y$  the values of  $V^*(y)$  are much like those in Table 1, while for large  $y$  they are more like those in Table 2. This is not unreasonable; for small  $y$  there is a big chance that the process will hit zero, and so an investment has to be made, while for big  $y$  the main cost is with dividend payments. When  $c_0 = d_0 = 0$  the control is singular, and this case is found by solving

$$V^*(0) = \frac{1}{1 - c_1}, \quad V'(y^*) = \frac{1}{1 + d_1}, \quad \text{and} \quad V''(y^*) = 0.$$

**Appendix. Proof of results in section 2.** The following result will be useful throughout.

LEMMA A.1. *Let  $\mu$  and  $\sigma$  satisfy A2–A4 and let  $f$  be a solution of  $Lf(y) = 0$ . On the interval  $[0, \infty)$ , the following hold:*

- (a) *If  $f$  has a zero, then  $f'$  has no zero.*
- (b) *If  $f'(\tilde{y}) = 0$  for some  $\tilde{y}$ , then  $(y - \tilde{y})f(y)f'(y) > 0$  for  $y \neq \tilde{y}$ .*
- (c) *If for some  $\tilde{y}$ ,  $f'(\tilde{y}) > 0$  and  $f''(\tilde{y}) \leq 0$ , then  $f$  is a concave function on  $[0, \tilde{y}]$ .*
- (d) *If  $f'$  has a zero, then  $f''$  has no zero.*
- (e) *If  $f''(\tilde{y}) = 0$  for some  $\tilde{y}$ , then  $(y - \tilde{y})f'(y)f''(y) > 0$  for  $y \neq \tilde{y}$ .*
- (f) *Assume that for some  $\tilde{y}$ ,  $f'(\tilde{y}) > 0$ . Then there are three possibilities as follows:*
  - (i)  *$f'$  is positive for all  $y$  and there is a  $y_c \in [0, \infty]$  so that  $f$  is concave on  $[0, y_c)$  (if  $y_c > 0$ ) and convex on  $(y_c, \infty)$  (if  $y_c < \infty$ ).*

- (ii)  $f$  is negative and concave for all  $y$  and there is a  $y_m \in [0, \infty)$  so that  $f'(y) > 0$  on  $(0, y_m)$  and  $f'(y) < 0$  on  $(y_m, \infty)$ .
- (iii)  $f$  is positive and convex for all  $y$  and there is a  $y_m \in [0, \infty)$  so that  $f'(y) < 0$  on  $(0, y_m)$  and  $f'(y) > 0$  on  $(y_m, \infty)$ .

*Proof.* Parts (a)–(c) are from [12, Lemma 4.2]. They consider bounded intervals, but there is no difference if we use the interval  $[0, \infty)$ . In the proof of their Lemma 4.2, Shreve, Lehoczky, and Gaver show that  $L_1 f' = 0$ , where the operator  $L_1$  satisfies the conditions for (a) and (b). Parts (d) and (e) are therefore (a) and (b) used on  $f'$  instead on  $f$ .

Now to (f). If  $f'$  is positive for all  $y$ , let  $y_c = \sup\{y : f''(y) \leq 0\}$ . Then  $f$  is concave on  $(0, y_c)$  and convex on  $(y_c, \infty)$  by (c). In particular if  $f(y_0) = 0$  for some  $y_0$ , then  $f'$  is positive by (a). For case (ii) assume that  $f$  is negative for all  $y$  and that  $f'(y_0) = 0$  for some  $y_0$ . By (b),  $(y - y_0)f'(y) < 0$  for  $y \neq y_0$ , and hence  $f'(y) > 0$  on  $(0, y_0)$  and  $f'(y) < 0$  on  $(y_0, \infty)$ . By (d),  $f''$  has no zero, and hence  $f''$  must be negative by what was just proved, i.e.,  $f$  is concave. Case (iii) follows from (ii) applied on  $-f$ .  $\square$

LEMMA A.2. Assume A2 and A3 and let  $g_1$  and  $g_2$  be two independent solutions of  $Lg = 0$  so that  $g'_2(y) \neq 0$  on  $[0, \bar{y}]$ . Let

$$v(y) = g'_1(y)g''_2(y) - g''_1(y)g'_2(y)$$

and

$$U(x, y) = g'_1(x)g'_2(y) - g'_1(y)g'_2(x).$$

Then

- (a)  $v(y) \neq 0$  on  $[0, \bar{y}]$ .
- (b)  $U(x, x) = 0$  on  $[0, \bar{y}]$  and  $U(x, y) \neq 0$  on  $0 \leq x < y \leq \bar{y}$ .

*Proof.* For (a), assume that  $v(y_0) = 0$  so that

$$\frac{g''_1(y_0)}{g'_1(y_0)} = \frac{g''_2(y_0)}{g'_2(y_0)}.$$

Multiplying both sides by  $\frac{1}{2}\sigma^2(y_0)$  and using that  $Lg_i = 0$  gives that this is equivalent to

$$\frac{g_1(y_0)}{g'_1(y_0)} = \frac{g_2(y_0)}{g'_2(y_0)},$$

or equivalently, that the Wronskian

$$W(g_1, g_2)(y_0) = g_1(y_0)g'_2(y_0) - g_2(y_0)g'_1(y_0) = 0.$$

But it is well known that the Wronskian of two independent solutions never vanishes, and hence we have arrived at a contradiction.

For (b), note that  $U(x_0, y_0) = 0$  is equivalent to  $h(x_0) = h(y_0)$ , where

$$h(x) = \frac{g'_1(x)}{g'_2(x)}.$$

But to obtain this result, we must have that  $h'(z) = 0$  for some  $z \in (x_0, y_0)$ . But

$$h'(z) = \frac{v(z)}{(g'_2(z))^2},$$

and this never vanishes according to (a). This proves the result.  $\square$

LEMMA A.3. Assume A2–A4 and let  $\bar{y} > 0$  be given. Then there exists two independent solutions  $g_1$  and  $g_2$  of  $Lg = 0$  so that

(i)  $g_1(0) = g_1(\bar{y}) = 1$ ,  $g'_1(0) < 0$ ,  $g'_1(\bar{y}) > 0$ , and  $g''_1(y) > 0$  on  $[0, \bar{y}]$ . Also  $g(y) > 0$  on  $[0, \bar{y}]$ .

(ii)  $g_2(0) = 1$ ,  $g'_2(0) = 0$ ,  $g'_2(y) > 0$  on  $(0, \bar{y}]$ , and  $g''_2(y) > 0$  on  $[0, \bar{y}]$ .

*Proof.* Clearly  $g_2$  is defined by the initial conditions, and by Lemma A.1(b),  $yg_2(y)g'_2(y) > 0$  for  $y > 0$ ; hence  $g'_2(y) > 0$  for  $y \in (0, \varepsilon)$  for some  $\varepsilon > 0$ . But by Lemma A.1(d),  $g''_2(y) \neq 0$ , and since  $g'_2(y) > g'_2(0)$  on  $(0, \varepsilon)$ , it follows that  $g''_2(y) > 0$ . But then  $g'_2(y) > 0$  for  $y > 0$  as well.

Next define  $g_0$  by  $Lg_0 = 0$ ,  $g_0(0) = 0$ , and  $g'_0(0) = 1$ , which implies by Lemma A.1(a) that  $g'_0(y) > 0$  for all  $y \geq 0$ . Let

$$g_1(y) = \frac{1 - g_2(\bar{y})}{g_0(\bar{y})}g_0(y) + g_2(y).$$

Clearly  $g_1(0) = g_1(\bar{y}) = 1$ . Also  $g'_1(0) = (1 - g_2(\bar{y}))/g_0(\bar{y}) < 0$ . There must exist a  $y_0 \in (0, \bar{y})$  so that  $g'_0(y_0) = 0$ , but this implies by Lemma A.1(d) that  $g''_0(y) \neq 0$ . Since  $g'_1(0) < 0$  it is necessary that  $g'_1(y) > 0$ . Finally, let  $\tau_0^y$  be the first time the process  $Y$ , subject to no control, hits the value 0 when  $Y_0 = y$ , and similarly let  $\tau_{\bar{y}}^y$  be the first time it hits  $\bar{y}$ . Also let  $T_{\bar{y}}^y = \min\{\tau_0^y, \tau_{\bar{y}}^y\}$ . By standard results in diffusion theory (see, e.g., [6, Chapter 15.3]),

$$g_1(y) = E^y \left[ e^{-rT_{\bar{y}}^y} \right],$$

and hence  $g_1(y) > 0$  on  $[0, \bar{y}]$ .  $\square$

LEMMA A.4. There exists a solution to the variational problem (2.2) with  $0 < \bar{\gamma} \leq \bar{y} - \bar{\delta} < \bar{y}$ .

*Proof.* Throughout the proof,  $g_1$  and  $g_2$  are as in Lemma A.3 so that a general solution to  $LV = 0$  is

$$V(y) = a_1g_1(y) + a_2g_2(y).$$

Assume first that  $c_1 + d_1 > 0$ . In order to satisfy  $V'(\gamma) = (1 - c_1)^{-1}$  and  $V'(\eta) = (1 + d_1)^{-1}$  (with  $\eta = \bar{y} - \delta$ ), a straightforward computation shows that

$$(A.1) \quad \begin{aligned} a_1 &= a_1(\gamma, \eta) = \frac{1}{U(\gamma, \eta)} \left( \frac{g'_2(\eta)}{1 - c_1} - \frac{g'_2(\gamma)}{1 + d_1} \right), \\ a_2 &= a_2(\gamma, \eta) = -\frac{1}{U(\gamma, \eta)} \left( \frac{g'_1(\eta)}{1 - c_1} - \frac{g'_1(\gamma)}{1 + d_1} \right), \end{aligned}$$

where  $U(\gamma, \eta) = g'_1(\gamma)g'_2(\eta) - g'_1(\eta)g'_2(\gamma)$ . Since  $U(0, \eta) = g'_1(0)g'_2(\eta) < 0$ , it follows by Lemma A.3(b) that  $U(\gamma, \eta) < 0$  when  $0 \leq \gamma < \eta \leq \bar{y}$ . Also, since both  $g_1$  and  $g_2$  are convex,  $a_1(\gamma, \eta) < 0$  and  $a_2(\gamma, \eta) > 0$ . Furthermore,  $a_1(\gamma, \eta) \rightarrow -\infty$  and  $a_2(\gamma, \eta) \rightarrow \infty$  as  $\eta - \gamma \rightarrow 0$ .

We will now prove that with  $a_1$  and  $a_2$  as in (A.1), the equation  $\alpha_\eta(\gamma) = 0$ , where

$$\begin{aligned} \alpha_\eta(\gamma) &= V(\gamma) - V(0) - \frac{\gamma + c_0}{1 - c_1} \\ &= a_1(\gamma, \eta)(g_1(\gamma) - 1) + a_2(\gamma, \eta)(g_2(\gamma) - 1) - \frac{\gamma + c_0}{1 - c_1}, \end{aligned}$$

has a solution  $\gamma < \eta$  for any  $\eta \in (0, \bar{y}]$ , and similarly that the equation  $\beta_\gamma(\eta) = 0$  with

$$\begin{aligned}\beta_\gamma(\eta) &= V(\bar{y}) - V(\eta) - \frac{\bar{y} - \eta - d_0}{1 + d_1} \\ &= a_1(\gamma, \eta)(g_1(\bar{y}) - g_1(\eta)) + a_2(\gamma, \eta)(g_2(\bar{y}) - g_2(\eta)) - \frac{\bar{y} - \eta - d_0}{1 + d_1}\end{aligned}$$

has a solution  $\eta > \gamma$  for any  $\gamma \in [0, \bar{y})$ . Making two simple graphs then shows that there is a point  $(\bar{\gamma}, \bar{\eta})$  so that  $\alpha_{\bar{\eta}}(\bar{\gamma}) = \beta_{\bar{\gamma}}(\bar{\eta}) = 0$ , and so existence is established.

To prove that  $\alpha_\eta(\gamma) = 0$  has a solution for some  $\gamma < \eta$ , note first that  $\alpha_\eta(0) = -c_0/(1 - c_1)$ . Furthermore, by the above asymptotic properties of  $a_i(\gamma, \eta)$ ,  $i = 1, 2$ ,  $\alpha_\eta(\gamma) \rightarrow \infty$  as  $\gamma \rightarrow \eta$ , and hence  $\alpha_\eta(\gamma) = 0$  has a solution.

The proof that  $\beta_\gamma(\eta) = 0$  for some  $\eta > \gamma$  is a bit trickier. Since  $\beta_\gamma(\bar{y}) = d_0/(1 + d_1)$ , it is sufficient to prove that  $\beta_\gamma(\eta) \rightarrow -\infty$  as  $\eta \rightarrow \gamma$ . Write

$$\beta_\gamma(\eta) = \frac{1}{U(\gamma, \eta)} k_\gamma(\eta) - \frac{\bar{y} - \eta - d_0}{1 + d_1},$$

where

$$k_\gamma(\eta) = \left( \frac{g'_2(\eta)}{1 - c_1} - \frac{g'_2(\gamma)}{1 + d_1} \right) (1 - g_1(\eta)) - \left( \frac{g'_1(\eta)}{1 - c_1} - \frac{g'_1(\gamma)}{1 + d_1} \right) (\bar{g}_2 - g_2(\eta))$$

and  $\bar{g}_2 = g_2(\bar{y})$ . Since  $1/U(\gamma, \eta) \rightarrow -\infty$  as  $\eta \rightarrow \gamma$ , it is sufficient to prove that  $k_\gamma(\gamma) > 0$ , or equivalently, since  $(1 - c_1)^{-1} - (1 + d_1)^{-1} > 0$ , that

$$(A.2) \quad h(\gamma) = g'_2(\gamma)(1 - g_1(\gamma)) - g'_1(\gamma)(\bar{g}_2 - g_2(\gamma)) > 0, \quad \gamma \in [0, \bar{y}).$$

Now  $h(0) = -g'_1(0)(\bar{g}_2 - 1) > 0$  and  $h(\bar{y}) = 0$ . Furthermore,

$$(A.3) \quad h'(\gamma) = g''_2(\gamma)(1 - g_1(\gamma)) - g''_1(\gamma)(\bar{g}_2 - g_2(\gamma))$$

so that  $h'(\bar{y}) = 0$ . But a Taylor expansion of  $g_i(\gamma)$  around  $\bar{y}$  and then of  $g'_i(\bar{y})$  around  $\gamma$  gives

$$h'(\gamma) = (\bar{y} - \gamma)v(\gamma) + o(\bar{y} - \gamma),$$

where  $v$  is as in Lemma A.2. Since  $v(0) = g''_2(0)g'_1(0) < 0$ , it follows from Lemma A.2(a) that  $v(y) < 0$  for  $y \in [0, \bar{y}]$ , and therefore  $h(y) > 0$  for  $y \in (\bar{y} - \varepsilon, \bar{y})$  for some  $\varepsilon > 0$ . As a consequence, if  $h(\gamma) = 0$  has a root in  $[0, \bar{y})$ , there will necessarily be at least two roots, and at two of these roots  $h'$  will have opposite signs. But  $h(\gamma) = 0$  implies that

$$\bar{g}_2 - g_2(\gamma) = \frac{g'_2(\gamma)}{g'_1(\gamma)}(1 - g_1(\gamma)),$$

so that in particular  $g'_1(\gamma) > 0$ , and furthermore using (A.3),

$$h'(\gamma) = \frac{1 - g_1(\gamma)}{g'_1(\gamma)} v(\gamma) < 0,$$

which is a contradiction. Hence (A.2) holds and this ends the proof for the case with  $c_1 + d_1 > 0$ .

Assume now that  $c_1 + d_1 = 0$ , which clearly implies that  $\bar{\gamma} = \bar{\eta}$ ; hence we must prove the existence of

$$(A.4) \quad V'(\gamma) = a_1 g_1'(\gamma) + a_2 g_2'(\gamma) = 1$$

as well as of

$$(A.5) \quad V(\gamma) - V(0) = a_1(g_1(\gamma) - 1) + a_2(g_2(\gamma) - 1) = \gamma + c_0$$

and

$$(A.6) \quad V(\bar{y}) - V(\gamma) = a_1(1 - g_1(\gamma)) + a_2(\bar{g}_2 - g_2(\gamma)) = \bar{y} - \gamma - d_0.$$

Here  $g_1$  and  $g_2$  are again as in Lemma A.3. Adding (A.5) and (A.6) gives

$$(A.7) \quad a_2 = \frac{\bar{y} + c_0 - d_0}{\bar{g}_2 - 1}.$$

It remains to prove that there is an  $a_1$  and a  $\gamma$  so that (A.4) and (A.5) are satisfied with  $a_2$  given by (A.7).

By the properties of  $g_1$ , there is a unique  $\gamma_0 \in (0, \bar{y})$  so that  $g_1'(\gamma_0) = 0$ . If  $a_2 g_2'(\gamma_0) = 1$ ,  $a_1$  can be chosen so that (A.5) is satisfied at the point  $\gamma_0$ , and we have a solution. If  $a_2 g_2'(\gamma_0) \neq 1$ , then by (A.4),

$$a_1 = a_1(\gamma) = \frac{1 - a_2 g_2'(\gamma)}{g_1'(\gamma)},$$

and inserting this into (A.5) gives the problem  $h(\gamma) = 0$ , where

$$h(\gamma) = \frac{g_1(\gamma) - 1}{g_1'(\gamma)} + a_2 \left( g_2(\gamma) - 1 - \frac{g_2'(\gamma)}{g_1'(\gamma)} (g_2(\gamma) - 1) \right) - \gamma - c_0.$$

It is easy to see that  $h(0) = -c_0$  and that  $h(\bar{y}) = -d_0$ . But  $h(\gamma) \rightarrow \infty$  as  $\gamma$  approaches  $\gamma_0$  from one side, while  $h(\gamma) \rightarrow -\infty$  as  $\gamma$  approaches  $\gamma_0$  from the other side. Therefore  $h(\gamma) = 0$  must have a solution, and we are done.  $\square$

LEMMA A.5. *The variational problem (2.2) has a unique solution with  $0 < \bar{\gamma} \leq \bar{y} - \bar{\delta} < \bar{y}$ .*

*Proof.* It remains only to prove uniqueness since existence was proved in Lemma A.4. We content ourselves with the case  $c_1 + d_1 > 0$ , since the case  $c_1 + d_1 = 0$  is easier. Assume there are two different sets of solutions  $V_i, \bar{\gamma}_i, \bar{\delta}_i$ ,  $i = 1, 2$ , and let  $\eta_i = \bar{y} - \bar{\delta}_i$ . For ease of notation, we replace  $\bar{\gamma}_i$  and  $\bar{\eta}_i$  by  $\gamma_i$  and  $\eta_i$ . Let  $V_0(y) = V_2(y) - V_1(y)$ , and assume without loss of generality that  $V_0(0) \geq 0$ .

Assume that  $V_0'(y) > 0$  for  $y \in (0, \bar{y})$ . The fact that  $V_1'(\gamma_1) = V_2'(\gamma_2)$  implies that  $\gamma_1 < \gamma_2$ . But then

$$\begin{aligned} \frac{c_0}{1 - c_1} &= \int_0^{\gamma_1} (V_1'(y) - (1 - c_1)^{-1}) dy \\ &< \int_0^{\gamma_1} (V_2'(y) - (1 - c_1)^{-1}) dy \\ &< \int_0^{\gamma_2} (V_2'(y) - (1 - c_1)^{-1}) dy = \frac{c_0}{1 - c_1}, \end{aligned}$$

which is a contradiction. The same argument can be used if  $V'_0(y) < 0$  for  $y \in (0, \bar{y})$ . So by Lemma A.1(a) we can conclude that  $V_0(y) > 0$  for  $y \in [0, \bar{y}]$  and that  $V'_0(y_0) = 0$  for some  $y_0 \in (0, \bar{y})$ . By Lemma A.1(b),

$$(A.8) \quad \begin{aligned} V'_2(y) &< V'_1(y), & y \in (0, y_0), \\ V'_2(y) &> V'_1(y), & y \in (y_0, \bar{y}). \end{aligned}$$

Assume now that  $\gamma_2 \leq y_0$ , which implies that  $\gamma_1 > \gamma_2$  by (A.8). Then

$$\begin{aligned} \frac{c_0}{1-c_1} &= \int_0^{\gamma_1} (V'_1(y) - (1-c_1)^{-1}) dy \\ &> \int_0^{\gamma_2} (V'_1(y) - (1-c_1)^{-1}) dy \\ &> \int_0^{\gamma_2} (V'_2(y) - (1-c_1)^{-1}) dy = \frac{c_0}{1-c_1}, \end{aligned}$$

which is a contradiction. Hence we must have that

$$(A.9) \quad y_0 < \gamma_1 < \gamma_2.$$

By (A.9),  $\eta_i > y_0$ , and hence by (A.8),

$$(A.10) \quad y_0 < \eta_1 < \eta_2.$$

But this gives

$$\begin{aligned} -\frac{d_0}{1+d_1} &= \int_{\eta_2}^{\bar{y}} (V'_2(y) - (1+d_1)^{-1}) dy \\ &> \int_{\eta_2}^{\bar{y}} (V'_1(y) - (1+d_1)^{-1}) dy \\ &> \int_{\eta_1}^{\bar{y}} (V'_1(y) - (1+d_1)^{-1}) dy = -\frac{d_0}{1+d_1}, \end{aligned}$$

which is a contradiction. In the last inequality we used that

$$\max_{y \in [\eta_1, \eta_2]} V'_1(y) = \max\{V'_1(\eta_1), V'_1(\eta_2)\} \leq \max\{V'_1(\eta_1), V'_2(\eta_2)\} = (1+d_1)^{-1}.$$

We have thus arrived at a contradiction, and so there must be uniqueness.  $\square$

LEMMA A.6. Assume that (2.2) holds. Then

$$V(y) - V(0) \leq \frac{y + c_0}{1 - c_1},$$

with equality if and only if  $y = \bar{\gamma}$ . Furthermore

$$V(\bar{y}) - V(y) \geq \frac{\bar{y} - y - d_0}{1 + d_1},$$

with equality if and only if  $y = \bar{y} - \bar{\delta}$ .

*Proof.* For simplicity we write  $\gamma = \bar{\gamma}$  and  $\delta = \bar{\delta}$ . Also set  $\eta = \bar{y} - \bar{\delta}$ . Now from  $V'(\eta) = (1 + d_1)^{-1}$  and

$$V(\bar{y}) - V(\eta) - \frac{\bar{y} - \eta}{1 + d_1} = \int_{\eta}^{\bar{y}} (V'(x) - (1 + d_1)^{-1}) dx = -\frac{d_0}{1 + d_1},$$

it follows that  $V'(y_0) < V'(\eta)$  for some  $y_0 > \eta$ , and hence  $V''(y_1) < 0$  for some  $y_1 > \eta$ . Therefore, by Lemma A.1(f), either  $V$  is concave on  $[0, \bar{y}]$  or there is a  $y_c$  with  $\eta < y_c < \bar{y}$  so that  $V$  is concave on  $[0, y_c)$  and convex on  $(y_c, \bar{y}]$ .

Now define

$$h(y) = V(y) - V(0) - \frac{y}{1 - c_1} = \int_0^y (V'(x) - (1 - c_1)^{-1}) dx.$$

Then  $h(0) = 0$ ,  $h(\gamma) = c_0/(1 - c_1)$ , and  $h'(\gamma) = 0$ . If  $V$  is concave on  $[0, \bar{y}]$ ,  $h$  will be increasing on  $[0, \gamma)$  and decreasing on  $(\gamma, \bar{y}]$ , and so  $h$  takes its maximum at  $\gamma$ . If  $y_c < \bar{y}$ , where  $y_c$  is as above, then since  $y_c > \eta$ ,  $h(\eta) \leq h(\gamma)$ , and so  $h(\bar{y}) - h(\eta) < 0$  will again imply that  $h$  takes its maximum at  $\gamma$ . But

$$h(\bar{y}) - h(\eta) = \frac{\bar{y} - \eta - d_0}{1 + d_1} - \frac{\bar{y} - \eta}{1 - c_1} < 0.$$

This gives the first part. The second part is proved similarly by defining

$$h(y) = V(\bar{y}) - V(y) - \frac{\bar{y} - y}{1 + d_1} = \int_y^{\bar{y}} (V'(x) - (1 + d_1)^{-1}) dx$$

and proceeding as above to prove that  $h$  takes a minimum at  $\eta$  with  $h(\eta) = -d_0/(1 + d_1)$ .  $\square$

*Proof of Proposition 2.2.* Using Lemmas A.5 and A.6, the proof follows along the same lines as the proof of Theorem 2.3(a), but is simpler. We therefore omit the details.  $\square$

With this result we can continue to the proof of Theorem 2.3, but first we give some lemmas.

LEMMA A.7. Assume that (2.3) has a solution. Then

- (a)  $LV(y) \leq 0$  for all  $y > 0$ .
- (b)  $\frac{y-x-d_0}{1+d_1} \leq V(y) - V(x) \leq \frac{y-x+c_0}{1-c_1}$ ,  $0 \leq x \leq y$ . There is left equality when  $y \geq y^*$ ,  $x = \delta^*$ , and right equality when  $y = \gamma^*$  and  $x = 0$ .
- (c)  $y^*$ ,  $\gamma^*$ ,  $\delta^*$ , and  $V$  are uniquely given.

*Proof.* Note first that since  $V'(y^*) = V'(y^* - \delta^*)$ , this is necessarily case (i) of Lemma A.1(f), with  $y^* - \delta^* < y_c < y^*$ . Therefore  $V''(y^* -) \geq 0$ , and so by continuity,

$$rV(y^*) = \frac{1}{2}\sigma^2(y^*)V''(y^* -) + \mu(y^*)V'(y^*) \geq \mu(y^*)(1 + d_1)^{-1}.$$

Using this inequality, we get for  $y > y^*$ ,

$$\begin{aligned} LV(y) &= \frac{\mu(y)}{1 + d_1} - r \left( V(y^*) + \frac{y - y^*}{1 + d_1} \right) \\ &= (1 + d_1)^{-1} (\mu(y) - \mu(y^*) - r(y - y^*)) + \mu(y^*)(1 + d_1)^{-1} - rV(y^*) \\ &\leq (1 + d_1)^{-1} \int_{y^*}^y (\mu'(x) - r) dx \leq 0. \end{aligned}$$

To prove (b), set  $\eta^* = y^* - \delta^*$ . From the observation at the beginning of the proof,  $V'(y) \geq (1 + d_1)^{-1}$  on  $(0, \eta^*)$  and  $V'(y) \leq (1 + d_1)^{-1}$  on  $(\eta^*, \infty)$ . Therefore

$$V(y) - V(x) - \frac{y - x}{1 + d_1} = \int_x^y (V'(u) - (1 + d_1)^{-1}) du$$

is smallest for  $x = \eta^*$  and  $y \geq y^*$ , and then it equals  $-d_0/(1 + d_1)$ . This gives the first inequality. For the second inequality, note that  $V'(y) \geq (1 - c_1)^{-1}$  on  $(0, \gamma^*)$  and  $V'(y) \leq (1 - c_1)^{-1}$  on  $(\gamma^*, \infty)$ . Therefore,

$$V(y) - V(x) - \frac{y - x}{1 - c_1} = \int_x^y (V'(u) - (1 - c_1)^{-1}) du$$

takes its maximum at  $x = 0$  and  $y = \gamma^*$ , and the maximum value is  $c_0/(1 - c_1)^{-1}$ .

For (c), let  $V_i, \gamma_i^*, \delta_i^*, y_i^*$ ,  $i = 1, 2$ , be two sets of solutions. Let  $V_0(y) = V_2(y) - V_1(y)$  and assume that  $V_0(0) \geq 0$ . The same arguments as in the proof of uniqueness in Lemma A.5 still hold up to and including (A.10). Furthermore, by (A.8) and the fact that  $V_1'(y_1^*) = V_2'(y_2^*)$ , it is necessary that  $y_2^* < y_1^*$ . This, together with (A.8) and (A.10), gives with  $\eta_i^* = y_i^* - \delta_i^*$ ,

$$\begin{aligned} -\frac{d_0}{1 + d_1} &= \int_{\eta_2^*}^{y_2^*} (V_2'(y) - (1 + d_1)^{-1}) dy \\ &> \int_{\eta_2^*}^{y_2^*} (V_1'(y) - (1 + d_1)^{-1}) dy \\ &> \int_{\eta_1^*}^{y_1^*} (V_1'(y) - (1 + d_1)^{-1}) dy = -\frac{d_0}{1 + d_1}, \end{aligned}$$

which is a contradiction. Hence uniqueness follows.  $\square$

LEMMA A.8. Assume that (2.3) has no solution. Denote a solution of (2.2) for given  $\bar{y}$  by  $V_{\bar{y}}(y)$ . Then  $V_{\bar{y}}'(\bar{y}-) < (1 + d_1)^{-1}$  for all  $\bar{y} > 0$ .

*Proof.* We denote  $\gamma = \bar{\gamma}$ ,  $\delta = \bar{\delta}$ , and  $\eta = \bar{y} - \bar{\delta}$ , and when there is no misunderstanding, sometimes we also write  $V$  for  $V_{\bar{y}}$ .

Let  $\bar{y} < d_0$ , giving  $V(\bar{y}) - V(\eta) = (\delta - d_0)/(1 + d_1) < 0$ . Therefore we have case (ii) of Lemma A.1(f), implying that  $V'(\bar{y}-) < 0$ . If we can prove that  $V_{\bar{y}}'(\bar{y}-)$  as a function of  $\bar{y}$  is continuous, then necessarily  $V_{\bar{y}}'(\bar{y}-) < (1 + d_1)^{-1}$  for all  $\bar{y} > 0$  since otherwise  $V_{\bar{y}_0}'(\bar{y}_0-) = (1 + d_1)^{-1}$  for some  $\bar{y}_0$ , in which case (2.3) would hold with  $y^* = \bar{y}_0$ .

To this end let  $g_1$  and  $g_2$  be two linearly independent solutions of  $Lg = 0$  with  $g_1(0) = 0$  and  $g_2(0) = 1$ . Also let the constants  $a_1$  and  $a_2$  be such that  $V_{\bar{y}}(y) = a_1 g_1(y) + a_2 g_2(y)$ ,  $y \leq \bar{y}$ . The second through the fifth equations of (2.2) then become

$$\begin{aligned} a_1 g_1(\gamma) + a_2 g_2(\gamma) - \frac{\gamma + c_0}{1 - c_1} &= 0, \\ a_1 g_1'(\gamma) + a_2 g_2'(\gamma) - \frac{1}{1 - c_1} &= 0, \\ a_1 (g_1(\bar{y}) - g_1(\eta)) + a_2 (g_2(\bar{y}) - g_2(\eta)) - \frac{\bar{y} - \eta - d_0}{1 + d_1} &= 0, \\ a_1 g_1'(\eta) + a_2 g_2'(\eta) - \frac{1}{1 + d_1} &= 0. \end{aligned}$$

This can be written as  $\mathbf{h}(\mathbf{x}, \bar{y}) = \mathbf{0}$  with  $\mathbf{x} = (a_1, a_2, \gamma, \eta)$ . Using these equations, the

Jacobian  $J = \frac{\partial \mathbf{h}}{\partial \mathbf{x}}$  becomes

$$J = \begin{bmatrix} g_1(\gamma) & g_2(\gamma) - 1 & 0 & 0 \\ g'_1(\gamma) & g'_2(\gamma) & V''(\gamma) & 0 \\ g_1(\bar{y}) - g_1(\eta) & g_2(\bar{y}) - g_2(\eta) & 0 & 0 \\ g'_1(\eta) & g'_2(\eta) & 0 & V''(\eta) \end{bmatrix}.$$

We will prove that the determinant  $|J| \neq 0$ . If  $V''(\eta) = 0$ , by Lemma A.1(f),  $V$  would be convex on  $[\eta, \bar{y}]$ , but then  $V(\bar{y}) - V(\eta) > (\bar{y} - \eta - d_0)/(1 + d_1)$ , which is a contradiction. Hence  $V''(\eta) < 0$  and then  $V''(\gamma) < 0$  as well. Therefore, for  $|J|$  to be zero, it is necessary that for nonzero constants  $b$  and  $c$ ,

$$\begin{aligned} bg_1(\gamma) + c(g_2(\gamma) - 1) &= 0, \\ b(g_1(\bar{y}) - g_1(\eta)) + c(g_2(\bar{y}) - g_2(\eta)) &= 0. \end{aligned}$$

Letting  $\tilde{V} = bg_1(y) + cg_2(y)$ , this gives

$$(A.11) \quad \tilde{V}(\gamma) = \tilde{V}(0) \quad \text{and} \quad \tilde{V}(\bar{y}) = \tilde{V}(\eta).$$

It follows that  $\tilde{V}$  must satisfy Lemma A.1(f), but according to this, (A.11) is impossible, and therefore  $|J| \neq 0$ . By the implicit function theorem,  $a_1 = a_1(\bar{y})$  and  $a_2 = a_2(\bar{y})$  are continuous functions of  $\bar{y}$ , and then so is  $V'_{\bar{y}}(\bar{y}-) = a_1(\bar{y})g'_1(\bar{y}) + a_2(\bar{y})g'_2(\bar{y})$ .  $\square$

LEMMA A.9. Assume that (2.3) has no solution, and let  $V_{\bar{y}_i}(y)$ ,  $i = 1, 2$ , be solutions of (2.2) for barriers  $\bar{y}_1 < \bar{y}_2$ . Then  $V_{\bar{y}_1}(y) < V_{\bar{y}_2}(y)$  for all  $y \geq 0$ . Furthermore,

$$V(y) = \lim_{\bar{y} \rightarrow \infty} V_{\bar{y}}(y)$$

is finite for all  $y \geq 0$ . In fact  $V$  is three times continuously differentiable with

$$V^{(i)}(y) = \lim_{\bar{y} \rightarrow \infty} V_{\bar{y}}^{(i)}(y), \quad i = 1, 2, 3,$$

so, in particular,

$$LV(y) = 0, \quad y > 0.$$

Finally,

$$\frac{y - x - d_0}{1 + d_1} < V(y) - V(x) \leq \frac{y - x + c_0}{1 - c_1}, \quad 0 \leq x \leq y.$$

*Proof.* For simplicity we write  $V_i = V_{\bar{y}_i}$ ,  $\gamma_i = \bar{\gamma}_i$ ,  $\delta_i = \bar{\delta}_i$ , and  $\eta_i = \bar{y}_i - \bar{\delta}_i$ .

Let  $V_0(y) = V_2(y) - V_1(y)$ . If  $V'_0(y) > 0$  on  $[0, \bar{y}_1]$ , i.e.,  $V'_2(y) > V'_1(y)$ , then  $\gamma_2 > \gamma_1$  and so

$$\begin{aligned} \frac{c_0}{1 - c_1} &= \int_0^{\gamma_1} (V'_1(y) - (1 - c_1)^{-1}) dy \\ &< \int_0^{\gamma_1} (V'_2(y) - (1 - c_1)^{-1}) dy \\ &< \int_0^{\gamma_2} (V'_2(y) - (1 - c_1)^{-1}) dy = \frac{c_0}{1 - c_1}, \end{aligned}$$

which is a contradiction. In a similar way it is easy to show that  $V'_0(y) < 0$  on  $[0, \bar{y}_1]$  also gives a contradiction.

By this and Lemma A.1(a) it is therefore necessary that  $V_0(y) \neq 0$  on  $[0, \bar{y}_1]$  and that there is a  $y_0 \in [0, \bar{y}_1]$  so that  $V'_0(y_0) = 0$ . Assuming that  $V_0(y) < 0$  on  $[0, \bar{y}_1]$ , Lemma A.1(b) gives

$$(A.12) \quad \begin{aligned} V'_1(y) &< V'_2(y), & y \in (0, y_0), \\ V'_1(y) &> V'_2(y), & y \in (y_0, \bar{y}_1). \end{aligned}$$

If  $\eta_1 < y_0$ , then  $\gamma_1 < y_0$  as well, and then from (A.12) it follows that  $\gamma_1 < \gamma_2$ . But this was proved above to give a contradiction, and hence  $\eta_1 \geq y_0$ . But then  $V'_2(\eta_1) \leq V'_1(\eta_1)$ , and hence  $\eta_2 \leq \eta_1$  by (A.12) and Lemma A.8, the latter saying that  $V'_2(\bar{y}_2-) < V'_1(\eta_1)$ . Therefore, again by Lemma A.8, the second inequality in (A.12) holds for  $y \in (0, \bar{y}_2)$  and so

$$\begin{aligned} -\frac{d_0}{1+d_1} &= \int_{\eta_1}^{\bar{y}_1} (V'_1(y) - (1+d_1)^{-1}) dy \\ &= \int_{\eta_1}^{\bar{y}_2} (V'_1(y) - (1+d_1)^{-1}) dy \\ &> \int_{\eta_1}^{\bar{y}_2} (V'_2(y) - (1+d_1)^{-1}) dy \\ &> \int_{\eta_2}^{\bar{y}_2} (V'_2(y) - (1+d_1)^{-1}) dy = -\frac{d_0}{1+d_1}, \end{aligned}$$

which is a contradiction. Hence we have proved that  $V_0(y) > 0$  on  $[0, \bar{y}_1]$  and that  $V'_0(y_0) = 0$  for some  $y_0 \in [0, \bar{y}_1]$ . Therefore (A.8) holds, where the second inequality is for  $y \in (y_0, \bar{y}_1)$ .

We will extend the result to  $(\bar{y}_1, \bar{y}_2]$ , and since  $V'_1(y) = V'_2(y)$  on  $[\bar{y}_2, \infty)$ , we are then in fact done. By Lemma A.8,  $V'_2(y) < (1+d_1)^{-1}$  on  $(\eta_2, \bar{y}_2)$ , while by definition  $V'_1(y) = (1+d_1)^{-1}$  on  $(\bar{y}_1, \bar{y}_2)$ . We have shown that  $V_2(\bar{y}_1) > V_1(\bar{y}_1)$ , and hence to finish the first part of the lemma it is sufficient to show that  $V_2(\bar{y}_2) > V_1(\bar{y}_2)$ . To this end, note first that if  $\eta_2 \leq y_0$ , then  $\gamma_2 \leq y_0$  as well, and so by (A.8),  $\gamma_1 > \gamma_2$ . However, this is proved to give a contradiction as before, and so  $\eta_2 > y_0$ , implying by (A.8) that  $\eta_1 < \eta_2$ . Now  $V'_2(y) > (1+d_1)^{-1}$  on  $(\eta_1, \eta_2)$ , and using that  $V_1(\bar{y}_2) = V_1(\eta_1) + (\bar{y}_2 - \eta_1 - d_0)/(1+d_1)$ , we get

$$\begin{aligned} V_2(\bar{y}_2) - V_1(\bar{y}_2) &= V_2(\eta_2) - V_1(\eta_1) - \frac{\eta_2 - \eta_1}{1+d_1} \\ &= \int_{\eta_1}^{\eta_2} (V'_2(y) - (1+d_1)^{-1}) dy + V_2(\eta_1) - V_1(\eta_1) > 0. \end{aligned}$$

For the second part let  $\tilde{V}_n$  be the value function with a barrier  $\bar{y}$  and  $c_0 = c_1 = d_0 = d_1 = 0$ , and let  $V_n = V_{\bar{y}_n}$  be as above. Then clearly  $V_n(y) \leq \tilde{V}_n(y)$ , but by [12, Theorem 4.4],  $\tilde{V}_n(y) \leq y + \mu(0)/r$ . Letting  $\bar{y}_n \rightarrow \infty$  gives boundedness. To prove that the derivatives converge, as in the proof of Lemma A.8, let

$$V_n(y) = a_1(\bar{y}_n)g_1(y) + a_2(\bar{y}_n)g_2(y),$$

where  $g_1(0) = 0$  and  $g_2(0) = 1$ . Then  $a_2(\bar{y}_n) = V_n(0) \rightarrow V(0) \stackrel{\text{def}}{=} a_2$  as  $\bar{y}_n \rightarrow \infty$ . Also using, e.g., that  $V_n(1) \rightarrow V(1)$  gives that  $a_1(\bar{y}_n) \rightarrow a_1$ , and so

$$V(y) = a_1g_1(y) + a_2g_2(y).$$

Convergence of the derivatives follows.

For the last part we use the notation above. We know that  $V'_n(y) > (1 - c_1)^{-1}$  on  $(0, \gamma_n)$ , and from Lemma A.8 we know that  $V'_n(y) < (1 - c_1)^{-1}$  on  $(\gamma_n, \bar{y}_n)$ . Therefore,

$$\begin{aligned} V_n(y) - V_n(x) - \frac{y-x}{1-c_0} &= \int_x^y (V'_n(u) - (1-c_1)^{-1}) du \\ &\leq \int_0^{\gamma_n} (V'_n(u) - (1-c_1)^{-1}) du = \frac{c_0}{1-c_1}. \end{aligned}$$

Letting  $\bar{y}_n \rightarrow \infty$  gives the second inequality.

For the first inequality we know likewise that  $V'_n(y) > (1 + d_1)^{-1}$  on  $(0, \eta_n)$  and that  $V'_n(y) < (1 + d_1)^{-1}$  on  $(\eta_n, \bar{y}_n)$ . We saw in the first part of the proof that  $\{\eta_n\}$  is increasing in  $\bar{y}_n$ . If  $\eta_n \rightarrow \infty$  as  $\bar{y}_n \rightarrow \infty$ , then with  $\eta_n > y$ ,

$$V_n(y) - V_n(x) - \frac{y-x}{1+d_1} = \int_x^y (V'_n(u) - (1+d_1)^{-1}) du > 0.$$

Letting  $\bar{y}_n \rightarrow \infty$  gives that  $V(y) - V(x) - (y-x)/(1+d_1) \geq 0$ . Assume instead that  $\eta_n \rightarrow \eta$  as  $\bar{y}_n \rightarrow \infty$ , and choose  $\bar{y}_n > y$ . If  $x < \eta$ , then for  $\bar{y}_n$  sufficiently large  $V_n(\eta) - V_n(x) - (\eta-x)/(1+d_1) \geq 0$ , and letting  $\bar{y}_n \rightarrow \infty$  shows that the contribution from the interval  $[x, \eta]$  is nonnegative. We may therefore assume that  $x \geq \eta$ . But for  $u \geq \eta$  we saw in the proof of the first part of the lemma that (A.8) applies, and hence  $\{V'_n(u)\}$  is increasing in  $\bar{y}_n$ , and in particular  $V'(u) > V'_n(u)$  for all  $n$  by convergence of the derivatives. Therefore  $V(y) - V(x) > V_n(y) - V_n(x)$  and so

$$V(y) - V(x) - \frac{y-x}{1+d_1} > V_n(y) - V_n(x) - \frac{y-x}{1+d_1} > -\frac{d_0}{1+d_1}. \quad \square$$

*Proof of Theorem 2.3.* Let  $\rho_n = \inf\{t : Y_t \vee C_t \vee D_t \geq n\}$  and let  $\nu_n = \inf\{t : C_t \vee D_t \geq n\}$ . Furthermore, let  $0 = S_0 < S_1 < S_2 < \dots$  be the times investments are made, and similarly let  $0 = T_0 < T_1 < T_2 < \dots$  be the times dividends are paid. If  $\lim_{n \rightarrow \infty} S_n < \infty$  or  $\lim_{n \rightarrow \infty} T_n < \infty$ , it is clear that  $E^y[\int_0^\infty e^{-rt} dA_t] = -\infty$ . Hence we may assume that  $\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} T_n = \infty$ .

Let  $V$  be as in (2.3) if this has a solution and be as in Lemma A.9 if (2.3) has no solution. By the generalized Itô formula, the fact that  $C^c = D^c = 0$ , together with Lemmas A.7 and A.9, we have

$$\begin{aligned} e^{-r(t \wedge \rho_n)} V(Y_{t \wedge \rho_n}) &= V(y) + \int_0^{t \wedge \rho_n} e^{-rs} \sigma(Y_s) V'(Y_s) dW_s \\ &\quad + \sum_{S_i \leq t \wedge \rho_n} e^{-rS_i} (V(Y_{S_i-} + \Delta Y_{S_i}) - V(Y_{S_i-})) \\ &\quad + \sum_{T_i \leq t \wedge \rho_n} e^{-rT_i} (V(Y_{T_i-} + \Delta Y_{T_i}) - V(Y_{T_i-})) \\ &\leq V(y) + \int_0^{t \wedge \rho_n} e^{-rs} \sigma(Y_s) V'(Y_s) dW_s \\ &\quad + \sum_{S_i \leq t \wedge \rho_n} e^{-rS_i} \frac{\Delta Y_{S_i} + c_0}{1-c_1} \\ &\quad + \sum_{T_i \leq t \wedge \rho_n} e^{-rT_i} \frac{\Delta Y_{T_i} + d_0}{1+d_1} \end{aligned}$$

$$\begin{aligned}
&= V(y) + \int_0^{t \wedge \rho_n} e^{-rs} \sigma(Y_s) V'(Y_s) dW_s \\
&\quad + \int_0^{t \wedge \rho_n} e^{-rs} dC_s - \int_0^{t \wedge \rho_n} e^{-rs} dD_s.
\end{aligned}$$

Therefore,

$$V(y) \geq E^y \left[ \int_0^{t \wedge \rho_n} e^{-rs} dD_s \right] - E^y \left[ \int_0^{t \wedge \rho_n} e^{-rs} dC_s \right] + E^y \left[ e^{-r(t \wedge \rho_n)} V(Y_{t \wedge \rho_n}) \right].$$

As in the proof of [12, Lemma 3.3] it follows that

$$M(t) = \int_0^{t-} e^{-rs} dA_s + e^{-rt} V(Y_{t-})$$

is a supermartingale. Again following the arguments in [12, Lemma 3.3] gives

$$\begin{aligned}
V(y) &\geq E^y \left[ \int_0^{\nu_n-} e^{-rs} dA_s \right] + E^y \left[ e^{-r\nu_n} V(Y_{\nu_n-}) \right] \\
&\geq E^y \left[ \int_0^{\nu_n-} e^{-rs} dA_s \right] + V(0) E^y \left[ e^{-r\nu_n} \right].
\end{aligned}$$

Clearly  $\nu_n \rightarrow \infty$  as  $n \rightarrow \infty$ ; hence,

$$V(y) \geq \limsup_{n \rightarrow \infty} E^y \left[ \int_0^{\nu_n-} e^{-rs} dA_s \right].$$

If (2.3) has a solution, then using the strategy of Theorem 2.3(a) gives the equalities above so that

$$V(y) = \int_0^t e^{-rs} dD_s - \int_0^t e^{-rs} dC_s - \int_0^t e^{-rs} \sigma(Y_s) V'(Y_s) dW_s + e^{-rt} V(Y_t).$$

But  $0 \leq Y_s \leq y^*$ , and hence the stochastic integral has expectation zero. Furthermore,

$$E^y \left[ \int_0^t e^{-rs} dD_s \right] < y + \frac{\delta^* - d_0}{1 + d_1} E^y \left[ \sum_{i=1}^{\infty} e^{-rT_i} \right] < \infty$$

since  $T_1, T_2, \dots$  is a renewal process. Therefore, taking expectations and using the monotone convergence theorem together with the dominated convergence theorem, we get

$$V(y) = E^y \left[ \int_0^{\infty} e^{-rt} dA_t \right].$$

Assume now that (2.3) does not have a solution, and let  $(C^*, D^*)$  be an optimal strategy. Let  $D'$  be “the more generous payout,”

$$\Delta D'_s = V(Y_{s-}) - V(Y_{s-} + \Delta Y_s) > \Delta D_s^* \quad \text{when} \quad \Delta D_s^* > 0,$$

where the inequality follows from Lemma A.9. Therefore,  $P(D'_{t \wedge \tau_y} > D^*_{t \wedge \tau_y}) > 0$  for  $t$  sufficiently large (otherwise  $E[\int_0^{\nu_n-} e^{-rs} dD_s^*] = 0$  for all  $n$ , and  $D^*$  is not optimal). Consequently, as in the first part of the proof with  $A^* = D^* - C^*$  and  $A' = D' - C'$ ,

$$V(y) \geq \limsup_{n \rightarrow \infty} E^y \left[ \int_0^{\nu_n-} e^{-rs} dA'_s \right] > \limsup_{n \rightarrow \infty} E^y \left[ \int_0^{\nu_n-} e^{-rs} dA_s^* \right].$$

Let

$$\varepsilon = V(y) - \limsup_{n \rightarrow \infty} E \left[ \int_{0-}^{\nu_n-} e^{-rs} dA_s^* \right].$$

By Lemma A.9, there exists a  $\bar{y}$  so that  $V(y) - V_{\bar{y}, \gamma(\bar{y}), \delta(\bar{y})}(y) < \varepsilon$ , and so  $(C^*, D^*)$  cannot be optimal. That  $V(y) = \lim_{\bar{y} \rightarrow \infty} V_{\bar{y}, \gamma(\bar{y}), \delta(\bar{y})}(y)$  follows from Lemma A.9. This ends the proof.  $\square$

*Proof of Proposition 2.4.* Let  $g(y) = V(y)$ , which is a solution by Lemma A.9. Also let

$$S(y) = \int_0^y e^{-\int_0^x \frac{2\mu(v)}{\sigma^2(v)} dv} dx$$

be the scale function. By the method of reduction of order (see, e.g., [14, p. 31]), another independent solution is

$$\tilde{g}_2(y) = g(y) \int_l^y \frac{1}{g^2(x)} S'(x) dx \stackrel{\text{def}}{=} g(y)(k(y) - k(l)),$$

where  $l$  is chosen large enough so that  $g(l) > 0$ .

Let  $\tau_0^y$  and  $\tau_{\bar{y}}^y$  be as in the proof of Lemma A.3. By results in [6, Chapter 15.1],

$$P^y(\tau_{\bar{y}}^y < \tau_0^y) = \frac{S(y)}{S(\bar{y})}.$$

This means that if  $S(\bar{y}) \rightarrow \infty$  as  $\bar{y} \rightarrow \infty$ , then  $P^y(\tau_0^y < \infty) = 1$ . But then it cannot be optimal to never pay out dividends, since this will result in a negative value function for all  $y$ , which clearly is wrong. Hence  $\lim_{y \rightarrow \infty} S(y) < \infty$ , and since  $S'(y) > 0$ , this implies in particular that  $\lim_{y \rightarrow \infty} S'(y) = 0$ .

By Lemma A.9 and what we have already proved, it is clear that  $k_\infty = \lim_{y \rightarrow \infty} k(y)$  exists and is finite. Therefore  $g_2(y) = g(y)(k(y) - k_\infty)$  is also a solution, and by L'Hospital's rule,

$$\lim_{y \rightarrow \infty} g_2(y) = \lim_{y \rightarrow \infty} \frac{k(y) - k_\infty}{\frac{1}{g(y)}} = \lim_{y \rightarrow \infty} \frac{S'(y)}{g'(y)} = 0,$$

since  $V' = \lim_{y \rightarrow \infty} g'(y) = 1/(1 + d_1)$  by Lemmas A.1(f) and A.9. Finally, any solution is a linear combination of  $V(y)$  and  $g_2(y)$ , and the last result follows.

To prove (b), observe first that  $V(y) \leq \tilde{V}(y)$ , where  $\tilde{V}$  is the value function when  $c_0 = c_1 = d_0 = 0$ . As in [12, Theorem 4.4],

$$\tilde{V}(y) = \frac{1}{1 + d_1} \left( y + \frac{\mu(0)}{r} \right).$$

Assume that there is an optimal policy. Then by Theorem 2.3(a) and the above, we obtain for  $y \geq y^*$ ,

$$V(y) = V(\eta^*) + \frac{y - \eta^* - d_0}{1 + d_1} \leq \frac{1}{1 + d_1} \left( y + \frac{\mu(0)}{r} - d_0 \right).$$

Let  $\bar{y} > y$  and let  $T_{\bar{y}}^y = \min\{\tau_0^y, \tau_{\bar{y}}^y\}$ . Using a barrier strategy at  $\bar{y}$  that pays the whole amount  $\bar{y}$  yields the value function

$$\begin{aligned} \hat{V}_{\bar{y}}(y) &= E^y \left[ e^{-rT_{\bar{y}}^y} 1_{\{Y_{T_{\bar{y}}^y-} = \bar{y}\}} \right] \left( \frac{\bar{y} - d_0}{1 + d_1} + \hat{V}_{\bar{y}}(0) \right) + E^y \left[ e^{-rT_{\bar{y}}^y} 1_{\{Y_{T_{\bar{y}}^y-} = 0\}} \right] \hat{V}_{\bar{y}}(0) \\ &= h_{\bar{y}}(y) \frac{\bar{y} - d_0}{1 + d_1} + k_{\bar{y}}(y) \hat{V}_{\bar{y}}(0), \end{aligned}$$

where

$$\begin{aligned} h_{\bar{y}}(y) &= E^y \left[ e^{-rT_{\bar{y}}^y} 1_{\{Y_{T_{\bar{y}}^y} = \bar{y}\}} \right], \\ k_{\bar{y}}(y) &= E^y \left[ e^{-rT_{\bar{y}}^y} \right]. \end{aligned}$$

Again by results from Chapter 15.3 in [6],  $h_{\bar{y}}$  is the solution of

$$Lh_{\bar{y}}(y) = 0, \quad h_{\bar{y}}(\bar{y}) = 1, \quad \text{and} \quad h_{\bar{y}}(0) = 0.$$

This gives

$$\hat{V}_{\bar{y}}(y) = \frac{\bar{y} - d_0}{1 + d_1} \left( \frac{g_1(y)}{g_1(\bar{y}) - \frac{g_1(0)}{g_2(0)}g_2(\bar{y})} - \frac{g_2(y)}{\frac{g_2(0)}{g_1(0)}g_1(\bar{y}) - g_2(\bar{y})} \right) + k_{\bar{y}}(y)\hat{V}_{\bar{y}}(0).$$

Clearly  $\hat{V}_{\bar{y}}(0)$  is bounded, and since  $Y$  increases only exponentially, letting  $\bar{y} = e^{y^2}$  implies that  $k_{\bar{y}}(y) \rightarrow 0$  as  $y \rightarrow \infty$ . Therefore, for any positive  $\varepsilon < d_0$  and  $y$  sufficiently large,

$$\hat{V}_{\bar{y}}(y) \geq \frac{1}{1 + d_1} \frac{g_1(y)}{g_1'} - \frac{\varepsilon}{2} \geq \frac{1}{1 + d_1} \left( y + \frac{\mu(0)}{r} \right) - \varepsilon > V(y),$$

which is a contradiction. Hence (2.3) cannot have a solution, and this proves (b).

Part (c) is the same as (a) since all solutions are a linear combination of  $g_1$  and  $g_2$  from (a).  $\square$

*Proof of Proposition 2.6.* As in the proof of Lemma A.9, let  $V_n(y)$  be the value function with barrier  $\bar{y}_n$ . Then  $V_n(y) = a_1(\bar{y}_n)g_1(y) + a_2(\bar{y}_n)g_2(y)$ , and by the proof of Lemma A.9,  $a_i(\bar{y}_n) \rightarrow a_i$  as  $\bar{y}_n \rightarrow \infty$ , where  $V(y) = a_1g_1(y) + a_2g_2(y)$ .

Let  $V' = \lim_{y \rightarrow \infty} V'(y)$ . By Lemma A.9,  $V' \geq (1 + d_1)^{-1}$ , and by Lemma A.8,

$$\frac{1}{1 + d_1} > V'_n(\bar{y}_n) = a_1(\bar{y}_n)g'_1(\bar{y}_n) + a_2(\bar{y}_n)g'_2(\bar{y}_n).$$

Letting  $\bar{y}_n \rightarrow \infty$  gives that  $(1 + d_1)^{-1} \geq V'$ , hence  $V' = (1 + d_1)^{-1}$ , and this proves (a). For (b) define

$$\begin{aligned} h(y) &= V(y) - V(0) - \frac{y + c_0}{1 - c_1}, \\ h_n(y) &= V_n(y) - V_n(0) - \frac{y + c_0}{1 - c_1}. \end{aligned}$$

Since  $V'_n(\gamma_n) = (1 - c_1)^{-1}$  and  $V_n$  is concave on  $[0, \gamma_n]$ , we have that  $h'_n(0) > 0$ , implying that  $h'(0) \geq 0$ . By (a),  $h'(y) < 0$  for all  $y$  sufficiently large, and so  $h$  must have a maximum at some  $\bar{\gamma}$ , and then  $h'(\bar{\gamma}) = 0$ , i.e.,  $V'(\bar{\gamma}) = (1 - c_1)^{-1}$ . By Lemma A.1(f),  $V'(y) > (1 - c_1)^{-1}$  for  $y < \bar{\gamma}$  and  $V'(y) < (1 - c_1)^{-1}$  for  $y > \bar{\gamma}$ . Since  $V$  is an optimal value function and all reinvestments at 0 have a marginal cost of  $(1 - c_1)^{-1}$ , it is optimal to reinvest as long as the marginal return on reinvestments is at least as high as the marginal cost of reinvesting, which by the above arguments just means that

$$(A.13) \quad V(\bar{\gamma}) = V(0) + \frac{\bar{\gamma} + c_0}{1 - c_1},$$

and this is the same as the second equation in (2.4).

Assume that  $\{\gamma_n\}$  is unbounded so that  $\gamma_n \rightarrow \infty$  along some sequence  $\bar{y}_n$ . Then for  $\varepsilon > 0$  and  $n$  large enough, since  $V_n$  is concave on  $[0, \gamma_n]$ ,

$$V'_n(\bar{\gamma} + \varepsilon) > (1 - c_1)^{-1} > V'(\bar{\gamma} + \varepsilon).$$

Letting  $n \rightarrow \infty$  gives a contradiction, hence  $\{\gamma_n\}$  is bounded, and so (along a subsequence)  $\gamma_n \rightarrow \gamma_0$  for some  $\gamma_0$ . But

$$V'(\gamma_0) = V'(\gamma_0) - V'_n(\gamma_0) + V'_n(\gamma_0) - V'_n(\gamma_n) + (1 - c_1)^{-1}.$$

However,

$$|V'(\gamma_0) - V'_n(\gamma_0)| + |V'_n(\gamma_0) - V'_n(\gamma_n)| \rightarrow 0 \quad \text{as } n \rightarrow \infty,$$

hence  $V'(\gamma_0) = (1 - c_1)^{-1}$ , and so  $\gamma_0 = \bar{\gamma}$ . Also  $h_n(\gamma_n) = 0$  so  $h(\bar{\gamma}) = 0$  as well, giving another proof of (A.13).

Finally for (c), if  $c_1 = d_1 = 0$  but the equations (2.4) have a solution, the argument is as above. So assume that (2.4) has no solution. Then  $V'(y) > 1$  for all  $y$ , and hence at  $y = 0$  it is desirable to reinvest as much as possible since the marginal return on reinvestment is higher than the marginal cost of reinvestment. Therefore, as in (A.13),

$$(A.14) \quad V(0) = \lim_{y \rightarrow \infty} (V(y) - y) - c_0.$$

Then (a) and (A.14), together with the limit results for  $g_2(y)$  given in Proposition 2.4(a), yield the result.  $\square$

## ON LOCAL TRANSVERSE FEEDBACK LINEARIZATION\*

CHRISTOPHER NIELSEN<sup>†</sup> AND MANFREDI MAGGIORE<sup>†</sup>

**Abstract.** Given a control-affine system and a controlled invariant submanifold, we present necessary and sufficient conditions for local feedback equivalence to a system whose dynamics transversal to the submanifold are linear and controllable. A key ingredient used in the analysis is the new notion of transverse controllability indices of a control system with respect to a set.

**Key words.** set stabilization, feedback linearization, controlled invariant sets, zero dynamics, multi-input systems, nonlinear geometric control

**DOI.** 10.1137/070682125

**1. Introduction.** Ever since Poincaré’s seminal work [22], the problem of equivalence of vector fields has been a central question in the field of dynamics. In his 1879 work, Poincaré found sufficient conditions for an analytic vector field to be locally equivalent to a linear one by means of an analytic transformation. Poincaré’s key insight in formulating this problem was that, rather than trying to solve a differential equation, it is convenient to seek a coordinate transformation reducing the associated vector field to its “simplest” form, the normal form. In control theory, the problem of equivalence of a control system to a linear controllable system by means of smooth coordinate transformations was first formulated by Krener in 1973 [14]. In 1978, Brockett [3] formulated and solved the feedback linearization problem for single-input, single-output systems, whereby the equivalence to a linear controllable system is established by means of a smooth coordinate transformation and a regular feedback transformation; this is referred to as feedback equivalence. The multi-input, multi-output extension of Brockett’s work was carried out by Jakubczyk and Respondek in [12] and, independently, by Hunt, Su, and Meyer in [8]; see also [26]. When a control system is not feedback linearizable, it is natural to ask whether it admits a feedback linearizable subsystem. This problem, first posed by Isidori and Krener in [10], is referred to as partial feedback linearization. For single-input systems, Krener, Isidori, and Respondek [13] investigated partial feedback linearization yielding a linear subsystem of maximal dimension. This result was extended by Marino in [15] to the multi-input case; see also [16], [23]. For systems with outputs, Xu and Hunt [30], [31], consider a similar problem.

In [2], Banaszuk and Hauser formulated and solved the transverse feedback linearization problem (TFLP) for periodic orbits of single-input control-affine systems. If  $\Gamma^*$  is a periodic orbit of the open-loop system, the problem entails finding conditions for feedback equivalence to a control system whose dynamics transversal to  $\Gamma^*$  are linear and controllable. In [19], we generalized Banaszuk and Hauser’s results to the case when  $\Gamma^*$  is an arbitrary controlled invariant embedded submanifold of the

state space. In this paper we present the complete solution to the local TFLP for multi-input systems, relying on a mild regularity assumption. A key ingredient used in the analysis of the problem is the new notion of transverse controllability indices of a control system with respect to a set. The transverse controllability indices are an adaptation of those introduced by Marino [15].

When the set  $\Gamma^*$  is an equilibrium point, the problem considered in this paper (see section 3) reduces to the classical state-space exact linearization problem. In this special case our conditions coincide with those of the classical results on feedback equivalence to linear, time-invariant, controllable systems [8], [12], and the transverse controllability indices coincide with the controllability indices introduced by Marino [15].

We now discuss some of the applications of transverse feedback linearization (TFL). While classical feedback linearization is used to stabilize equilibria of non-linear systems, TFL is applicable to the more general set stabilization problem. Indeed, if a system is transversely feedback linearizable with respect to a controlled invariant manifold  $\Gamma^*$ , then designing a controller that locally stabilizes  $\Gamma^*$  amounts to designing a stabilizer for the origin of a linear time-invariant system, and so the set stabilization problem is greatly simplified (see section 3 for a more precise discussion). In light of the above, TFL is relevant to all those problems where the control objective is the stabilization of a manifold, rather than an equilibrium. Consider, for instance, the simplest synchronization (or state agreement) problem: make the states of two coupled dynamical systems converge to one another. This is equivalent to stabilizing the diagonal subspace. In the more general case, when one wants to make the outputs of several coupled dynamical systems converge to one another, then, generally, the set to be stabilized is a manifold. As other relevant applications of TFL we mention path following (make the output of a dynamical system approach and follow a path) [2], [18], [19], and the stabilization of virtual constraints in mechanical systems [24].

Another important application of our main result is the solution of the following *zero dynamics assignment problem with relative degree*. Given a control-affine system and a controlled invariant manifold  $\Gamma^*$ , does there exist an output function yielding a well-defined vector relative degree whose associated zero dynamics manifold locally coincides with  $\Gamma^*$ ? Our main result in Theorem 3.2 gives checkable necessary and sufficient conditions that completely answer this question.

This paper is organized as follows. Section 2 contains mathematical preliminaries. Section 3 presents the formal problem statement, the statement of our main result, Theorem 3.2, and a comparison of our result to the solution of the classical state-space exact linearization problem [8], [12]. A relationship to the partial feedback linearization problem is established in Theorem 3.5. In section 4 we introduce the notion of transverse indices, compare them to the controllability indices of Marino [15] in Lemma 4.1, and establish their feedback invariance. The proof of the main result is presented in section 5, and section 6 contains concluding remarks.

**2. Preliminaries.** Consider a control system  $\Sigma$  modeled by equations of the form

$$(2.1) \quad \Sigma : \quad \dot{x} = f(x) + \sum_{i=1}^m g_i(x)u_i =: f(x) + g(x)u.$$

Here  $x \in \mathbb{R}^n$  is the state, and  $u = (u_1, \dots, u_m) \in \mathbb{R}^m$  is the control input. The vector fields  $f, g_1, \dots, g_m : \mathbb{R}^n \longrightarrow T\mathbb{R}^n$  are smooth ( $C^\infty$ ). We assume throughout this paper

that  $g_1, \dots, g_m$  are linearly independent.

When we talk of a manifold  $M$ , we mean a smooth manifold without boundary. By a submanifold we mean an embedded submanifold. All objects are presumed to be smooth. In this paper we consider submanifolds of  $\mathbb{R}^n$ , where  $\mathbb{R}^n$  is identified with Euclidean  $n$ -space.

**2.1. Notation.** If  $k$  is a positive integer,  $\mathbf{k}$  denotes the set of integers  $\{0, 1, \dots, k-1\}$ . We let  $\text{col}(x_1, \dots, x_k) := [x_1 \ \dots \ x_k]^\top$  and, given two column vectors  $a$  and  $b$ , we let  $\text{col}(a, b) := [a^\top \ b^\top]^\top$ . If  $U$  is an open set of  $\mathbb{R}^n$ , let  $\text{Diff}(U)$  denote the collection of diffeomorphisms from  $U$  to some open set  $\tilde{U} \subset \mathbb{R}^n$ . If  $F : M \rightarrow N$  is a map between manifolds, then  $dF_x : T_x M \rightarrow T_{F(x)} N$  denotes its differential. If  $M$  and  $N$  are vector spaces, then use  $dF_x$  to denote the Jacobian matrix of  $F$  at  $x$ . If  $F : M \rightarrow N$  is a diffeomorphism between two manifolds, and if  $v$  is a vector field on  $M$ , then the differential of  $F$  can be used to define a vector field on  $N$  by means of the push-forward map  $F_*$ , defined as  $F_* v(q) = (dF_p v(p))|_{p=F^{-1}(q)}$ . This corresponds to the usual change of coordinates in a differential equation. We denote by  $I_m$  the  $m \times m$  identity matrix. The direct sum of two matrices  $A$  and  $B$  is the block diagonal matrix

$$A \oplus B = \begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix},$$

where the zeros denote matrices of suitable size. Given two subspaces  $V$  and  $W$  of the same vector space, the notation  $V \oplus W$  (internal direct sum) is used to represent the subspace  $V + W$  when  $V$  and  $W$  are linearly independent.

**DEFINITION 2.1.** *Given an open set  $U \subseteq \mathbb{R}^n$ , a regular static feedback, denoted  $(\alpha, \beta)$ , on  $U$  for the control system (2.1) is a relation*

$$u = \alpha(x) + \beta(x)v,$$

where  $u = (u_1, \dots, u_m)$  and  $\alpha : U \rightarrow \mathbb{R}^m$ ,  $\beta : U \rightarrow \text{GL}(m, \mathbb{R})$  are smooth mappings. We denote by  $\tilde{f} := f + g\alpha$  and  $\tilde{g} := g\beta$  the vector fields obtained after the application of  $(\alpha, \beta)$ .

**DEFINITION 2.2.** *Two control systems,  $\Sigma : \dot{x} = f(x) + g(x)u$  and  $\hat{\Sigma} : \dot{\hat{x}} = \hat{f} + \hat{g}\hat{u}$ , are feedback equivalent on an open set  $U \subseteq \mathbb{R}^n$  if there exist a regular static feedback  $(\alpha, \beta)$  defined on  $U$  and a diffeomorphism  $\Xi \in \text{Diff}(U)$  such that*

$$\hat{f} = \Xi_*(f + g\alpha), \quad \hat{g} = \Xi_*(g\beta)$$

on  $U$ .

On a manifold  $M$ ,  $\mathbf{V}(M)$  will denote the set of all smooth vector fields on  $M$ , and  $C^\infty(M)$  will denote the ring of smooth real-valued functions on  $M$ . Given  $v \in \mathbf{V}(M)$ ,  $\phi_t^v(p)$  denotes the solution of  $\dot{x} = v(x)$  with initial condition  $x(0) = p$  at time  $t$ . A closed connected set  $N \subset M$  is said to be invariant for  $f \in \mathbf{V}(M)$  if

$$(p_0 \in N) \Rightarrow (\forall t \in \mathbb{R})(\phi_t^f(p_0) \in N).$$

A closed connected set  $N \subset \mathbb{R}^n$  is called controlled invariant for (2.1) if there exists a smooth feedback  $\bar{u} : N \rightarrow \mathbb{R}^m$  making  $N$  an invariant set for the closed-loop system. Following [28], we denote the class of closed, connected, embedded submanifolds of  $\mathbb{R}^n$  which are controlled invariant for (2.1) by  $\mathcal{I}(f, g, \mathbb{R}^n)$ . If  $N \in \mathcal{I}(f, g, \mathbb{R}^n)$ , we write

$\mathcal{F}(f, g, N)$  for the collection of maps that render  $N$  controlled invariant, i.e., maps  $\bar{u} : N \rightarrow \mathbb{R}^m$  such that  $f + g\bar{u}$  is tangent to  $N$ , i.e.,

$$(f + g\bar{u})|_N : N \rightarrow TN.$$

If  $f \in \mathbf{V}(M)$  and  $\lambda \in C^\infty(M)$ , then

$$L_f \lambda(p) = \lim_{h \rightarrow 0} \frac{1}{h} \left[ \lambda(\phi_h^f(p)) - \lambda(p) \right]$$

is the Lie derivative of  $\lambda$  with respect to  $f$  at  $p$ ; it is also an element of  $C^\infty(M)$ . If  $f, g \in \mathbf{V}(M)$ , then the Lie bracket of  $f$  and  $g$  is defined by the relation

$$L_{[f,g]} \lambda = L_f(L_g \lambda) - L_g(L_f \lambda) \quad \forall \lambda \in C^\infty(M).$$

We will use the following standard notation for iterated Lie derivatives and Lie brackets:

$$\begin{aligned} L_g L_f \lambda &:= L_g(L_f \lambda), \\ L_g^0 \lambda &:= \lambda, \quad L_g^k \lambda := L_g(L_g^{k-1} \lambda), \\ ad_f^0 g &:= g, \quad ad_f^k g := \left[ f, ad_f^{k-1} g \right], \quad k \geq 1. \end{aligned}$$

The set  $\mathbf{V}(M)$  can be equipped with different algebraic structures. For our purposes it suffices to consider  $\mathbf{V}(M)$  as either (i) a vector space (infinite dimensional) over  $\mathbb{R}$  which, when endowed with the Lie bracket  $[\cdot, \cdot] : \mathbf{V}(M) \times \mathbf{V}(M) \rightarrow \mathbf{V}(M)$ , becomes a Lie algebra, or (ii) a module over the ring  $C^\infty(M)$ . Given a Lie algebra  $\mathfrak{g}$ , a subset  $\mathfrak{h} \subset \mathfrak{g}$  is called a subalgebra if  $h_1, h_2 \in \mathfrak{h}$  implies  $[h_1, h_2] \in \mathfrak{h}$ .

Finally, if  $A \subset M$  is any subset, then a smooth map  $r : M \rightarrow A$  such that  $r|_A = 1_A$ , where  $1_A$  is the identity map on  $A$ , is called a smooth retraction of  $M$  onto  $A$ . The following lemma regarding retractions is a simpler, local version of the tubular neighborhood theorem [5].

**LEMMA 2.3.** *Let  $N \subset \mathbb{R}^n$  be an  $n^*$ -dimensional submanifold of  $\mathbb{R}^n$ . Then, for every  $p \in N$  there exist a neighborhood  $U$  of  $p$  in  $\mathbb{R}^n$  and a smooth retraction  $r : U \rightarrow N \cap U$ .*

**2.2. Vector bundles.** The discussion, terminology, and notation of this section is standard and can be found in [6] or [25]. A smooth  $n$ -dimensional vector bundle (or  $n$ -plane bundle)  $\xi = (\pi, E, B)$  can be thought of as<sup>1</sup> a family  $\{E_p\}_{p \in B}$  of disjoint  $n$ -dimensional vector spaces parameterized by a space  $B$ . The union of these vector spaces is the space  $E$ , and  $B$  is called the base space. The map  $\pi : E \rightarrow B$ ,  $E_p \mapsto p$  is a smooth surjective submersion and is called the vector bundle projection. Moreover,  $\xi$  is “locally trivial” in the sense that, locally (with respect to  $B$ ),  $E$  looks like a product with  $\mathbb{R}^n$ : for each  $p \in B$ , there is a neighborhood  $U$  of  $p$  and a diffeomorphism  $t : \pi^{-1}(U) \rightarrow U \times \mathbb{R}^n$ ,  $v_q \mapsto (t_1(q), t_2(q)v)$ , which is an isomorphism from each fiber  $\pi^{-1}(q)$  onto  $q \times \mathbb{R}^n$  for each  $q \in U$ . This property is exhibited by the commutative diagram below, where  $\tilde{\pi}(q, v) = q$ :

$$\begin{array}{ccc} \pi^{-1}(U) & \xrightarrow{t} & U \times \mathbb{R}^n \\ \pi \downarrow & \swarrow \tilde{\pi} & \\ U & & \end{array}$$

<sup>1</sup>The discussion here is informal. In particular we define a vector bundle as a triple  $(\pi, E, B)$ , where more formally one defines a vector bundle as a 5-tuple by augmenting the above triple with two operations  $\oplus$  and  $\otimes$ . See [6] and [25] for more details.

The pair  $(\pi^{-1}(U), t)$  is called a vector bundle chart with domain  $U$  and dimension  $n$ . The collection of all vector bundle charts of  $\xi$  is a vector bundle atlas. A vector bundle is a manifold in its own right with an atlas of compatible vector bundle charts. We will usually refer to a vector bundle as simply  $\xi$ , or  $\pi : E \rightarrow B$ , or even denote the bundle by  $E$  alone.

If  $A \subset B$  is any subset and  $\xi = (\pi, E, B)$ , then we denote  $\pi^{-1}(A)$  by  $E|_A$ , the restriction of  $\xi$  to  $A$ . It is a well-defined vector bundle. A subbundle of the bundle  $\xi = (\pi, E, B)$  is a bundle  $\xi_0 = (\pi_0, E_0, B)$ , over the same base space  $B$  such that  $E_0 \subset E$ , and  $\pi|_{E_0} = \pi_0$ . Additionally, there must exist a vector bundle atlas  $\Phi$  for  $\xi$  such that if  $(\pi^{-1}(U), t) \in \Phi$ , the following diagrams commute:

$$\begin{array}{ccc} \pi^{-1}(U) & \xrightarrow{t} & U \times \mathbb{R}^k \times \mathbb{R}^{n-k} \\ \pi \downarrow & \nearrow \tilde{\pi} & \\ U & & \end{array} \quad \begin{array}{ccc} \pi_0^{-1}(U) & \xrightarrow{t} & U \times \mathbb{R}^k \times \{0\} \\ \pi_0 \downarrow & \nearrow \tilde{\pi} & \\ U & & \end{array}$$

The prime example of a vector bundle is the tangent bundle  $\pi : TM \rightarrow M$  of a manifold  $M$ . If  $N \subset M$  is a submanifold of  $M$ , then  $TN$  is a subbundle of  $TM|_N$ :

$$TN = \{v_x \in TM|_N : v(x) \in T_x N\}.$$

The algebraic normal bundle of  $N$  in  $M$  is the subbundle over  $N$  whose fibers are the quotient spaces  $T_x M / T_x N$ . It is denoted  $TM|_N / TN$ .

Let  $\xi = (\pi, E, B)$  be a smooth vector bundle. A  $C^\infty$  inner product or orthogonal structure on  $\xi$  is a family  $\{\alpha_p\}_{p \in B}$ , where each  $\alpha_p$  is an inner product on  $E_p$  and the map  $(p, y, z) \mapsto \alpha_p(y, z)$  defined on  $\{(p, y, z) \in B \times E \times E : p = \pi(y) = \pi(z)\}$  is  $C^\infty$ . The pair  $(\xi, \alpha)$  is called an orthogonal vector bundle. If  $M$  is a manifold, a  $C^\infty$  orthogonal structure on  $TM$  is called a Riemannian metric. In this paper, orthogonal structures will always arise in subbundles of  $T\mathbb{R}^n|_V$ , where  $V$  is a submanifold of  $\mathbb{R}^n$ , whereby the standard inner product on  $\mathbb{R}^n$  is used. Suppose  $(\xi, \alpha)$  is an orthogonal vector bundle. If  $y, z$  are in the same fiber  $E_p$ , we write  $\langle y, z \rangle$  or  $\langle y, z \rangle_p$  for  $\alpha_p(y, z)$ . If  $\xi = (\pi^0, E^0, B) \subset \eta = (\pi, E, B)$  is a subbundle, the orthogonal complement  $\xi^\perp \subset \eta$  is the subbundle defined fiberwise as

$$(\xi^\perp)_p = (\xi_p)^\perp = \{y \in E_p : \langle y, z \rangle = 0, z \in E_p^0\}.$$

Note that  $\xi^\perp$  is isomorphic to  $\eta/\xi$ . Of particular interest to us will be the case when  $N \subset M$  is a submanifold and  $M$  has a Riemannian metric. In this case  $TN^\perp \subset TM|_N$  is called the geometric normal bundle of  $N$  in  $M$ .

**2.3. Distributions.** A smooth distribution  $D$  on a manifold  $M$  is an assignment to each  $p \in M$  of a subspace  $D(p) \subseteq T_p M$  which varies smoothly as  $p$  varies. Locally, a smooth distribution is spanned by a collection of smooth vector fields which are called local generators. A point  $p \in M$  is a regular point of  $D$  if there exists a neighborhood  $U$  containing  $p$  for which  $\dim(D(q))$  is constant for all  $q \in U$ . In this case  $D$  is said to be nonsingular on  $U$ . If  $p$  is a regular point of a distribution  $D$  with  $\dim D(p) = d$ , then there exist an open neighborhood  $U^0$  of  $p$  and  $d$  smooth local generators  $f_1, \dots, f_d$  defined on  $U^0$  such that for each  $q \in U^0$ ,  $D(q) = \text{span}\{f_1(q), \dots, f_d(q)\}$ . We will write  $D = \text{span}\{f_1, \dots, f_d\}$  when such a finite set of local generators exists.

A nonsingular distribution can be viewed as a subbundle of  $TM$ . As such, when  $TM$  has an orthogonal structure, we will use the notation  $D^\perp$  to indicate the orthogonal complement of  $D$  in  $TM$ . This stands in contrast to the notation  $\text{ann}(D)$  which

we use to denote the annihilator of  $D$  contained in  $TM^*$ , the cotangent bundle. If  $D$  is a distribution defined on a manifold  $M$  and  $N \subset M$  is a submanifold we will at times consider the subbundles  $TN + D$  and  $TN \cap D$  of  $TM|_N$  defined fiberwise, for each  $p \in N$ , by  $T_p N + D(p)$  and  $T_p N \cap D(p)$ , respectively. The following fact is used in what follows.

LEMMA 2.4. *Let  $N \subset M$  be a  $C^\infty$ -submanifold of the  $C^\infty$ -manifold  $M$ . Let  $p \in N$  be a regular point of a  $C^\infty$ -distribution  $D$  on  $M$ . Suppose there exists an open neighborhood  $V$  in  $N$  such that  $\dim(T_p N \cap D(p))$  is constant for all  $p \in V$ . Then there exists a neighborhood  $U$  of  $p$  in  $V$  such that  $TN \cap D$  and  $(TN \cap D)^\perp$  are smooth in  $U$ .*

Given a smooth distribution  $D$  on  $M$ , we denote by  $\bar{D}$  the involutive closure of  $D$ , i.e., the intersection of all involutive distributions containing  $D$ . We denote by  $\text{Lie}(D)$  the smallest subalgebra of  $\mathcal{V}(M)$  containing the vector fields in  $D$ . We will use  $\text{Lie}_{C^\infty(M)}(D)$  to denote the smooth distribution spanned by vector fields in  $\text{Lie}(D)$ . Then  $\text{Lie}_{C^\infty(M)}(D) \subseteq \bar{D}$ , and generally the inclusion is proper.

If  $\Delta$  and  $\Lambda$  are distributions and  $f$  is a vector field, then we use the following notation:

$$\begin{aligned} [\Delta, \Lambda] &= \text{span}\{[X, Y] : X \in \Delta, Y \in \Lambda\}, \\ [f, \Delta] &= \text{span}\{[f, \tau] : \tau \in \Delta\}. \end{aligned}$$

A smooth distribution  $\Delta$  is invariant under a vector field  $f$  if  $[f, \Delta] \subseteq \Delta$ . A distribution  $\Delta$  defined on an open set  $U$  is said to be locally controlled invariant for the dynamics (2.1) if for each  $x_0 \in U$  there exist a neighborhood  $U^0$  of  $x_0$  and a regular static feedback  $(\alpha, \beta)$  on  $U^0$  such that

$$\begin{aligned} [\tilde{f}, \Delta] &\subseteq \Delta, \\ [\tilde{g}_i, \Delta] &\subseteq \Delta, \quad i \in \{1, \dots, m\}, \end{aligned}$$

where  $\tilde{f} = f + g\alpha$  and  $\tilde{g} = g\beta$ .

THEOREM 2.5 (see [7], [9], [11], [20], [21]). *Let  $\Delta$  be an involutive distribution. Suppose  $\Delta$  and  $\Delta + \text{span}\{g_1, \dots, g_m\}$  are nonsingular on  $U$ . Then  $\Delta$  is locally controlled invariant for the dynamics (2.1) if and only if*

$$\begin{aligned} [f, \Delta] &\subseteq \Delta + \text{span}\{g_1, \dots, g_m\}, \\ [g_i, \Delta] &\subseteq \Delta + \text{span}\{g_1, \dots, g_m\}, \quad i \in \{1, \dots, m\}. \end{aligned}$$

**3. Local transverse feedback linearization problem and solution.** In this section we present the main problem studied in this paper. Suppose we are given a pair  $(\Gamma^*, u^*)$ , where  $\Gamma^* \in \mathcal{A}(f, g, \mathbb{R}^n)$ ,  $\dim \Gamma^* = n^*$ , and  $u^* \in \mathcal{F}(f, g, \Gamma^*)$ . In this presentation we consider the controlled invariant set  $\Gamma^*$  as given data. For example, in a mechanical system this might correspond to a motion planning task being solved in order to obtain the shortest path between two given points. In most situations, however, one is given a set  $\Gamma$ , perhaps defined by virtual constraints or design goals, and then one must pare away pieces of  $\Gamma$  until all which remains is the largest controlled invariant submanifold  $\Gamma^*$  contained in  $\Gamma$ . Various tools in the literature exist for this purpose (see, for instance, the zero dynamics algorithm [9] or the constrained dynamics algorithm [21]). Generally, the existing tools generate a local characterization of  $\Gamma^*$  about the initialization point of the algorithms. In some cases, viability

theory [1] can be used to obtain global characterizations of invariant sets for dynamical systems. The main problem investigated in this paper, stated next, concerns the decomposition of the system dynamics into a subsystem describing the motion on  $\Gamma^*$  and one describing the motion transversal to  $\Gamma^*$ , with the essential requirement that the transversal subsystem be feedback linearizable.

**Local transverse feedback linearization problem.** Given a pair  $(\Gamma^*, u^*) \in \mathcal{S}(f, g, \mathbb{R}^n) \times \mathcal{T}(f, g, \mathbb{R}^n)$  and a point  $p_0 \in \Gamma^*$  find, if possible, a neighborhood  $U$  of  $p_0$  in  $\mathbb{R}^n$ , a transformation  $\Xi \in \text{Diff}(U)$ ,  $\Xi : U \rightarrow \mathbb{R}^{n^*} \times \mathbb{R}^{n-n^*}$ ,  $x \mapsto (z, \xi)$ , and a feedback transformation  $(\alpha, \beta)$ , such that (2.1) is feedback equivalent on  $U$  to

$$(3.1) \quad \begin{aligned} \dot{z} &= f^0(z, \xi) + g^1(z, \xi)v_1 + g^2(z, \xi)v_2, \\ \dot{\xi} &= A\xi + Bv_1, \end{aligned}$$

where  $v = \text{col}(v_1, v_2) \in \mathbb{R}^m$ ;  $B$  is full rank, the pair  $(A, B)$  is controllable, and  $\Xi(\Gamma^* \cap U) = \{(z, \xi) \in \mathbb{R}^{n^*} \times \mathbb{R}^{n-n^*} : \xi = 0\}$ .

In words, we seek to characterize conditions under which (2.1) is feedback equivalent to a system whose dynamics transversal to the set  $\Gamma^*$  are linear, time-invariant, and controllable. LTFLP asks for a coordinate and feedback transformation valid on  $U$  which generates a normal form with two types of decompositions. On the one hand, system dynamics near  $\Gamma^* \cap U$  are decomposed into a tangential subsystem, the  $z$ -dynamics, and a transversal subsystem, the  $\xi$ -dynamics. On the other hand, the original  $m$  control inputs are decomposed into transversal and tangential components  $v_1$  and  $v_2$ , respectively.

The terminology “transverse feedback linearization” should not be mistaken for “transverse linearization,” a technique consisting of the Jacobian linearization of the dynamics transversal to a periodic orbit. In the special case when  $\Gamma^*$  is a periodic orbit, the notions of “transverse feedback linearization” and “transverse linearization” differ similarly to the way that “feedback linearization” around an equilibrium differs from “linearization” around the equilibrium.

Transverse feedback linearization finds application in the stabilization of  $\Gamma^*$ . For, if a transversal controller  $v_1$  is designed that stabilizes  $\xi = 0$ , and the trajectories of the closed-loop system are bounded, then the controller stabilizes  $\Gamma^*$  in original coordinates. If, on the other hand, the trajectories of the closed-loop system are not all bounded, then stabilization of  $\xi = 0$  implies the stabilization of  $\Gamma^*$  in original coordinates if there exists a class- $\mathcal{K}$  function  $\alpha$  such that  $\|\xi(x)\| \geq \alpha(\|x\|_{\Gamma^*})$ , where  $\|x\|_{\Gamma^*}$  is the point-to-set distance of a point  $x$  to the set  $\Gamma^*$ , defined as  $\|x\|_{\Gamma^*} := \inf_{p \in \Gamma^*} \|x - p\|$ . Hereafter, we assume that the preliminary regular feedback  $(u^*, I_m)$  is applied to (2.1) so that  $f|_{\Gamma^*}$  is tangent to  $\Gamma^*$ . Next, we present a technical result which is useful in proving the main theorem.

**THEOREM 3.1.** *LTFLP is solvable if and only if there exist  $\rho_0$  smooth  $\mathbb{R}$ -valued functions  $\alpha_1, \dots, \alpha_{\rho_0}$ , defined on an open neighborhood  $U$  of  $p_0$  in  $\mathbb{R}^n$ , such that*

1.  $U \cap \Gamma^* \subset \{x \in U : \alpha_i(x) = 0, i = 1, \dots, \rho_0\}$ ; and
2. the system

$$(3.2) \quad \begin{aligned} \dot{x} &= f(x) + \sum_{i=1}^m g_i(x)u_i, \\ y' &= \text{col}(\alpha_1(x), \dots, \alpha_{\rho_0}(x)) \end{aligned}$$

has vector relative degree  $\{k_1, \dots, k_{\rho_0}\}$  with  $k_1 + \dots + k_{\rho_0} = n - n^*$  at  $p_0$ .

Moreover, the zero dynamics  $\mathcal{Z}^*$  of (3.2) coincide with  $\Gamma^*$  on  $U$ :  $\mathcal{Z}^* \cap U = \Gamma^* \cap U$ .

We omit the proof of Theorem 3.1 and instead refer the reader to [19, Theorem 4.1] whose proof is identical. System (3.2) has  $m$  inputs and  $\rho_0$  outputs and hence is not square. The notion of vector relative degree of a nonsquare system is the same as that of a square system given in section 5.1 of [9], with the difference that the  $\rho_0 \times m$  decoupling matrix  $A(x)$  with components  $a_{ij}(x) = L_{g_j} L_f^{k_i-1} \alpha_i(x)$  is assumed to be full-rank, rather than nonsingular, at  $p_0$ .

In section 4 we give the coordinate-free definition of transverse controllability indices. It turns out (see Lemma 4.3) that  $\{k_1, \dots, k_{\rho_0}\}$  in Theorem 3.1 are precisely the transverse controllability indices of (2.1) with respect to  $\Gamma^*$ .

Theorem 3.1 characterizes the solvability of LTFLP in terms of the existence of a virtual output function  $\alpha : U \rightarrow \mathbb{R}^{\rho_0}$  satisfying (1) and (2). Once the output function is known, a coordinate and feedback transformation yielding (3.1) is found constructively using [9, Proposition 5.1.2] and additional elementary manipulations. The theorem also shows that LTFLP is equivalent to the *zero dynamics assignment problem with relative degree* mentioned in the introduction. For, the theorem states that LTFLP is solvable if and only if  $\Gamma^*$  can be made into the zero dynamics manifold of (2.1) induced by a suitable output yielding a well-defined vector relative degree. On the other hand, Theorem 3.1 does not give any way of finding the output function or even to determine whether it exists. Hence, it has limited value for constructing the coordinate and feedback transformation.

Consider the distributions

$$(3.3) \quad G_i := \text{span}\{ad_f^j g_k : 0 \leq j \leq i, 1 \leq k \leq m\}$$

and recall from section 2 that  $\bar{G}_i$  denotes the involutive closure of  $G_i$ . Now we give the main result of this paper.

**THEOREM 3.2** (main result). *Suppose that  $\bar{G}_i$ ,  $i \in \mathbf{n} - \mathbf{n}^* - \mathbf{1}$ , are regular at  $p_0 \in \Gamma^*$ . Then, LTFLP is solvable at  $p_0$  if and only if*

- (a)  $\dim(T_{p_0} \Gamma^* + G_{\mathbf{n} - \mathbf{n}^* - \mathbf{1}}(p_0)) = n$ , and
- (b) *there exists an open neighborhood  $U$  of  $p_0$  in  $\mathbb{R}^n$  such that for all  $i \in \mathbf{n} - \mathbf{n}^* - \mathbf{1}$  ( $\forall p \in \Gamma^* \cap U$ )  $\dim(T_p \Gamma^* + G_i(p)) = \dim(T_p \Gamma^* + \bar{G}_i(p)) = \text{constant}$ .*

It is useful to specialize Theorem 3.2 to the case when  $\Gamma^*$  is an equilibrium, because in this special case LTFLP coincides with the state-space exact linearization problem whose solution was given in [8], [12].

**COROLLARY 3.3.** *Assume that  $\Gamma^* = \{p_0\}$  is an equilibrium point of the open-loop system  $\dot{x} = f(x)$  and that  $\bar{G}_i$ ,  $i \in \mathbf{n} - \mathbf{1}$ , are regular at  $p_0$ . Then, LTFLP is solvable at  $p_0$  if and only if*

- (a)  $\dim G_{\mathbf{n} - \mathbf{1}}(p_0) = n$ , and
- (b)'  $G_i$ ,  $i \in \mathbf{n} - \mathbf{1}$ , are involutive and regular at  $p_0$ .

*Proof.* It suffices to show that, under the assumption that the distributions  $\bar{G}_i$  are regular, (b)' is equivalent to condition (b) in Theorem 3.2. Assume that (b) holds, i.e.,  $G_i(p_0) = \bar{G}_i(p_0)$ . For all  $p$  in a neighborhood of  $p_0$ , one has

$$\dim(G_i(p_0)) \leq \dim(G_i(p)) \leq \dim(\bar{G}_i(p)) = \dim(\bar{G}_i(p_0)) = \dim(G_i(p_0)),$$

and so all inequalities above are equalities. Therefore,  $\dim(G_i(p)) = \dim(G_i(p_0))$  and  $\dim(G_i(p)) = \dim(\bar{G}_i(p))$ , proving that (b)  $\implies$  (b)'. The converse implication is obvious.  $\square$

We recall the following classical result.

**THEOREM 3.4** (state-space exact linearization [8], [12]). *Assume that  $\Gamma^* = \{p_0\}$  is an equilibrium point of the open-loop system  $\dot{x} = f(x)$ . Then, LTFLP is solvable at  $p_0$  if and only if conditions (a) and (b)' in Corollary 3.3 hold.*

Note that conditions (a) and (b)' in Corollary 3.3 imply that the distributions  $\bar{G}_i$ ,  $i \in \mathbf{n} - \mathbf{1}$ , are regular at  $p_0$ . Thus, in the special case when  $\Gamma^*$  is an equilibrium point, the conditions of our main result coincide with those of the state-space exact linearization problem. The difference between Corollary 3.3 and Theorem 3.4 is that the former relies on the *preliminary assumption* that the distributions  $\bar{G}_i$  are regular at  $p_0$ , while the latter shows that regularity of  $\bar{G}_i$  at  $p_0$  is actually necessary for the solvability of LTFLP, and hence there is no need to impose it as a preliminary requirement.

The assumptions of Theorem 3.2 are checkable; however, its proof does not provide a constructive procedure for finding the virtual outputs described in Theorem 3.1. The next result sheds additional light on LTFLP by relating it to the partial feedback linearization problem. The result isn't a viable solution to LTFLP because its assumptions are not checkable. On the other hand, the theorem provides guidelines for finding the output function in Theorem 3.1, as discussed below.

**THEOREM 3.5.** *Suppose that  $\bar{G}_i$ ,  $i \in \mathbf{n} - \mathbf{n}^* - \mathbf{1}$ , are regular at  $p_0 \in \Gamma^*$ . Then, LTFLP is solvable at  $p_0$  if and only if there exist a neighborhood  $U$  of  $p_0$  and a smooth, involutive, and regular distribution  $\Delta$  on  $U$  such that*

- (i)  $\Delta|_{\Gamma^*} = T\Gamma^*$ .
- (ii)  $\Delta$  is locally controlled invariant under (2.1).
- (iii)  $(\forall p \in \Gamma^* \cap U) \dim(T_p\Gamma^* + G_{n-n^*-1}(p)) = n$ .
- (iv)  $(\forall i \in \mathbf{n} - \mathbf{n}^* - \mathbf{1}) \Delta + G_i$  is regular and involutive on  $U$ .

*Proof.* Suppose that LTFLP is solvable at  $p_0$ . The necessity of conditions (i)–(iv) can be easily shown by considering the normal form (3.1) and taking

$$(3.4) \quad \Delta = \text{span} \left\{ \frac{\partial}{\partial z_1}, \dots, \frac{\partial}{\partial z_{n^*}} \right\}.$$

Conversely, suppose conditions (i)–(iv) hold. These conditions imply the conditions of [10, Theorem 2.1]. In particular, condition (iv) implies conditions (a) and (b) of [10, Theorem 2.1]. Therefore, by [10, Theorem 2.1] we obtain a system whose dynamics in transformed coordinates is given by (3.1) and where  $\Delta$  is given by (3.4). The integral submanifolds of  $\Delta$  foliate a neighborhood  $U$  of  $p_0$  and are locally given by the sets  $\{(z, \xi) : \xi = \xi^0 = \text{constant}\}$ . Condition (i) means that one of the leaves of the foliation is precisely  $\Gamma^* \cap U$ . Without loss of generality this leaf is taken as the zero level set  $\{(z, \xi) : \xi = 0\}$ .  $\square$

Note that the distribution  $\Delta$  in Theorem 3.5 is not unique. Also note that this theorem involves an interaction between the concepts of controlled invariant distributions and controlled invariant manifolds. Together, Theorems 3.1, 3.2, and 3.5 can be used to find solutions to LTFLP. The following steps outline the typical procedure one may follow in searching for the output function.

1. Represent  $\Gamma^*$  in a neighborhood of  $p_0$  as the zero level set of  $n - n^*$   $\mathbb{R}$ -valued functions. Using Theorem 3.1, check if there exists a subset of  $\rho_0$  of these functions, with  $\rho_0$  defined in (4.1), yielding the correct vector relative degree.
2. If the above step fails, check the conditions of Theorem 3.2 to verify whether or not the problem is solvable. In simple cases, the procedure described in the proof of Theorem 3.2 may yield the desired output functions.
3. If Theorem 3.2 establishes that the problem is solvable, then there exists a

distribution  $\Delta$  satisfying the conditions in Theorem 3.5. If  $\Delta$  is found then, after computing the controllability indices defined in (4.2), the output functions are obtained by finding those exact one-forms that span the codistributions  $\text{ann}(\Delta + G_i)$ ,  $i = 0, \dots, k_1 - 2$ , and arranging them in the order illustrated below, with the integers  $\rho_i$  defined in (4.1).

$\text{ann}(\Delta + G_{k_1-2})$	$d\alpha_1$			
$\vdots$	$\vdots$			
$\text{ann}(\Delta + G_{k_1-2-j})$	$dL_f^j \alpha_1$			
$\vdots$	$\vdots$			
$\text{ann}(\Delta + G_{k_2-2})$	$dL_f^{k_1-k_2} \alpha_1$	$d\alpha_2$		
$\vdots$	$\vdots$	$\vdots$		
$\text{ann}(\Delta + G_{k_2-2-j})$	$dL_f^{k_1-k_2+j} \alpha_1$	$dL_f^j \alpha_2$		
$\vdots$	$\vdots$	$\vdots$		
$\text{ann}(\Delta + G_{k_3-2})$	$dL_f^{k_1-k_3} \alpha_1$	$dL_f^{k_2-k_3} \alpha_2$	$d\alpha_3$	
$\vdots$	$\vdots$	$\vdots$	$\vdots$	
$\text{ann}(\Delta + G_{k_{\rho_0}-2})$	$dL_f^{k_1-k_{\rho_0}} \alpha_1$	$dL_f^{k_2-k_{\rho_0}} \alpha_2$	$\dots$	$d\alpha_{\rho_0}$
$\vdots$	$\vdots$	$\vdots$		$\vdots$
$\text{ann}(\Delta + G_0)$	$dL_f^{k_1-2} \alpha_1$	$dL_f^{k_2-2} \alpha_2$	$\dots$	$dL_f^{k_{\rho_0}-2} \alpha_{\rho_0}$

In each row of the above table, the codistribution in the left column is locally spanned by all the differentials in that row *plus* all the differentials in the rows above. For example, locally we have that

$$\text{ann}(\Delta + G_{k_2-2}) = \text{span}\{d\alpha_1, dL_f \alpha_1, \dots, dL_f^{k_1-k_2} \alpha_1, d\alpha_2\}.$$

The functions  $\alpha_1, \dots, \alpha_{\rho_0}$ , resulting from the integration of the exact one-forms  $d\alpha_1, \dots, d\alpha_{\rho_0}$  along the diagonal of the table are the required outputs. Next we present an example to illustrate the use of Theorems 3.1, 3.2, and 3.5.

*Example.* Consider the system

$$(3.5) \quad \dot{x} = \begin{bmatrix} -x_2 \\ x_1 \\ x_3 x_4 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ x_3 \\ 1 \end{bmatrix} u_1 + \begin{bmatrix} -x_2 \\ x_1 \\ 0 \\ 0 \end{bmatrix} u_2$$

along with the pair  $(\Gamma^*, u^*) \in \mathcal{S}(f, g, \mathbb{R}^4) \times \mathcal{F}(f, g, \mathbb{R}^4)$ ,

$$\begin{aligned} \Gamma^* &= \{x \in \mathbb{R}^4 : x_1^2 + x_2^2 - x_3 = x_4 = 0\}, \\ u^* &= \text{col}(0, 0). \end{aligned}$$

The set  $\Gamma^*$  is an elliptic paraboloid embedded in the subspace  $\{x \in \mathbb{R}^4 : x_4 = 0\}$ . We want to perform TFL of (3.5) with respect to  $\Gamma^*$  near  $p_0 = \text{col}(4, 0, 2, 0)$ . In this example  $n = 4$  and  $n^* = 2$ , so we seek to feedback linearize a subsystem of dimension  $n - n^* = 2$ . The natural approach to solving this problem is to check if one of the two constraints which define  $\Gamma^*$  satisfies the conditions of Theorem 3.1. In this case, both constraints, taken individually as scalar outputs, yield a well-defined

relative degree near  $p_0$  of 1 which does not equal  $n - n^*$ . Taken together, as a vector output, the constraints do not yield a well-defined vector relative degree. In both cases, the conditions of Theorem 3.1 are not satisfied by these constraints. Next, we check whether or not LTFLP is solvable for (3.5) using Theorem 3.2. Checking condition (a) one finds

$$\dim(T_{p_0}\Gamma^* + G_1(p_0)) = 4.$$

Also, since  $[g_1, g_2] = 0$ , it follows that  $G_0 = \bar{G}_0$  everywhere. It is then an easy matter to check that for any  $p \in \Gamma^*$ ,  $\dim(T_p\Gamma^* + G_0(p)) = 3$ . Thus condition (b) holds and LTFLP is solvable despite the fact that the constraints which locally define  $\Gamma^*$  do not satisfy Theorem 3.1.

The fact that Theorem 3.2 holds for this system implies that there exists a distribution  $\Delta$  satisfying Theorem 3.5. After some trial and error, one finds that the distribution

$$\Delta = \text{span} \left\{ \begin{bmatrix} -x_2 \\ x_1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} x_1 \\ x_2 \\ 2x_3 \\ 0 \end{bmatrix} \right\}$$

satisfies the conditions of Theorem 3.5. Then, by the Frobenius theorem, there exists an exact one-form  $d\alpha$  which spans  $\text{ann}(\Delta + G_0)$ . The corresponding function  $\alpha$  is given by

$$\alpha(x) = \ln \left( \frac{x_3}{x_1^2 + x_2^2} \right) - x_4$$

which yields a well-defined relative degree of 2 at  $p_0$  and satisfies Theorem 3.1. As a result, the coordinate transformation  $\Xi: x \mapsto \text{col}(z_1, z_2, \xi_1, \xi_2)$  defined as  $z_1 = x_1$ ,  $z_2 = x_2$ ,  $\xi_1 = \alpha$ ,  $\xi_2 = L_f\alpha = x_4$ , directly yields the normal form (3.1), with  $v_1 = u_1$  and  $v_2 = u_2$ . The coordinate transformation  $\Xi(x)$  is valid on  $\mathbb{R}^4 \setminus (\{x \in \mathbb{R}^4 : x_1 = x_2 = 0\} \cup \{x \in \mathbb{R}^4 : x_3 = 0\})$ .

**4. Transverse controllability indices and preliminary results.** In linear systems theory, controllability indices (see [4] and [29]) describe certain properties which are invariant under coordinate and nonsingular feedback transformations and serve to categorize controllable linear systems. Controllability indices have been ported to the nonlinear setting. They have been used to characterize the largest feedback linearizable subsystem of a nonlinear system [15], and conditions under which a system is feedback linearizable; see [17], [21]. Here, we adapt these ideas to the framework of TFL. Let  $V$  be an open subset of  $\Gamma^*$ . For each  $p \in V$ , let

$$(4.1) \quad \begin{aligned} \rho_0(p) &:= \dim(T_p\Gamma^* + G_0(p)) - n^*, \\ \rho_i(p) &:= \dim(T_p\Gamma^* + \bar{G}_{i-1}(p) + \text{ad}_f^i G_0(p)) - \dim(T_p\Gamma^* + \bar{G}_{i-1}(p)), \end{aligned}$$

$i = 1, 2, \dots$ , where  $G_i$  are as defined in (3.3), and

$$\text{ad}_f^i G_0 = \text{span}\{\text{ad}_f^i X : X \in G_0\}, \quad i = 0, 1, \dots$$

Geometrically, at each  $p \in \Gamma^*$ , the integers  $\rho_i(p)$  represent the number of linearly independent vectors in  $\text{ad}_f^i G_0(p)$  which are not in  $T_p\Gamma^* + \bar{G}_{i-1}(p)$ . Associated to the

list  $\{\rho_0(p), \dots, \rho_i(p), \dots\}$  is a set of  $\rho_0(p)$  integers,  $\{k_1(p), \dots, k_{\rho_0(p)}\}$ , which we refer to as the *transverse controllability indices of (2.1) with respect to  $\Gamma^*$* , defined as (we omit the argument  $p$ )

$$(4.2) \quad k_i := \text{card} \{\rho_j \geq i, j \geq 0\}, \quad i \in \{1, \dots, \rho_0\}.$$

Note that  $k_1 \geq k_2 \geq \dots \geq k_{\rho_0}$ . We show in Corollary 4.2 that the transverse controllability indices are invariant under coordinate and feedback transformations.

Condition (b) of Theorem 3.2 implies that  $\rho_0, \rho_1, \dots, \rho_{n-n^*-2} = \text{constant}$ , while condition (a) implies that  $\sum_i \rho_i = n - n^*$ . In the special case when  $\Gamma^*$  is an equilibrium point, it is useful to compare our definition of controllability indices with the definition by Marino in [15]. Marino's definition relies on the distributions

$$\begin{aligned} \mathcal{G}_f &= f + G_0 = \{f + g : g \in G_0\}, \\ \mathcal{G}_i &= \mathcal{G}_{i-1} + [\mathcal{G}_f, \mathcal{G}_{i-1}], \quad \mathcal{G}_0 = G_0, \quad i = 1, 2, \dots, \\ \mathcal{S}_i &= \bar{\mathcal{G}}_{i-1} + \text{ad}_f^i G_0, \quad \mathcal{S}_0 = G_0, \quad i = 1, 2, \dots, \end{aligned}$$

and uses the integers

$$\begin{aligned} r_0 &= \dim \mathcal{G}_0, \\ r_i &= \dim \mathcal{S}_i - \dim \bar{\mathcal{G}}_{i-1} \end{aligned}$$

in place of the integers  $\rho_i$  in the definition of controllability indices. We now show that, when  $\Gamma^*$  is an equilibrium point, the integers  $\rho_i$  and  $r_i$  are identical, and thus the notion of transverse controllability indices reduces to the classical notion of controllability indices.

LEMMA 4.1. *For all nonnegative integers  $i$ ,  $\bar{G}_i = \bar{\mathcal{G}}_i$ . Thus, when  $\Gamma^* = \{p_0\}$  is an equilibrium point,  $\rho_i = r_i$ .*

*Proof.* By definition,  $G_0 = \mathcal{G}_0$ , so the lemma trivially holds for  $i = 0$ . We now show that  $\bar{G}_i \subseteq \bar{\mathcal{G}}_i$  for all  $i \in \mathbb{N}$ . By definition,

$$\mathcal{G}_i = \mathcal{G}_{i-1} + [\mathcal{G}_f, \mathcal{G}_{i-1}].$$

Since  $f \in \mathcal{G}_f$ , it follows that  $G_i \subseteq \mathcal{G}_i$  for all nonnegative integers  $i$ , which implies  $\bar{G}_i \subseteq \bar{\mathcal{G}}_i$ .

Next, we show that  $\mathcal{G}_i \subseteq \bar{G}_i$  for all  $i \in \mathbb{N}$  which implies  $\bar{\mathcal{G}}_i \subseteq \bar{G}_i$ . To this end, it suffices to prove that  $\mathcal{G}_i \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$  since  $\text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i) \subseteq \bar{G}_i$ . It is obvious that  $\mathcal{G}_0 \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_0)$  and

$$\begin{aligned} \mathcal{G}_1 &= G_0 + [\mathcal{G}_f, G_0] \\ &= \text{span}\{g_1, \dots, g_m, \text{ad}_f g_1, \dots, \text{ad}_f g_m, [g, g_1], \dots, [g, g_m] : g \in G_0\} \\ &\subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_1). \end{aligned}$$

For the induction, assume that, for some positive integer  $I \geq 2$ ,

$$\mathcal{G}_{i-1} \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_{i-1}), \quad i \in \{2, \dots, I\}.$$

We must show that  $\mathcal{G}_i = \mathcal{G}_{i-1} + [\mathcal{G}_f, \mathcal{G}_{i-1}] \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$  for  $i \in \{2, \dots, I\}$ . It is enough to prove that  $[\mathcal{G}_f, \mathcal{G}_{i-1}] = [f, \mathcal{G}_{i-1}] + [G_0, \mathcal{G}_{i-1}] \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ . However, since  $[G_0, \mathcal{G}_{i-1}] \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_{i-1}) \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ , all we are left to show is that  $[f, \mathcal{G}_{i-1}] \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ .

Let  $\tau_1 = g_1$ ,  $\tau_2 = g_2, \dots, \tau_{im-1} = ad_f^{i-1} g_{m-1}$ ,  $\tau_{im} = ad_f^{i-1} g_m$ . Then a general vector field in  $\text{Lie}_{C^\infty(\mathbb{R}^n)}(G_{i-1})$  is a  $C^\infty(\mathbb{R}^n)$ -linear combination of vector fields of the form

$$(4.3) \quad \vartheta = [\tau_{j_k}, [\tau_{j_{k-1}}, \dots, [\tau_{j_2}, \tau_{j_1}]]],$$

$1 \leq j_k \leq im$ ,  $1 \leq k < \infty$ . By assumption, any vector field in  $\mathcal{G}_{i-1}$  can also be expressed in this way. Take any vector field  $h \in \mathcal{G}_{i-1}$  and consider

$$[f, h] = \left[ f, \sum_{i \in \mathcal{I}} c_i \vartheta_i \right] = \sum_{i \in \mathcal{I}} [f, c_i \vartheta_i],$$

where  $\mathcal{I}$  is some finite index set,  $c_i \in C^\infty(\mathbb{R}^n)$ , and  $\vartheta_i$  are of the form (4.3). Each term in the above summation can be expressed as  $[f, c_i \vartheta_i] = c_i[f, \vartheta_i] + (L_f c_i) \vartheta_i$ , so it is enough to show that  $[f, \vartheta] \in \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ , where  $\vartheta$  is of the form (4.3).

When  $k = 1$ , i.e.,  $\vartheta = \tau_{j_1}$ , then  $[f, \tau_{j_1}] \in G_i \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ . Next assume that

$$\vartheta = [\tau_{j_{k-1}}, [\tau_{j_{k-2}}, \dots, [\tau_2, \tau_1]]]$$

is such that  $[f, \vartheta] \in \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ . We will show that  $[f, [\tau_{j_k}, \vartheta]] \in \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ . Clearly,  $[\tau_{j_k}, \vartheta] \in \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_{i-1})$  for any  $1 \leq j_k \leq im$ . By the Jacobi identity,

$$[f, [\tau_{j_k}, \vartheta]] = [[\vartheta, f], \tau_{j_k}] + [[f, \tau_{j_k}], \vartheta],$$

and since  $[\vartheta, f] \in \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$  and  $\tau_{j_k} \in G_{i-1}$ , it follows that  $[[\vartheta, f], \tau_{j_k}] \in \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ . Also,  $[f, \tau_{j_k}] \in G_i$  so that  $[[f, \tau_{j_k}], \vartheta] \in \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i)$ . This induction argument shows that  $[f, \mathcal{G}_{i-1}] \subseteq \text{Lie}_{C^\infty(\mathbb{R}^n)}(G_i) \subseteq G_i$ , as required.  $\square$

**COROLLARY 4.2.** *The transverse controllability indices of system (2.1) with respect to a set  $\Gamma^*$  are invariant under coordinate and feedback transformations.*

*Proof.* The push-forward map  $F_*$  associated with any  $F \in \text{Diff}(U)$  is an isomorphism at each  $p \in \Gamma^* \cap U$ . It follows from the definition of the integers  $\rho_0, \dots, \rho_i, \dots$  that they do not change under coordinate transformations. By Lemma 4.1,

$$\rho_i(p) = \dim(T_p \Gamma^* + \mathcal{S}_i(p)) - \dim(T_p \Gamma^* + \bar{\mathcal{G}}_{i-1}(p)).$$

In [15, Proposition 2] it is shown that  $\mathcal{S}_i$  and  $\bar{\mathcal{G}}_{i-1}$  are feedback invariant, and so the integers  $\rho_0, \dots, \rho_i, \dots$  are also invariant under feedback transformations.  $\square$

**LEMMA 4.3.** *Suppose that LTFLP is solvable at  $p_0 \in \Gamma^*$ . Then the transverse controllability indices of (2.1) with respect to  $\Gamma^*$  coincide with the controllability indices of  $(A, B)$  in (3.1).*

*Proof.* This lemma will be proved by direct calculation of the integers  $\rho_i$  in  $(z, \xi)$  coordinates. Let  $V = \Xi(\Gamma^* \cap U)$ . By the properties of the normal form (3.1), for any  $\tilde{p} \in \Gamma^* \cap U$ ,  $\Xi(\tilde{p}) = \text{col}(p, 0)$ . Hence, in  $(z, \xi)$  coordinates we have that for any  $p \in V$  and any  $i \in \mathbf{n} - \mathbf{n}^*$ ,

$$(4.4) \quad T_p V + G_i(\text{col}(p, 0)) = \text{Im} \left( \begin{bmatrix} I_{n^*} & \star & \star & \cdots & \star \\ 0_{n-n^* \times n^*} & B & AB & \cdots & A^i B \end{bmatrix} \right).$$

In  $(z, \xi)$  coordinates, consider the collection of constant distributions  $\Delta_i$ ,  $i \in \mathbf{n} - \mathbf{n}^*$ , given by

$$\Delta_i = \text{Im} (I_{n^*} \oplus [B \quad AB \quad \cdots \quad A^i B]).$$

At each  $p \in V$ ,  $\Delta_i(p) = T_p V + G_i(\text{col}(p, 0))$ . Furthermore, since each  $\Delta_i$  is (trivially) involutive and  $G_i|_V \subset \Delta_i$ , it follows that  $\bar{G}_i|_V \subseteq \Delta_i$ . This shows that for all  $i \in \mathbf{n} - \mathbf{n}^*$ ,

$$TV + \bar{G}_i \subseteq \Delta_i = TV + G_i.$$

On the other hand,  $TV + G_i \subseteq TV + \bar{G}_i$  always holds, and so we have shown that  $\Delta_i = TV + G_i = TV + \bar{G}_i$ . Calculating the integers  $\rho_i$ , we have

$$\begin{aligned} \rho_i(p) &= \dim(T_p \Gamma^* + \bar{G}_{i-1}(p) + \text{ad}_{\tilde{f}}^i G_0(p)) - \dim(T_p \Gamma^* + \bar{G}_{i-1}(p)) \\ &= \dim(T_p \Gamma^* + G_{i-1}(p) + \text{ad}_{\tilde{f}}^i G_0(p)) - \dim(T_p \Gamma^* + G_{i-1}(p)) \\ &= \dim(T_p \Gamma^* + G_i(p)) - \dim(T_p \Gamma^* + G_{i-1}(p)) \\ &= \text{rank}(\Delta_i) - \text{rank}(\Delta_{i-1}) \\ &= \text{rank}([B \ \cdots \ A^i B]) - \text{rank}([B \ \cdots \ A^{i-1} B]). \end{aligned}$$

The claim follows from the definition of the integers  $\{k_1, \dots, k_{\rho_0}\}$ .  $\square$

When the transverse controllability indices are constant on an open subset of  $\Gamma^*$  and the distributions  $\bar{G}_i$  are regular, the next two lemmas establish the existence of a feedback transformation yielding a particularly useful set of local generators for each  $\bar{G}_i$ .

LEMMA 4.4. *Let  $\tilde{U}$  be an open subset of  $\mathbb{R}^n$  such that  $\tilde{V} := \tilde{U} \cap \Gamma^* \neq \emptyset$ . Assume that, for all  $i \in \mathbf{n} - \mathbf{n}^*$ ,*

$$\begin{aligned} (\forall p \in \tilde{V}) \quad \dim(T_p \Gamma^* + G_i(p)) &= \dim(T_p \Gamma^* + \bar{G}_i(p)) = \text{constant}, \\ (\forall p \in \tilde{U}) \quad \dim(\bar{G}_i(p)) &= \nu_i = \text{constant}. \end{aligned}$$

*Then,  $\rho_0 \geq \rho_1 \geq \dots \geq \rho_{n-n^*-1}$  and there exist an open set  $U \subseteq \tilde{U}$  and a regular static feedback  $(\alpha, \beta)$  on  $U$  such that, letting  $V := U \cap \Gamma^*$ , for all  $p \in V$  and for all  $i \in \mathbf{n} - \mathbf{n}^*$ , the following holds:*

$$(4.5) \quad T_p \Gamma^* + \bar{G}_i(p) = T_p \Gamma^* \oplus \left( \bigoplus_{j=0}^i \text{span} \left\{ \text{ad}_{\tilde{f}}^j \tilde{g}_k : 1 \leq k \leq \rho_j \right\} (p) \right).$$

*Proof.* Choose an open set  $U \subseteq \tilde{U}$  such that  $V := U \cap \Gamma^* \neq \emptyset$  and such that  $V$  is covered by a coordinate chart in the atlas of  $\Gamma^*$ . Apply the preliminary feedback transformation  $(u^*, I_m)$  defined on  $V$ . Let  $\tilde{f} = f + gu^*$ . On  $V$ , define the distribution (i.e., a subbundle of  $T\mathbb{R}^n|_V$  defined using the natural orthogonal structure on  $\mathbb{R}^n$ )

$$\mathcal{G}_0 = [\bar{G}_0 \cap TV]^\perp \cap \bar{G}_0.$$

On  $V$ ,  $\bar{G}_0 \cap TV$  is constant dimensional since

$$\dim(\bar{G}_0 \cap TV) = \dim(TV) + \dim(\bar{G}_0) - \dim(TV + \bar{G}_0).$$

Since  $\bar{G}_0$  and  $TV$  are regular distributions and their intersection is constant dimensional, it follows from Lemma 2.4 that, by possibly shrinking  $U$  (and hence  $V$ ),  $\bar{G}_0 \cap TV$  is smooth, and so too is  $[\bar{G}_0 \cap TV]^\perp$ . Thus,  $\mathcal{G}_0$  is the intersection of smooth, regular distributions. Furthermore,  $\mathcal{G}_0$  has constant dimension on  $V$  since, for each  $p \in V$ ,

$$\begin{aligned} \dim(\mathcal{G}_0(p)) &= n - \dim(\bar{G}_0(p) \cap T_p V) + \dim(\bar{G}_0(p)) - \dim([\bar{G}_0(p) \cap T_p V]^\perp + \bar{G}_0(p)) \\ &= \dim(\bar{G}_0(p)) - \dim(\bar{G}_0(p) \cap T_p V) \\ &= \rho_0. \end{aligned}$$

Since  $\mathcal{G}_0 \subseteq \bar{G}_0$  and  $\mathcal{G}_0 \cap TV = (\bar{G}_0^\perp + TV^\perp) \cap (\bar{G}_0^\perp + TV^\perp)^\perp = 0$ , we have

$$(\forall p \in V) \ T_p V \oplus \mathcal{G}_0(p) = T_p V + \bar{G}_0(p) = T_p V + G_0(p).$$

By construction,  $V$  is covered by a coordinate chart, so there exist  $n^*$  vector fields on  $V$  such that at each  $p \in V$ ,  $T_p V = \text{span}\{v_1, \dots, v_{n^*}\}(p)$ . Moreover, by possibly shrinking  $U$  (and hence  $V$ ), there exist  $\rho_0$  vector fields  $w_1, \dots, w_{\rho_0} : V \rightarrow T\mathbb{R}^n|_V$  such that  $\mathcal{G}_0 = \text{span}\{w_1, \dots, w_{\rho_0}\}$  so that, on  $V$ ,

$$TV \oplus \mathcal{G}_0 = \text{span}\{v_1, \dots, v_{n^*}\} \oplus \text{span}\{w_1, \dots, w_{\rho_0}\}.$$

Using the fact that  $\mathcal{G}_0 \subset TV + G_0$ , we write

$$(4.6) \quad w_j = \sum_{k=1}^{n^*} \alpha_k^j v_k + \sum_{k=1}^m \beta_k^j g_k, \quad j = 1, \dots, \rho_0,$$

where  $\alpha_k^j : V \rightarrow \mathbb{R}$ ,  $\beta_k^j : V \rightarrow \mathbb{R}$  are  $C^\infty(V)$  functions. Let  $\beta_0$  be the  $m \times \rho_0$  matrix of real-valued functions whose  $(k, j)$ th element is  $\beta_k^j$  and let

$$\begin{bmatrix} \tilde{g}_1 & \cdots & \tilde{g}_{\rho_0} \end{bmatrix} = \begin{bmatrix} g_1 & \cdots & g_m \end{bmatrix} \beta_0.$$

We now show that  $\tilde{g}_1, \dots, \tilde{g}_{\rho_0}$  are linearly independent, which implies that  $\beta_0$  is full rank. Suppose there exist  $\rho_0$  functions  $c_i \in C^\infty(V)$  such that  $\sum_{i=1}^{\rho_0} c_i \tilde{g}_i = 0$ . Then by (4.6),  $\sum_{i=1}^{\rho_0} c_i w_i \in TV$ , which implies  $c_i = 0$ ,  $i = 1, \dots, \rho_0$ , since  $\mathcal{G}_0 \cap TV = 0$ . Note that this argument also shows that  $\text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_0}\} \cap TV = 0$ . For if this were false, then there would exist a linear combination of the  $w_i$ 's in (4.6) which, pointwise, belongs to  $T_p V$ .

Next, we seek  $m - \rho_0$  vector fields  $\tilde{g}_{\rho_0+1}, \dots, \tilde{g}_m$  which belong to  $TV$  and such that, on  $V$ ,  $\text{span}\{\tilde{g}_1, \dots, \tilde{g}_m\} = G_0$ . By possibly shrinking  $U$  (and hence  $V$ ), there exists a set of smooth local generators,  $\tilde{g}_{\rho_0+1}, \dots, \tilde{g}_m$ , for  $G_0 \cap TV$ . We now have the desired decomposition on  $V$ ,

$$TV + G_0 = TV + \bar{G}_0 = TV \oplus \text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_0}\},$$

where, in the new basis for  $G_0$ , at each  $p \in V$ ,

$$(4.7) \quad \begin{aligned} \tilde{g}_1(p), \dots, \tilde{g}_{\rho_0}(p) &\in G_0(p), \\ \tilde{g}_{\rho_0+1}(p), \dots, \tilde{g}_m(p) &\in T_p V. \end{aligned}$$

On  $V$ ,  $\tilde{f}(p) \in T_p V$ , so we have that  $ad_{\tilde{f}}^j \tilde{g}_k \in TV + \bar{G}_{j-1}$ ,  $\rho_0 + 1 \leq k \leq m$ ,  $j = 0, 1, \dots$ , and hence  $\rho_0 \geq \rho_1, \dots, \rho_{n-n^*-1}$ .

Now we perform the induction step. Assume that, for some positive integer  $I$ , and any  $i \in \{0, \dots, I\}$ , there exists a basis  $\{\hat{g}_1, \dots, \hat{g}_m\}$  for  $G_0$  such that

$$\begin{aligned} \text{(a)} \quad TV + \bar{G}_{i-1} &= TV \oplus \left( \bigoplus_{j=0}^{i-1} \text{span} \left\{ ad_{\tilde{f}}^j \hat{g}_k : 1 \leq k \leq \rho_j \right\} \right), \\ \text{(b)} \quad (\forall k \in \{\rho_{i-1} + 1, \dots, m\}) \quad ad_{\tilde{f}}^{i-1} \hat{g}_k &\in TV + \bar{G}_{i-2}. \end{aligned}$$

Property (b) implies that  $\rho_{i-1} \geq \rho_i, \dots, \rho_{n-n^*-1}$ . We now seek a basis  $\{\tilde{g}_1, \dots, \tilde{g}_m\}$  for  $G_0$  such that for any  $i \in \{0, \dots, I\}$ ,

$$\begin{aligned} \text{(a)'} \quad TV + \bar{G}_i &= TV \oplus \left( \bigoplus_{j=0}^i \text{span}\{ad_{\tilde{f}}^j \tilde{g}_k : 1 \leq k \leq \rho_j\} \right), \\ \text{(b)'} \quad (\forall k \in \{\rho_i + 1, \dots, m\}) \quad ad_{\tilde{f}}^i \tilde{g}_k &\in TV + \bar{G}_{i-1}. \end{aligned}$$

On  $V$ , define the distribution

$$\mathcal{G}_i = [\bar{G}_i \cap (TV + \bar{G}_{i-1})]^\perp \cap \bar{G}_i.$$

Note that  $\bar{G}_i \cap (TV + \bar{G}_{i-1})$  is constant dimensional since

$$\dim(\bar{G}_i \cap (TV + \bar{G}_{i-1})) = \dim(\bar{G}_i) + \dim(TV + \bar{G}_{i-1}) - \dim(TV + \bar{G}_i).$$

The distribution  $\bar{G}_i$  is regular on  $U$  and  $TV + \bar{G}_{i-1}$  is constant dimensional on  $V$ . Since their intersection is constant dimensional, it follows from Lemma 2.4 that the orthogonal complement of their intersection is smooth, and thus  $\mathcal{G}_i$ , being the intersection of two smooth and regular distributions, is smooth. Furthermore,

$$\begin{aligned} \dim \mathcal{G}_i &= n - \dim(\bar{G}_i) - \dim(TV + \bar{G}_{i-1}) + \dim(TV + \bar{G}_i) \\ &\quad + \dim(\bar{G}_i) - \dim([\bar{G}_i \cap (TV + \bar{G}_{i-1})]^\perp + \bar{G}_i) \\ &= \dim(TV + \bar{G}_i) - \dim(TV + \bar{G}_{i-1}) \\ &= \rho_i. \end{aligned}$$

By construction,  $\mathcal{G}_i \subseteq \bar{G}_i$  and  $\mathcal{G}_i \cap (TV + \bar{G}_{i-1}) = 0$ , so by dimensionality we have that

$$(4.8) \quad (TV + \bar{G}_{i-1}) \oplus \mathcal{G}_i = TV + \bar{G}_i = TV + G_i.$$

By possibly shrinking  $U$  (and hence  $V$ ), there exist  $\rho_i$  smooth vector fields  $w_1, \dots, w_{\rho_i}$  such that on  $V$ ,  $\mathcal{G}_i = \text{span}\{w_1, \dots, w_{\rho_i}\}$ . Hence, by (4.8) we can write

$$(4.9) \quad w_j = \bar{w} + \sum_{k=1}^{\rho_{i-1}} \beta_k^j ad_{\tilde{f}}^i \hat{g}_k + \sum_{k=\rho_{i-1}+1}^m \beta_k^j ad_{\tilde{f}}^i \hat{g}_k, \quad j \in \{1, \dots, \rho_i\},$$

where  $\bar{w} \in TV + \bar{G}_{i-1}$  and each  $\beta_k^j : V \rightarrow \mathbb{R}$  is a  $C^\infty(V)$  function. By property (b), for all  $k \in \{\rho_{i-1} + 1, \dots, m\}$ ,  $ad_{\tilde{f}}^i \hat{g}_k \in TV + \bar{G}_{i-1}$ . Let

$$(4.10) \quad \hat{w}_j := \sum_{k=1}^{\rho_{i-1}} \beta_k^j ad_{\tilde{f}}^i \hat{g}_k, \quad j = 1, \dots, \rho_i.$$

Notice that  $\text{span}\{\hat{w}_1, \dots, \hat{w}_{\rho_i}\} \cap (TV + \bar{G}_{i-1}) = 0$ . For if this were false, then there would exist a  $C^\infty(V)$ -linear combination of the  $w_j$  belonging to  $TV + \bar{G}_{i-1}$  which, by (4.8), is not possible. Furthermore,  $\hat{w}_1, \dots, \hat{w}_{\rho_i}$  are linearly independent because if there exist  $\rho_i$  functions  $c_i \in C^\infty(V)$  such that on  $V$   $c_1 \hat{w}_1 + \dots + c_{\rho_i} \hat{w}_{\rho_i} = 0$ , then, for some  $w^* \in TV + \bar{G}_{i-1}$ ,  $c_1 w_1 + \dots + c_{\rho_i} w_{\rho_i} - w^* = 0$ , thus  $c_1 w_1 + \dots + c_{\rho_i} w_{\rho_i} = 0$ ,

implying  $c_1 = \cdots = c_{\rho_i} = 0$ . Now let  $\beta_i$  be the  $\rho_{i-1} \times \rho_i$  matrix of smooth functions whose  $(k, j)$ th element is  $\beta_k^j$  obtained from (4.10) so that

$$\begin{bmatrix} \hat{w}_1 & \cdots & \hat{w}_{\rho_i} \end{bmatrix} = \begin{bmatrix} ad_{\tilde{f}}^i \hat{g}_1 & \cdots & ad_{\tilde{f}}^i \hat{g}_{\rho_{i-1}} \end{bmatrix} \beta_i.$$

The vector fields  $\hat{w}_1, \dots, \hat{w}_{\rho_i}$  are linearly independent and are generated as the image of  $\rho_{i-1}$  linearly independent vector fields under  $\beta_i$ . Therefore  $\beta_i$  is full rank. We can now write

$$TV + \bar{G}_i = (TV + \bar{G}_{i-1}) \oplus \text{span}\{\hat{w}_1, \dots, \hat{w}_{\rho_i}\}.$$

Let

$$\begin{bmatrix} \tilde{g}_1 & \cdots & \tilde{g}_{\rho_i} \end{bmatrix} = \begin{bmatrix} \hat{g}_1 & \cdots & \hat{g}_{\rho_{i-1}} \end{bmatrix} \beta_i.$$

The vector fields  $\{\tilde{g}_1, \dots, \tilde{g}_{\rho_i}\}$  are linearly independent because the vector fields  $\{\hat{g}_1, \dots, \hat{g}_{\rho_{i-1}}\}$  are linearly independent and  $\beta_i$  is full rank. Moreover, since  $\text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_i}\} \subseteq \text{span}\{\hat{g}_1, \dots, \hat{g}_{\rho_{i-1}}\}$  and both are constant dimensional, we can find (making  $U$ , and hence  $V$ , smaller if necessary)  $\rho_{i-1} - \rho_i$  vector fields  $\tilde{g}_{\rho_{i-1}+1}, \dots, \tilde{g}_{\rho_{i-1}}$  such that  $\text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_{i-1}}\} = \text{span}\{\hat{g}_1, \dots, \hat{g}_{\rho_{i-1}}\}$  (hence preserving property (a) from the induction assumption) and  $ad_{\tilde{f}}^i \tilde{g}_{\rho_{i-1}+1}, \dots, ad_{\tilde{f}}^i \tilde{g}_{\rho_{i-1}} \in TV + \bar{G}_{i-1}$ . This is done by finding local generators for the smooth distribution

$$\text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_i}\}^\perp \cap \text{span}\{\hat{g}_1, \dots, \hat{g}_{\rho_{i-1}}\},$$

which has constant dimension  $\rho_{i-1} - \rho_i$ . Finally, let  $\tilde{g}_{\rho_{i-1}+1} = \hat{g}_{\rho_{i-1}+1}, \dots, \tilde{g}_m = \hat{g}_m$ . We have therefore obtained a basis  $\{\tilde{g}_1, \dots, \tilde{g}_m\}$  for  $G_0$  in which properties (a)' and (b)' hold. In summary, the induction process gives a basis for  $G_0$  in which the input vector fields are arranged in such a way that for  $i \in \mathbf{n} - \mathbf{n}^*$ ,

$$(TV + \bar{G}_{i-1} + ad_{\tilde{f}}^i G_0) / (TV + \bar{G}_{i-1}) \simeq \text{span}\{ad_{\tilde{f}}^i \tilde{g}_1, \dots, ad_{\tilde{f}}^i \tilde{g}_{\rho_i}\}.$$

We are left to show that this arrangement can be achieved using a regular static feedback and that the arrangement is valid on  $U$ , and not just on  $V$ , as is presently the case. To this end, let  $\tilde{g} = [\tilde{g}_1 \cdots \tilde{g}_m]$  and define a regular static feedback defined on  $V$  by  $(\hat{\alpha}, \hat{\beta})$ , where  $\hat{\alpha} = u^*$  and  $\hat{\beta} = (g^\top g)^{-1} g^\top \tilde{g}$ . To obtain a feedback transformation defined off of  $\Gamma^*$ , we can, by possibly shrinking  $U$  (and hence  $V$ ) and applying Lemma 2.3, introduce a retraction  $r : U \rightarrow V$  of  $U$  onto  $V$ . Then, let  $\alpha = \hat{\alpha} \circ r$  and  $\beta = \hat{\beta} \circ r$ . The regular static feedback  $(\alpha, \beta)$  has the desired properties.  $\square$

In order to identify directions in the intersection  $T_p V \cap \bar{G}_i(p)$  which are not contained in the intersection  $T_p V \cap \bar{G}_{i-1}(p)$ , it is useful to define the integers

$$\begin{aligned} \mu_0(p) &:= \dim(T_p V \cap \bar{G}_0(p)), \\ \mu_i(p) &:= \dim(T_p V \cap \bar{G}_i(p)) - \dim(T_p V \cap \bar{G}_{i-1}(p)) \end{aligned}$$

for  $i \in \mathbb{N}$ , and let

$$n_i(p) := \sum_{j=0}^i \mu_j(p),$$

so that  $\dim(T_p V \cap \bar{G}_i(p)) = n_i(p)$ . Under the assumption of Lemma 4.4, we have that  $\dim(T_p V \cap \bar{G}_i(p)) = n^* + \nu_i - \dim(T_p V + \bar{G}_i(p))$ , and hence the  $\mu_i$  are constant for all  $i \in \mathbf{n} - \mathbf{n}^*$ , and we have the following result.

LEMMA 4.5. *Let  $\tilde{U}$  be an open subset of  $\mathbb{R}^n$  such that  $\tilde{V} := \tilde{U} \cap \Gamma^* \neq \emptyset$ . Assume that, for all  $i \in \mathbf{n} - \mathbf{n}^*$ , the conditions of Lemma 4.4 hold. Then, there exists an open set  $U \subseteq \tilde{U}$  and  $n_{n-\mathbf{n}^*-1}$  vector fields  $v_\ell^j \in \mathbf{V}(U)$ ,  $0 \leq j \leq n - \mathbf{n}^* - 1$  such that, after the feedback transformation of Lemma 4.4, letting  $V := U \cap \Gamma^*$ , and*

$$G_i^\parallel := \text{span}\{v_1^0, \dots, v_{\mu_0}^0, \dots, v_1^i, \dots, v_{\mu_i}^i\}$$

*one has that, for all  $i \in \mathbf{n} - \mathbf{n}^*$ , on  $U$ ,*

$$\bar{G}_i = G_i^\parallel \oplus \left( \bigoplus_{j=0}^i \text{span} \left\{ \text{ad}_{\tilde{f}}^j \tilde{g}_k : 1 \leq k \leq \rho_j \right\} \right)$$

and  $G_i^\parallel|_V = TV \cap \bar{G}_i$ .

*Proof.* Suppose the feedback transformation  $(\alpha, \beta)$  of Lemma 4.4 has been applied, which is valid on  $U \subseteq \tilde{U}$  as defined therein. Since every point  $p$  of  $U$  is a regular point for the distributions  $\bar{G}_i$ , we can, by possibly shrinking  $U$  (and hence  $V$ ), find a set of local generators  $X_1^i, \dots, X_{\nu_i}^i$  valid on  $U$  for  $\bar{G}_i$ ,  $i \in \mathbf{n} - \mathbf{n}^*$ .

On  $V$ , define the distribution  $Q_0 = TV \cap \bar{G}_0$ . By assumption,  $Q_0$  has constant dimension  $\mu_0$ . Moreover, since  $Q_0$  is the intersection of two smooth, regular distributions and is constant dimensional, it is, by Lemma 2.4, smooth. By shrinking  $U$  (and hence  $V$ ) we can find a basis such that, on  $V$ ,  $Q_0 = \text{span}\{\hat{v}_1, \dots, \hat{v}_{\mu_0}\}$ . By construction,  $Q_0 \subset \bar{G}_0$  so that each  $\hat{v}_k \in Q_0$  can be expressed as

$$\hat{v}_k = \sum_{j=1}^{\nu_0} \hat{c}_{j0}^k X_j^0, \quad k \in \{1, \dots, \mu_0\},$$

where each  $\hat{c}_{j0}^k : V \rightarrow \mathbb{R}$  is a  $C^\infty(V)$  function. Next, we apply Lemma 2.3 and, by possibly shrinking  $U$  (and hence  $V$ ), introduce a retraction  $r : U \rightarrow V$  of  $U$  onto  $V$ . Let  $c_{j0}^k = \hat{c}_{j0}^k \circ r$  so that

$$v_k^0 := \sum_{i=1}^{\nu_0} c_{i0}^k X_i^0, \quad k \in \{1, \dots, \mu_0\},$$

are now vector fields defined on  $U$ , and let  $G_0^\parallel := \text{span}\{v_1^0, \dots, v_{\mu_0}^0\}$ . It follows that  $G_0^\parallel \subset \bar{G}_0$  in  $U$  and  $G_0^\parallel|_V = Q_0$ . By Lemma 4.4,  $TV + \bar{G}_0 = TV \oplus \text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_0}\}$  so that  $Q_0 \cap \text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_0}\} = 0$ . The distribution  $\bar{G}_0$  has dimension  $\nu_0 = n_0 + \rho_0$  throughout  $U$  so that

$$\begin{aligned} (\forall p \in U) \quad \bar{G}_0(p) &\supseteq \text{span}\{v_1^0, \dots, v_{\mu_0}^0\}(p) + \text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_0}\}(p), \\ (\forall p \in V) \quad \bar{G}_0(p) &= \text{span}\{v_1^0, \dots, v_{\mu_0}^0\}(p) \oplus \text{span}\{\tilde{g}_1, \dots, \tilde{g}_{\rho_0}\}(p), \\ \text{where} \quad \text{span}\{v_1^0, \dots, v_{\mu_0}^0\} &\subseteq TV. \end{aligned}$$

The vector fields  $v_1^0, \dots, v_{\mu_0}^0, \tilde{g}_1, \dots, \tilde{g}_{\rho_0}$  are linearly independent on  $V$ ; therefore they remain linearly independent in some open neighborhood of  $V$  in  $\mathbb{R}^n$ , without loss of generality,  $U$ . Therefore, they are local generators for  $\bar{G}_0$  on  $U$ . Next, we perform the

induction step. Assume that, for some positive integer  $I$ , and any  $i \in \{0, \dots, I\}$ , on  $U$ ,

$$(4.11) \quad \begin{aligned} \bar{G}_{i-1} &= G_{i-1}^{\parallel} \oplus \left( \bigoplus_{j=0}^{i-1} \text{span} \left\{ ad_{\tilde{f}}^j \tilde{g}_k : 1 \leq k \leq \rho_j \right\} \right) \\ \text{and } G_{i-1}^{\parallel} \Big|_V &= TV \cap \bar{G}_{i-1}. \end{aligned}$$

We want to show the existence of  $\mu_i$  vector fields  $v_1^i, \dots, v_{\mu_i}^i$  such that, for any  $i \in \{0, \dots, I\}$ , letting  $G_i^{\parallel} = G_{i-1}^{\parallel} \oplus \text{span}\{v_1^i, \dots, v_{\mu_i}^i\}$ , one has that, on  $U$ ,

$$(4.12) \quad \begin{aligned} \bar{G}_i &= G_i^{\parallel} \oplus \left( \bigoplus_{j=0}^i \text{span} \left\{ ad_{\tilde{f}}^j \tilde{g}_k : 1 \leq k \leq \rho_j \right\} \right) \\ \text{and } G_i^{\parallel} \Big|_V &= TV \cap \bar{G}_i. \end{aligned}$$

On  $V$ , define the distribution  $Q_i$  by  $Q_i = (TV \cap \bar{G}_i) \cap (TV \cap \bar{G}_{i-1})^{\perp}$ . The distribution  $Q_i$  is the intersection of two smooth, regular distributions. Furthermore, for all  $p \in V$ ,

$$\begin{aligned} \dim(Q_i(p)) &= \dim(T_p V \cap \bar{G}_i(p)) - \dim(T_p V \cap \bar{G}_{i-1}(p)) \\ &= \mu_i \end{aligned}$$

is constant by assumption, and thus, by Lemma 2.4,  $Q_i$  is a smooth regular distribution. Locally, by making  $U$  (and hence  $V$ ) smaller if necessary, there exist local generators  $\hat{v}_k$ ,  $k \in \{1, \dots, \mu_i\}$ , for  $Q_i$ . By construction,  $Q_i \subset \bar{G}_i$  so that each  $\hat{v}_k \in Q_i$  can be expressed as

$$\hat{v}_k = \sum_{j=1}^{\nu_i} \hat{c}_{ji}^k X_j^i, \quad k \in \{1, \dots, \mu_i\},$$

where each  $\hat{c}_{ji}^k : V \rightarrow \mathbb{R}$  is a  $C^\infty(V)$  function. Let  $c_{ji}^k = \hat{c}_{ji}^k \circ r$  so that

$$v_k^i := \sum_{j=1}^{\nu_i} c_{ji}^k X_j^i, \quad k \in \{1, \dots, \mu_i\}$$

are vector fields defined on  $U$ , and let  $G_{i/i-1}^{\parallel} := \text{span}\{v_1^i, \dots, v_{\mu_i}^i\}$ . It follows that  $G_{i/i-1}^{\parallel} \subset \bar{G}_i$  and  $G_{i/i-1}^{\parallel} \Big|_V = Q_i$ . By the definition of  $Q_i$  and by (4.11), it follows that  $G_{i-1}^{\parallel} \Big|_V \cap G_{i/i-1}^{\parallel} \Big|_V = (TV \cap \bar{G}_{i-1}) \cap Q_i = 0$ . Furthermore, since  $(TV \cap \bar{G}_{i-1}) \subset (TV \cap \bar{G}_i)$ , we have that  $TV \cap \bar{G}_i = G_{i-1}^{\parallel} \oplus G_{i/i-1}^{\parallel} =: G_i^{\parallel}$ . In addition, by Lemma 4.4, on  $V$ ,

$$G_i^{\parallel} \cap \left( \bigoplus_{j=0}^i \text{span} \left\{ ad_{\tilde{f}}^j \tilde{g}_k : 1 \leq k \leq \rho_j \right\} \right) = 0.$$

Finally, since  $\dim(\bar{G}_i) = n_i + \sum_{j=0}^i \rho_j$  we have that (4.12) holds on  $V$ . Thus, since  $G_i^{\parallel} \subset \bar{G}_i$  on  $U$ , (4.12) also holds in a neighborhood of  $V$ , without loss of generality,  $U$ .  $\square$

**5. Proof of the main result (Theorem 3.2).** Suppose that LTFLP is solvable at  $p_0 \in \Gamma^*$ . Let  $V = \Xi(\Gamma^* \cap U)$  and consider the expression (4.4) for  $TV + G_i$  in local coordinates. It is clear from (4.4) that the subspace  $T_p V + G_i(\text{col}(p, 0))$  has constant dimension  $n^* + \text{rank}([B \ \cdots \ A^i B])$ . Since the pair  $(A, B)$  is controllable, we have that  $\text{rank}([B \ \cdots \ A^{n-n^*-1} B]) = n - n^*$  and condition (a) holds. As far as condition (b) is concerned, we have already shown in the proof of Lemma 4.3 that  $TV + G_i = TV + \tilde{G}_i$ .

Conversely, suppose conditions (a) and (b) hold. These two conditions, along with the regularity of  $\tilde{G}_i$ ,  $i \in \mathbf{n} - \mathbf{n}^* - 1$ , allow one to invoke Lemmas 4.4 and 4.5. Specifically, there exist a neighborhood  $\tilde{U}$  of  $p_0$  in  $\mathbb{R}^n$ , a regular static feedback  $(\alpha, \beta)$  on  $\tilde{U}$ , and  $n_{k_1-1}$  vector fields defined on  $\tilde{U}$  such that, letting  $\tilde{V} := \tilde{U} \cap \Gamma^*$ , the distributions  $\tilde{G}_i$  have the representation given in (4.13), (4.14) on  $\tilde{U}$ , and at each  $p \in \tilde{V}$  the  $n$  vector fields of the array (4.16) are linearly independent.

Having applied the static feedback  $(\alpha, \beta)$ , we will denote  $\tilde{f}$  and  $\tilde{g}$  by, respectively,  $f$  and  $g$  to simplify notation. We construct  $\rho_0$  functions  $\alpha_i : U \rightarrow \mathbb{R}$  satisfying Theorem 3.1. Pick the point  $p_0$  as the origin for the  $s$ -coordinate system to be generated from the vector fields in (4.16) (see [25], [27]). Compose the flows generated by the vector fields in (4.16) starting from the bottom row. Consider the mapping

$$\begin{aligned} F_\emptyset : W_\emptyset \subset \mathbb{R}^{n^*-n_{k_1-1}} &\rightarrow V \\ : S_\emptyset = (s_1^\parallel, \dots, s_{n^*-n_{k_1-1}}^\parallel) &\mapsto \phi_{s_{n^*-n_{k_1-1}}^\parallel}^{v_{n^*-n_{k_1-1}}} \circ \cdots \circ \phi_{s_1^\parallel}^{v_1}(p_0). \end{aligned}$$

We continue by moving upwards in the array (4.16) to generate a sequence of mappings similar to  $F_\emptyset$ . To each pair  $(G_{i/i-1}^\nabla, G_{i/i-1}^\parallel)$ ,  $0 \leq i \leq k_1 - 1$ , we associate a set of times<sup>3</sup>  $S_{i/i-1} = (S_{i/i-1}^\nabla; S_{i/i-1}^\parallel) := (s_{(i/i-1,1)}^\nabla, \dots, s_{(i/i-1,\rho_i)}^\nabla; s_{(i/i-1,1)}^\parallel, \dots, s_{(i/i-1,\mu_i)}^\parallel)$  and a mapping

$$\begin{aligned} F_{i/i-1} : W_{i/i-1} \subset \mathbb{R}^{\mu_i + \rho_i} &\rightarrow \mathbb{R}^n \\ : (S_{i/i-1}^\parallel, S_{i/i-1}^\nabla) &\mapsto \Phi_{i/i-1}^\parallel \circ \Phi_{i/i-1}^\nabla(p). \end{aligned}$$

Here  $\Phi_{i/i-1}^\parallel$  is the composition of flows generated by vector fields spanning  $G_{i/i-1}^\parallel$ , and  $\Phi_{i/i-1}^\nabla$  is the composition of flows generated by the vector fields spanning  $G_{i/i-1}^\nabla$ . Specifically,

$$\begin{aligned} \Phi_{i/i-1}^\parallel &= \phi_{s_{(i/i-1,\mu_i)}^\parallel}^{v_{\mu_i}} \circ \cdots \circ \phi_{s_{(i/i-1,1)}^\parallel}^{v_1}, \\ \Phi_{i/i-1}^\nabla &= \phi_{s_{(i/i-1,\rho_i)}^\nabla}^{ad_f^i g_{\rho_i}} \circ \cdots \circ \phi_{s_{(i/i-1,1)}^\nabla}^{ad_f^i g_1}. \end{aligned}$$

Let

$$(5.1) \quad s = \text{col}(S_\emptyset; S_{k_1-1/k_1-2}; \dots; S_{1/0}; S_0)$$

and let  $W \subset \mathbb{R}^n$  be a neighborhood of  $s = 0$ , sufficiently small, to ensure that the map

$$(5.2) \quad \begin{aligned} F : W &\rightarrow F(W) \\ s &\mapsto F_0 \circ F_{1/0} \circ \cdots \circ F_{k_1-2/k_1-3} \circ F_{k_1-1/k_1-2} \circ F_\emptyset(p_0) \end{aligned}$$

<sup>3</sup>We define  $i/(i-1) := 0$  when  $i = 0$  to be consistent with the array (4.16).

is a diffeomorphism onto its image and that  $F(W) \subset \tilde{U}$ . The existence of  $W$  is guaranteed by the inverse function theorem and the fact that the differential of  $F$  at  $s = 0$ ,

$$(5.3) \quad dF_0 = \begin{bmatrix} v_1 & \cdots & v_{n^*-n_{k_1-1}} & ad_f^{k_1-1}g_1 & \cdots & g_1 & \cdots & g_{\rho_0} & v_1^0 & \cdots & v_{\mu_0}^0 \end{bmatrix} (p_0),$$

is an  $n \times n$  square matrix whose columns span the subspace  $T_{p_0}\Gamma^* + G_{k_1-1}(p_0)$  which, by condition (a), has dimension  $n$ . As candidate (virtual) output functions, let  $\alpha_i$ ,  $i \in \{1, \dots, \rho_0\}$  be the time spent flowing along  $ad_f^{k_i-1}g_i$ , i.e.,

$$(5.4) \quad \alpha_i(x) = s_{(k_i-1/k_i-2, i)}^\dagger(x), \quad i \in \{1, \dots, \rho_0\}.$$

The image of  $\tilde{V}$  under  $F^{-1}$  is the hyperplane

$$F^{-1}(\tilde{V}) = \{s \in W : S_0^\dagger = 0, S_{1/0}^\dagger = 0, \dots, S_{k_1-1/k_1-2}^\dagger = 0\}.$$

Since the chosen functions  $\alpha_1, \dots, \alpha_{\rho_0}$  are a subset of the functions whose zero level set defines  $F(\tilde{V})$ , the  $\alpha_i$  are identically zero on  $F(\tilde{V})$ , and hence condition (1) of Theorem 3.1 is satisfied. Next, we must show that  $\alpha = \text{col}(\alpha_1, \dots, \alpha_{\rho_0})$  yields a well-defined vector relative degree (VRD) of  $(k_1, \dots, k_{\rho_0})$  at  $p_0 = F^{-1}(0)$ . As per [9], this entails showing that

(VRD1)  $L_{ad_f^{k_j}g_j}\alpha_i(x) = 0$  for all  $1 \leq j \leq \rho_0$ , for all  $0 \leq k \leq k_i-2$ , for all  $1 \leq i \leq \rho_0$ , and for all  $x$  in a neighborhood of  $p_0$ .

(VRD2) the  $\rho_0 \times \rho_0$  matrix

$$(5.5) \quad \begin{pmatrix} L_{ad_f^{k_1-1}g_1}\alpha_1(p_0) & \cdots & L_{ad_f^{k_1-1}g_{\rho_0}}\alpha_1(p_0) \\ L_{ad_f^{k_2-1}g_1}\alpha_2(p_0) & \cdots & L_{ad_f^{k_2-1}g_{\rho_0}}\alpha_2(p_0) \\ \vdots & \vdots & \vdots \\ L_{ad_f^{k_{\rho_0}-1}g_1}\alpha_{\rho_0}(p_0) & \cdots & L_{ad_f^{k_{\rho_0}-1}g_{\rho_0}}\alpha_{\rho_0}(p_0) \end{pmatrix}$$

is nonsingular at  $p = p_0$  (if this matrix is nonsingular, then the decoupling matrix has full rank).

First we show that VRD1 holds. Fix a set of times  $S_\emptyset = c_\emptyset$ ,  $S_{k_1-1/k_1-2} = c_{k_1-1/k_1-2}$ ,  $\dots$ ,  $S_{k_i-1/k_i-2} = c_{k_i-1/k_i-2}$ , where each  $c_j$  is a constant vector, to uniquely determine the hyperplane

$$H_i = \{s \in W : S_\emptyset = c_\emptyset, S_{k_1-1/k_1-2} = c_{k_1-1/k_1-2}, \dots, S_{k_i-1/k_i-2} = c_{k_i-1/k_i-2}\}.$$

Consider the point  $s = \text{col}(c_\emptyset, \dots, c_{k_i-1/k_i-2}, 0, \dots, 0) \in H_i$  and let  $x = F(s) \in \tilde{U}$ . Through  $x$  there passes an integral submanifold of each  $\tilde{G}_i$ ,  $i \in \mathbf{k}_1 - \mathbf{1}$ , which we denote by  $L_i(x)$ . Consider the map  $F_0 \circ F_{1/0} \circ \cdots \circ F_{k_i-2/k_i-3}(x)$ . It is the composition of the flows defined by vector fields which are local generators for  $\tilde{G}_{k_i-2}$ . Therefore the image of this map is the  $\nu_{k_i-2}$ -dimensional manifold  $L_{k_i-2}(x) \cap \tilde{U}$ . On the other hand, the image of this map in  $s$ -coordinates is the hyperplane  $H_i$ , i.e.,  $H_i = F^{-1}(L_{k_i-2}(x) \cap \tilde{U})$ . Therefore for each  $s \in H_i$ ,  $T_s H_i = (F^{-1})_* \tilde{G}_{k_i-2}(s) = \text{Im}(\text{col}(0, I_{\nu_{k_i-2}}))$ . The function  $\alpha_i$  is among those fixed times which define the hyperplane  $H_i$ . Therefore,  $d\alpha_i \in \text{ann}(\tilde{G}_{k_i-2}) \subset \cdots \subset \text{ann}(G_0)$ , and hence VRD1 holds in a sufficiently small neighborhood of  $p_0$ .

Next we show that VRD2 holds. Treating  $T\mathbb{R}^n$  as an orthogonal bundle with the usual inner product, we see that the value of the  $(i, j)$ th entry of (5.5) is equal to

$$\left\langle d\alpha_i, ad_f^{k_i-1} g_j \right\rangle (p_0).$$

From the expression (5.3) for  $dF_0$  it follows that

$$ad_f^{k_i-1} g_j(p_0) = \left[ F_\star \left( \frac{\partial}{\partial s_{(k_i-1/k_i-2, j)}^\flat} \right) \right] \Big|_{s=0}, \quad 1 \leq i \leq j \leq \rho_0,$$

so that

$$\frac{\partial}{\partial s_{(k_i-1/k_i-2, j)}^\flat} = \left[ F_\star^{-1} \left( ad_f^{k_i-1} g_j(x) \right) \right] \Big|_{x=p_0}, \quad 1 \leq i \leq j \leq \rho_0.$$

In light of this and the definition of  $\alpha_i$ ,  $i \in \{1, \dots, \rho_0\}$ , given by (5.4), in  $s$ -coordinates the values of the entries of (5.5), along and below the diagonal, at  $p_0$  are

$$\left\langle ds_{k_i-1/k_i-2, i}^\flat, \frac{\partial}{\partial s_{(k_i-1/k_i-2, j)}^\flat} \right\rangle = \delta_{ij}, \quad 1 \leq i \leq j \leq \rho_0,$$

where  $\delta_{ij}$  is the Kronecker delta function. Thus, at  $0 = F^{-1}(p_0)$  the matrix (5.5), in  $s$ -coordinates, has ones along its diagonal and zeros below. Therefore it is nonsingular at  $s = 0$ , which is equivalent to being nonsingular at  $p_0 = F(0)$ .  $\square$

**6. Conclusions.** We have determined necessary and sufficient conditions under which a multi-input nonlinear control-affine system is locally transversally feedback linearizable with respect to a given invariant submanifold. Our main conditions are checkable, though we do not present a constructive procedure for finding the coordinate and feedback transformations.

One can similarly pose the global transverse feedback linearization problem (GTFLP) in which one, roughly speaking, seeks a single coordinate and feedback transformation such that (2.1) is feedback equivalent to the normal form (3.1) in a tubular neighborhood of  $\Gamma^*$ . Clearly the geometry of  $\Gamma^*$  will play an increased role in characterizing the solution. In [19], we provided sufficient conditions for the solvability of GTFLP in the single-input case. GTFLP for multi-input systems remains an open problem.

## NECESSARY CONDITIONS FOR MULTIOBJECTIVE OPTIMAL CONTROL PROBLEMS WITH FREE END-TIME\*

B. T. KIEN<sup>†</sup>, N.-C. WONG<sup>‡</sup>, AND J.-C. YAO<sup>‡</sup>

**Abstract.** Necessary conditions of optimality are derived for multiobjective optimal control problems with free end-time, in which the dynamics constraint is modeled as a nonconvex differential inclusion. The obtained results cover some previous results on necessary conditions for multiobjective and single objective optimal control problems.

**Key words.** multiobjective optimal control problems, free end-time, preference, nonconvex differential inclusion, nonsmooth analysis

**AMS subject classifications.** 49K24, 90C29

**DOI.** 10.1137/080714683

**1. Introduction.** The derivation of necessary conditions for multiobjective optimal control (MOC for short) problems in which the dynamic constraint is modeled as a differential inclusion has been a recent area of research. Problems of MOC naturally arise, for example, in economics (see [6]), in chemical engineering (see [3]), and in multiobjective control design (see [26]). Let us assume that  $\prec$  is a preference in  $R^m$ . We are interested in deriving necessary conditions for the following problem with free end-times and state constraints:

$$\begin{aligned} \text{(P)} \quad & \text{Minimize } g(a, x(a), b, x(b)) \\ & \text{over intervals } [a, b] \text{ and arcs } x \in W^{1,1}([a, b], R^n) \text{ which satisfy} \\ & \dot{x}(t) \in F(t, x(t)), \text{ a.e., } t \in [a, b], \\ & (a, x(a), b, x(b)) \in C, \end{aligned}$$

where  $g : R \times R^n \times R \times R^n \rightarrow R^m$  is a given mapping,  $F : R \times R^n \rightrightarrows R^n$  is a given multifunction,  $C$  is a closed set in  $R \times R^n \times R \times R^n$ , and  $W^{1,1}([a, b], R^n)$  is the space of absolutely continuous functions  $x : [a, b] \rightarrow R^n$ .

Given  $x \in W^{1,1}([a, b], R^n)$  we define  $x^e$  to be an extension of  $x$  obtained by constants extension for the left endpoint on  $(-\infty, a)$  and for the right endpoint on  $(b, +\infty)$ . A feasible process  $([a, b], x)$  comprises a closed interval  $[a, b]$  and an arc  $x \in W^{1,1}([a, b], R^n)$  which satisfy the constraints of (P). A feasible process  $([a_*, b_*], x_*)$  is said to be a local solution of (P) if there does not exist any feasible process  $([a, b], x)$  with  $d([a, b], x), ([a_*, b_*], x_*) \leq \epsilon$  such that  $g(a, x(a), b, x(b)) \prec g(a_*, x_*(a_*), b_*, x_*(b_*))$  for some  $\epsilon > 0$ . Here

$$d([a, b], x), ([a', b'], y) := |a - a'| + |b - b'| + |x(a) - y(a')| + \int_{a \wedge a'}^{b \vee b'} |\dot{x}^e(s) - \dot{y}^e(s)| ds,$$

in which  $a \wedge a' := \min\{a, a'\}$  and  $b \vee b' := \max\{b, b'\}$ . We remark that the notion of  $W^{1,1}$  local optimizers to differential inclusions was first introduced and studied

in [15] under the name of “intermediate local minimizers,” which are different from the classical notions of weak and strong local minimizers in variational and optimal control problems.

In the scalar case ( $m = 1$ ), there are several papers dealing with necessary conditions of the Euler–Lagrange type for (P). The generalized Euler–Lagrange condition was first established by Mordukhovich [15] for problems governed by nonconvex, compact-valued, Lipschitzian differential inclusions on the fixed time interval and then was extended to free-time problems in [14]. Further extensions for unbounded differential inclusions were given by Ioffe [8] and Loewen and Rockafellar [10], by Vinter and Zheng [25] for problems with unbounded differential inclusions on the fixed time interval, and by Vinter and Zheng [23] and Vinter [22] for free-time problems.

Particularly, Vinter [22] provided an efficient scheme for deriving necessary conditions of local optimization solutions of (P) (see [22, Theorem 8.4.1]). A notable feature of the new free end-time necessary conditions is that they cover problems with measurable time-dependent data. For such problems, standard analytical techniques for deriving free-time necessary conditions, which depend on a transformation of the time variable, no longer work.

It is natural to ask whether the conclusions of theorems in [22] are still valid for the case of MOC problems. The goal of this paper is to obtain such results for (P).

Unfortunately, the scheme of the proof given by [22] fails to apply to our problem. The reason is that in this case we cannot use scalar estimations nor differentiable property of functions for the problem. However, that scheme helps us derive necessary conditions for the Bolza problem with finite Lagrangian which plays an important role in the establishment of necessary conditions for (P).

In a close connection, recently Zhu [28] established a result on the Hamiltonian necessary conditions for a nonsmooth MOC problem with endpoint constraints involving regular preferences. This result was extended later by Bellaassali and Jourani [2]. Based on an analysis of Ioffe’s scheme [8], as it was mentioned, Bellaassali and Jourani [2] obtained an interesting result on necessary conditions for MOC problems. However, [2] and [28] considered only optimal problems with the fixed time interval.

In order to derive necessary conditions of the Euler–Lagrange type for (P), we use a variant of Ioffe’s scheme [8] to reduce the problem to the scalar case, as has been done in [2] and [24]. We then use the Ekeland principle and necessary conditions for the Bolza problem. Together with the maximum theorem and some analytical techniques of nonsmooth analysis we finally obtain desired results.

The rest of the paper contains three sections. In section 2 we present some notions and auxiliary results involving generalized differentiation. In section 3 we derive necessary conditions for the Bolza problems. The final section is devoted to deriving necessary conditions for problem (P).

**2. Preliminaries and auxiliary results.** Throughout the paper  $B$  stands for the closed unit ball in  $R^n$ , and  $R_\infty$  stands for  $R \cup \{+\infty\}$ .

In what follows we often deal with set-valued mappings  $\Gamma : R^n \rightrightarrows R^n$ , for which the notation

$$\text{Limsup}_{x \rightarrow \bar{x}} \Gamma(x) := \{x^* \in R^n : \exists x_k \rightarrow \bar{x}, x_k^* \rightarrow x^* \text{ with } x_k^* \in \Gamma(x_k)\}$$

denotes the sequential Painlevé–Kuratowski upper limit of  $\Gamma$  at a point  $\bar{x} \in R^n$ . The

set

$$\text{Gph}\Gamma := \{(x, y) \in R^n \times R^n : y \in \Gamma(x)\}$$

is called the graph of  $\Gamma$ .

Take a closed set  $A \subset R^n$  and point  $x \in A$ . The set

$$\hat{N}_A(x) := \left\{ x^* \in R^n : \limsup_{u \xrightarrow{A} x} \frac{\langle x^*, u - x \rangle}{\|u - x\|} \leq 0 \right\}$$

is called the Fréchet normal cone to  $A$  at  $x$ . Let  $\bar{x} \in A$ ; the set

$$N_A(\bar{x}) := \text{Limsup}_{x \rightarrow \bar{x}} \hat{N}_A(x)$$

is the limiting normal cone to  $A$  at  $\bar{x}$ .

Given a lower semicontinuous (l.s.c.) function  $f : R^n \rightarrow R_\infty$  and a point  $x \in R^n$  such that  $f(x) < \infty$ , the limiting subdifferential of  $f$  at  $x$  is the set

$$\partial f(x) = \{x^* : (x^*, -1) \in N_{\text{epi}f}(x, f(x))\}.$$

It is well known that if  $f$  is Lipschitz continuous around  $x$  with rank  $K$ , then for any  $x^* \in \partial f(x)$ , one has  $\|x^*\| \leq K$ . The limiting normal cone and limiting subdifferential were introduced by Mordukhovich [18]. We refer the reader to Chapter 1 in [12] for comprehensive commentaries. Further properties of limiting normal cone and limiting subdifferential can be founded in [12] and [4].

Let  $\Gamma : X \subset R^n \rightarrow 2^{R^n}$  be a multifunction. We now assume that  $\Gamma$  has closed values and define the function  $\rho_\Gamma : X \times R^n \rightarrow R$  by

$$\rho_\Gamma(x, y) = d(y, \Gamma(x)) := \inf_{v \in \Gamma(x)} \|y - v\|.$$

The following property of the subdifferential of  $\rho_\Gamma$ , which was first established in [21], will be needed in section 4.

LEMMA 2.1. *Assume that  $\text{Gph}\Gamma$  is closed and  $(\bar{x}, \bar{y}) \in \text{Gph}\Gamma$ . Then one has*

$$N_{\text{Gph}\Gamma}(\bar{x}, \bar{y}) = \bigcup_{\lambda \geq 0} \lambda \partial \rho_\Gamma(\bar{x}, \bar{y}).$$

Moreover, if  $\rho_\Gamma(x, y) > 0$  and  $v \in \partial_y \rho_\Gamma(x, y)$ , then there exists a point  $z \in \Pi_{\Gamma(x)}(y)$  such that  $v = \frac{y-z}{\|y-z\|}$ . Here  $\Pi_{\Gamma(x)}(y)$  is the set of metric projections of  $y$  onto  $\Gamma(x)$ .

The proof of Lemma 2.1 can also be found in [8], [12], and [24].

Recall that the multifunction  $\Gamma : X \subset R^n \rightrightarrows R^n$  is said to be l.s.c. on  $X$  if for each  $x_0 \in X$  and an open set  $V$  satisfying  $F(x_0) \cap V \neq \emptyset$ , there exists a neighborhood  $U$  of  $x_0$  such that  $F(x) \cap V \neq \emptyset$  for all  $x \in U \cap X$ .  $F$  is said to be upper semicontinuous (u.s.c.) on  $X$  if for each  $x_0 \in X$  and an open set  $V$  in  $R^n$  satisfying  $F(x_0) \subset V$ , there exists a neighborhood  $U$  of  $x_0$  such that  $F(x) \subset V$  for all  $x \in U \cap X$ .  $F$  is said to be continuous on  $X$  if it is both l.s.c. and u.s.c. on  $X$ .

In what follows we shall need the next lemma.

LEMMA 2.2. *Let  $X \subset R^n$ ,  $Y \subset R^n$  be nonempty sets,  $\phi : Y \times R^n \rightarrow R$  be a continuous function, and  $\Gamma : X \subset R^n \rightrightarrows R^n$  be a multifunction with compact values. Assume that  $\Gamma$  is Lipschitz continuous on  $X$ ; that is, there exists a constant  $k > 0$  such that*

$$\Gamma(x') \subset \Gamma(x) + k|x' - x|B$$

for all  $x, x' \in X$ . Then the function  $M$  defined by

$$M(x, y) = \max\{\phi(y, u) : u \in \Gamma(x)\}$$

is continuous on  $X \times Y$ .

*Proof.* We first show that  $\Gamma$  is l.s.c. on  $X$ . Indeed, take any point  $x_0 \in X$  and a open set  $V$  such that  $\Gamma(x_0) \cap V \neq \emptyset$ . We want to prove that there exists a neighborhood  $U$  of  $x_0$  such that  $\Gamma(x) \cap V \neq \emptyset$  for all  $x \in U$ . Otherwise, there is a sequence  $x_n \rightarrow x_0$  satisfying  $\Gamma(x_n) \cap V = \emptyset$ . Take  $y_0 \in \Gamma(x_0) \cap V$ . By the property of  $\Gamma$ ,  $d(y_0, \Gamma(x_n)) \leq k|x_0 - x_n|$ . Hence for each  $n$ , there exists  $y_n \in \Gamma(x_n)$  such that  $|y_0 - y_n| \leq k|x_0 - x_n|$ . Consequently,  $y_n \rightarrow y_0$  and so  $y_n \in V$  for  $n$  sufficiently large. It follows that  $y_n \in \Gamma(x_n) \cap V$  for  $n$  sufficiently large, which is a contradiction. Thus  $\Gamma$  is l.s.c. on  $X$ . By the standard arguments, we can also show that  $\Gamma$  is u.s.c. on  $X$ .

For each  $(x, y) \in X \times Y$  we put  $z = (x, y)$ . Define mappings  $\hat{\phi} : R^n \times Y \times R^n \rightarrow R$  and  $\hat{\Gamma} : X \times Y \rightarrow R^n$  by  $\hat{\phi}(z, u) = \phi(y, u)$  and  $\hat{\Gamma}(z) = \Gamma(x)$ . Then we have

$$M(x, y) = M(z) = \max\{\hat{\phi}(z, u) : u \in \hat{\Gamma}(z)\}.$$

Since  $\hat{\Gamma}$  is continuous on  $X \times Y$  with compact values and  $\hat{\phi}$  is a continuous function, the maximum theorem (see [1, Maximum theorem, p. 116]) implies that  $M$  is continuous on  $X \times Y$ .  $\square$

We remark that in [13] Mordukhovich and Nam showed that under certain conditions,  $M$  is locally Lipschitz continuous (see [13, Theorem 5.2]). However, they required that the cost function  $\phi$  is locally Lipschitzian. As we need only the continuity of  $M$ , in Lemma 2.2, we did not require that  $\phi$  is locally Lipschitzian.

The rest of this section is destined for some notion of preferences in  $R^m$ . The concept of a preference first appeared in the value theory of economics. In the area of multiobjective optimization and optimal control much research has been devoted to the weak Pareto solution and its generalizations. The preference relation between vectors  $x, y \in R^m$  in the sense of weak Pareto is defined by  $x \prec y$  if and only if  $x_i \leq y_i$  for  $i = 1, \dots, m$  and at least one of the inequalities is strict. In other words,  $x \prec y$  if and only if  $x - y \in R_-^m$  and  $x \neq y$ , where  $R_-^m := \{z \in R^m : z_i \leq 0, i = 1, 2, \dots, m\}$ . In this paper we use more general preference relations for which necessary conditions of the weak Pareto solution and its generalization can be derived and refined from our necessary conditions.

Let  $\prec$  be a preference in  $R^m$  and  $r \in R^m$ . We will call the set  $\mathcal{L}[r] := \{s \in R^m : s \prec r\}$  a level set at  $r$ , and  $\bar{\mathcal{L}}[r]$  is the closure of  $\mathcal{L}[r]$ .

We shall use the following definition (see [12, Definition 5.55] and [28]).

**DEFINITION 2.3.** A preference  $\prec$  is closed provided that

- (a) for any  $r \in R^n$ ,  $r \in \bar{\mathcal{L}}[r]$ ; and
- (b) for any  $r \prec s$ ,  $t \in \bar{\mathcal{L}}[r]$  implies that  $t \prec s$ .

We say that  $\prec$  is regular at  $\bar{r}$  (in the sense of [28]) provided that

- (c)

$$\text{Limsup}_{r, \theta \rightarrow \bar{r}} N_{\bar{\mathcal{L}}[r]}(\theta) \subset N_{\bar{\mathcal{L}}[\bar{r}]}(\bar{r}).$$

It is noted that the regularity notion for preference was introduced in [17] as *normal semicontinuity*, the name under which it is studied in Chapter 5 of [12]. In the above definition, the regularity is somewhat different from that in Definition 5.69 of [12], where a preference  $\prec$  is regular at  $(\bar{\theta}, \bar{r}) \in \text{Gph} \mathcal{L}$  if

$$\text{Limsup}_{(r, \theta) \xrightarrow{\text{Gph} \mathcal{L}} (\bar{\theta}, \bar{r})} \hat{N}_{\mathcal{L}[r]}(\theta) = N_{\mathcal{L}[\bar{\theta}]}(\bar{r}).$$

Let us give some examples for Definition 2.3.

*Example 2.4* (single objective problem). When  $m = 1$  the relation  $r \prec s$  becomes  $r < s$ . It is obvious that this relation satisfies conditions (a)–(c). Therefore necessary conditions for (P) are true generalizations of necessary conditions for single objective optimal control (see Corollary 4.2).

*Example 2.5* (weak Pareto optimal control problem). In a weak Pareto optimal control problem we define the preference by  $r \prec s$  if and only if  $r_i \leq s_i$ ,  $i = 1, 2, \dots, m$ , and at least one of the inequalities is strict. It is easy to check that this  $\prec$  satisfies (a) and (b) at any  $r \in R^n$ . Moreover, for any  $r \in R^m$ ,  $\mathcal{L}[r] = r + R_-^m$ , where  $R_-^m := \{s \in R^m : s_i \leq 0, i = 1, 2, \dots, m\}$ . It follows that  $N_{\mathcal{L}[r]}(\theta) \subset R_+^m = N_{\mathcal{L}[r]}(r)$  for all  $r$  and  $\theta$ . Hence (c) is also satisfied. Thus the necessary conditions for (P) with respect to  $\prec$  are true for weak Pareto optimal control problems (see Corollary 4.3).

**3. The Bolza problem with finite Lagrangian.** In this section we derive necessary conditions of the Bolza problem

$$(BP) \quad \text{Minimize } J(a, b, x) := l(a, x(a), b, x(b)) + \int_a^b L(t, x(t), \dot{x}(t)) dt$$

over intervals  $[a, b]$  and arcs  $x \in W^{1,1}([a, b], R^n)$ ,

where  $l : R \times R^n \times R \times R^n \rightarrow R_\infty$  and  $L : R \times R^n \times R^n \rightarrow R$  are given functions.

A triple  $([a, b], x)$  which satisfies the constraint of (PB) is called a feasible process. A feasible process  $([a_*, b_*], x_*)$  is a local solution of (BP) if there exists  $\epsilon > 0$  such that  $J(a, b, x) \geq J(a_*, b_*, x_*)$  for all feasible process satisfying  $d(([a, b], x), ([a_*, b_*], x_*)) \leq \epsilon$ .

We now fix a feasible process  $([a_*, b_*], x_*)$  for the problem and assume the following assumptions which involve positive numbers  $\delta, \delta_0, \delta_1$ :

(BH1)  $l$  is Lipschitz continuous near  $(a_*, x_*(a_*), b_*, x_*(b_*))$  with rank  $k_l$ .

(BH2)  $L(\cdot, x, \cdot)$  is  $\mathcal{L} \times \mathcal{B}$  measurable for each  $x \in R^n$ , and  $L(t, \cdot, \cdot)$  is l.s.c. for a.e.  $t \in [a_*, b_*]$ .

(BH3) For all  $N$  there exists  $k_N \in L^1[a_*, b_*]$  such that

$$|L(t, x, v) - L(t, x', v)| \leq k_N(t)|x - x'|, \quad L(t, x_*(t), v) \geq -k_N(t)$$

for all  $x, x' \in x_*(t) + \delta B$  and  $v \in \dot{x}_*(t) + NB$  a.e.  $t \in [a_*, b_*]$ .

(BH4) There exist essentially bounded functions  $\bar{u} : [a_* - \delta_0, a_*] \rightarrow R^n$  and  $\tilde{u} : [b_*, b_* + \delta_1] \rightarrow R^n$  such that the functions  $t \mapsto L(t, x_*(a_*), \bar{u}(t))$  and  $t \mapsto L(t, x_*(b_*), \tilde{u}(t))$  are essentially bounded on  $[a_* - \delta_0, a_*]$  and  $[b_*, b_* + \delta_1]$ , respectively. Moreover, there exist positive constants  $k_0, k_1$  such that for all  $u \in R^n$ , one has

$$|L(t, x, u) - L(t, x', u)| \leq k_0|x - x'| \quad \forall x, x' \in x_*(a_*) + \delta B \text{ a.e. } t \in [a_* - \delta_0, a_*]$$

and

$$|L(t, x, u) - L(t, x', u)| \leq k_1|x - x'| \quad \forall x, x' \in x_*(b_*) + \delta B \text{ a.e. } t \in [b_*, b_* + \delta_1].$$

Define

$$\mathcal{H}_\lambda(t, x, v, p) = \langle p, v \rangle - \lambda L(t, x, v).$$

We have the following result on necessary conditions for (BP).

**THEOREM 3.1.** Assume that  $([a_*, b_*], x_*)$  is a local minimizer of (BP), for which  $J(a_*, x_*, b_*) < \infty$  and (BH1)–(BH3) are satisfied.

Then there exist an arc  $p \in W^{1,1}([a_*, b_*], R^n)$  and real numbers  $\xi$ ,  $\eta$ , and  $\lambda \geq 0$  such that

- (i)  $\lambda + \|p\|_\infty = 1$ ;
- (ii)  $\dot{p}(t) \in \text{co}\{(\alpha, p(t)) \in \lambda \partial L(t, x_*(t), \dot{x}_*(t))\}$  a.e.  $t \in [a_*, b_*]$ ;
- (iii)  $(-\xi, p(a_*), \eta, -p(b_*)) \in \lambda \partial l(a_*, x_*(a_*), b_*, x_*(b_*))$ ;
- (iv)  $\langle p(t), \dot{x}_*(t) \rangle - \lambda L(t, x_*(t), \dot{x}_*(t)) \geq \langle p(t), v \rangle - \lambda L(t, x_*(t), v)$  for all  $v \in R^n$  a.e.; and
- (v)

$$\xi \leq \lim_{\sigma \rightarrow 0} \text{ess sup}_{t \in [a_* - \sigma, a_* + \sigma]} \mathcal{H}_\lambda(t, x_*(t), \dot{x}_*(t), p(a_*))$$

and

$$\eta \leq \lim_{\sigma \rightarrow 0} \text{ess sup}_{t \in [b_* - \sigma, b_* + \sigma]} \mathcal{H}_\lambda(t, x_*(t), \dot{x}_*(t), p(b_*)).$$

Moreover, if (BH4) holds, then

$$\xi \geq \lim_{\sigma \rightarrow 0} \text{ess inf}_{t \in [a_* - \sigma, a_*]} \mathcal{H}_\lambda(t, x_*(a_*), \bar{u}(t), p(a_*))$$

and

$$\eta \geq \lim_{\sigma \rightarrow 0} \text{ess inf}_{t \in [b_*, b_* + \sigma]} \mathcal{H}_\lambda(t, x_*(b_*), \tilde{u}(t), p(b_*)).$$

*Proof.* To prove the theorem, we use a variant of the scheme in [22, Theorem 8.4.1].

*Step 1.* Take  $a_* \in R$ ,  $g_1 : R^n \rightarrow R_\infty$ ,  $g_2 : R \times R^n \rightarrow R_\infty$ , and  $g_3 : R \rightarrow R_\infty$ . Let  $([a_*, b_*], x_*)$  be a  $W^{1,1}$  local minimizer for the following problem:

$$\begin{aligned} & \text{Minimize } g_1(x(a_*)) + g_2(b, x(b)) + g_3(b) + \int_{a_*}^b L(t, x(t), \dot{x}(t)) dt \\ & \text{over processes } ([a_*, b], x) \text{ which satisfy } x \in W^{1,1}([a_*, b]). \end{aligned}$$

Assume that (BH2) and (BH3) are satisfied,  $g_1$  is Lipschitz continuous near  $x_*(a_*)$ ,  $g_2$  is twice continuously differentiable near  $(b_*, x_*(b_*))$ , and  $g_3$  is Lipschitz continuous near  $b_*$ .

We show that there exist  $p \in W^{1,1}$  and  $\lambda \geq 0$  such that

- (A1)  $\lambda + \|p\|_\infty = 1$ ;
- (B1)  $\dot{p}(t) \in \text{co}\{(\alpha, p(t)) \in \lambda \partial L(t, x_*(t), \dot{x}_*(t))\}$  a.e.;
- (C1)  $p(a_*) \in \lambda \partial g_1(x_*(a_*))$ ,  $-p(b_*) = \lambda \nabla_x g_2(b_*, x_*(b_*))$ ;
- (D1)  $\langle p(t), \dot{x}_*(t) \rangle - \lambda L(t, x_*(t), \dot{x}_*(t)) \geq \langle p(t), v \rangle - \lambda L(t, x_*(t), v)$  for all  $v \in R^n$  a.e.;
- and
- (E1)

$$\lambda \nabla_b g_2(b_*, x_*(b_*)) \leq \text{ess sup}_{[b_* - \sigma, b_* + \sigma]} \mathcal{H}_\lambda(t, x_*(t), \dot{x}_*(t), p(b_*)) + \lambda k_3,$$

in which  $k_3$  is a Lipschitz constant for  $g_3$ . Moreover, if (BH4) holds, then

$$-\lambda k_3 + \lim_{\sigma \rightarrow 0} \text{ess inf}_{[b_* - \sigma, b_* + \sigma]} \mathcal{H}_\lambda(t, x_*(b_*), \bar{u}(t), p(b_*)) \leq \lambda \nabla_b g_2(b_*, x_*(b_*)).$$

Conditions (A1)–(D1) follow directly from the fixed end-time conditions in [24, Theorem 3]. It remains to prove (E1). For  $\sigma > 0$  sufficiently small,  $([a_*, b_* - \sigma], x_*)$  must have cost not less than that of  $([a_*, b_*], x_*)$ . Hence we have

$$g_2(b_*, x_*(b_*)) + g_3(b_*) + \int_{a_*}^{b_*} L_*(t) dt \leq g_2(b_* - \sigma, x_*(b_* - \sigma)) + g_3(b_* - \sigma) + \int_{a_*}^{b_* - \sigma} L_*(t) dt,$$

where  $L_*(t) := L(t, x_*(t), \dot{x}_*(t))$ . Since  $g_2$  is  $C^2$ , we get

$$0 \leq -\nabla_b g_2(b_*, x_*(b_*))\sigma - \nabla_x g_2(b_*, x_*(b_*)) \int_{b_* - \sigma}^{b_*} \dot{x}_*(t) dt + o(\sigma) + k_3\sigma - \int_{b_* - \sigma}^{b_*} L_*(t) dt.$$

Consequently,

$$\begin{aligned} 0 &\leq -\lambda \nabla_b g_2(b_*, x_*(b_*))\sigma - \lambda \nabla_x g_2(b_*, x_*(b_*)) \\ &\quad \times \int_{b_* - \sigma}^{b_*} \dot{x}_*(t) dt + \lambda o(\sigma) + k_3\sigma - \lambda \int_{b_* - \sigma}^{b_*} L_*(t) dt \\ &= -\lambda \nabla_b g_2(b_*, x_*(b_*))\sigma + \int_{b_* - \sigma}^{b_*} [\langle p(b_*), \dot{x}_*(t) \rangle - \lambda L_*(t)] dt + \lambda o(\sigma) + \lambda k_3\sigma. \end{aligned}$$

Hence

$$\begin{aligned} \lambda \nabla_b g_2(b_*, x_*(b_*)) &\leq \lim_{\sigma \rightarrow 0} \frac{1}{\sigma} \int_{b_* - \sigma}^{b_*} [\langle p(b_*), x_*(t) \rangle - \lambda L_*(t)] dt + \lambda k_3 \\ &\leq \lim_{\sigma \rightarrow 0} \operatorname{ess\,sup}_{[b_* - \sigma, b_* + \sigma]} \mathcal{H}_\lambda(t, x_*(t), \dot{x}_*(t), p(b_*)) + \lambda k_3. \end{aligned}$$

We now assume that (BH4) is fulfilled. Define a multifunction

$$F : [b_*, b_* + \delta_1] \times R^n \times R \rightarrow R^n \times R$$

by setting  $F(t, x, y) = \{(u, v) \in R^n \times R : v = L(t, x, u)\}$ . It is clear that for a.e.  $t \in [b_*, b_* + \delta_1]$ , the multifunction  $(x, y) \mapsto F(t, x, y)$  is Lipschitz continuous with rank  $k_1$  in a neighborhood of  $(x_*(b_*), y(b_*))$ , where  $y$  is a given constant function. Define the function  $\hat{z} : [b_*, b_* + \delta_1] \rightarrow R^n \times R$  by  $\hat{z}(t) = (\hat{x}(t), \hat{y}(t))$ , where

$$\hat{x}(t) = x_*(b_*) + \int_{b_*}^t \tilde{u}(s) ds, \quad \hat{y}(t) = y(b_*) + \int_{b_*}^t L(s, x_*(b_*), \tilde{u}(s)) ds.$$

We see that  $\hat{z}(t) \in F(t, x_*(b_*), y(b_*))$ . For each  $\sigma < \delta_1$  we put  $K_\sigma = \exp(\int_{b_*}^{b_* + \sigma} k_1 dt)$ ,  $\rho_\sigma(\hat{z}) = \int_{b_*}^{b_* + \sigma} \rho_F(t, \hat{z}(t), \dot{\hat{z}}(t)) dt$ , where  $\rho_F(t, z(t), \dot{z}(t)) := d(\dot{z}(t), F(t, z(t)))$  and  $z(t) = (x(t), y(t))$ . Since  $t \mapsto \tilde{u}(t)$  and  $t \mapsto L(t, x_*(b_*), \tilde{u}(t))$  are essentially bounded, there exists a constant  $M > 0$  such that

$$|\hat{z}(t) - (x_*(b_*), y(b_*))| \leq M|t - b_*|.$$

Hence  $\hat{z}(t) \rightarrow (x_*(b_*), y(b_*))$  as  $t \rightarrow b_*$ . By the Lipschitz continuity of  $F$ , we have

$$F(t, x_*(b_*), y(b_*)) \subset F(t, \hat{z}(t)) + k_1 |\hat{z}(t) - (x_*(b_*), y(b_*))|$$

for a.e.  $t \in [b_*, b_* + \sigma_1]$  for some  $\sigma_1 < \delta_1$ . This implies that  $\rho(t, \hat{z}(t), \dot{\hat{z}}(t)) \leq k_1 M |t - b_*|$  for a.e.  $t \in [b_*, b_* + \sigma_1]$ . Hence for all  $\sigma \in (0, \sigma_1)$  we have

$$\rho_\sigma(\hat{z}) = \int_{b_*}^{b_* + \sigma} \rho_F(t, \hat{z}(t), \dot{\hat{z}}(t)) dt \leq M k_1 \sigma^2.$$

Consequently,  $K_\sigma \rho_\sigma(\hat{z}) \rightarrow 0$  as  $\sigma \rightarrow 0$ . By Theorem 3.16 in [5], for each  $\sigma \in (0, \sigma_1)$  there exists a solution  $z_\sigma(t) = (x_\sigma(t), y_\sigma(t))$ ,  $t \in [b_*, b_* + \sigma]$ ,  $\dot{z}_\sigma(t) \in F(t, z_\sigma(t))$  with  $z_\sigma(b_*) = \hat{z}(b_*)$  satisfying

$$\int_{b_*}^{b_* + \sigma} |\dot{z}_\sigma(t) - \dot{\hat{z}}(t)| dt \leq K_\sigma \int_{b_*}^{b_* + \sigma} \rho_F(t, \hat{z}(t), \dot{\hat{z}}(t)) dt \leq K_\sigma M k_1 \sigma^2.$$

This implies that

$$\int_{b_*}^{b_* + \sigma} |\dot{x}_\sigma(t) - \tilde{u}(t)| dt \leq K_\sigma M k_1 \sigma^2$$

and

$$\int_{b_*}^{b_* + \sigma} |L(t, x_\sigma(t), \dot{x}_\sigma(t)) - L(t, x_*(b_*), \tilde{u}(t))| dt \leq K_\sigma M k_1 \sigma^2.$$

Fixing any  $\sigma \in (0, \sigma_1)$ , we define a function  $x$  by concatenating  $x_*(t)$ ,  $a_* \leq t \leq b_*$ , and  $x_\sigma(t)$ ,  $b_* \leq t \leq b_* + \sigma$ . We therefore obtain a feasible process  $([a_*, b_* + \sigma], x)$ . Since  $([a_*, b_* + \sigma], x)$  must have cost not less than that of  $([a_*, b_*], x_*)$ , we conclude that

$$\begin{aligned} g_2(b_*, x_*(b_*)) + g_3(b_*) + \int_{a_*}^{b_*} L_*(t) dt &\leq g_2(b_* + \sigma, x(b_* + \sigma)) + g_3(b_* + \sigma) \\ &+ \int_{a_*}^{b_* + \sigma} L(t, x(t), \dot{x}(t)) dt. \end{aligned}$$

Hence

$$\begin{aligned} 0 &\leq \nabla_b g_2(b_*, x_*(b_*)) \sigma + o(\sigma) + k_3 \sigma + \int_{b_*}^{b_* + \sigma} \nabla_x g_2(b_*, x_*(b_*)) \dot{x}_\sigma(t) dt \\ &+ \int_{b_*}^{b_* + \sigma} L(t, x_\sigma(t), \dot{x}_\sigma(t)) dt \\ &\leq \nabla_b g_2(b_*, x_*(b_*)) \sigma + o(\sigma) + k_3 \sigma \\ &+ \int_{b_*}^{b_* + \sigma} \nabla_x \langle g_2(b_*, x_*(b_*)), \tilde{u}(t) \rangle dt + |\nabla_x g_2(b_*, x_*(b_*))| K_\sigma M k_1 \sigma^2 \\ &+ \int_{b_*}^{b_* + \sigma} L(t, x_*(b_*), \dot{\hat{z}}(t)) dt + K_\sigma M k_1 \sigma^2. \end{aligned}$$

Multiplying the latter inequality by  $\lambda \geq 0$  and dividing by  $\sigma > 0$  yields

$$\begin{aligned} & - \lambda k_3 + \frac{1}{\sigma} \int_{b_*}^{b_* + \sigma} [p(b_*) \tilde{u}(t) - \lambda L(t, x_*(b_*), \tilde{u}(t))] dt \\ & \leq K_\sigma M k_1 \sigma (\nabla_x g_2(b_*, x_*(b_*)) + 1) + \lambda \nabla_b g_2(b_*, x_*(b_*)). \end{aligned}$$

This implies that

$$-\lambda k_3 + \lim_{\sigma \rightarrow 0} \operatorname{ess\,inf}_{[b_* - \sigma, b_* + \sigma]} \mathcal{H}_\lambda(t, x_*(b_*), \tilde{u}(t), p(b_*)) \leq \lambda \nabla_b g_2(b_*, x_*(b_*)).$$

Thus assertions of Step 1 are obtained.

*Step 2.* Take  $a_* \in R$  and  $g : R \times R^n \times R^n \rightarrow R_\infty$ . Let  $([a_*, b_*], x_*)$  be a  $W^{1,1}$  local minimizer for the following problem:

$$\begin{aligned} & \text{Minimize } g(x(a_*), b, x(b)) + \int_{a_*}^b L(t, x(t), \dot{x}(t)) dt \\ & \text{over processes } ([a_*, b], x) \text{ which satisfy } x \in W^{1,1}([a_*, b]). \end{aligned}$$

Assume that (BH2) and (BH3) are satisfied and  $g$  is Lipschitz continuous near  $(x_*(a_*), b_*, x_*(b_*))$  with a rank  $k_g$ . We show that there exist  $p \in W^{1,1}$ , and real numbers  $\eta$  and  $\lambda \geq 0$  such that

$$\begin{aligned} & \text{(A2) } \lambda + \|p\|_\infty + |\eta| = 1, \\ & \text{(B2) } \dot{p}(t) \in \operatorname{co}\{\alpha : (\alpha, p(t)) \in \lambda \partial L(t, x_*(t), \dot{x}_*(t))\} \text{ a.e.,} \\ & \text{(C2) } (p(a_*), \eta, -p(b_*)) \in \lambda \partial g(x_*(a_*), b_*, x_*(b_*)), \\ & \text{(D2) } \langle p(t), \dot{x}_*(t) \rangle - \lambda L(t, x_*(t), \dot{x}_*(t)) \geq \langle p(t), v \rangle - \lambda L(t, x_*(t), v) \text{ for all } v \in R^n \text{ a.e.,} \\ & \text{and} \\ & \text{(E2)} \end{aligned}$$

$$\eta \leq \lim_{\sigma \rightarrow 0} \operatorname{ess\,sup}_{[b_* - \sigma, b_*]} \mathcal{H}_\lambda(t, x_*(t), \dot{x}_*(t), p(b_*)).$$

Moreover, if (BH4) holds, then

$$\eta \geq \lim_{\sigma \rightarrow 0} \operatorname{ess\,inf}_{[b_*, b_* + \sigma]} \mathcal{H}_\lambda(t, x_*(b_*), \tilde{u}(t), p(b_*)).$$

Take a sequence  $K_i \rightarrow \infty$  and define

$$\begin{aligned} J_i(b, x, \tau, y) &:= g(x(a_*), \tau(a_*), y(a_*)) \\ &+ \int_{a_*}^b L(t, x(t), \dot{x}(t)) dt + K_i(|\tau(b) - b|^2 + |y(b) - x(b)|^2), \end{aligned}$$

where  $\tau$  and  $y$  are constant functions. Denote by  $W$  the set of all  $([a_*, b], z = (x, \tau, y))$  such that  $x \in W^{1,1}([a_*, b], R^n)$ ,  $\tau \in R$ ,  $y \in R^n$ . With respect to the metric

$$\begin{aligned} & d([a_*, b], (x, \tau, y), [a_*, b'], (x', \tau', y')) \\ &= |b - b'| + |x(a_*) - x'(a_*)| + \|\dot{x}^e - \dot{x}'^e\|_{L^1} + |\tau - \tau'| + |y - y'|, \end{aligned}$$

$W$  is complete and  $J_i$  is continuous. Let us define a sequence  $\epsilon_i$  by

$$\epsilon_i^2 := J_i(b_*, x_*, b_*, x_*(b_*)) - \inf_W J_i(b, x, \tau, y).$$

By similar arguments as in Step 5 to follow, we can show that  $\epsilon_i \rightarrow 0$ . The Ekeland principle now gives us, for each  $i$ , a point  $(b_i, x_i, \tau_i, y_i)$  in  $W$  such that

$$(1) \quad d[(b_i, x_i, \tau_i, y_i), (b_*, x_*, b_*, x_*(b_*))] \leq \epsilon_i,$$

$$(2) \quad J_i(b_i, x_i, \tau_i, y_i) \leq J_i(b, x, \tau, y) + \epsilon_i d[(b_i, x_i, \tau_i, y_i), (b, x, \tau, y)] \quad \forall (b, x, \tau, y) \in W.$$

From (1), it follows that  $b_i \rightarrow b_*$ ,  $\tau_i \rightarrow b_*$ ,  $y_i \rightarrow x_*(b_*)$ ,  $x_i^e \rightarrow x_*^e$  uniformly,  $\dot{x}_i^e \rightarrow \dot{x}_*^e$  a.e. and in  $L^1$ . Also, (2) implies that  $(b_i, \tau_i, x_i, y_i)$  is a  $W$  minimizer of the functional

$$\begin{aligned} \tilde{J}_i(b, z) &:= g(x(a_*), \tau(a_*), y(a_*)) + \epsilon_i(|\tau(a_*) - \tau_i| + |x(a_*) - x_i(a_*)| + |y(a_*) - y_i|) \\ &+ K_i(|\tau(b) - b|^2 + |y(b) - x(b)|^2) + \epsilon_i(|b - b_i| + \int_b^{b \vee b_i} |\dot{x}_i^e(t)| dt) \\ &+ \int_{a_*}^b (L(t, x(t), \dot{x}(t)) + \epsilon_i|\dot{x} - \dot{x}_i^e|) dt. \end{aligned}$$

Put

$$g_1(z(a_*)) = g(x(a_*), \tau(a_*), y(a_*)) + \epsilon_i(|\tau(a_*) - \tau_i| + |x(a_*) - x_i(a_*)| + |y(a_*) - y_i|),$$

$$g_2(b, z(b)) = K_i(|\tau(b) - b|^2 + |y(b) - x(b)|^2),$$

and

$$g_3(b) = \epsilon_i \left( |b - b_i| + \int_b^{b \vee b_i} |\dot{x}_i^e(t)| dt \right).$$

According to Step 1, there exist  $p_i$  and real numbers  $\lambda_i \geq 0$ ,  $\eta_i$ , and  $r_i$  such that

- (i)  $\lambda_i + |\eta_i| + \|p_i\|_\infty = 1$ ,
- (ii)  $\dot{p}_i(t) \in \text{co}\{\alpha : (\alpha, p_i(t)) \in \lambda_i \partial L(t, x_i(t), \dot{x}_i(t)) + \epsilon_i \lambda_i \{0\} \times B\}$  a.e.  $t \in [a_*, b_i]$ ,
- (iii)  $(p_i(a_*), \eta_i, r_i) \in \lambda_i \partial g(x_i(a_*), \tau_i, y_i) + \lambda_i \epsilon_i B \times B \times B$  and  $-(p_i(b_i), \eta_i, r_i) = \lambda_i \nabla_z g_2(b_i, x_i(b_i), \tau_i(b_i), y_i(b_i))$ ,
- (iv)  $\langle p_i(t), \dot{x}_i(t) \rangle - \lambda_i L(t, x_i(t), \dot{x}_i(t)) \geq \langle p_i(t), v \rangle - \lambda L(t, x_i(t), v) - \lambda_i \epsilon_i |v - \dot{x}_i|$  for all  $v \in R^n$  and a.e.  $t \in [a_*, b_i]$ , and
- (v)

$$\begin{aligned} &\lambda_i \nabla_b g_2(b_i, x_i(b_i), \tau_i(b_i), y_i(b_i)) \\ &\leq \lim_{\sigma \rightarrow 0} \text{ess sup}_{[b_i - \sigma, b_i]} \mathcal{H}_{\lambda_i}(t, x_i(t), \dot{x}_i(t), p_i(b_i)) + \lambda_i \epsilon_i k_3. \end{aligned}$$

Assume that (BH4) is fulfilled. Putting  $\tilde{u}_i = \tilde{u}^e$ , we see that functions  $u_i$  and

$$t \mapsto L(t, x_i(b_i), u_i(t)) + \epsilon_i |\tilde{u}_i(t)|$$

are essentially bounded on  $[b_i, b_i + \delta_1]$ . Moreover, for  $i$  sufficiently large, the function

$$x \mapsto L(t, x, u) + \epsilon_i |u - x_i^e(t)|$$

is Lipschitz continuous with rank  $k_1$  for a.e.  $t \in [b_i, b_i + \delta_1]$ .

By the conclusion of Step 1, one has

$$\begin{aligned} &\lambda_i \nabla_b g_2(b_i, x_i(b_i), \tau_i(b_i), y_i(b_i)) \\ &\geq -\lambda_i \epsilon_i k_3 + \lim_{\sigma \rightarrow 0} \text{ess inf}_{[b_i, b_i + \sigma]} [\langle p_i(b_i), u_i(t) \rangle - \lambda_i L(t, x_i(b_i), \tilde{u}_i(t)) - \lambda_i \epsilon_i |\tilde{u}_i(t)|]. \end{aligned}$$

From (iii) we have  $-p_i(b_i) = -2\lambda_i K_i(y_i(b_i) - x_i(b_i))$ ,  $-\eta_i = 2\lambda_i K_i(\tau_i - b_i)$ ,  $-r_i = 2\lambda_i K_i(y_i(b_i) - x_i(b_i))$ . Hence  $-p_i(b_i) = r_i$  and  $\lambda_i \nabla_b g_2(b_i, x_i(b_i), \tau_i(b_i), y_i(b_i)) = \eta_i$ .

Since the  $p_i$ 's are bounded and their derivatives are bounded by an integrable function,  $p_i \rightarrow p$  uniformly and  $\dot{p}_i \rightarrow \dot{p}$  weakly in  $L^1$  for some  $p \in W^{1,1}$ . A further

subsequence extraction ensures that  $\lambda_i \rightarrow \lambda$ ,  $\eta_i \rightarrow \eta$  for some  $\lambda \geq 0$  and  $\eta$ . By passing to the limits as  $i \rightarrow \infty$  in (i)–(v), we obtain (B2)–(E2).

Since  $\lambda_i + \|p_i\|_\infty + |\eta_i| \neq 0$ , by scaling multipliers we can arrange so that  $\lambda_i + \|p_i\|_\infty + |\eta_i| = 1$ . Letting  $i \rightarrow \infty$  we obtain (A2). The proof of Step 2 is complete.

*Step 3* (necessary conditions for fixed right end-time problem). Take  $b_* \in R$  and  $g : R \times R^n \times R^n \rightarrow R_\infty$ . Let  $([a_*, b_*], x_*)$  be a  $W^{1,1}$  local solution of the following problem:

$$\begin{aligned} & \text{Minimize } g(a, x(a), x(b_*)) + \int_a^{b_*} L(t, x(t), \dot{x}(t)) dt \\ & \text{over processes } ([a, b_*], x) \text{ which satisfy } x \in W^{1,1}([a, b_*], R^n). \end{aligned}$$

Assume that (BH2) and (BH3) are satisfied and  $g$  is Lipschitz continuous in a neighborhood of  $(a_*, x_*(a_*), x_*(b_*))$ . We show that there exist  $p$  and real numbers  $\xi$  and  $\lambda \geq 0$  such that

$$\begin{aligned} \text{(A3)} \quad & \lambda + \|p\|_\infty + |\xi| = 1, \\ \text{(B3)} \quad & \dot{p}(t) \in \text{co}\{\alpha : (\alpha, p(t)) \in \lambda \partial L(t, x_*(t), \dot{x}_*(t))\} \text{ a.e. } t \in [a_*, b_*], \\ \text{(C3)} \quad & (-\xi, p(a_*), -p(b_*)) \in \lambda \partial g(a_*, x_*(a_*), x_*(b_*)), \\ \text{(D3)} \quad & \langle p(t), \dot{x}_*(t) \rangle - \lambda L(t, x_*(t), \dot{x}_*(t)) \geq \langle p(t), v \rangle - \lambda L(t, x_*(t), v) \text{ for all } v \in R^n \text{ a.e.} \\ & t \in [a_*, b_*], \text{ and} \\ \text{(E3)} \quad & \end{aligned}$$

$$\xi \leq \lim_{\sigma \rightarrow 0} \text{ess sup}_{[a_*, a_* + \sigma]} \mathcal{H}_\lambda(t, x_*(t), \dot{x}_*(t), p(a_*)).$$

Moreover,

$$\xi \geq \lim_{\sigma \rightarrow 0} \text{ess inf}_{[a_* - \sigma, a_*]} \mathcal{H}_\lambda(t, x_*(a_*), \bar{u}(t), p(a_*))$$

whenever (BH4) is fulfilled.

Put  $a'_* = -b_*$ ,  $b' = -a$ ,  $b'_* = -a_*$ ,  $x'(s) = x(-s)$ ,  $\bar{u}'(s) = -\bar{u}(-s)$ ,  $x'_*(s) = x_*(-s)$ ,  $g'(t, x, y) = g(-t, x, y)$ , and  $L'(s, x, y) = L(-s, x, -y)$ . By considering a change of independent variable  $s = -t$ , it follows that  $([a'_*, b'_*], x'_*)$  is a solution of the following problem:

$$\begin{aligned} & \text{Minimize } g'(b', x(b'), x(a'_*)) + \int_{a'_*}^{b'} L'(s, x'(s), \dot{x}'(s)) ds \\ & \text{over processes } ([a'_*, b'], x') \text{ which satisfy } x' \in W^{1,1}([a'_*, b'], R^n). \end{aligned}$$

According to Step 2, there exist  $p', \mu', \gamma', \lambda'$ , and  $\eta'$  such that

$$\begin{aligned} \text{(i)} \quad & \lambda' + \|p'\|_\infty + |\eta'| = 1, \\ \text{(ii)} \quad & \dot{p}'(s) \in \text{co}\{\alpha : (\alpha, p'(s)) \in \lambda' \partial L'(s, x'_*(s), \dot{x}'_*(s))\} \text{ a.e. } s \in [a', b'_*], \\ \text{(iii)} \quad & (\eta', -p'(b'_*), p'(a'_*)) \in \lambda' \partial g'(b'_*, x'_*(b'_*), x'_*(a'_*)), \\ \text{(iv)} \quad & \langle p'(s), \dot{x}'_*(s) \rangle - \lambda' L'(s, x'_*(s), \dot{x}'_*(s)) \geq \langle p'(s), v \rangle - \lambda' L'(s, x'_*(s), v) \text{ for all } v \in R^n \\ & \text{a.e., and} \\ \text{(v)} \quad & \end{aligned}$$

$$\eta' \leq \lim_{\sigma \rightarrow 0} \text{ess sup}_{[b'_* - \sigma, b'_*]} [\langle p'(b'_*), \dot{x}'_*(s) \rangle - \lambda' L'(s, x'_*(s), \dot{x}'_*(s))].$$

Moreover,

$$\eta' \geq \lim_{\sigma \rightarrow 0} \text{ess} \inf_{[b'_*, b'_* + \sigma]} [\langle p'(b'_*), \bar{u}'(s) \rangle - \lambda L'(s, x'_*(s), \bar{u}'(s))]$$

whenever (BH6) is fulfilled.

Put  $\xi = \eta'$ ,  $\lambda = \lambda'$ , and  $p(s) = -p'(-s)$ . By simple computation we obtain (A3)–(E3) from assertions (i)–(v).

*Step 4.* Take  $g_1, g_2 : R \times R^n \rightarrow R_\infty$ ,  $g_3 : R \rightarrow R_\infty$ . Let  $([a_*, b_*], x_*)$  be a solution of the following problem:

$$\begin{aligned} & \text{Minimize } g_1(a, x(a)) + g_2(b, x(b)) + g_3(b) + \int_a^b L(t, x(t), \dot{x}(t)) dt \\ & \text{over processes } ([a, b], x) \text{ which satisfy } x \in W^{1,1}([a, b], R^n). \end{aligned}$$

Assume that (BH2) and (BH3) are satisfied,  $g_1$  is Lipschitz continuous near  $(a_*, x_*(a_*))$ ,  $g_2$  is twice differentiable near  $(b_*, x_*(b_*))$ , and  $g_3$  is Lipschitz continuous near  $b_*$  with rank  $k_3$ .

Fixing  $b = b_*$ , we see that  $([a_*, b_*], x_*)$  is a solution of the following problem:

$$\begin{aligned} & \text{Minimize } g_1(a, x(a)) + g_2(b_*, x(b_*)) + g_3(b_*) + \int_a^{b_*} L(t, x(t), \dot{x}(t)) dt \\ & \text{over processes } ([a, b_*], x) \text{ which satisfy } x \in W^{1,1}([a, b_*], R^n). \end{aligned}$$

According to Step 3, there exist  $p$  and real numbers  $\lambda \geq 0$  and  $\xi$  such that

- (A4)  $\lambda + \|p\|_\infty + |\xi| = 1$ ;
- (B4)  $\dot{p}(t) \in \text{co}\{\alpha : (\alpha, p(t)) \in \lambda \partial L(t, x_*(t), \dot{x}_*(t))\}$  a.e.  $t \in [a_*, b_*]$ ;
- (C4)  $(-\xi, p(a_*)) \in \lambda \partial g_1(a_*, x_*(a_*))$ ,  $-p(b_*) = \lambda \nabla_x g_2(b_*, x_*(b_*))$ ;
- (D4)  $\langle p(t), \dot{x}_*(t) \rangle - \lambda L(t, x_*(t), \dot{x}_*(t)) \geq \langle p(t), v \rangle - \lambda L(t, x_*(t), v)$  for all  $v \in R^n$  a.e.  $t \in [a_*, b_*]$ ; and
- (E4)

$$\xi \leq \lim_{\sigma \rightarrow 0} \text{ess} \sup_{[a_*, a_* + \sigma]} \mathcal{H}_\lambda(t, x_*(t), \dot{x}_*(t), p(a_*)).$$

Moreover,

$$\xi \geq \lim_{\sigma \rightarrow 0} \text{ess} \inf_{[a_* - \sigma, a_*]} \mathcal{H}_\lambda(t, x_*(a_*), \bar{u}(t), p(a_*)).$$

Since  $([a_*, b_*], x_*)$  is also a solution of the following problem:

$$\begin{aligned} & \text{Minimize } g_1(a_*, x(a_*)) + g_2(b, x(b)) + g_3(b) + \int_{a_*}^b L(t, x(t), \dot{x}(t)) dt \\ & \text{over processes } ([a_*, b], x) \text{ which satisfy } x \in W^{1,1}([a_*, b], R^n), \end{aligned}$$

a similar argument as in Step 1 shows that

$$\begin{aligned} & -\lambda k_3 + \lim_{\sigma \rightarrow 0} \text{ess} \inf_{[b_*, b_* + \sigma]} \mathcal{H}_\lambda(t, x_*(b_*), \tilde{u}(t), p(b_*)) \leq \lambda \nabla_b g_2(b_*, x_*(b_*)) \\ & \leq \lim_{\sigma \rightarrow 0} \text{ess} \sup_{[b_* - \sigma, b_*]} \mathcal{H}_\lambda(t, x_*(t), \dot{x}_*(t), p(b_*)) + \lambda k_3. \end{aligned}$$

*Step 5.* We now return to the problem (BP). Let  $([a_*, b_*], x_*)$  be a solution of (BP), which we reiterate here:

$$\begin{aligned} &\text{Minimize } J(a, b, x) := l(a, x(a), b, x(b)) + \int_a^b L(t, x(t), \dot{x}(t)) dt \\ &\text{over intervals } [a, b] \text{ and arcs } x \in W^{1,1}([a, b], R^n). \end{aligned}$$

We want to show that there exist  $p$ , and real numbers  $\lambda \geq 0$ ,  $\xi$ , and  $\eta$  which satisfy the conclusion of Theorem 3.1.

Take a sequence  $K_i \rightarrow \infty$ . For each  $i$  we put

$$\begin{aligned} (3) \quad J_i(a, b, x, \tau, y) &= l(a, x(a), \tau(a), y(a)) \\ &\quad + \int_a^b L(t, x(t), \dot{x}(t)) dt + K_i(|\tau(b) - b|^2 + |y(b) - x(b)|^2), \end{aligned}$$

where  $\tau$  and  $y$  are constant functions. Denote by  $\tilde{W}$  the set of all  $(a, b, z = (x, \tau, y))$  such that  $x \in W^{1,1}([a, b], R^n)$ ,  $\tau \in R$ ,  $y \in R^n$ . It is clear that  $\tilde{W}$  is a metric space with respect to metric  $d$  induced by the norm

$$|(a, b, x, \tau, y)| = |a| + |b| + |x(a)| + \|\dot{x}^e\|_{L^1} + |\tau| + |y|.$$

Moreover,  $J_i$  is continuous on  $\tilde{W}$ . Define a sequence  $\epsilon_i$  by

$$\epsilon_i^2 := J_i(a_*, b_*, x_*, b_*, x_*(b_*)) - \inf_{\tilde{W}} J_i(a, b, x, \tau, y).$$

We claim that  $\epsilon_i \rightarrow 0$ . In fact, from (BH1) we get

$$l(a, x(a), \tau, y) \geq l(a, x(a), b, x(b)) - k_l(|\tau - b| + |y - x(b)|).$$

Hence

$$\begin{aligned} J_i(a, b, x, \tau, y) &\geq l(a, x(a), b, x(b)) + \int_a^b L(t, x(t), \dot{x}(t)) dt \\ &\quad - k_l(|\tau - b| + |y - x(b)|) + K_i(|\tau(b) - b|^2 + |y(b) - x(b)|^2) \\ &\geq J_i(a_*, b_*, x_*, b_*, x_*(b_*)) - k_l^2/2K_i. \end{aligned}$$

This implies that  $\epsilon_i \leq \frac{k_l}{\sqrt{2K_i}} \rightarrow 0$ . Since  $(a_*, b_*, x_*, b_*, x_*(b_*))$  is an  $\epsilon_i$  minimizer, Ekeland's principle gives us, for each  $i$ , a point  $(a_i, b_i, x_i, \tau_i, y_i)$  such that

$$(4) \quad d[(a_i, b_i, x_i, \tau_i, y_i), (a_*, b_*, x_*, b_*, x_*(b_*))] \leq \epsilon_i,$$

$$\begin{aligned} (5) \quad J_i(a_i, b_i, x_i, \tau_i, y_i) &\leq J_i(a, b, x, \tau, y) \\ &\quad + \epsilon_i d[(a, b, x, \tau, y), (a_i, b_i, x_i, \tau_i, y_i)] \quad \forall (a, b, x, \tau, y) \in \tilde{W}. \end{aligned}$$

From (4) we get  $a_i \rightarrow a_*$ ,  $b_i \rightarrow b_*$ ,  $\tau_i \rightarrow b_*$ ,  $y_i \rightarrow x_*(b_*)$ ,  $x_i \rightarrow x_*$  uniformly,  $\dot{x}_i^e \rightarrow \dot{x}_*^e$  a.e. and in  $L^1$ . It follows from (5) that  $(a_i, b_i, x_i, \tau_i, y_i)$  is a  $\tilde{W}$  minimizer of the functional

$$\begin{aligned} \tilde{J}_i(a, z) &:= l(a, x(a), \tau(a), y(a)) + \epsilon_i(|a - a_i| + |x(a) - x_i(a_i)| + |\tau - \tau_i| + |y - y_i|) \\ &\quad + \epsilon_i \int_{a \wedge a_i}^a |\dot{x}_i^e(t)| dt + \int_a^b (L(t, x(t), \dot{x}(t)) + \epsilon_i |\dot{x}(t) - \dot{x}_i^e(t)|) dt \\ &\quad + \epsilon_i K_i(|\tau(b) - b|^2 + |y(b) - x(b)|^2) + \epsilon_i \left( |b - b_i| + \int_b^{b \vee b_i} |\dot{x}_i^e(t)| dt \right), \end{aligned}$$

where  $z := (x, \tau, y)$ .

According to Step 4, there exist  $p_i$  and real numbers  $\lambda_i \geq 0$ ,  $\xi_i$ ,  $\eta_i$ , and  $r_i$  such that

- (A5)  $\lambda_i + \|p_i\|_\infty + |\xi_i| + |\eta_i| + |r_i| = 1$ ,
- (B5)  $\dot{p}_i(t) \in \text{co}\{\alpha : (\alpha, p_i(t)) \in \lambda \partial L(t, x_i(t), \dot{x}_i(t)) + \epsilon_i \lambda_i \{0\} \times B\}$  a.e.  $t \in [a_i, b_i]$ ,
- (C5)  $(-\xi_i, p_i(a_i), \eta_i, r_i) \in \lambda_i \partial l(a_i, x_i(a_i), \tau_i, y_i) + \lambda_i \epsilon_i k_3(B \times \{0\} \times \{0\} \times \{0\}) + \lambda_i \epsilon_i B^4$   
and  $-(p_i(b_i), \eta_i, r_i) = 2\epsilon_i K_i(-y_i + x_i(b_i), \tau_i - b_i, y_i - x_i(b_i))$ ,
- (D5)  $\langle p_i(t), \dot{x}_i(t) \rangle - \lambda_i L(t, x_i(t), \dot{x}_i(t)) \geq \langle p_i(t), v \rangle - \lambda L(t, x_i(t), v) - \lambda_i \epsilon_i |v - \dot{x}_i|$  for all  $v \in R^n$  and a.e.  $t \in [a_i, b_i]$ , and
- (E5)

$$\begin{aligned} & \lim_{\sigma \rightarrow 0} \text{ess} \inf_{[a_i - \sigma, a_i]} [\langle p_i(a_i), \bar{u}_i(t) \rangle - \lambda_i L(t, x_i(t), \dot{x}_i(t)) - \lambda_i \epsilon_i |\bar{u}_i(t)|] \leq \xi_i \\ & \leq \lim_{\sigma \rightarrow 0} \text{ess} \sup_{[a_i, a_i + \sigma]} [\langle p_i(a_i), \dot{x}_i(t) \rangle - \lambda_i L(t, x_i(t), \dot{x}_i(t))] \end{aligned}$$

and

$$\begin{aligned} & -\lambda_i \epsilon_i (1 + M) + \lim_{\sigma \rightarrow 0} \text{ess} \inf_{[b_i, b_i + \sigma]} [\langle p_i(b_i), \tilde{u}_i(t) \rangle - \lambda_i L(t, x_i(t), \tilde{u}_i(t)) - \lambda_i \epsilon_i |\tilde{u}_i(t)|] \\ & \leq 2K_i \epsilon_i (b_i - \tau_i) = \eta_i \leq \lim_{\sigma \rightarrow 0} \text{ess} \sup_{[b_i - \sigma, b_i]} [\langle p_i(b_i), \dot{x}_i(t) \rangle - \lambda L(t, x_i(t), \dot{x}_i(t))] \\ & \quad + \lambda_i \epsilon_i (1 + M), \end{aligned}$$

where  $\bar{u}_i = \bar{u}^c$  and  $\tilde{u}_i = \tilde{u}^c$ .

Since  $p_i$ 's are bounded and their derivatives are bounded by an integrable function,  $p_i \rightarrow p$  uniformly and  $\dot{p}_i \rightarrow \dot{p}$  weakly in  $L^1$  for some  $p \in W^{1,1}$ . A further subsequence extraction ensures that  $\lambda_i \rightarrow \lambda$ ,  $\eta_i \rightarrow \eta$ ,  $\xi_i \rightarrow \xi$ , and  $r_i \rightarrow -p(b_*)$ . Note that since  $-p_i(b_i) = r_i$ , it follows that  $\lambda + \|p\| \neq 0$ . By passing to the limit and standard arguments we can show that  $\lambda$  and  $p$  satisfy the conclusion of the theorem. The proof of the theorem is complete.  $\square$

*Remark 3.2.* Theorem 8.4.1 in [22] gave necessary conditions for problem (P) in the scalar case. It is possible to reduce (BP) to (P) (in the case  $m = 1$ ) and process it as in [23]. However, this transformation causes the structure of the problem to deteriorate and so it is difficult to obtain the desired conclusions. In the above argument, we exploited the structure of (BP) and gave a direct proof to establish our result.

**4. Necessary conditions for MOC.** In this section we derive necessary conditions for (P). Fix a feasible triple  $([a_*, b_*], x_*)$  and assume the following hypotheses which involve positive number  $\delta$ , a nonnegative function  $k_F \in L^1[a_*, b_*]$ , and a number  $\beta \geq 0$ :

- (H1)  $g$  is Lipschitz continuous on a neighborhood of  $(a_*, x_*(a_*), b_*, x_*(b_*))$  with rank  $k_g$  and  $C$  is a closed set.
- (H2)  $F$  is  $\mathcal{L} \times \mathcal{B}$  measurable with nonempty values and  $\text{Gph} F(t, \cdot)$  is closed.
- (H3)  $F$  has the integrable sub-Lipschitzian property (see [10]), that is,

$$F(t, x') \cap (x_*(t) + NB) \subset F(t, x) + (k_F(t) + \beta N)|x' - x|B$$

for all  $N \geq 0$ ,  $x', x \in x_*(t) + \delta B$ , a.e.  $t \in [a_*, b_*]$ .

- (H4) There exist positive constants  $c_0, c_1$ ,  $k_0$ , and  $k_1$  such that

$$\begin{cases} F(t, x) \subset c_0 B, \\ F(t, x') \subset F(t, x) + k_0 |x' - x| B \end{cases}$$

for a.e.  $t \in [a_* - \delta, a_*]$  and for all  $x, x' \in x_*(a_*) + \delta B$ ; and

$$\begin{cases} F(t, x) \subset c_1 B, \\ F(t, x') \subset F(t, x) + k_1 |x' - x| B \end{cases}$$

for a.e.  $t \in [b_*, b_* + \delta]$  and for all  $x, x' \in x_*(b_*) + \delta B$ .

In what follows,  $H(t, x, p) := \sup\{\langle p, v \rangle : v \in F(t, x(t))\}$  and  $\text{ess}_{\tau \rightarrow t} f(\tau)$  is the essential value of a real value function  $f$  at  $t \in I \subset \mathbb{R}$ , that is,  $\text{ess}_{\tau \rightarrow t} f(\tau) := [a_-, a_+]$ , where

$$a_- := \lim_{\delta \rightarrow 0} \text{ess inf}_{\tau \in [t-\delta, t+\delta]} f(\tau) \text{ and } a_+ := \lim_{\delta \rightarrow 0} \text{ess sup}_{\tau \in [t-\delta, t+\delta]} f(\tau).$$

We refer the reader to [22, Proposition 8.3.2] for properties of essential values.

We are ready to state our main result.

**THEOREM 4.1.** *Suppose  $([a_*, b_*], x_*)$  is a local minimizer of (P), preference  $\prec$  is regular at  $g(a_*, x_*(a_*), b_*, x_*(b_*))$ , and assumptions (H1)–(H4) are satisfied. Then there exist an arc  $p \in W^{1,1}([a_*, b_*], \mathbb{R}^n)$ , a vector  $w \in N_{\bar{L}[g(a_*, x_*(a_*), b_*, x_*(b_*))]}(g(a_*, x_*(a_*), b_*, x_*(b_*)))$  with  $|w| = 1$ , and real numbers  $\lambda \geq 0$ ,  $\xi$ , and  $\eta$  such that*

- (i)  $\lambda + \|p\|_\infty = 1$ ,
- (ii)  $\dot{p}(t) \in \text{co}\{\alpha : (\alpha, p(t)) \in N_{\text{Gph}F(t, \cdot)}(x_*(t), \dot{x}_*(t))\}$  a.e.  $t \in [a_*, b_*]$ ,
- (iii)  $(-\xi, p(a_*), \eta, -p(b_*)) \in \lambda \partial \langle w, g(a_*, x_*(a_*), b_*, x_*(b_*)) \rangle + N_C(a_*, x_*(a_*), b_*, x_*(b_*))$ ,
- (iv)  $\langle p(t), \dot{x}_*(t) \rangle = H(t, x_*(t), p(t))$  a.e.  $t \in [a_*, b_*]$ ,
- (v)  $\xi \in \text{ess}_{t \rightarrow a_*} H(t, x_*(a_*), p(a_*))$  and  $\eta \in \text{ess}_{t \rightarrow b_*} H(t, x_*(b_*), p(b_*))$ .

*Proof.* Define a mapping  $\rho_F : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$  by

$$\rho_F(t, x, \dot{x}) = \inf\{|\dot{x} - v| : v \in F(t, x)\}.$$

According to Lemma 7 in [24] it follows from (H3) that  $\rho_F(t, \cdot, \cdot)$  satisfies condition (BH3) for a.e.  $t \in [a_*, b_*]$ . Put

$$W_\epsilon = \{([a, b], x) : x \in W^{1,1}([a, b]), d((([a, b], x), [a_*, b_*], x_*)) \leq \epsilon\}$$

and

$$S_\epsilon = \{([a, b], x) \in W_\epsilon : (a, x(a), b, x(b)) \in C, \dot{x}(t) \in F(t, x(t)) \text{ a.e.}\}.$$

It is clear that  $W_\epsilon$  is a complete metric space and  $S_\epsilon$  is a closed set in  $W_\epsilon$ .

Fix  $N$  and reduce the size of  $\epsilon$  such that  $([a_*, b_*], x_*)$  is the solution of (P) in  $S_\epsilon$ .

As in [24] and [2], we use a variant of Ioffe's scheme [8] by considering the following two possible situations:

- (a) There exist  $\epsilon' \in (0, \epsilon)$  and  $K > 0$  such that for any  $([a, b], x) \in W_{\epsilon'}$ , one has

$$(6) \quad d((([a, b], x), S_\epsilon) \leq K \left[ \int_a^b \rho_F(t, x(t), \dot{x}(t)) dt + K d_C(a, x(a), b, x(b)) \right].$$

- (b) There exist a sequence  $\epsilon'_k \rightarrow 0$  and a sequence  $([a_k, b_k], x_k) \in W_{\epsilon'_k}$  such that

$$(7) \quad d((([a_k, b_k], x_k), S_\epsilon) > 2k \left[ \int_{a_k}^{b_k} \rho_F(t, x_k(t), \dot{x}_k(t)) dt + 2k d_C(a_k, x_k(a_k), b_k, x_k(b_k)) \right].$$

Case (a). Since  $g(a_*, x_*(a), b_*, x_*(b_*)) \in \overline{\mathcal{L}}[g(a_*, x_*(a_*), b_*, x_*(b_*))]$ , there exists a sequence  $\theta_k \in \mathcal{L}[g(a_*, x_*(a_*), b_*, x_*(b_*))]$  such that  $|\theta_k - g(a_*, x_*(a_*), b_*, x_*(b_*))| \leq 1/k^2$ . Put  $\Omega_k = \overline{\mathcal{L}}[\theta_k]$  and define the function

$$\varphi(a, b, x, \theta) = \begin{cases} |g(a, x(a), b, x(b)) - \theta| & \text{if } (a, b, x, \theta) \in S_{\epsilon'} \times \Omega_k, \\ +\infty & \text{otherwise.} \end{cases}$$

We claim that  $\varphi$  is l.s.c. on  $W_{\epsilon'} \times \Omega_k$ . Indeed, assume that  $((a, b, x), \theta) \in W_{\epsilon'} \times \Omega_k$  and  $((a_n, b_n, x_n), \theta_n) \xrightarrow{W_{\epsilon'}} ((a, b, x), \theta)$ . If  $(a, b, x, \theta) \in S_{\epsilon'} \times \Omega_k$ , then it follows from Lipschitzian continuity of  $g$  that

$$\begin{aligned} |\varphi(a_n, b_n, x_n, \theta_n) - \varphi(a, b, x, \theta)| &\leq k_g(|a_n - a| + |b_n - b| + |x_n(a_n) - x(a)| \\ &\quad + |x_n(b_n) - x(b)|) + |\theta_n - \theta| \\ &\leq k_g(|a_n - a| + |b_n - b| + 2\|x_n - x\|_{\infty}) + |\theta_n - \theta| \rightarrow 0. \end{aligned}$$

If  $(a, b, x, \theta) \notin S_{\epsilon'} \times \Omega_k$ , then  $(a_n, b_n, x_n, \theta_n) \notin S_{\epsilon'} \times \Omega_k$  for  $n$  sufficiently large because  $S_{\epsilon'} \times \Omega_k$  is closed in  $W_{\epsilon'} \times R^m$ . Hence  $\lim_{n \rightarrow \infty} \varphi(a_n, b_n, x_n, \theta_n) = +\infty \geq \varphi(a, b, x, \theta)$ . Thus  $\varphi$  is l.s.c. Since  $\varphi(a, b, x, \theta) \geq 0$ , one has

$$\varphi(a_*, b_*, x_*, \theta_k) \leq \inf_{(x, \theta) \in W_{\epsilon'} \times \Omega_k} \varphi(a, b, x, \theta) + 1/k^2.$$

The Ekeland principle gives us, for each  $k$ , a point  $(a_k, b_k, x_k, \chi_k) \in W_{\epsilon'} \times \Omega_k$  such that

$$(8) \quad \varphi(a_k, b_k, x_k, \chi_k) \leq \varphi(a_*, b_*, x_*, \theta_k) < \frac{1}{k^2},$$

$$(9) \quad |a_k - a_*| + |b_k - b_*| + |x_k(a_k) - x_*(a_*)| + \|\dot{x}_k^e - \dot{x}_*^e\|_{L^1} + |\chi_k - \theta_k| \leq 1/k,$$

$$(10) \quad \varphi(a_k, b_k, x_k, \chi_k) \leq \varphi(a, b, x, \theta) + \frac{1}{k} [d([a, b], x), ([a_k, b_k], x_k) + |\theta - \chi_k|]$$

for all  $((a, b, x), \theta) \in W_{\epsilon'} \times \Omega_k$ . From (8), we get  $(a_k, b_k, x_k) \in S_{\epsilon'}$ . Inequality (9) implies that  $a_k \rightarrow a_*$ ,  $b_k \rightarrow b_*$ ,  $x_k(a_k) \rightarrow x_*(a_*)$ ,  $x_k^e \rightarrow x_*^e$  uniformly,  $\dot{x}_k^e \rightarrow \dot{x}_*^e$  a.e., and  $\chi_k \rightarrow g(a_*, x_*(a_*), b_*, x_*(b_*))$ . We claim that  $\chi_k \neq g(a_k, x_k(a_k), b_k, x_k(b_k))$ . Indeed, suppose that  $\chi_k = g(a_k, x_k(a_k), b_k, x_k(b_k))$ . Since  $\prec$  is closed, the relations  $\chi_k \in \overline{\mathcal{L}}[\chi_k]$  and  $\chi_k \prec g(a_*, x_*(a_*), b_*, x_*(b_*))$  imply that

$$g(a_k, x_k(a_k), b_k, x_k(b_k)) = \chi_k \prec g(a_*, x_*(a_*), b_*, x_*(b_*)).$$

This contradicts the fact that  $([a_*, b_*], x_*)$  is a minimizer.

Put

$$w_k = \frac{\chi_k - g(a_k, x_k(a_k), b_k, x_k(b_k))}{|\chi_k - g(a_k, x_k(a_k), b_k, x_k(b_k))|}.$$

We can assume that  $w_k \rightarrow w$  with  $|w| = 1$ . Substituting  $(a, b, x) = (a_k, b_k, x_k)$  into (10), it follows that

$$0 \in \partial \left( |g(a_k, x_k(a_k), b_k, x_k(b_k)) - \cdot| + \frac{1}{k} |\cdot - \chi_k| \right) (\chi_k) + N_{\Omega_k}(\chi_k).$$

This implies that  $w_k \in \frac{1}{k}B + N_{\Omega_k}(\chi_k)$ . Hence

$$w \in \lim_{k \rightarrow \infty} N_{\Omega_k}(\chi_k) \subset N_{\bar{\mathcal{E}}[g(a_*, x_*(a_*), b_*, x_*(b_*))]}(g(a_*, x_*(a_*), b_*, x_*(b_*))).$$

Also, substituting  $\theta = \chi_k$  into (10), it follows that

$$\varphi(a_k, b_k, x_k, \chi_k) \leq \varphi(a, b, x, \chi_k) + \frac{1}{k}d([a, b], x), ([a_k, b_k], x_k).$$

Combining this with (6) yields

$$\begin{aligned} \varphi(a_k, b_k, x_k, \chi_k) &\leq \varphi(a, b, x, \chi_k) + \frac{1}{k}d([a, b], x), ([a_k, b_k], x_k) \\ &\quad + \left[ \int_a^b \rho_F(t, x(t), \dot{x}(t)) dt + Kd_C(a, x(a), b, x(b)) \right] \end{aligned}$$

for all  $([a, b], x) \in W_{\epsilon'}$ . This implies that  $([a_k, b_k], x_k)$  is a  $W_{\epsilon'}$  minimizer of the following Bolza problem:

$$\begin{aligned} J(a, b, x) &:= \int_a^b \left( \rho_F(t, x(t), \dot{x}(t)) + \frac{1}{k}|\dot{x} - \dot{x}_k^e| \right) dt + |g(a, x(a), b, x(b)) - \chi_k| \\ &\quad + Kd_C(a, x(a), b, x(b)) + \frac{1}{k}(|a - a_k| + |b - b_k| + |x(a) - x_k(a_k)| \\ &\quad + \int_{a_k \wedge a}^a |\dot{x}_k^e| dt + \int_b^{b \vee b_k} |\dot{x}_k^e| dt. \end{aligned}$$

Put

$$\begin{aligned} L(t, x(t), \dot{x}(t)) &= \rho_F(t, x(t), \dot{x}(t)) + \frac{1}{k}|\dot{x} - \dot{x}_k^e|, \\ l(a, x(a), b, x(b)) &= |g(a, x(a), b, x(b)) - \chi_k| + Kd_C(a, x(a), b, x(b)) \\ &\quad + \frac{1}{k} \left( |a - a_k| + |b - b_k| + |x(a) - x_k(a_k)| + \int_{a_k \wedge a}^a |\dot{x}_k^e| dt + \int_b^{b \vee b_k} |\dot{x}_k^e| dt \right). \end{aligned}$$

It is easy to check that hypotheses (BH1)–(BH3) hold for  $l$  and  $L$ . By Theorem 3.1, there exist  $p_k \in W^{1,1}$ , and real numbers  $\lambda_k \geq 0$ ,  $\xi_k$ ,  $\eta_k$  such that

- (A)  $\lambda_k + |p_k|_\infty = 1$ ,
- (B)  $\dot{p}_k(t) \in \text{co}\{\alpha : (\alpha, p_k(t)) \in \lambda_k \partial \rho_F(t, x_k(t), \dot{x}_k(t)) + \frac{\lambda_k}{k} \{0\} \times B\}$  a.e.  $t \in [a_k, b_k]$ ,
- (C)  $(-\xi_k, p_k(a_k), \eta_k, -p_k(b_k)) \in \lambda_k \partial \langle w_k, g(a_k, x_k(a_k), b_k, x_k(b_k)) \rangle + \frac{\lambda_k}{k} B^3 \times \{0\} + \frac{\lambda_k}{k} M(B \times \{0\} \times B \times \{0\}) + \lambda_k K \partial d_C(a_k, x_k(a_k), b_k, x_k(b_k))$ ,
- (D)  $\langle p_k(t), \dot{x}_k(t) \rangle - \lambda_k \rho_F(t, x_k(t), \dot{x}_k(t)) \geq \langle p_k(t), \dot{v} \rangle - \lambda_k \rho_F(t, x_k(t), v) - \frac{\lambda_k}{k} |v - \dot{x}_k^e|$  for all  $v \in R^n$  a.e., and
- (E)

$$(11) \quad \xi_k \leq \lim_{\sigma \rightarrow 0} \text{ess sup}_{t \in [a_k - \sigma, a_k]} (\langle p_k(a_k), \dot{x}_k(t) \rangle - \lambda_k \rho_F(t, x_k(t), \dot{x}_k(t)))$$

and

$$(12) \quad \eta_k \leq \lim_{\sigma \rightarrow 0} \text{ess sup}_{t \in [b_k, b_k + \sigma]} (\langle p_k(b_k), \dot{x}_k(t) \rangle - \lambda_k \rho_F(t, x_k(t), \dot{x}_k(t))).$$

Fix any  $\sigma < \delta$ . By (H4) we can find essentially bounded selections  $\bar{u}_k$  and  $\tilde{u}_k$  of  $F(\cdot, x_k(a_k))$  and  $F(\cdot, x_k(b_k))$ , respectively, such that

$$(13) \quad \langle p_k(a_k), \bar{u}_k(t) \rangle = \max_{u \in F(t, x_k(a_k))} \langle p_k(a_k), u \rangle = H(t, x_k(a_k), p_k(a_k)) \text{ a.e. } t \in [a_k - \sigma, a_k]$$

and

$$(14) \quad \langle p_k(b_k), \tilde{u}_k(t) \rangle = \max_{u \in F(t, x_k(b_k))} \langle p_k(b_k), u \rangle = H(t, x_k(b_k), p_k(b_k)) \text{ a.e. } t \in [b_k, b_k + \sigma].$$

Since  $L(t, x_k(a_k), \bar{u}_k(t)) = \frac{1}{k} |\bar{u}_k(t)|$ , the function  $t \mapsto L(t, x_k(a_k), \bar{u}_k(t))$  is essentially bounded on  $[a_k - \sigma, a_k]$ . Moreover, the function  $x \mapsto L(t, x, u)$  is Lipschitz continuous with rank  $k_0$  in a neighborhood  $x_k(a_k)$  for  $k$  sufficiently large and for a.e.  $t \in [a_k - \sigma, a_k]$ . Also, the function  $t \mapsto L(t, x_k(b_k), \tilde{u}_k(t))$  is essentially bounded on  $[b_k, b_k + \sigma]$ , and  $x \mapsto L(t, x, u)$  is Lipschitz continuous with rank  $k_1$  for a.e.  $t \in [b_k, b_k + \sigma]$ . Hence (BH4) is fulfilled. By the conclusion of Theorem 3.1 we have

$$(15) \quad \xi_k \geq \lim_{\sigma \rightarrow 0} \text{ess} \inf_{t \in [a_k - \sigma, a_k]} \left( H(t, x_k(a_k), p_k(a_k)) - \frac{\lambda_k}{k} |\bar{u}_k(t)| \right)$$

and

$$(16) \quad \eta_k \geq \lim_{\sigma \rightarrow 0} \text{ess} \inf_{t \in [b_k, b_k + \sigma]} \left( H(t, x_k(b_k), p_k(b_k)) - \frac{\lambda_k}{k} |\tilde{u}_k(t)| \right).$$

Since  $p_k$ 's are bounded and their derivatives are bounded by an integrable function,  $p_k \rightarrow p$  uniformly and  $\dot{p}_k \rightarrow \dot{p}$  weakly in  $L^1$  for some  $p \in W^{1,1}$ . A further subsequence extraction ensures that  $\lambda_k \rightarrow \lambda$ ,  $\eta_k \rightarrow \eta$ ,  $\xi_k \rightarrow \xi$ .

By passing to the limit as  $k \rightarrow \infty$  in (A) we obtain (i). From (B) and Lemma 2.1, we have

$$\dot{p}_k(t) \in \text{co} \left\{ \alpha : (\alpha, p_k(t)) \in N_{\text{Grph}F(t, \cdot)}(x_k(t), \dot{x}_k(t)) + \frac{\lambda_k}{k} \{0\} \times B \right\}.$$

Passing to the limit as  $k \rightarrow \infty$  yields

$$\dot{p}(t) \in \text{co} \{ \alpha : (\alpha, p(t)) \in N_{\text{Grph}F(t, \cdot)}(x_*(t), \dot{x}_*(t)) \}.$$

Hence (ii) follows. As

$$\lambda_k K \partial d_C(a_k, x_k(a_k), b_k, x_k(b_k)) \subset N_C(a_k, x_k(a_k), b_k, x_k(b_k)),$$

passing to the limit in (C) and (D), we obtain (iii) and (iv), respectively.

By Lemma 2.2,  $H(t, \cdot, \cdot)$  is continuous for a.e.  $t$ . Passing to the limit in (11) and (15), and using properties of essential values (see [22, Proposition 8.3.2]), we get

$$(17) \quad \lim_{\sigma \rightarrow 0} \text{ess} \inf_{t \in [a_* - \sigma, a_*]} H(t, x_*(a_*), p(a_*)) \leq \xi \leq \lim_{\sigma \rightarrow 0} \text{ess} \sup_{t \in [a_* - \sigma, a_*]} \langle p(a_*), \dot{x}_*(t) \rangle.$$

By (H4), we have

$$F(t, x_*(t)) \subset F(t, x_*(a_*)) + k_0 |x_*(t) - x_*(a_*)| B \text{ for a.e. } t \in [a_* - \sigma, a_*].$$

Hence

$$\sup_{u \in F(t, x_*(t))} \langle p(a_*), u \rangle \leq \sup_{u \in F(t, x_*(a_*))} (\langle p(a_*), u \rangle + k_0 |x_*(t) - x_*(a_*)|).$$

This implies that

$$(18) \quad \lim_{\sigma \rightarrow 0} \operatorname{ess\,sup}_{t \in [a_* - \sigma, a_*]} H(t, x_*(t), p(a_*)) \leq \lim_{\sigma \rightarrow 0} \operatorname{ess\,sup}_{t \in [a_* - \sigma, a_*]} H(t, x_*(a_*), p(a_*)).$$

Combining (17) with (18) yields

$$\lim_{\sigma \rightarrow 0} \operatorname{ess\,inf}_{t \in [a_* - \sigma, a_* + \sigma]} H(t, x_*(a_*), p(a_*)) \leq \xi \leq \lim_{\sigma \rightarrow 0} \operatorname{ess\,sup}_{t \in [a_* - \sigma, a_* + \sigma]} H(t, x_*(a_*), p(a_*)),$$

which means that  $\xi \in \operatorname{ess}_{t \rightarrow a_*} H(t, x_*(a_*), p(a_*))$ . By similar arguments, we can show that  $\eta \in \operatorname{ess}_{t \rightarrow b_*} H(t, x_*(b_*), p(b_*))$ . Thus (v) follows.

Case (b). Putting  $\epsilon_k = d([a_k, b_k, x_k], S_\epsilon)$ , we have

$$0 < \epsilon_k \leq d([a_k, b_k], x_k), ([a_*, b_*], x_*) \leq \epsilon'_k \rightarrow 0.$$

From (7) it follows that

$$\inf_{(a, b, x) \in W_\epsilon} \tilde{J}(a, b, x) + \frac{\epsilon_k}{2k} > \tilde{J}(a_k, b_k, x_k),$$

where  $\tilde{J}(a, b, x) := \int_a^b \rho_F(t, x(t), \dot{x}(t)) dt + 2kd_C(a, x(a), b, x(b))$ . By the Ekeland principle, for each  $k$  there exists a triple  $([\bar{a}_k, \bar{b}_k], \bar{x}_k) \in W_\epsilon$  such that

$$(19) \quad d([\bar{a}_k, \bar{b}_k], \bar{x}_k), ([a_k, b_k], x_k) \leq \epsilon_k/2$$

and  $([\bar{a}_k, \bar{b}_k], \bar{x}_k)$  is a  $W_\epsilon$  minimizer of the functional

$$(20) \quad J_*(a, b, x) := \tilde{J}(a, b, x) + \frac{1}{k} d([a, b], x), ([\bar{a}_k, \bar{b}_k], \bar{x}_k).$$

It is clear that (19) implies  $([\bar{a}_k, \bar{b}_k], \bar{x}_k) \xrightarrow{W_\epsilon} ([a_*, b_*], x_*)$  and  $([\bar{a}_k, \bar{b}_k], \bar{x}_k) \notin S_\epsilon$ . Rewrite (20) in the form

$$\begin{aligned} J_*(a, b, x) = & \int_a^b \rho_F(t, x(t), \dot{x}(t)) dt + |\dot{x}(t) - \dot{\bar{x}}^e(t)| dt + 2kd_C(a, x(a), b, x(b)) \\ & + \frac{1}{k} \left( |a - \bar{a}_k| + |b - \bar{b}_k| + \int_{a \wedge \bar{a}_k}^a |\dot{\bar{x}}_k^e| dt + \int_b^{b \vee \bar{b}_k} |\dot{\bar{x}}_k^e| dt \right). \end{aligned}$$

According to Theorem 3.1, there exist  $p_k$  and real numbers  $\lambda_k \geq 0$ ,  $\xi_k$ , and  $\eta_k$  such that

- (A)'  $\lambda_k + |p_k|_\infty = 1$ ,
- (B)'  $\dot{p}_k(t) \in \operatorname{co}\{\alpha : (\alpha, p_k(t)) \in \lambda_k \partial \rho_F(t, \bar{x}_k(t), \dot{\bar{x}}_k(t)) + \frac{\lambda_k}{k} \{0\} \times B\}$  a.e.  $t \in [\bar{a}_k, \bar{b}_k]$ .
- (C)'  $(-\xi_k, p_k(\bar{a}_k), \eta_k, -p_k(\bar{b}_k)) \in \lambda_k 2k \partial d_C(\bar{a}_k, \bar{x}_k(a_k), \bar{b}_k, \bar{x}_k(b_k)) + \frac{\lambda_k}{k} B^2 \times \{0\} \times \{0\} + \frac{\lambda_k}{k} M(B \times B \times \{0\} \times \{0\})$ ,
- (D)'  $\langle p_k(t), \dot{\bar{x}}_k(t) \rangle - \lambda_k \rho_F(t, \bar{x}_k(t), \dot{\bar{x}}_k(t)) \geq \langle p_k(t), v \rangle - \lambda_k \rho_F(t, \bar{x}_k(t), v) - \frac{\lambda_k}{k} |v - \dot{\bar{x}}_k^e|$  for all  $v \in R^n$  a.e., and

(E)'

$$\begin{aligned} & \lim_{\sigma \rightarrow 0} \operatorname{ess} \inf_{t \in [\bar{a}_k - \sigma, \bar{a}_k]} \left( H(t, \bar{x}_k(\bar{a}_k), p_k(\bar{a}_k), \cdot) - \frac{\lambda_k}{k} |\bar{u}_k(t)| \right) \leq \xi_k \\ & \leq \lim_{\sigma \rightarrow 0} \operatorname{ess} \sup_{t \in [\bar{a}_k - \sigma, \bar{a}_k]} (\langle p_k(\bar{a}_k), \dot{\bar{x}}_k(t) \rangle - \lambda_k \rho_F(t, \bar{x}_k(t), \dot{\bar{x}}_k(t))) \end{aligned}$$

and

$$\begin{aligned} & \lim_{\sigma \rightarrow 0} \operatorname{ess} \inf_{t \in [\bar{b}_k - \sigma, \bar{b}_k]} \left( H(t, \bar{x}_k(\bar{b}_k), p_k(\bar{b}_k), \cdot) - \frac{\lambda_k}{k} |\tilde{u}_k(t)| \right) \leq \eta_k \\ & \leq \lim_{\sigma \rightarrow 0} \operatorname{ess} \sup_{t \in [\bar{b}_k - \sigma, \bar{b}_k]} (\langle p_k(\bar{b}_k), \dot{\bar{x}}_k(t) \rangle - \lambda_k \rho_F(t, \bar{x}_k(t), \dot{\bar{x}}_k(t))), \end{aligned}$$

where  $\bar{u}_k$  and  $\tilde{u}_k$  are essentially bounded selections of  $F(\cdot, \bar{x}_k(\bar{a}_k))$  and  $F(\cdot, \bar{x}_k(\bar{b}_k))$ , respectively, which satisfy

$$\langle p_k(\bar{a}_k), \bar{u}_k(t) \rangle = H(t, \bar{x}_k(\bar{a}_k), p_k(\bar{a}_k)) \text{ a.e. } t \in [\bar{a}_k - \sigma, \bar{a}_k]$$

and

$$\langle p_k(\bar{b}_k), \tilde{u}_k(t) \rangle = H(t, \bar{x}_k(\bar{b}_k), p_k(\bar{b}_k)) \text{ a.e. } t \in [\bar{b}_k, \bar{b}_k + \sigma].$$

Note that  $\operatorname{esssup} \bar{u}_k \leq c_0$  and  $\operatorname{esssup} \tilde{u}_k \leq c_1$  for  $k$  sufficiently large. By using similar arguments as in part (a), we can assume that  $p_k \rightarrow p$  uniformly and  $\dot{p}_k \rightarrow \dot{p}$  weakly in  $L^1$ ,  $\lambda_k \rightarrow \lambda_0$ ,  $\eta_k \rightarrow \eta$ ,  $\xi_k \rightarrow \xi$ . By passing to the limits from (A)'–(E)' we get

- (i)  $\lambda_0 + \|p\|_\infty = 1$ .
- (ii)  $\dot{p}(t) \in \operatorname{co}\{\alpha : (\alpha, p(t)) \in N_{\operatorname{Gph} F(t, \cdot)}(x_*(t), \dot{x}_*(t))\}$  a.e.
- (iii)  $(-\xi, p(a_*), \eta, -p(b_*)) \in N_C(a_*, x_*(a_*), b_*, x_*(b_*))$ .
- (iv)  $\langle q(t), \dot{x}(t) \rangle \geq \langle q(t), v \rangle$  for all  $v \in F(t, x_*(t))$  a.e.
- (v)  $\xi \in \operatorname{ess}_{t \rightarrow a_*} H(t, x_*(a_*), p(a_*))$  and  $\eta \in \operatorname{ess}_{t \rightarrow a_*} H(t, x_*(b_*), p(b_*))$ .

We now claim that  $\|p\| \neq 0$ . Indeed, suppose that  $p = 0$ . Then from the fact  $([\bar{a}_k, \bar{b}_k], \bar{x}_k) \notin S_\epsilon$  we have either  $(\bar{a}_k, \bar{x}_k(\bar{a}_k), \bar{b}_k, \bar{x}_k(\bar{b}_k)) \notin C$  or  $(\bar{x}_k(t), \dot{\bar{x}}_k(t)) \notin \operatorname{Gph} F(t, \cdot)$ . If  $(\bar{a}_k, \bar{x}_k(\bar{a}_k), \bar{b}_k, \bar{x}_k(\bar{b}_k)) \notin C$ , then (C)' implies

$$|\xi_k| + |p_k(\bar{a}_k)| + |\eta_k| + |p_k(\bar{b}_k)| \geq 2k\lambda_k - \frac{\lambda_k}{k}(1 + M).$$

Hence

$$\frac{|\xi_k| + |p_k(\bar{a}_k)| + |\eta_k| + |p_k(\bar{b}_k)|}{2k} \geq \lambda_k - \frac{\lambda_k}{2k^2}(1 + M).$$

By letting  $k \rightarrow \infty$  we get  $\lambda_0 = 0$ . This contradicts  $\lambda_0 = 1$ .

If  $(\bar{x}_k(t), \dot{\bar{x}}_k(t)) \notin \operatorname{Grap} F(t, \cdot)$  then (D)' implies that

$$p_k(t) \in \lambda_k \partial_{\dot{x}} \rho_F(t, \bar{x}_k(t), \dot{\bar{x}}_k(t)) + \frac{\lambda_k}{k} B.$$

By Lemma 2.1,  $|p_k(t)| \geq \lambda_k - \frac{\lambda_k}{k}$ . This implies that

$$\lambda_k - \frac{\lambda_k}{k} \leq \|p_k\|.$$

By letting  $k \rightarrow \infty$  we obtain  $\lambda_0 = 0$ , which is absurd. Thus it must have  $\|p\| = 1 - \lambda_0 \neq 0$ . By scaling multipliers, we can assume that  $\|p\| = 1$ . Hence we obtain the conclusion of the theorem by putting  $\lambda = 0$ . The proof is complete.  $\square$

We remark, as pointed out by a referee, that actually the “regularity” (normal semicontinuity) assumption on the preference is not needed in the main theorem, Theorem 4.1, if we use the extended limiting normal cone mentioned above for the level set instead of the basic/limiting one. Let us give some corollaries of Theorem 4.1.

When  $m = 1$ , (P) becomes a single objective problem. In this case, we have the following.

**COROLLARY 4.2** (see [22, Theorem 8.4.1]). *Suppose  $([a_*, b_*], x_*)$  is a local minimizer of (P) and assumptions (H1)–(H4) are satisfied. Then there exist an arc  $p \in W^{1,1}$ , and real numbers  $\lambda \geq 0$ ,  $\xi$ , and  $\eta$  such that*

- (i)  $\lambda + \|p\|_\infty = 1$ ,
- (ii)  $\dot{p}(t) \in \text{co}\{\alpha : (\alpha, p(t)) \in N_{\text{Grph}F(t, \cdot)}(x_*(t), \dot{x}_*(t))\}$  a.e.,
- (iii)  $(-\xi, p(a_*), \eta, -p(b_*)) \in \lambda \partial g(a_*, x_*(a_*), b_*, x_*(b_*)) + N_C(a_*, x_*(a_*), b_*, x_*(b_*))$ ,
- (iv)  $\langle p(t), \dot{x}_*(t) \rangle = H(t, x_*(t), p(t))$  a.e.  $t \in [a_*, b_*]$ , and
- (v)  $\xi \in \text{ess}_{t \rightarrow a_*} H(t, x_*(a_*), p(a_*))$  and  $\eta \in \text{ess}_{t \rightarrow b_*} H(t, x_*(b_*), p(b_*))$ .

When (P) is a weak Pareto optimal problem, we have the following.

**COROLLARY 4.3.** *Suppose  $([a_*, b_*], x_*)$  is a weak Pareto solution to the multiobjective optimal problem (P) and assumptions (H1)–(H4) are satisfied. Then there exist an arc  $p \in W^{1,1}$ , real numbers  $\lambda \geq 0$ ,  $\xi$ ,  $\eta$  and a vector  $w \in R_+^m$  with  $\sum_{i=1}^m w_i = 1$  such that*

- (i)  $\lambda + \|p\|_\infty = 1$ ,
- (ii)  $\dot{p}(t) \in \text{co}\{\alpha : (\alpha, p(t)) \in N_{\text{Grph}F(t, \cdot)}(x_*(t), \dot{x}_*(t))\}$  a.e.,
- (iii)  $(-\xi, p(a_*), \eta, -p(b_*)) \in \lambda \partial \langle w, g(a_*, x_*(a_*), b_*, x_*(b_*)) \rangle + N_C(a_*, x_*(a_*), b_*, x_*(b_*))$ ,
- (iv)  $\langle p(t), \dot{x}_*(t) \rangle = H(t, x_*(t), p(t))$  for a.e.  $t \in [a_*, b_*]$ , and
- (v)  $\xi \in \text{ess}_{t \rightarrow a_*} H(t, x_*(a_*), p(a_*))$  and  $\eta \in \text{ess}_{t \rightarrow b_*} H(t, x_*(b_*), p(b_*))$ .

To provide some perspective on what we have obtained, in the rest of the paper we give an illustrative example.

**Example 4.4.** Consider the following weak Pareto optimal control problem:

$$\text{Minimize } g(x(b)) = (x_1(b) - x_2(b), x_1(b))$$

over intervals  $[0, b]$  and arcs  $x = (x_1, x_2) \in W^{1,1}([0, b], R^2)$  which satisfy

$$\begin{cases} (\dot{x}_1(t), \dot{x}_2(t)) \in F(t, x(t)), \\ b \leq 2, \\ (x_1(0), x_2(0)) = (0, -2), \end{cases}$$

where

$$F(t, x) := \begin{cases} [-1, 1] \times \{1\} & \text{if } t \leq 1, \\ \{1, t\} \times \{1\} & \text{if } t > 1. \end{cases}$$

Evidently, this is problem (P) with the initial time fixed ( $a = 0$ ) and

$$C = \{0\} \times \{(0, -2)\} \times (-\infty, 2] \times R^2.$$

For each  $w = (w_1, w_2)$ ,  $w_1 + w_2 = 1$ , we have  $\langle w, g(x(b)) \rangle = x_1(b) - w_1 x_2(b)$ . By simple computation, we have

$$H(t, (x_1, x_2), (p_1, p_2)) = \begin{cases} |p_1| + p_2 & \text{if } t \leq 1, \\ \max\{p_1 + p_2, tp_1 + p_2\} & \text{if } t > 1. \end{cases}$$

We now assume that  $([0, b], x)$  is a solution of the problem. By Corollary 4.3, there exist  $p$ , real numbers  $\lambda \geq 0$  and  $\eta$  and vector  $w = (w_1, w_2) \in R_+^2$ ,  $w_1 + w_2 = 1$  such that assertions (i)–(v) of Corollary 4.3 are satisfied.

Since

$$\text{Gph}F(t, \cdot) = \begin{cases} R^2 \times ([-1, 1] \times \{1\}) & \text{if } t \leq 1, \\ R^2 \times \{1, t\} \times \{1\} & \text{if } t > 1, \end{cases}$$

we get

$$N_{\text{Gph}F(t, \cdot)}(x(t), \dot{x}(t)) = \begin{cases} \{(0, 0)\} \times N_{[-1, 1] \times \{1\}}(\dot{x}(t)) & \text{if } t \leq 1, \\ \{(0, 0)\} \times N_{\{1, t\} \times \{1\}}(\dot{x}(t)) & \text{if } t > 1. \end{cases}$$

Hence (ii) implies  $\dot{p} = (0, 0)$ . Consequently,  $p = (p_1, p_2)$ , where  $p_1$  and  $p_2$  are constants. From (iii) we get

$$(\eta, -p(b)) \in \lambda\{0\} \times \{(1, -w_1)\} + N_{(-\infty, 2]}(b) \times \{(0, 0)\}.$$

This implies that

$$(21) \quad \eta \in N_{(-\infty, 2]}(b) \text{ and } p(b) = (p_1, p_2) = (-\lambda, \lambda w_1).$$

From (iv) of Corollary 4.3, we obtain the equation

$$p_1 \dot{x}_1 + p_2 \dot{x}_2 = \begin{cases} |p_1| + p_2 & \text{if } t \leq 1, \\ \max\{p_1 + p_2, tp_1 + p_2\} & \text{if } t > 1 \end{cases}$$

for a.e.  $t \in [0, b]$ . Since  $\dot{x}_2 = 1$ , we get  $x_2 = t - 2$  and

$$p_1 \dot{x}_1 = \begin{cases} |p_1| & \text{if } t \leq 1, \\ \max\{p_1, tp_1\} & \text{if } t > 1 \end{cases}$$

for a.e.  $t \in [0, b]$ . Since  $p_1 = -\lambda \leq 0$ , we obtain the equation

$$p_1 \dot{x}_1 = \begin{cases} -p_1 & \text{if } t \leq 1, \\ p_1 & \text{if } t > 1 \end{cases}$$

for a.e.  $t \in [0, b]$ .

We now consider the following cases.

*Case 1.* Consider  $b < 2$ . Then we have  $\eta = 0$  because of (21). By (v) we have  $0 = H(b, x(b), p(b))$ . This implies that  $|p_1| + p_2 = 0$  if  $0 \leq b \leq 1$  and  $p_1 + p_2 = 0$  if  $1 < b < 2$ . Hence if  $0 \leq b \leq 1$ , then  $p = \lambda = 0$ , which is a contradiction. Thus we must have  $1 < b < 2$  and  $0 = p_1 + p_2 = \lambda(w_1 - 1)$ . It follows that  $w_1 = 1$  and  $\lambda \neq 0$ . From above we obtain

$$x_1 = \begin{cases} -t & \text{if } 0 \leq t \leq 1, \\ t - 2 & \text{if } 1 < t \leq b. \end{cases}$$

Case 2. Consider  $b = 2$ . From (21) it follows that  $\eta \geq 0$ . By (v) we get

$$\eta \in H(2, x(2), p(2)) = p_1 + p_2 = \lambda(w_1 - 1).$$

In this case we also have  $p_1 \neq 0$ . So it yields

$$x_1 = \begin{cases} -t & \text{if } 0 \leq t \leq 1, \\ t - 2 & \text{if } 1 < t \leq 2. \end{cases}$$

Thus we showed that if  $([0, b_*], x_* = (x_{1*}, x_{2*}))$  is a solution, then  $1 < b_* \leq 2$ ,  $x_{2*} = t - 2$ , and

$$x_{1*} = \begin{cases} -t & \text{if } 0 \leq t \leq 1, \\ t - 2 & \text{if } 1 < t \leq b_*. \end{cases} \quad \square$$

# A RIESZ BASIS METHODOLOGY FOR PROPORTIONAL AND INTEGRAL OUTPUT REGULATION OF A ONE-DIMENSIONAL DIFFUSIVE-WAVE EQUATION\*

BOUMEDIÈNE CHENTOUF<sup>†</sup> AND JUN-MIN WANG<sup>‡</sup>

**Abstract.** In this article, we consider a dam-river system modeled by a diffusive-wave equation. This model is commonly used in hydraulic engineering to describe dynamic behavior of the unsteady flow in a river for shallow water when the flow variations are not important. In order to stabilize and regulate the system, we propose a proportional and integral boundary controller. Contrary to many physical systems, we end up with a nondissipative closed-loop system with noncollocated actuators and sensors. We show that the closed-loop system is a Riesz spectral system and generates an analytic semigroup. Then, we shall be able to assign the spectrum of the closed-loop system in the open left half-plane to ensure its exponential stability as well as the output regulation independently of any known or unknown constant perturbation. These results are illustrated by several numerical examples.

**Key words.** dam-river system, proportional and integral boundary control, analytic semigroup, Riesz basis, stability

**1. Introduction and background.** It is well known that the flow dynamics in an irrigation river are generally described by nonlinear coupled hyperbolic partial differential equations and are called de Saint-Venant equations [37]. Nevertheless, by adopting several assumptions such as (i) neglecting lateral inflow and inertia terms, (ii) assuming small flow variations as well as small bed slope of the river, (iii) observing that the flow can be reasonably represented by a one-dimensional model, and (iv) observing that the range of flow values is somewhat reduced, one can consider the following system (see [3], [18], or [31] for more details):

$$\frac{\partial Q(x, t)}{\partial t} = \alpha \frac{\partial^2 Q(x, t)}{\partial x^2} - \beta \frac{\partial Q(x, t)}{\partial x} + w, \quad 0 < x < \ell,$$

where  $Q$  is the water flow and  $w$  is the lateral discharge, which is assumed to be constant for sake of simplicity ( $w > 0$  represents the lateral inflow due to rains, for example, whereas  $w < 0$  is the lateral outflow due to water withdrawals). The positive constants  $\alpha$ ,  $\beta$ ,  $\ell$  and the variables  $x$  and  $t$  denote, respectively, the diffusion, the celerity, the length of the river, the distance in the downstream direction, and the time. This model is used in hydraulic engineering to describe dynamic behavior of the unsteady flow in a river for shallow water when the flow variations are not important (see [18] and the references therein).

In practice, an irrigation system often consists of natural rivers to convey water released from an upstream dam to consumption locations, which are distributed along the reach. The system under consideration consists of a dam and one river reach with a measuring station at its downstream end. The control action variable is the upstream water flow, which means that the control acts so that the desired discharge is delivered. Therefore, we shall take the upstream flow as a control input variable, take the downstream flow as an output observation, and leave the downstream boundary condition as free (no control). In other words, the downstream influence is negligible for the mass transfer, that is to say, the flow variations are negligible, which is realistic in the case of long river reaches. This leads us to the following system:

$$(1.1) \quad \begin{cases} \frac{\partial Q(x, t)}{\partial t} = \alpha \frac{\partial^2 Q(x, t)}{\partial x^2} - \beta \frac{\partial Q(x, t)}{\partial x} + w, & 0 < x < \ell, \\ Q(0, t) = u(t), \quad Q_x(\ell, t) = 0, \\ y(t) = Q(\ell, t), \end{cases}$$

where  $u(t)$  is the input (actuator) control and  $y(t)$  is the output (sensor) observation. Obviously, the actuator and sensor are not implemented at the same “location.” Hence the duality condition  $C = B^*$  does not arise, where  $B$  and  $C$  are, respectively, the input and output operators. This leads to a concrete example of a system with non-collocated actuators and sensors. As the reader may know, one of the main objectives in the management of irrigation systems is to keep the flow rate at the downstream end of the river close to a reference flow rate (target) fixed by the administration in charge of the river and calculated in order to ensure good environmental conditions for wildlife in the river.

Based on the above reasons, we shall investigate the stabilization and regulation problem of the system (1.1) with the following boundary proportional and integral controllers:

$$(1.2) \quad \begin{cases} u(t) = k_P y(t) + k_I \xi(t), \\ \dot{\xi}(t) = y(t) - y_r, \end{cases}$$

where  $k_P, k_I \in \mathbb{R} \setminus \{0\}$  are, respectively, the proportional and the integral gains, whereas  $y_r$  is the constant reference signal to track. The role of the proportional gain  $k_P$  is to speed up the exponential decay rate for stability if necessary, while the role of integral gain  $k_I$  is to obtain the regulation property, namely, (i) reject disturbances  $w$ , such as rains or withdrawals; (ii) make the output  $y(t) = Q(\ell, t)$  track a given constant reference signal  $y_r$  in spite of the constant perturbation  $w$ ; and (iii) achieve the exponential stability of the closed-loop system (1.1)–(1.2).

Note that the system (1.1) has been studied by many authors by means of approximation methods such as discretization (see, for instance, [18], [19], and [31] and the references therein), and hence the distributed character of (1.1) is not preserved. Recently, a qualitative analysis of (1.1) has been carried out in [2] by using the tools of infinite-dimensional systems theory [4]. In fact, stability and regulation results for the closed-loop system are proved when only an integral controller is applied in (1.2), that is,  $k_P = 0$ . Note also that there is a considerable literature devoted to the design theory of integral and/or proportional controllers for infinite-dimensional systems. Indeed, in [34] and [41], the authors have been concerned with the existence of proportional and integral controllers for a class of infinite-dimensional systems with *distributed controls*. Moreover, the control operators are assumed to be bounded, and

hence their results cannot be applied to our problem. Furthermore, there exists a few research papers (see [35] and [36]) where the authors proposed an integral controller for a class of infinite-dimensional systems with boundary and distributed controls. However, in these works, the authors have been primarily interested in designing *only integral controllers* for systems with *bounded boundary input and output operators* via *smooth* (twice differentiable) controls. Once again, these restrictions do not permit us to use this approach. In a related area, there is a vast literature devoted to the frequency-domain robust controller design approach for systems described by transfer functions (see, for instance, [5], [11], [12], [21], [23], [27], [28] for low-gain control; [22] and [29] for high-gain control; and [24], [25], and [26] for regular systems subject to actuator nonlinearities). Unfortunately, we have met with some technical difficulties when using this approach. Finally, the reader may also find many articles where the general theoretical results obtained in the works cited above are applied or adapted to physical systems such as heat-exchangers and linearized Saint-Venant systems (see [6], [7], [8], [9], and [39]).

The main contribution of this paper is to adopt the Riesz basis approach and the shooting method in order to extend the results obtained in [2] on the system (1.1)–(1.2) without proportional gain ( $k_P = 0$ ) to the case when the feedback control (1.2) involves a proportional gain  $k_P \neq 0$ . Contrary to the work in [2], where  $k_P = 0$  in (1.2), the advantage of the presence of the proportional gain  $k_P$  is to allow us to have more freedom in designing the stabilizing controller. Moreover, by a suitable choice of the proportional gain  $k_P$ , one can improve, if necessary, the decay rate for the stability of the closed-loop system (1.1)–(1.2) compared to the case when only an integral controller is applied. It is important to note that it is not obvious to deduce neither the well-posedness nor stability results of the closed-loop system (1.1)–(1.2) from those obtained in [2]. This is due to the fact that the domain of the operator studied in [2] is perturbed, and hence the classical theory of perturbation of operators [13] fails. We also point out that the system (1.1)–(1.2) is nondissipative and has noncollocated actuator and sensor. Hence two major difficulties arise: first, how to show the  $C_0$ -semigroup generation [33], and second, the stability for the system. To overcome this situation, the Riesz basis methodology [15], [16], [40] is used to show that the closed-loop system is a Riesz spectral system and generates an analytic semigroup. Concerning the exponential stability of the system (1.1)–(1.2), the shooting method is applied to assign the spectrum of the closed-loop system in the open left half-plane by means of an appropriate choice of the proportional and integral gains  $k_P$  and  $k_I$ . We should note that the existence results of such gains are theoretic, whereas their tuning is not dealt with here and still remain an open problem. Furthermore, the output regulation is guaranteed independently of any constant (known or unknown) perturbation.

The paper is organized as follows. In the next section, some preliminary results are stated for the uncontrolled system. We also convert the closed-loop system (1.1)–(1.2) into an evolution equation in an appropriate Hilbert space and then state the main results of this article. Sections 3 and 4 are devoted to the proof of the main results. First, we deal with the eigenvalue problem, and asymptotic expansions of both eigenvalues and eigenfunctions of the system are explicitly presented. Next, we use the Green's function approach to obtain an estimate of the resolvent which leads to the completeness of the root subspace. Then, the Riesz basis property and the  $C_0$ -semigroup generation of the system are proved. Finally, we establish, under certain conditions on the feedback gains  $k_P$  and  $k_I$ , the exponential stability and deduce the regulation of the closed-loop system (1.1)–(1.2). These results are illustrated by some

numerical applications in the last section.

**2. Preliminaries and main results.** First, let us consider the uncontrolled system ( $u(t) = 0$ ) with no disturbances:

$$(2.1) \quad \begin{cases} \frac{\partial Q(x, t)}{\partial t} = \alpha \frac{\partial^2 Q(x, t)}{\partial x^2} - \beta \frac{\partial Q(x, t)}{\partial x}, & 0 < x < \ell, \\ Q(0, t) = Q_x(\ell, t) = 0. \end{cases}$$

Taking the Hilbert state space  $\mathcal{H}_0 = L^2(0, \ell)$  equipped with the usual inner product, the system (2.1) can be written in the following abstract form:

$$\dot{Q}(t) = A_0 Q(t),$$

where  $A_0$  is an unbounded linear operator defined by

$$(2.2) \quad \mathcal{D}(A_0) := \left\{ Q \in H^2(0, \ell); Q(0) = Q'(\ell) = 0 \right\} \quad \text{and} \quad A_0 := \alpha \frac{\partial^2}{\partial x^2} - \beta \frac{\partial}{\partial x}.$$

Clearly,  $\lambda^0$  is an eigenvalue of  $A_0$  if and only if the system

$$(2.3) \quad \alpha f_0'' - \beta f_0' - \lambda^0 f_0 = 0,$$

$$(2.4) \quad f_0(0) = f_0'(\ell) = 0$$

has a nonzero solution.

The principal properties of the operator  $A_0$  are summarized as follows (see [2] for details).

LEMMA 2.1. *The operator  $A_0$  generates an exponentially stable  $C_0$ -semigroup of contractions  $S_0(t)$  on  $\mathcal{H}_0$ . Moreover, the spectrum  $\sigma(A_0)$  of  $A_0$  consists of negative real numbers of the form  $-\frac{\alpha\tau^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , where  $\tau$  is a nonzero solution to*

$$(2.5) \quad \beta\ell \sin \tau + 2\alpha\tau \cos \tau = 0.$$

Consider now the function  $x \mapsto f_0(x, \lambda)$  as the solution of (2.3) subject to the conditions

$$(2.6) \quad f_0'(\ell, \lambda) = 0, \quad f_0(\ell, \lambda) = 1.$$

Then, it is obvious that the zeros of  $f_0(0, \lambda)$  are the eigenvalues of  $A_0$ , which are real and negative by Lemma 2.5, namely,

$$\dots < \lambda_n^0 < \dots < \lambda_1^0 < 0.$$

We have the following result, whose proof is given in [2].

PROPOSITION 2.2. *Consider the normalized solution of (2.3)–(2.4) by  $f_0(\ell, \lambda) = 1$ . Then the zeros of  $f_0(0, \lambda)$  are the eigenvalues  $\lambda_i^0$  of the operator  $A_0$ , which are negative real numbers and simple. In addition, we have*

$$(2.7) \quad f_0(0, \lambda) = \prod_{i=1}^{\infty} \left( 1 - \frac{\lambda}{\lambda_i^0} \right).$$

Denote

$$B(\lambda) := \lambda f_0(0, \lambda) = \lambda \prod_{i=1}^{\infty} \left( 1 - \frac{\lambda}{\lambda_i^0} \right).$$

FIG. 1. The polynomial  $B_n(\lambda)$ .

The infinite product  $B(\lambda)$  will play a crucial role in the stability of the closed-loop system (1.1)–(1.2). It follows from Lemma 2.5 and Proposition 2.2 that the zeros of  $B$ , namely,  $\lambda_i^0$ , are simple and negative. Furthermore, between two consecutive zeros, the function  $B$  attains its local maxima and minima. Thus, let

$$M_k = \min_{\lambda_{2k+1}^0 < \lambda < \lambda_{2k}^0} B(\lambda)$$

denote negative minima when  $B$  is negative between two zeros, and let  $m_k$  be the ordered set of values  $M_k$  as follows (see Figure 1):

$$(2.8) \quad \cdots < m_2 < m_1 < 0.$$

Using the same arguments as in [2], one can prove the following lemma.

**LEMMA 2.3.** *The polynomials  $B_n(\lambda) := \lambda \prod_{i=1}^n (1 - \frac{\lambda}{\lambda_i^0})$  converge uniformly to  $B(\lambda)$  in any compact domain of the complex plane. Furthermore, any compact domain of the complex plane, not containing the zeros of  $B(\cdot) - ((\cdot)k_p + k_I)$  on its boundary, contains the same number of zeros of  $B(\cdot) - ((\cdot)k_p + k_I)$  and  $B(\cdot) - ((\cdot)k_p + k_I)$  for  $n$  large enough.*

Now, let us convert the closed-loop system (1.1)–(1.2) into an evolution equation in an appropriate Hilbert space and then state the basic properties of the system operator. Clearly, the closed-loop system (1.1)–(1.2) is governed in the “augmented” state space

$$\mathcal{H} := L^2(0, \ell) \times \mathbb{C},$$

equipped with the inner product induced by the norm

$$\|(f, \xi)\|^2 = \int_0^\ell |f(x)|^2 dx + |\xi|^2 \quad \forall (f, \xi) \in \mathcal{H},$$

by the system

$$(2.9) \quad \dot{\phi}(t) = \mathcal{A}_{PI}\phi(t) + (w, -y_r).$$

Here  $\phi = (f, \xi)$  and  $\mathcal{A}_{PI}$  is an unbounded linear operator defined by

$$(2.10) \quad \mathcal{D}(\mathcal{A}_{PI}) := \left\{ (f, \xi) \in H^2(0, \ell) \times \mathbb{C}; f(0) = k_P f(\ell) + k_I \xi; f'(\ell) = 0 \right\}$$

and

$$(2.11) \quad \mathcal{A}_{PI}(f, \xi) := \left( \alpha f'' - \beta f', f(\ell) \right) \text{ for any } (f, \xi) \in \mathcal{D}(\mathcal{A}_{PI}).$$

Recall that  $\alpha$ ,  $\beta$ , and  $\ell$  are positive constants and the feedback gains  $k_P$  and  $k_I$  are nonzero numbers.

Now, one can show that, given  $(g, \eta) \in \mathcal{H}$ , the equation  $\mathcal{A}_{PI}(f, \xi) = (g, \eta)$  has a unique solution  $(f, \xi) \in \mathcal{D}(\mathcal{A}_{PI})$  given by

$$\begin{cases} f(x) = \eta + \frac{1}{\beta} \left[ \int_x^\ell (1 - e^{\omega(x-\xi)}) g(\xi) d\xi \right], \\ \xi = \frac{1}{k_I} (f(0) - k_P f(\ell)), \end{cases}$$

where  $\omega = \beta/\alpha$ . Therefore, the operator  $(\mathcal{A}_{PI})^{-1} \in \mathcal{L}(\mathcal{H})$ . Moreover, by the Sobolev embedding theorem [1], we deduce that  $(\mathcal{A}_{PI})^{-1}$  is compact on  $\mathcal{H}$ , and hence the spectrum  $\sigma(\mathcal{A}_{PI})$  consists of isolated eigenvalues only [13].

Before stating our main results, let us recall that a nonzero  $Y$ , of a Hilbert space  $H$ , is called a generalized eigenvector of a linear operator  $\mathcal{A}$ , corresponding to an eigenvalue  $\lambda$  (with finite algebraic multiplicity) of  $\mathcal{A}$ , if there is a positive integer  $n$  such that  $(\lambda - \mathcal{A})^n Y = 0$ .

Let  $\text{Sp}(\mathcal{A})$  be the root subspace of a linear operator  $\mathcal{A}$  which is defined as the closed subspace spanned by all generalized eigenvectors of  $\mathcal{A}$ .

A sequence in  $H$  is said to be complete if its linear span is dense in  $\mathcal{H}$ . Also, a sequence in  $H$  is called *minimal* if each element of this sequence lies outside the closed linear span of the remaining elements. In turn, two sequences  $\{e_i\}$  and  $\{e_i^*\}$  are said to be *biorthogonal* in  $H$  if

$$\langle e_i, e_j^* \rangle = \delta_{ij} = \begin{cases} 1, & i = j, \\ 0, & i \neq j, \end{cases}$$

for every  $i$  and  $j$ . It is well known that for a given sequence  $\{e_i\}$ , a biorthogonal sequence  $\{e_i^*\}$  exists if and only if  $\{e_i\}$  is minimal, and  $\{e_i^*\}$  is uniquely determined if and only if  $\{e_i\}$  is complete.

Now, a sequence  $\{e_i\}_{i=1}^\infty$  is called a Bessel sequence in  $H$  if for any  $x \in H$ , the series  $\{\langle x, e_i \rangle\}_{i=1}^\infty \in \ell^2$ . On the other hand, a sequence  $\{e_i\}_{i=1}^\infty$  is called a basis for  $H$  if any element  $x \in H$  has a unique representation,

$$(2.12) \quad x = \sum_{i=1}^{\infty} a_i e_i,$$

and the convergence of the series is in the norm of  $H$ . Finally, a sequence  $\{e_i\}_{i=1}^\infty$  with a biorthogonal sequence  $\{e_i^*\}_{i=1}^\infty$  is called a Riesz basis for  $H$  if  $\{e_i\}_{i=1}^\infty$  is an

approximately normalized basis of  $H$  and the series in (2.12) converges unconditionally in the norm of  $H$ . Another different, but equivalent, condition for a Riesz basis property has the following form (see [42, p. 27]):

- (a) both  $\{e_i\}_{i=1}^\infty$  and  $\{e_i^*\}_{i=1}^\infty$  are complete in  $H$ ; and
- (b) both  $\{e_i\}_{i=1}^\infty$  and  $\{e_i^*\}_{i=1}^\infty$  are Bessel sequences in  $H$ .

It is also well known that  $\{e_i\}_{i=1}^\infty$  is a Riesz basis for  $H$  if and only if its biorthogonal sequence  $\{e_i^*\}_{i=1}^\infty$  is a Riesz basis for  $H$ .

Now, we are able to state the main results of this work. Indeed, the first main result is related to the Riesz basis property.

**THEOREM 2.4.** *Let  $|\tilde{k}_P| \neq 1$ , where  $\tilde{k}_P := k_P e^{\frac{1}{2} \frac{\ell \beta}{\alpha}}$ . Then, the generalized eigenfunctions of the operator  $\mathcal{A}_{PI}$  form a Riesz basis in  $\mathcal{H}$ . In turn, if  $|\tilde{k}_P| = 1$ , then the generalized eigenfunctions of  $\mathcal{A}_{PI}$  form, in  $\mathcal{H}$ , a Riesz basis with parentheses.*

The second result is mainly concerned with the properties of the semigroup generated by the operator  $\mathcal{A}_{PI}$ .

**THEOREM 2.5.** *The operator  $\mathcal{A}_{PI}$  defined by (2.10)–(2.11) generates a  $C_0$ -semigroup  $S_{PI}(t)$  in  $\mathcal{H}$ . Therefore,  $S_{PI}(t)$  satisfies the spectrum-determined growth condition  $S(\mathcal{A}_{PI}) = \omega(\mathcal{A}_{PI})$ , where  $S(\mathcal{A}_{PI}) = \sup_{\lambda \in \sigma(\mathcal{A}_{PI})} \operatorname{Re} \lambda$  is the spectral bound and  $\omega(\mathcal{A}_{PI})$  is the growth order of the semigroup  $S_{PI}(t)$ . Moreover,  $S_{PI}(t)$  is an analytic semigroup in  $\mathcal{H}$ .*

Finally, regarding the third main result, we use notation from (2.8) and Figure 1 to state the stability and regulation properties of the closed-loop system.

**THEOREM 2.6.** (i) *If  $m_1 < k_I < 0$  and  $k_P$  is a sufficiently small positive number, then the spectrum  $\sigma(\mathcal{A}_{PI})$  consists of negative real numbers.*

(ii) *If  $m_2 < k_I < m_1 < 0$  and  $k_P$  is a positive number sufficiently small, then the spectrum  $\sigma(\mathcal{A}_{PI})$  of the operator  $\mathcal{A}_{PI}$  consists of negative real numbers, except two which are complex conjugate numbers with positive or negative real parts.*

*Therefore, in both cases where the spectrum of the operator  $\mathcal{A}_{PI}$ , defined by (2.10)–(2.11) has negative real part, the analytic semigroup  $S_{PI}(t)$  is exponentially stable. Moreover, for any initial data  $\phi_0 = (Q_0, \xi_0) \in \mathcal{D}(\mathcal{A}_{PI})$  and for any constant perturbation  $w$  in  $\mathcal{H}$ , we have the output regulation*

$$\lim_{t \rightarrow \infty} y(t) = \lim_{t \rightarrow \infty} Q(\ell, t) = y_r.$$

*Furthermore, the closed-loop system (1.1)–(1.2) is exponentially stable in  $\mathcal{H}$  in spite of the constant perturbation  $w \in \mathcal{H}$ .*

**3. Proof of Theorems 2.4 and 2.5.** In this section, we are going to show Theorems 2.4 and 2.5, namely, the well-posedness and the Riesz basis generation of the system. For sake of clarity, we divide this section into three parts.

**3.1. Eigenvalue problem.** We shall establish, in this subsection, the basic results of the eigenvalue problem related to the operator  $\mathcal{A}_{PI}$ . From the eigenvalue equation  $\mathcal{A}_{PI}(f, \xi) = \lambda(f, \xi)$ , we have the characteristic equation in  $\lambda$ :

$$(3.1) \quad \begin{cases} f''(x) - \frac{\beta}{\alpha} f'(x) - \frac{1}{\alpha} \lambda f(x) = 0, & 0 < x < \ell, \\ (\lambda k_P + k_I) f(\ell) = \lambda f(0), \quad f'(\ell) = 0. \end{cases}$$

In order to solve the above equation, we introduce the following transformation that can translate the interval  $[0, \ell]$  into  $[0, 1]$ :

$$(3.2) \quad x = z\ell, \quad f(x) = g(z), \quad z \in [0, 1].$$

Then, (3.1) changes into

$$(3.3) \quad \begin{cases} g''(z) - \frac{\ell\beta}{\alpha}g'(z) - \frac{\ell^2}{\alpha}\lambda g(z) = 0, & 0 < z < 1, \\ (\lambda k_P + k_I)g(1) = \lambda g(0), \quad g'(1) = 0. \end{cases}$$

Let

$$(3.4) \quad \tau_1(\lambda) = \frac{\ell\beta + \ell\sqrt{\beta^2 + 4\alpha\lambda}}{2\alpha}, \quad \tau_2(\lambda) = \frac{\ell\beta - \ell\sqrt{\beta^2 + 4\alpha\lambda}}{2\alpha}.$$

Clearly,  $e^{\tau_1 z}$  and  $e^{\tau_2 z}$  are two independent solutions of  $g''(z) - \frac{\ell\beta}{\alpha}g'(z) - \frac{\ell^2}{\alpha}\lambda g(z) = 0$ , and thus the general solution form of (3.3) can be given by

$$g(z) = c_1 e^{\tau_1 z} + c_2 e^{\tau_2 z},$$

where  $c_1$  and  $c_2$  satisfy the following system:

$$\begin{cases} (\lambda k_P + k_I)(c_1 e^{\tau_1} + c_2 e^{\tau_2}) = \lambda(c_1 + c_2), \\ c_1 \tau_1 e^{\tau_1} + c_2 \tau_2 e^{\tau_2} = 0. \end{cases}$$

Hence, (3.3) has a nontrivial solution if and only if

$$\det(\Delta(\lambda)) = 0,$$

where  $\Delta(\lambda)$  is the coefficient matrix given by

$$(3.5) \quad \Delta(\lambda) := \begin{bmatrix} (\lambda k_P + k_I)e^{\tau_1} - \lambda & (\lambda k_P + k_I)e^{\tau_2} - \lambda \\ \tau_1 e^{\tau_1} & \tau_2 e^{\tau_2} \end{bmatrix}.$$

By a direct computation, we have

$$\begin{aligned} \det(\Delta(\lambda)) &= (\tau_2 - \tau_1)(\lambda k_P + k_I)e^{\tau_1 + \tau_2} - \lambda(\tau_2 e^{\tau_2} - \tau_1 e^{\tau_1}) \\ &= -\frac{\ell\sqrt{\beta^2 + 4\alpha\lambda}}{\alpha}(\lambda k_P + k_I)e^{(\ell\beta)/\alpha} - \lambda(\tau_2 e^{\tau_2} - \tau_1 e^{\tau_1}). \end{aligned}$$

Let  $\lambda := \frac{\alpha\rho^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , with  $\rho \in \mathbb{C}$  and  $\arg \rho \in [-\pi/2, \pi/2)$ . Then  $\tau_1(\lambda)$  and  $\tau_2(\lambda)$ , defined by (3.4), become

$$(3.6) \quad \tau_1(\rho) = \frac{\ell\beta}{2\alpha} + \rho, \quad \tau_2(\rho) = \frac{\ell\beta}{2\alpha} - \rho.$$

We also have

$$\begin{aligned} (3.7) \quad e^{-\frac{\ell\beta}{2\alpha}} \det(\Delta(\rho)) &= -2\rho \left( \frac{\alpha\rho^2}{\ell^2} - \frac{\beta^2}{4\alpha} \right) \tilde{k}_P - 2\rho \tilde{k}_I \\ &\quad - \left( \frac{\alpha\rho^2}{\ell^2} - \frac{\beta^2}{4\alpha} \right) \left( \frac{\ell\beta}{2\alpha} e^{-\rho} - \rho e^{-\rho} - \frac{\ell\beta}{2\alpha} e^{\rho} - \rho e^{\rho} \right) \\ &= \frac{\alpha\rho^3}{\ell^2} (e^{-\rho} + e^{\rho} - 2\tilde{k}_P) - \frac{\beta\rho^2}{2\ell} (e^{-\rho} - e^{\rho}) \\ &\quad - \frac{\beta^2}{4\alpha} \rho \left( e^{-\rho} + e^{\rho} - 2\tilde{k}_P + \frac{8\alpha}{\beta^2} \tilde{k}_I \right) + \frac{\ell\beta^3}{8\alpha^2} (e^{-\rho} - e^{\rho}), \end{aligned}$$

where

$$(3.8) \quad \tilde{k}_P := k_P e^{\frac{1}{2} \frac{\ell\beta}{\alpha}}, \quad \tilde{k}_I := k_I e^{\frac{1}{2} \frac{\ell\beta}{\alpha}}.$$

Let us summarize the previous results in the following lemma.

LEMMA 3.1. *Let  $\lambda := \frac{\alpha\rho^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , with  $\arg \rho \in [-\pi/2, \pi/2)$ . Then the characteristic determinant  $\det(\Delta(\rho))$  has the following form:*

$$(3.9) \quad e^{-\frac{\ell\beta}{2\alpha}} \det(\Delta(\rho)) = \frac{\alpha\rho^3}{\ell^2} (e^{-\rho} + e^{\rho} - 2\tilde{k}_P) - \frac{\beta\rho^2}{2\ell} (e^{-\rho} - e^{\rho}) \\ - \frac{\beta^2}{4\alpha} \rho \left( e^{-\rho} + e^{\rho} - 2\tilde{k}_P + \frac{8\alpha}{\beta^2} \tilde{k}_I \right) + \frac{\ell\beta^3}{8\alpha^2} (e^{-\rho} - e^{\rho}),$$

with  $\tilde{k}_P$  and  $\tilde{k}_I$  being given by (3.8).

Then, we have the following.

THEOREM 3.2. *Let  $|\tilde{k}_P| > 1$ . Then the eigenvalues  $\lambda_n$  of the operator  $\mathcal{A}_{PI}$  are the solutions of the eigenvalue problem (3.3) and have the following asymptotic expansion: for  $s = 1, 2$ ,*

$$(3.10) \quad \lambda_{ns} = - \left( \frac{\beta}{\ell} + \frac{\beta^2}{4\alpha} \right) + \frac{(\ln |\tilde{k}_{Ps}|)^2 - (2n\pi + \delta)^2 + i(4n\pi + 2\delta) \ln |\tilde{k}_{Ps}|}{\alpha^{-1}\ell^2} + \mathcal{O}(n^{-1}),$$

where  $n$  are positive integers,

$$(3.11) \quad \tilde{k}_{P1} := \tilde{k}_P + \sqrt{\tilde{k}_P^2 - 1}, \quad \tilde{k}_{P2} := \tilde{k}_P - \sqrt{\tilde{k}_P^2 - 1},$$

and

$$(3.12) \quad \delta := \begin{cases} 0 & \text{when } \tilde{k}_P \geq 1; \\ \pi & \text{when } \tilde{k}_P \leq -1. \end{cases}$$

In turn, if  $|\tilde{k}_P| = 1$ , then the eigenvalues  $\lambda_{n1}$  and  $\lambda_{n2}$  are not separable when their moduli are large enough and have the following asymptotic expression:

$$(3.13) \quad \lambda_{ns} = -\frac{\beta^2}{4\alpha} - \frac{\alpha(2n\pi + \delta)^2}{\ell^2} + \mathcal{O}(n^{-1}), \quad s = 1, 2.$$

*Proof.* Using (3.9), the characteristic equation  $\det(\Delta(\rho)) = 0$  means that  $\rho$ , with  $\arg \rho \in [-\pi/2, \pi/2)$ , satisfies the following:

$$(3.14) \quad e^{\rho} + e^{-\rho} - 2\tilde{k}_P - \frac{1}{2} \frac{\ell\beta}{\alpha} (e^{-\rho} - e^{\rho}) \rho^{-1} + \mathcal{O}(\rho^{-2}) = 0,$$

which leads to

$$(3.15) \quad e^{\rho} + e^{-\rho} - 2\tilde{k}_P + \mathcal{O}(\rho^{-1}) = 0.$$

Assume now that  $|\tilde{k}_P| > 1$ . Then, it follows that the solutions of the equation

$$e^{\rho} + e^{-\rho} - 2\tilde{k}_P = 0$$

are given by

$$(3.16) \quad \tilde{\rho}_{ns} = \ln |\tilde{k}_{Ps}| + 2n\pi i + \delta i, \quad s = 1, 2, \quad n \in \mathbb{N},$$

where  $\delta$  is as defined in (3.12). Rouché's theorem can be applied to (3.15) to obtain

$$(3.17) \quad \rho_{ns} = \tilde{\rho}_{ns} + \alpha_{ns}, \quad \alpha_{ns} = \mathcal{O}(n^{-1}), \quad s = 1, 2,$$

for sufficiently large positive integers  $n$ . Substituting  $\rho_{ns}$  into (3.14), we get

$$e^{\tilde{\rho}_{ns} + \alpha_{ns}} + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} - 2\tilde{k}_P - \frac{1}{2} \frac{\ell\beta}{\alpha} (e^{-\tilde{\rho}_{ns} - \alpha_{ns}} - e^{\tilde{\rho}_{ns} + \alpha_{ns}}) \rho_{ns}^{-1} + \mathcal{O}(\rho_{ns}^{-2}) = 0.$$

Note that

$$e^{\tilde{\rho}_{ns}} + e^{-\tilde{\rho}_{ns}} - 2\tilde{k}_P = 0, \quad e^{\tilde{\rho}_{ns}} = \tilde{k}_{P_s},$$

and hence

$$\begin{aligned} e^{\tilde{\rho}_{ns} + \alpha_{ns}} + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} &= e^{\alpha_{ns}} \left[ 2\tilde{k}_P - e^{-\tilde{\rho}_{ns}} \right] + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} \\ &= 2\tilde{k}_P e^{\alpha_{ns}} - e^{\alpha_{ns}} e^{-\tilde{\rho}_{ns}} + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} \\ &= 2\tilde{k}_P [1 + \alpha_{ns} + \mathcal{O}(n^{-2})] - e^{-\tilde{\rho}_{ns}} [e^{\alpha_{ns}} - e^{-\alpha_{ns}}] \\ &= 2\tilde{k}_P + 2\alpha_{ns} \tilde{k}_P + \mathcal{O}(n^{-2}) - e^{-\tilde{\rho}_{ns}} [2\alpha_{ns} + \mathcal{O}(n^{-2})] \\ &= 2\tilde{k}_P + 2\alpha_{ns} \tilde{k}_P + \mathcal{O}(n^{-2}) - \tilde{k}_{P_s}^{-1} [2\alpha_{ns} + \mathcal{O}(n^{-2})] \\ &= 2\tilde{k}_P + 2\alpha_{ns} (\tilde{k}_P - \tilde{k}_{P_s}^{-1}) + \mathcal{O}(n^{-2}), \end{aligned}$$

where we have also expanded the exponential functions according to their Taylor series. Similarly,

$$\begin{aligned} e^{\tilde{\rho}_{ns} + \alpha_{ns}} - e^{-\tilde{\rho}_{ns} - \alpha_{ns}} &= e^{\alpha_{ns}} \left[ 2\tilde{k}_P - e^{-\tilde{\rho}_{ns}} \right] - e^{-\tilde{\rho}_{ns} - \alpha_{ns}} \\ &= 2\tilde{k}_P e^{\alpha_{ns}} - e^{\alpha_{ns}} e^{-\tilde{\rho}_{ns}} - e^{-\tilde{\rho}_{ns} - \alpha_{ns}} \\ &= 2\tilde{k}_P [1 + \alpha_{ns} + \mathcal{O}(n^{-2})] - e^{-\tilde{\rho}_{ns}} [e^{\alpha_{ns}} + e^{-\alpha_{ns}}] \\ &= 2\tilde{k}_P + 2\alpha_{ns} \tilde{k}_P + \mathcal{O}(n^{-2}) - e^{-\tilde{\rho}_{ns}} [2 + \mathcal{O}(n^{-2})] \\ &= 2\tilde{k}_P + 2\alpha_{ns} \tilde{k}_P + \mathcal{O}(n^{-2}) - \tilde{k}_{P_s}^{-1} [2 + \mathcal{O}(n^{-2})] \\ &= 2 (\tilde{k}_P - \tilde{k}_{P_s}^{-1}) + 2\tilde{k}_P \alpha_{ns} + \mathcal{O}(n^{-2}). \end{aligned}$$

These two estimates lead us to write

$$\begin{aligned} 0 &= e^{\tilde{\rho}_{ns} + \alpha_{ns}} + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} - 2\tilde{k}_P - \frac{1}{2} \frac{\ell\beta}{\alpha} (e^{-\tilde{\rho}_{ns} - \alpha_{ns}} - e^{\tilde{\rho}_{ns} + \alpha_{ns}}) \rho_{ns}^{-1} + \mathcal{O}(\rho_{ns}^{-2}) \\ &= 2\tilde{k}_P + 2\alpha_{ns} (\tilde{k}_P - \tilde{k}_{P_s}^{-1}) - 2\tilde{k}_P \\ &\quad + \frac{1}{2} \frac{\ell\beta}{\alpha} \left( 2 (\tilde{k}_P - \tilde{k}_{P_s}^{-1}) + 2\tilde{k}_P \alpha_{ns} + \mathcal{O}(n^{-2}) \right) \tilde{\rho}_{ns}^{-1} + \mathcal{O}(n^{-2}) \\ &= 2\alpha_{ns} (\tilde{k}_P - \tilde{k}_{P_s}^{-1}) + \frac{1}{2} \frac{\ell\beta}{\alpha} \left( 2 (\tilde{k}_P - \tilde{k}_{P_s}^{-1}) + 2\tilde{k}_P \alpha_{ns} \right) \tilde{\rho}_{ns}^{-1} + \mathcal{O}(n^{-2}) \\ &= 2\alpha_{ns} (\tilde{k}_P - \tilde{k}_{P_s}^{-1}) + \frac{\ell\beta}{\alpha} (\tilde{k}_P - \tilde{k}_{P_s}^{-1}) \tilde{\rho}_{ns}^{-1} + \mathcal{O}(n^{-2}). \end{aligned}$$

Thus, we obtain

$$\alpha_{ns} = -\frac{\ell\beta}{2\alpha\tilde{\rho}_{ns}} + \mathcal{O}(n^{-2}) = -\frac{\ell\beta}{2\alpha\left(\ln|\tilde{k}_{Ps}| + 2n\pi i + \delta i\right)} + \mathcal{O}(n^{-2}).$$

This, together with (3.16)–(3.17), yields

$$(3.18) \quad \rho_{ns} = \ln|\tilde{k}_{Ps}| + 2n\pi i + \delta i - \frac{\ell\beta}{2\alpha\left(\ln|\tilde{k}_{Ps}| + 2n\pi i + \delta i\right)} + \mathcal{O}(n^{-2}),$$

and so

$$\rho_{ns}^2 = (\ln|\tilde{k}_{Ps}|)^2 - (2n\pi + \delta)^2 + i(4n\pi + 2\delta)\ln|\tilde{k}_{Ps}| - \frac{\ell\beta}{\alpha} + \mathcal{O}(n^{-1}).$$

Now, using the fact that  $\lambda_{ns} = \frac{\alpha\rho_{ns}^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , the desired result (3.10) is directly obtained.

Finally, when  $|\tilde{k}_P| = 1$ , similar arguments permit us to claim that  $\lambda_{n1}$  and  $\lambda_{n2}$ , for  $n \in \mathbb{N}$ , are not separable when their moduli are large enough and have the asymptotic expression given by (3.13). We omit the details here.  $\square$

The following result deals with the case  $|\tilde{k}_P| < 1$ .

**THEOREM 3.3.** *Let  $|\tilde{k}_P| < 1$ . Then the eigenvalues  $\lambda_n$  of the operator  $\mathcal{A}_{PI}$  are the solutions of the eigenvalue problem (3.3) and have the following asymptotic expansion: for  $s = 1, 2$ ,*

$$(3.19) \quad \lambda_{ns} = -\left(\frac{\beta}{\ell} + \frac{\beta^2}{4\alpha}\right) - \frac{\alpha(2n\pi + \theta_s)^2}{\ell^2} + \mathcal{O}(n^{-1}),$$

where  $n$  are positive integers and

$$(3.20) \quad \theta_1 := \tan^{-1}\left(\frac{\sqrt{1 - \tilde{k}_P^2}}{\tilde{k}_P}\right), \quad \theta_2 := -\theta_1.$$

*Proof.* Let  $\rho \in \mathbb{C}$  with  $\arg \rho \in [-\pi/2, \pi/2)$ . When  $|\tilde{k}_P| < 1$ , the equation

$$e^\rho + e^{-\rho} - 2\tilde{k}_P = 0$$

has solutions

$$(3.21) \quad \tilde{\rho}_{ns} = \theta_s i + 2n\pi i, \quad s = 1, 2, \quad n \in \mathbb{N}.$$

Applying Rouché's theorem to (3.15) yields

$$(3.22) \quad \rho_{ns} = \tilde{\rho}_{ns} + \alpha_{ns}, \quad \alpha_{ns} = \mathcal{O}(n^{-1}), \quad s = 1, 2,$$

for sufficiently large positive integers  $n$ . Next, inserting  $\rho_{ns}$  into (3.14), we obtain, after a careful computation,

$$e^{\tilde{\rho}_{ns} + \alpha_{ns}} + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} - 2\tilde{k}_P - \frac{1}{2} \frac{\ell\beta}{\alpha} (e^{-\tilde{\rho}_{ns} - \alpha_{ns}} - e^{\tilde{\rho}_{ns} + \alpha_{ns}}) \rho_{ns}^{-1} + \mathcal{O}(\rho_{ns}^{-2}) = 0.$$

Then, since

$$e^{\tilde{\rho}_{ns}} + e^{-\tilde{\rho}_{ns}} - 2\tilde{k}_P = 0, \quad e^{\tilde{\rho}_{ns}} = e^{i\theta_s} = \tilde{k}_P + i\sqrt{1 - \tilde{k}_P^2},$$

one can get, as for the case  $|\tilde{k}_P| > 1$ , the estimates

$$\begin{aligned}
 e^{\tilde{\rho}_{ns} + \alpha_{ns}} + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} &= e^{\alpha_{ns}} \left[ 2\tilde{k}_P - e^{-\tilde{\rho}_{ns}} \right] + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} \\
 &= 2\tilde{k}_P e^{\alpha_{ns}} - e^{\alpha_{ns}} e^{-\tilde{\rho}_{ns}} + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} \\
 &= 2\tilde{k}_P \left[ 1 + \alpha_{ns} + \mathcal{O}(n^{-2}) \right] - e^{-\tilde{\rho}_{ns}} \left[ e^{\alpha_{ns}} - e^{-\alpha_{ns}} \right] \\
 &= 2\tilde{k}_P + 2\alpha_{ns}\tilde{k}_P + \mathcal{O}(n^{-2}) - e^{-\tilde{\rho}_{ns}} \left[ 2\alpha_{ns} + \mathcal{O}(n^{-2}) \right] \\
 &= 2\tilde{k}_P + 2\alpha_{ns}\tilde{k}_P + \mathcal{O}(n^{-2}) - e^{-i\theta_s} \left[ 2\alpha_{ns} + \mathcal{O}(n^{-2}) \right] \\
 &= 2\tilde{k}_P + 2\alpha_{ns}\tilde{k}_P + \mathcal{O}(n^{-2}) - \left( \tilde{k}_P - i\sqrt{1 - \tilde{k}_P^2} \right) \left[ 2\alpha_{ns} + \mathcal{O}(n^{-2}) \right] \\
 &= 2\tilde{k}_P + 2i\alpha_{ns}\sqrt{1 - \tilde{k}_P^2} + \mathcal{O}(n^{-2})
 \end{aligned}$$

and

$$\begin{aligned}
 e^{\tilde{\rho}_{ns} + \alpha_{ns}} - e^{-\tilde{\rho}_{ns} - \alpha_{ns}} &= e^{\alpha_{ns}} \left[ 2\tilde{k}_P - e^{-\tilde{\rho}_{ns}} \right] - e^{-\tilde{\rho}_{ns} - \alpha_{ns}} \\
 &= 2\tilde{k}_P e^{\alpha_{ns}} - e^{\alpha_{ns}} e^{-\tilde{\rho}_{ns}} - e^{-\tilde{\rho}_{ns} - \alpha_{ns}} \\
 &= 2\tilde{k}_P \left[ 1 + \alpha_{ns} + \mathcal{O}(n^{-2}) \right] - e^{-\tilde{\rho}_{ns}} \left[ e^{\alpha_{ns}} + e^{-\alpha_{ns}} \right] \\
 &= 2\tilde{k}_P + 2\alpha_{ns}\tilde{k}_P + \mathcal{O}(n^{-2}) - e^{-\tilde{\rho}_{ns}} \left[ 2 + \mathcal{O}(n^{-2}) \right] \\
 &= 2\tilde{k}_P + 2\alpha_{ns}\tilde{k}_P + \mathcal{O}(n^{-2}) - e^{-i\theta_s} \left[ 2 + \mathcal{O}(n^{-2}) \right] \\
 &= 2\tilde{k}_P + 2\alpha_{ns}\tilde{k}_P + \mathcal{O}(n^{-2}) - \left( \tilde{k}_P - i\sqrt{1 - \tilde{k}_P^2} \right) \left[ 2 + \mathcal{O}(n^{-2}) \right] \\
 &= 2i\sqrt{1 - \tilde{k}_P^2} + 2\tilde{k}_P\alpha_{ns} + \mathcal{O}(n^{-2}).
 \end{aligned}$$

Hence

$$\begin{aligned}
 0 &= e^{\tilde{\rho}_{ns} + \alpha_{ns}} + e^{-\tilde{\rho}_{ns} - \alpha_{ns}} - 2\tilde{k}_P - \frac{1}{2} \frac{\ell\beta}{\alpha} \left( e^{-\tilde{\rho}_{ns} - \alpha_{ns}} - e^{\tilde{\rho}_{ns} + \alpha_{ns}} \right) \rho_{ns}^{-1} + \mathcal{O}(\rho_{ns}^{-2}) \\
 &= 2\tilde{k}_P + 2i\alpha_{ns}\sqrt{1 - \tilde{k}_P^2} - 2\tilde{k}_P + \frac{1}{2} \frac{\ell\beta}{\alpha} \left( 2i\sqrt{1 - \tilde{k}_P^2} + 2\tilde{k}_P\alpha_{ns} + \mathcal{O}(n^{-2}) \right) \tilde{\rho}_{ns}^{-1} + \mathcal{O}(n^{-2}) \\
 &= 2i\alpha_{ns}\sqrt{1 - \tilde{k}_P^2} + \frac{1}{2} \frac{\ell\beta}{\alpha} \left( 2i\sqrt{1 - \tilde{k}_P^2} + 2\tilde{k}_P\alpha_{ns} \right) \tilde{\rho}_{ns}^{-1} + \mathcal{O}(n^{-2}) \\
 &= 2i\alpha_{ns}\sqrt{1 - \tilde{k}_P^2} + i\frac{\ell\beta}{\alpha} \sqrt{1 - \tilde{k}_P^2} \tilde{\rho}_{ns}^{-1} + \mathcal{O}(n^{-2}),
 \end{aligned}$$

which, together with (3.21), gives

$$\alpha_{ns} = -\frac{\ell\beta}{2\alpha} \tilde{\rho}_{ns}^{-1} + \mathcal{O}(n^{-2}) = -\frac{\ell\beta}{2\alpha(\theta_s i + 2n\pi i)} + \mathcal{O}(n^{-2}).$$

Therefore

$$(3.23) \quad \rho_{ns} = \theta_s i + 2n\pi i - \frac{\ell\beta}{2\alpha(\theta_s i + 2n\pi i)} + \mathcal{O}(n^{-2}),$$

and so

$$\rho_{ns}^2 = -(2n\pi + \theta_s)^2 - \frac{\ell\beta}{\alpha} + \mathcal{O}(n^{-1}).$$

Finally, since  $\lambda_{ns} = \frac{\alpha\rho_{ns}^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , one can deduce (3.19). This completes the proof.  $\square$

We are now in a position to investigate the asymptotic behavior of the eigenfunctions. The result is described as follows.

**THEOREM 3.4.** *Let  $\sigma(\mathcal{A}_{PI}) = \{\lambda_{n1}, \lambda_{n2}, n \in \mathbb{N}\}$  be the eigenvalues of  $\mathcal{A}_{PI}$ . If  $|\tilde{k}_P| > 1$  (respectively,  $|\tilde{k}_P| < 1$ ), then  $\lambda_n = \frac{\alpha\rho_n^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , with  $\rho_n \in \mathbb{C}$  and  $\arg \rho_n \in [-\pi/2, \pi/2)$ , are given by (3.10) and (3.18) (respectively, (3.19) and (3.23)). Furthermore, the corresponding eigenfunctions  $\{(f_{n1}, \xi_{n1}), (f_{n2}, \xi_{n2})\}$  have the following asymptotics: for  $s = 1, 2$ ,*

$$(3.24) \quad \begin{cases} f_{ns}(x) = g_{ns}(z) = e^{\frac{1}{2}\frac{\ell\beta}{\alpha}z} e^{-\rho_{ns}(1-z)} + e^{\frac{1}{2}\frac{\ell\beta}{\alpha}z} e^{\rho_{ns}(1-z)} + \mathcal{O}(n^{-1}) \\ \quad = e^{\frac{1}{2}\frac{\beta}{\alpha}x} e^{-\rho_{ns}(1-\frac{x}{\ell})} + e^{\frac{1}{2}\frac{\beta}{\alpha}x} e^{\rho_{ns}(1-\frac{x}{\ell})} + \mathcal{O}(n^{-1}), \quad x = z\ell, \\ \xi_{ns} = \frac{g_{ns}(0) - k_P g_{ns}(1)}{k_I} = \mathcal{O}(n^{-1}) \end{cases}$$

for sufficiently large positive integer  $n$ , where  $f_{ns}(x) = g_{ns}(z)$  with  $x = z\ell$  given in (3.2). Moreover,  $\{(f_{n1}, \xi_{n1}), (f_{n2}, \xi_{n2})\}$  is approximately normalized in  $\mathcal{H}$  in the sense that there exist positive constants  $c_1, c_2$  independent of  $n$ , such that

$$(3.25) \quad c_1 \leq \|f_{ns}\|_{L^2(0,\ell)} = \sqrt{\ell} \|g_{ns}\|_{L^2(0,1)}, \quad |\xi_{ns}| \leq c_2, \quad n \in \mathbb{N}, \quad s = 1, 2,$$

*Proof.* We consider only the case  $|\tilde{k}_P| > 1$ , and the same arguments can be applied when  $|\tilde{k}_P| < 1$ . From (3.3), (3.5), (3.6), and linear algebra theory, the function  $g$ , with respect to the eigenvalue  $\lambda = \frac{\alpha\rho^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , where  $\rho \in \mathbb{C}$  and  $\arg \rho \in [-\pi/2, \pi/2)$ , is given by

$$(3.26) \quad e^{-\frac{1}{2}\frac{\ell\beta}{\alpha}z} g(z, \rho) = e^{-\frac{1}{2}\frac{\ell\beta}{\alpha}z} \begin{vmatrix} e^{\tau_1 z} & e^{\tau_2 z} \\ \tau_1 e^{\tau_1} & \tau_2 e^{\tau_2} \end{vmatrix} = \tau_2 e^{\frac{1}{2}\frac{\ell\beta}{\alpha}z} e^{-\rho(1-z)} - \tau_1 e^{\frac{1}{2}\frac{\ell\beta}{\alpha}z} e^{\rho(1-z)}.$$

The first estimate of (3.24) is a consequence of (3.26) by setting

$$g_{ns}(z) = -\rho_{ns}^{-1} e^{-\frac{1}{2}\frac{\ell\beta}{\alpha}z} g(z, \rho_{ns}), \quad s = 1, 2,$$

in (3.26). Regarding the second one, it can be proved as follows:

$$\xi_{ns} = \frac{g_{ns}(0) - k_P g_{ns}(1)}{k_I} = \frac{2\tilde{k}_P - 2k_P e^{\frac{1}{2}\frac{\ell\beta}{\alpha}}}{k_I} + \mathcal{O}(n^{-1}) = \mathcal{O}(n^{-1}),$$

where we have used the fact that

$$e^{\rho_{ns}} + e^{-\rho_{ns}} - 2\tilde{k}_P = \mathcal{O}(n^{-1})$$

and the definition of  $\tilde{k}_P$  given in (3.8). Finally, in order to prove (3.25), we use (3.18) to obtain that  $\|e^{\frac{1}{2}\frac{\beta}{\alpha}x} e^{\rho_{ns}(1-\frac{x}{\ell})}\|_{L^2(0,1)}^2$  and  $\|e^{\frac{1}{2}\frac{\beta}{\alpha}x} e^{-\rho_{ns}(1-\frac{x}{\ell})}\|_{L^2(0,1)}^2$  are uniformly bound in  $(0, 1)$ . This, together with  $|\xi_{ns}|^2 = \mathcal{O}(n^{-2})$ , gives

$$\int_0^\ell |f_{ns}(x)|^2 dx = \ell \int_0^1 |g_{ns}(z)|^2 dz$$

and the desired inequalities (3.25)  $\square$

Now, one can notice that the same process can also produce asymptotic expansions for the eigenpairs of  $\mathcal{A}_{PI}^*$ , which is the adjoint operator of  $\mathcal{A}_{PI}$  and is given by

$$(3.27) \quad \mathcal{A}_{PI}^* \begin{pmatrix} h \\ \eta \end{pmatrix} := \begin{pmatrix} \alpha h'' + \beta h' \\ \alpha k_I h'(0) \end{pmatrix} \vee \begin{pmatrix} h \\ \eta \end{pmatrix} \in \mathcal{D}(\mathcal{A}_{PI}^*)$$

and

$$(3.28) \quad \mathcal{D}(\mathcal{A}_{PI}^*) := \{(z, \eta) \in H^2(0, \ell) \times \mathbb{C} : h(0) = 0, \eta = \alpha h'(\ell) + \beta h(\ell) - \alpha k_P h'(0)\}.$$

Since  $\mathcal{A}_{PI}$  is a discrete operator, then so is  $\mathcal{A}_{PI}^*$  (see [10, p. 2354]). Moreover, if  $\lambda$  is an eigenvalue of  $\mathcal{A}_{PI}$ , then  $\bar{\lambda}$  is an eigenvalue of  $\mathcal{A}_{PI}^*$  (see [20, p. 26]). Hence, we can get the eigenvalues of  $\mathcal{A}_{PI}^*$  directly from (3.10) and (3.19) for  $|\tilde{k}_P| > 1$  and  $|\tilde{k}_P| < 1$ , respectively, with the same algebraic multiplicity (see [10, p. 2354]). Also, the same arguments used in the proof in Theorem 3.4 will yield the counterpart of Theorem 3.4 for  $\mathcal{A}_{PI}^*$ , namely, the following.

**THEOREM 3.5.** *Let  $\sigma(\mathcal{A}_{PI}^*) = \{\bar{\lambda}_{n1}, \bar{\lambda}_{n2}, n \in \mathbb{N}\}$  be the eigenvalues of  $\mathcal{A}_{PI}^*$ . If  $|\tilde{k}_P| > 1$  (respectively,  $|\tilde{k}_P| < 1$ ),  $\lambda_n = \frac{\alpha \rho_n^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , with  $\rho_n \in \mathbb{C}$  and  $\arg \rho_n \in [-\pi/2, \pi/2)$ , are given by (3.10) and (3.18) (respectively, (3.19) and (3.23)). Furthermore, the corresponding eigenfunctions  $\{(h_{n1}, \eta_{n1}), (h_{n2}, \eta_{n2})\}$  have the following asymptotics: for  $s = 1, 2$ ,*

$$(3.29) \quad \begin{cases} h_{ns}(x) = \phi_{ns}(z) = e^{-\frac{1}{2}\frac{\ell\beta}{\alpha}z} e^{\overline{\rho_{ns}}z} - e^{-\frac{1}{2}\frac{\ell\beta}{\alpha}z} e^{-\overline{\rho_{ns}}z} = e^{-\frac{1}{2}\frac{\beta}{\alpha}x} e^{\overline{\rho_{ns}}\frac{x}{\ell}} - e^{-\frac{1}{2}\frac{\beta}{\alpha}x} e^{-\overline{\rho_{ns}}\frac{x}{\ell}}, \\ \eta_{ns} = \mathcal{O}(n^{-1}) \end{cases}$$

for sufficiently large positive integer  $n$ , where

$$(3.30) \quad x = z\ell, \quad h(x) = \phi(z), \quad z \in [0, 1].$$

Moreover,  $\{(h_{ns}, \eta_{ns}), s = 1, 2\}$  is approximately normalized in  $\mathcal{H}$ .

*Proof.* From (3.27) and (3.28), the eigenvalue problem of  $\mathcal{A}_{PI}^*$  is

$$(3.31) \quad \begin{cases} h''(x) + \frac{\beta}{\alpha}h'(x) - \frac{1}{\alpha}\lambda h(x) = 0, & 0 < x < \ell, \\ h(0) = 0, \quad \alpha(\lambda k_P + k_I)h'(0) = \lambda\alpha h'(\ell) + \lambda\beta h(\ell). \end{cases}$$

By the transformation (3.30), which is similar to (3.2), the above equation changes into

$$(3.32) \quad \begin{cases} \phi''(z) + \frac{\ell\beta}{\alpha}\phi'(z) - \frac{\ell^2}{\alpha}\lambda\phi(z) = 0, & 0 < z < 1, \\ \phi(0) = 0, \quad \alpha(\lambda k_P + k_I)\phi'(0) = \lambda\alpha\phi'(1) + \lambda\beta\ell\phi(1). \end{cases}$$

Then  $e^{-\tau_1 z}$  and  $e^{-\tau_2 z}$  are two independent solutions of  $\phi''(z) + \frac{\ell\beta}{\alpha}\phi'(z) - \frac{\ell^2}{\alpha}\lambda\phi(z) = 0$ . As in the proof of Theorem 3.4, the function  $\phi$  with respect to the eigenvalue  $\bar{\lambda}$  of  $\mathcal{A}_{PI}^*$ , where  $\lambda = \frac{\alpha \rho^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , with  $\rho \in \mathbb{C}$  and  $\arg \rho \in [-\pi/2, \pi/2)$ , is given by

$$(3.33) \quad \phi(z, \rho) = \begin{vmatrix} 1 & 1 \\ e^{-\tau_1 z} & e^{-\tau_2 z} \end{vmatrix} = e^{-\tau_2 z} - e^{-\tau_1 z} = e^{-\frac{1}{2}\frac{\ell\beta}{\alpha}z} e^{\rho z} - e^{-\frac{1}{2}\frac{\ell\beta}{\alpha}z} e^{-\rho z}.$$

The first expression of (3.29) then follows from (3.33) by setting

$$\phi_{ns}(z) = \phi(z, \overline{\rho_{ns}}), \quad s = 1, 2,$$

in (3.33), and  $\eta_{ns}$  can be obtained by

$$\eta_{ns} = \alpha h'_{ns}(\ell) + \beta h_{ns}(\ell) - \alpha k_P h'_{ns}(0) = \frac{\alpha}{\ell} \phi'_{ns}(1) + \beta \phi_{ns}(1) - \frac{\alpha}{\ell} k_P \phi'_{ns}(0) = \mathcal{O}(n^{-1}).$$

Here we have used the fact that

$$e^{\overline{\rho_{ns}}} + e^{-\overline{\rho_{ns}}} - 2\tilde{k}_P = \mathcal{O}(n^{-1})$$

and the definition of  $\tilde{k}_P$  in (3.8). A direct computation can further show that  $\{(h_{ns}, \eta_{ns}), s = 1, 2\}$  is approximately normalized.  $\square$

**3.2. Completeness of the root subspace.** First, we have the following.

**THEOREM 3.6.** *Let  $\sigma(\mathcal{A}_{PI}) = \{\lambda_{n1}, \lambda_{n2}, n \in \mathbb{N}\}$  be the eigenvalues of  $\mathcal{A}_{PI}$ , and let  $\lambda_n = \frac{\alpha \rho_n^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , with  $\rho_n \in \mathbb{C}$  and  $\arg \rho_n \in [-\pi/2, \pi/2)$ . Then there exists a constant  $\widetilde{M} > 0$  independent of  $\lambda$  such that*

$$(3.34) \quad \|R(\lambda, \mathcal{A}_{PI})\| \leq \widetilde{M} |\lambda|^{-1/2}$$

for all  $\lambda = \frac{\alpha \rho^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , with  $\rho \in \mathbb{C}$ , and  $\arg \rho \in [-\pi/2, \pi/2)$  lies outside all circles of radius  $\varepsilon > 0$  and the circles are centered at the zeros of  $\det(\Delta(\rho)) = 0$  (see (3.9)).

*Proof.* Let  $\lambda = \alpha \rho^2 / \ell^2 - \frac{1}{4} \beta^2 / \alpha \in \rho(\mathcal{A}_{PI})$ , with  $\rho \in \mathbb{C}$  and  $\arg \rho \in [-\pi/2, \pi/2)$ , and let  $(\phi, c) \in \mathcal{H}$ . Our aim is to solve the resolvent equation

$$(\lambda I - \mathcal{A}_{PI}) \begin{pmatrix} f \\ \xi \end{pmatrix} = \begin{pmatrix} \phi \\ c \end{pmatrix},$$

or, equivalently,

$$\begin{cases} \lambda f(x) - \alpha f''(x) + \beta f'(x) = \phi(x), \\ \lambda \frac{f(0) - k_P f(\ell)}{k_I} - f(\ell) = c, \end{cases}$$

or

$$(3.35) \quad \begin{cases} f''(x) - \frac{\beta}{\alpha} f'(x) - \frac{1}{\alpha} \lambda f(x) = -\frac{1}{\alpha} \phi(x), & 0 < x < \ell, \\ \lambda f(0) - \lambda k_P f(\ell) - k_I f(\ell) = k_I c, & f'(\ell) = 0. \end{cases}$$

By using the transformation (3.2), we obtain

$$(3.36) \quad \begin{cases} g''(z) - \frac{\ell \beta}{\alpha} g'(z) - \frac{\ell^2}{\alpha} \lambda g(z) = -\frac{\ell^2}{\alpha} \phi(z\ell), & 0 < z < 1, \\ \lambda g(0) - (\lambda k_P + k_I) g(1) = k_I c, & g'(1) = 0. \end{cases}$$

Set

$$(3.37) \quad \Phi(z, \lambda) := g(z) - \frac{k_I c}{\lambda(1 - k_P) - k_I}, \quad \lambda(1 - k_P) \neq k_I.$$

Then,  $\Phi(z, \lambda)$  satisfies

$$(3.38) \quad \begin{cases} \Phi''(z, \lambda) - \frac{\ell\beta}{\alpha}\Phi'(z, \lambda) - \frac{\ell^2}{\alpha}\lambda\Phi(z, \lambda) = -\frac{\ell^2}{\alpha}\phi(z\ell) + \frac{\ell^2}{\alpha}\frac{\lambda k_{Ic}}{\lambda(1-k_P) - k_I}, \\ \lambda\Phi(0, \lambda) - (\lambda k_P + k_I)\Phi(1, \lambda) = 0, \quad \Phi'(1, \lambda) = 0. \end{cases}$$

Therefore, every solution  $\Phi(z, \lambda)$  of (3.38) can be represented as (see, e.g., [32, p. 31, Theorem 2])

$$(3.39) \quad \Phi(z, \lambda) = \int_0^1 G(z, \xi, \lambda) \left( -\frac{\ell^2}{\alpha}\phi(\xi\ell) + \frac{\ell^2}{\alpha}\frac{\lambda k_{Ic}}{\lambda(1-k_P) - k_I} \right) d\xi,$$

and hence the solution of (3.36) can be written as follows:

$$(3.40) \quad g(z) = \int_0^1 G(z, \xi, \lambda) \left( -\frac{\ell^2}{\alpha}\phi(\xi\ell) + \frac{\ell^2}{\alpha}\frac{\lambda k_{Ic}}{\lambda(1-k_P) - k_I} \right) d\xi + \frac{k_{Ic}}{\lambda(1-k_P) - k_I}.$$

Here  $G(x, \xi, \lambda)$  is the Green's function given by

$$G(z, \xi, \lambda) := \frac{1}{\det(\Delta(\lambda))} H(z, \xi, \lambda),$$

with

$$(3.41) \quad H(z, \xi, \lambda) := \begin{vmatrix} e^{\tau_1 z} & e^{\tau_2 z} & \eta(z, \xi, \lambda) \\ U_1(e^{\tau_1 z}) & U_1(e^{\tau_2 z}) & U_2(e^{\tau_1 z}) \\ U_2(e^{\tau_2 z}) & U_2(y_2) & U_2(\eta) \end{vmatrix},$$

$$(3.42) \quad \eta(z, \xi, \lambda) := \frac{1}{4\rho} \text{sign}(z - \xi) \left( e^{\tau_1(z-\xi)} - e^{\tau_2(z-\xi)} \right),$$

where we have used the fact that  $\lambda = \frac{\alpha\rho^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ ,  $U_1(g) := (\lambda k_P + k_I)g(1) - \lambda g(0)$ , and  $U_2(g) := g'(1)$ . Based on the above equations, we can claim that for  $\lambda \in \rho(\mathcal{A}_{PI})$ , with  $|\lambda|$  large enough, there exists a constant  $M$  independent of  $z, \xi \in [0, 1]$  so that

$$(3.43) \quad |H(z, \xi, \lambda)| \leq M e^{\frac{\ell\beta}{2\alpha}} |\rho|^2 e^{|\rho|}, \quad \rho \in \mathbb{C}, \quad \arg \rho \in [-\pi/2, \pi/2].$$

Thus we conclude from (3.9) that

$$(3.44) \quad |G(z, \xi, \lambda)| \leq M_1 |\rho|^{-1}$$

holds for all  $\rho \in \mathbb{C}$ , with  $\arg \rho \in [-\pi/2, \pi/2]$  outside those circles of radius  $\varepsilon > 0$  and centered at the zeros of  $\det(\Delta(\rho)) = 0$ , where  $M_1$  is some constant independent of  $z, \xi \in [0, 1]$ . This will, in turn, yield estimates for  $g(z)$ ,  $f(x)$ , and  $\|R(\lambda, \mathcal{A}_{PI})\|$ , respectively, as follows:

$$(3.45) \quad |f(x)| = |g(z)| \leq M_2 |\rho|^{-1}$$

and

$$(3.46) \quad \|R(\lambda, \mathcal{A}_{PI})\| \leq M_3 |\rho|^{-1}$$

for all  $\rho \in \mathbb{C}$ , with  $\arg \rho \in [-\pi/2, \pi)$  outside those circles of radius  $\varepsilon > 0$  and centered at the zeros of  $\det(\Delta(\rho)) = 0$ , where  $M_2$  and  $M_3$  are some constants independent of  $z, \xi \in [0, 1]$ . This achieves the proof of the desired result by taking  $\widetilde{M} = M_3$ .  $\square$

Note that we can obtain a more precise estimate for  $\|R(\lambda, \mathcal{A}_{PI})\|$  as follows (for more details, the reader is referred to [14]).

**THEOREM 3.7.** *There exist positive constants  $r$  and  $M_r$  such that for an arbitrary  $\kappa \in (\pi/2, \pi)$ , we have*

$$\Sigma_{\kappa, r} := \{\lambda \in \mathbb{C} : |\arg(\lambda - r)| < \kappa, \lambda \neq 0\} \subset \rho(\mathcal{A}_{PI})$$

and

$$(3.47) \quad \|R(\lambda, \mathcal{A}_{PI})\| \leq \frac{M_r}{|\lambda - r|} \quad \forall \lambda \in \Sigma_{\kappa, r}.$$

We have the following lemma.

**LEMMA 3.8.** *Let  $\sigma(\mathcal{A}_{PI}) = \{\lambda_{n1}, \lambda_{n2}, n \in \mathbb{N}\}$  be the eigenvalues of  $\mathcal{A}_{PI}$ . If  $|\widetilde{k}_P| > 1$  (respectively,  $0 < |\widetilde{k}_P| < 1$ ), then  $\lambda_n = \frac{\alpha \rho_n^2}{\ell^2} - \frac{\beta^2}{4\alpha}$ , with  $\rho_n \in \mathbb{C}$  and  $\arg \rho_n \in [-\pi/2, \pi/2)$ , are given by (3.10) and (3.18) (respectively, (3.19) and (3.23)). In addition, for any sufficiently large  $n$ , each eigenvalue  $\lambda_{ni}$ ,  $i = 1, 2$ , of  $\mathcal{A}_{PI}$  is algebraically simple.*

*Proof.* From (3.40), the multiplicity of each  $\lambda \in \sigma(\mathcal{A}_{PI})$  with sufficiently large modulus, as a pole of  $R(\lambda, \mathcal{A}_{PI})$ , is less than or equal to the multiplicity of  $\lambda$  as a zero of the entire function  $\det(\Delta(\rho))$  with respect to  $\rho$ . On the other hand, it is a routine exercise to verify that  $\lambda$  is geometrically simple. Since from (3.14), under the assumption  $|\widetilde{k}_P| \neq 1$ , all zeros of  $\det(\Delta(\rho)) = 0$  with large moduli are simple, the result then follows from the general formula  $m_a \leq p \cdot m_g$  (see, e.g., [30, p. 148]), where  $p$  denotes the order of the pole of the resolvent operator and  $m_a, m_g$  denote, respectively, the algebraic and geometric multiplicity.  $\square$

The next result follows.

**PROPOSITION 3.9.** *Both root subspaces of the operators  $\mathcal{A}_{PI}$  and  $\mathcal{A}_{PI}^*$  are complete in  $\mathcal{H}$ , that is to say,  $\text{Sp}(\mathcal{A}_{PI}) = \text{Sp}(\mathcal{A}_{PI}^*) = \mathcal{H}$ .*

*Proof.* It follows from Lemma 5 on page 2355 of [10] that the following orthogonal decomposition holds:

$$\mathcal{H} = \sigma_\infty(\mathcal{A}_{PI}^*) \oplus \text{Sp}(\mathcal{A}_{PI}),$$

where  $\sigma_\infty(\mathcal{A}_{PI}^*)$  consists of those  $Y \in \mathcal{H}$  so that  $R(\lambda, \mathcal{A}_{PI}^*)Y$  is an analytic function of  $\lambda$  in the whole complex plane. Hence  $\text{Sp}(\mathcal{A}_{PI}) = \mathcal{H}$  if and only if  $\sigma_\infty(\mathcal{A}_{PI}^*) = \{0\}$ . Now suppose that  $Y \in \sigma_\infty(\mathcal{A}_{PI}^*)$ . Since  $R(\lambda, \mathcal{A}_{PI}^*)Y$  is an analytic function of  $\lambda$ , it is also for  $\rho$ , and hence by the maximum modulus principle (or the Phragmén-Lindelöf theorem) of analytic functions and the fact that  $\|R(\lambda, \mathcal{A}_{PI}^*)\| = \|R(\bar{\lambda}, \mathcal{A}_{PI})\|$ , it follows from Theorem 3.6 that

$$\|R(\lambda, \mathcal{A}_{PI}^*)Y\| \leq M|\lambda|^{-1/2}\|Y\| \quad \forall \lambda \in \mathbb{C}$$

for some constant  $M > 0$ . By Theorem 1 on page 3 of [17], we conclude that  $R(\lambda, \mathcal{A}_{PI}^*)Y$  is a constant with respect to  $\lambda$ , i.e.,

$$R(\lambda, \mathcal{A}_{PI}^*)Y = Y_0 \quad \text{for some } Y_0 \in \mathcal{H}.$$

Thus

$$Y = (\lambda - \mathcal{A}_{PI}^*)Y_0 = -\mathcal{A}_{PI}^*Y_0 + \lambda Y_0 \quad \forall \lambda \in \mathbb{C}.$$

Finally, comparing the coefficients of  $\lambda^j$ , one can readily find that  $Y_0 = 0$ . This concludes the proof of the result.  $\square$

**3.3. Riesz basis generation.** In order to establish the Riesz basis property of the root subspace of  $\mathcal{A}_{PI}$ , we need the following lemma from [38].

LEMMA 3.10. *Suppose that a sequence  $\{\nu_n\}$  has asymptotics*

$$(3.48) \quad \nu_n = \alpha(n + i\beta \ln n) + \mathcal{O}(1), \quad \alpha \neq 0, \quad n = 1, 2, 3, \dots,$$

where  $\beta$  is a real number and  $\sup_{n \geq 1} \operatorname{Re} \nu_n < \infty$ . Then the sequence  $\{e^{\nu_n x}\}_{n=1}^\infty$  is a Bessel sequence in  $L^2(0, 1)$ .

Then, we have the following.

LEMMA 3.11. *Let  $\rho_{ns}$ ,  $s = 1, 2$ , be given by (3.18) and (3.23) according to  $|\tilde{k}_P| > 1$  and  $|\tilde{k}_P| < 1$ , respectively. Then  $\{e^{\rho_{n1}z}, e^{\rho_{n2}z}\}_{n=1}^\infty$  and  $\{e^{-\rho_{n1}z}, e^{-\rho_{n2}z}\}_{n=1}^\infty$  are two Bessel sequences in  $L^2(0, 1)$ . Hence,  $\{e^{\rho_{n1}x/\ell}, e^{\rho_{n2}x/\ell}\}_{n=1}^\infty$  and  $\{e^{-\rho_{n1}x/\ell}, e^{-\rho_{n2}x/\ell}\}_{n=1}^\infty$  are also two Bessel sequences in  $L^2(0, \ell)$ .*

*Proof.* Let  $\nu_{ns} := \rho_{ns}$ ,  $s = 1, 2$ . Then the result concerning the sequence  $\{e^{\rho_{n1}z}, e^{\rho_{n2}z}\}_{n=1}^\infty$  can be directly obtained from Lemma 3.10 by setting  $\beta = 0$  and  $\alpha = 2\pi i$  in (3.48). Similarly, for the sequence  $\{e^{-\rho_{n1}z}, e^{-\rho_{n2}z}\}_{n=1}^\infty$ , one can take  $\nu_n := -\rho_{ns}$ ,  $s = 1, 2$ ,  $\beta = 0$ , and  $\alpha = -2\pi i$  in (3.48). The last result is obvious since it can be directly verified from the definition of Bessel sequences (see [42, p. 122]).  $\square$

Now, we are able to prove the Riesz basis property for the operator  $\mathcal{A}_{PI}$  stated in Theorem 2.4.

*Proof of Theorem 2.4.* Let  $|\tilde{k}_P| \neq 1$  and let  $\sigma(\mathcal{A}_{PI}) = \{\lambda_{n1}, \lambda_{n2}, n \in \mathbb{N}\}$  be the eigenvalues of  $\mathcal{A}_{PI}$ . From Lemma 3.8, we have that each eigenvalue of  $\mathcal{A}_{PI}$  with sufficient large modulus is simple, and hence there exists an integer  $N > 0$  so that for all  $n > N$ ,  $\lambda_{ns}$ ,  $s = 1, 2$ , is simple. For  $n \leq N$ , if the algebraic multiplicity of each  $\lambda_{ns}$  is  $m_{ns}$ , we can find the highest order generalized eigenfunction  $\Phi_{n,s,1}$  from

$$(\mathcal{A}_{PI} - \lambda_{ns})^{m_{ns}} \Phi_{n,s,1} = 0 \quad \text{but} \quad (\mathcal{A}_{PI} - \lambda_{ns})^{m_{ns}-1} \Phi_{n,s,1} \neq 0, \quad s = 1, 2.$$

The other lower order linearly independent generalized eigenfunctions associated with  $\lambda_{ns}$  can be found through  $\Phi_{n,s,j} = (\mathcal{A}_{PI} - \lambda_{ns})^{j-1} \Phi_{n,s,1}$ ,  $j = 2, 3, \dots, m_{ns}$ . Assume  $\Phi_{ns}$  is an eigenfunction of  $\mathcal{A}_{PI}$  corresponding to  $\lambda_{ns}$  with  $n > N$ . Then  $\{\{\{\Phi_{n,s,j}\}_{j=1}^{m_{ns}}\}_{n \leq N} \cup \{\Phi_{ns}\}_{n > N}\}_{s=1}^2$  are all linearly independent generalized eigenfunctions of  $\mathcal{A}_{PI}$ . Let  $\{\{\{\Psi_{n,s,j}\}_{j=1}^{m_{ns}}\}_{n \leq N} \cup \{\Psi_{ns}\}_{n > N}\}$  be the biorthogonal sequence of  $\{\{\{\Phi_{n,s,j}\}_{j=1}^{m_{ns}}\}_{n \leq N} \cup \{\Phi_{ns}\}_{n > N}\}$ . Then  $\{\{\{\Psi_{n,s,j}\}_{j=1}^{m_{ns}}\}_{n \leq N} \cup \{\Psi_{ns}\}_{n > N}\}_{s=1}^2$  are all linearly independent generalized eigenfunctions of  $\mathcal{A}_{PI}^*$ . It is well known that these two sequences are minimal in  $\mathcal{H}$ , and from Proposition 3.9 they are also complete in  $\mathcal{H}$ .

Hence, in order to prove the Riesz basis of the system, it suffices to show that both eigenfunctions  $\{\Phi_{ns}\}_{n > N, s=1,2}$  and  $\{\Psi_{ns}\}_{n > N, s=1,2}$  of the operators  $\mathcal{A}_{PI}$  and  $\mathcal{A}_{PI}^*$  are, respectively, Bessel sequences in  $\mathcal{H}$ . Since  $1 \leq \|\Phi_{ns}\| \|\Psi_{ns}\| \leq M$  for some constant  $M$  independent of  $n$  (see [42, p. 19]), we may assume without loss of generality that  $\Phi_{ns} = (f_{ns}, \xi_{ns})$  given by (3.24) and  $\Psi_{ns} = (h_{ns}, \eta_{ns})$  given by (3.29) for all  $n > N$ . Then it follows from Lemma 3.11 and the expansions (3.24) and (3.29) that both sequences  $\{f_{n1}, f_{n2}\}_{n > N}$  and  $\{h_{n1}, h_{n2}\}_{n > N}$  are Bessel sequences in  $L^2(0, \ell)$  and both  $\{\xi_{n1}, \xi_{n2}\}_{n > N}$  and  $\{\eta_{n1}, \eta_{n2}\}_{n > N}$  are Bessel sequences in  $\mathbb{C}$ . Therefore both of  $\{\Phi_{ns}\}_{n > N, s=1,2}$  and  $\{\Psi_{ns}\}_{n > N, s=1,2}$  are also Bessel sequences in  $\mathcal{H}$ , and the result follows.

Now, let  $|\tilde{k}_P| = 1$ . From (3.13), we already know that the eigenvalues  $\lambda_{n1}$  and  $\lambda_{n2}$  are not separable when their moduli are large enough, and hence the system may have the same eigenvalues depending on the feedback constants  $k_P$  and  $k_I$ . For such a case, the generalized eigenfunctions of the operator  $\mathcal{A}_{PI}$  form, in  $\mathcal{H}$ , a Riesz basis with parentheses, and each eigenspace, corresponding to eigenvalues with enough large modulus, has dimension two [38]. We omit the details here and leave this as an exercise for the reader.  $\square$

Finally, we reach the proof of the second main result of this work.

*Proof of Theorem 2.5.* We shall assume that  $|\tilde{k}_P| \neq 1$  (the case  $|\tilde{k}_P| = 1$  can be treated similarly). First, the existence of the  $C_0$ -semigroup  $S_{PI}(t)$  follows from Lemma 3.8 and Theorem 2.4. Indeed, since  $\{\{\Phi_{n,s,j}\}_{j=1}^{m_n}\}_{n \leq N, s=1,2} \cup \{\Phi_{ns}\}_{n > N, s=1,2}$  forms a Riesz basis for  $\mathcal{H}$ , then any  $Y \in \mathcal{H}$  can be expanded as follows:

$$Y = \sum_{s=1}^2 \sum_{n=1}^N \sum_{j=1}^{m_n} a_{nsj} \Phi_{n,s,j} + \sum_{s=1}^2 \sum_{n=N+1}^{\infty} a_{ns} \Phi_{ns},$$

where  $a_{nsj}$  and  $a_{ns}$  are constants. Moreover, for such  $Y$ , the semigroup  $S_{PI}(t)$  satisfies

$$(3.49) \quad S_{PI}(t)Y = \sum_{s=1}^2 \sum_{n=1}^N e^{\lambda_{ns}t} \sum_{j=1}^{m_n} a_{nsj} \sum_{i=0}^{m_{ns}-j} \frac{t^i}{i!} \Phi_{n,s,i} + \sum_{s=1}^2 \sum_{n=N+1}^{\infty} e^{\lambda_{ns}t} a_{ns} \Phi_{ns}.$$

Then, using the estimate (3.47) of  $\|R(\lambda, \mathcal{A}_{PI})\|$  on  $\Sigma_{\kappa,r}$ , one can deduce the analytic property of the semigroup (see [33]). Finally, the spectrum-determined growth condition is a direct consequence of the Riesz basis property (also from the analyticity of the semigroup).  $\square$

**4. Proof of Theorem 2.6.** It is well known that although the spectrum of the uncontrolled operator  $A_0$  lies in the open left half-plane (see Lemma 2.5), the operator  $\mathcal{A}_{PI}$  (see (2.10)–(2.11)) of the closed-loop system may have eigenvalues in the right half-complex-plane, and hence the semigroup  $S_{PI}(t)$  will be unstable if the proportional and/or integral gains  $k_P$  and/or  $k_I$  are not properly chosen. We thus need to propose a design method for the proportional and integral gains  $k_P$  and  $k_I$  so that the closed-loop system (2.9) will be exponentially stable.

Using Theorem 4.3 of [33], one can claim that in order to get the exponential stability of the analytic semigroup  $S_{PI}(t)$ , it suffices to show that all the eigenvalues of the operator  $\mathcal{A}_{PI}$  defined by (2.10)–(2.11) have negative real part. Unfortunately, this property turns out to be very difficult to establish in our case since (i) it is not obvious to prove the dissipativity of the operator  $\mathcal{A}_{PI}$  even if under conditions on the proportional and integral gains  $k_P$  and  $k_I$ , and (ii) the problem of obtaining an explicit expression of the eigenvalues of  $\mathcal{A}_{PI}$  is equivalent to solving an unusual transcendental equation. Therefore, it is not easy to get an explicit condition on the proportional and integral gains  $k_P$  and  $k_I$ , which involves the system parameters  $\alpha$ ,  $\beta$ , and  $\ell$  so that the eigenvalues lie in the open left half-plane. In return, we are able to give some implicit conditions on  $k_P$  and  $k_I$  to resolve this hard problem.

First, we have the following result.

**PROPOSITION 4.1.** *If the proportional and integral gains  $k_P$  and  $k_I$  are negative, then any real eigenvalue of the operator  $\mathcal{A}_{PI}$ , defined by (2.10)–(2.11), must be necessarily negative.*

*Proof.* Let  $\lambda$  be an eigenvalue of  $\mathcal{A}_{PI}$  and  $\phi = (f, \xi)$  an associated eigenfunction. Then its eigenvalue problem (3.1) has two characteristic roots given by

$$\eta_{1,2} = \frac{\beta \pm \sqrt{\Delta_\lambda}}{2\alpha}, \quad \text{where } \Delta_\lambda = \beta^2 + 4\alpha\lambda.$$

Consider the following two cases.

*Case (i).*  $\eta_1 = \eta_2$ . This implies that  $\Delta_\lambda = 0$ , i.e.  $\lambda = -\frac{\beta^2}{4\alpha}$ . Next, one can readily prove that  $\lambda = -\frac{\beta^2}{4\alpha}$  is an eigenvalue if and only if

$$\frac{\beta^2}{4\alpha} k_P - k_I = \frac{\beta^2}{4\alpha} \left( 1 + \frac{\beta\ell}{2\alpha} \right) e^{-\frac{\beta\ell}{2\alpha}}.$$

Hence for appropriate negative proportional and integral gains,  $\lambda = -\frac{\beta^2}{4\alpha} < 0$  is an eigenvalue.

*Case (ii).*  $\eta_1 \neq \eta_2$ . In this case, let us consider the normalized solution, of (3.1), at  $x = \ell$ , by  $f(\ell) = 1$ . This, together with the boundary condition  $f'(\ell) = 0$ , implies that the solution of (3.1) is

$$(4.1) \quad f(x) = \frac{e^{-\frac{\beta\ell}{\alpha}}}{2\sqrt{\Delta_\lambda}} \left[ \left( \beta + \sqrt{\Delta_\lambda} \right) e^{\eta_1 L + \eta_2 x} - \left( \beta - \sqrt{\Delta_\lambda} \right) e^{\eta_2 L + \eta_1 x} \right].$$

Now let  $k_P, k_I < 0$  and assume that  $\lambda = \gamma^2$ , where  $\gamma \in \mathbb{R} \setminus \{0\}$ , is an eigenvalue of  $\mathcal{A}_{PI}$ . This is equivalent to claiming that the other boundary condition  $(\lambda k_P + k_I) = \lambda f(0)$  holds. In return, using (4.1) and the fact that  $f(\ell) = 1$ , it follows after a simple calculation that the following equation holds:

$$\left( \beta + \sqrt{\Delta(\gamma)} \right) e^{\frac{\sqrt{\Delta(\gamma)}\ell}{2\alpha}} - \left( \beta - \sqrt{\Delta(\gamma)} \right) e^{-\frac{\sqrt{\Delta(\gamma)}\ell}{2\alpha}} = 2e^{\frac{\beta\ell}{\alpha}} \frac{\sqrt{\Delta(\gamma)}}{\gamma^2} (k_P \gamma^2 + k_I),$$

where  $\Delta(\gamma) = \beta^2 + 4\alpha\gamma^2$ . Finally, since  $\sqrt{\Delta(\gamma)} > \beta$  and  $k_P, k_I < 0$ , the above equation leads to a contradiction.  $\square$

Let us rewrite the spectral system (3.1) in the following form:

$$(4.2) \quad \begin{cases} \alpha f''(x, \lambda) - \beta f'(x, \lambda) = \lambda f(x, \lambda), & 0 \leq x \leq \ell, \\ \lambda f(0, \lambda) = (\lambda k_P + k_I) f(\ell, \lambda), & f'(\ell, \lambda) = 0. \end{cases}$$

Then, by considering the normalized solution at  $x = \ell$  via  $f(\ell, \lambda) = 1$ , it follows that all eigenvalues of (4.2) are the roots of the left-end boundary condition  $\lambda f(0, \lambda) = \lambda k_P + k_I$ . Since  $f(\cdot, \lambda)$  satisfies the same equation, as in (2.3) and (2.6), it necessarily has the same representation given by (2.7), and hence the condition  $\lambda f(0, \lambda) = \lambda k_P + k_I$  yields

$$(4.3) \quad B(\lambda) := \lambda \prod_{i=1}^{\infty} \left( 1 - \frac{\lambda}{\lambda_i^0} \right) = \lambda k_P + k_I.$$

Recall that we have to exclude the zero solution  $\lambda = 0$  of the above equation as  $0 \in \rho(\mathcal{A}_{PI})$ , the resolvent set of  $\mathcal{A}_{PI}$ . We are now able to prove the third main result stated as Theorem 2.6.

*Proof of Theorem 2.6.* (i) First, one can claim from the definition of  $B(\lambda)$  that  $B(\lambda) > 0$  whenever  $\lambda$  is a positive real number, and hence any real root of  $B(\lambda)$  should

FIG. 2.  $B_n(\lambda) = \lambda k_P + k_I$  has  $n + 1$  negative distinct real roots.FIG. 3.  $n - 1$  negative distinct real roots and one double negative real roots to  $B_n(\lambda) = \lambda k_P + k_I$ .

be negative. Second, since both  $\lambda_i^0$  and  $k_I$  are negative and  $k_P$  is positive, it follows that  $B(\lambda_i^0) \neq k_P \lambda_i^0 + k_I$ , and thus for  $n$  large enough, the zeros of  $B(\cdot) - ((\cdot)k_P + k_I)$  and  $B_n(\cdot) - ((\cdot)k_P + k_I)$  coincide. in the finite strip  $\lambda_i^0 \leq \operatorname{Re}(z) \leq 0$  and  $|\operatorname{Im}(z)| \leq \varepsilon$  which contains a piece of the negative real axis.

Now if  $m_1 < k_I < 0$  and  $k_P$  is a positive number sufficiently small (see Figure 2), then the  $n + 1$  roots of  $B_n(\lambda) = \lambda k_P + k_I$  are all real and negative. Finally, note that in this case, we may have  $n - 1$  negative distinct real roots and one double negative real root (see Figure 3). Since these properties are valid for all  $B_n$ , they also hold true for  $B$  by Lemma 2.3.

(ii) Consider now a large enough strip that would include the points where  $B_n$  attains the minima  $m_1$  and  $m_2$  (see Figure 4). Then using the graph of  $B_n$ , one can see that if  $m_2 < k_I < m_1$  and  $k_P$  is a positive number sufficiently small, the equation  $B_n(\lambda) = \lambda k_P + k_I$  has only  $n - 1$  real roots instead of  $n + 1$ . Hence two roots are missing. Since  $B_n(\lambda) = \lambda k_P + k_I$  must have  $n + 1$  roots, the two missing roots should

go conjugate complex (which is a bifurcation) with positive or negative real part. These properties still remain true for  $B$ , by Lemma 2.3.

Finally, we are going to show the output regulation and the exponential stability of the closed-loop system (1.1)–(1.2). Although the proof is similar to that of Theorem 4.1 in [2], we would rather give some details for sake of completeness.

FIG. 4.  $n - 1$  negative distinct real roots and two complex conjugate roots to  $B_n(\lambda) = \lambda k_P + k_I$ .

Due to Theorem 2.5 and the exponential stability of the semigroup  $S_{PI}(t)$ , the solution  $\phi(t) = (Q(\cdot, t), \xi(t))$  of the closed-loop system (2.9), or alternatively (1.1)–(1.2), stemming from the initial data  $\phi_0 = (Q_0, \xi_0) \in \mathcal{D}(\mathcal{A}_{PI})$ , can be written as

$$\phi(t) = S_{PI}(t)\phi_0 + \int_0^t S_{PI}(t-s)(w, -y_r)ds = S_{PI}(t)\phi_0 + \mathcal{A}_{PI}^{-1}(S_{PI}(t) - I)(w, -y_r)$$

and satisfies

$$(4.4) \quad \lim_{t \rightarrow \infty} \phi(t) = \lim_{t \rightarrow \infty} (Q(\cdot, t), \xi(t)) = -\mathcal{A}_{PI}^{-1}(w, -y_r).$$

Let  $\phi^* := (Q^*, y_r^*) = -\mathcal{A}_{PI}^{-1}(w, -y_r)$  and hence  $\mathcal{A}_{PI}(Q^*, y_r^*) = (-w, y_r)$ . Using (2.10)–(2.11), it follows that  $Q^*(\ell) = y_r$ . This, together with (4.4), implies that  $\lim_{t \rightarrow \infty} y(t) = \lim_{t \rightarrow \infty} Q(\ell, t) = y_r$ . Concerning the stability of the closed-loop system (2.9), we first note that the steady state is  $\phi^* = \mathcal{A}_{PI}^{-1}(-w, y_r)$ . Then, setting  $\tilde{\phi} := \phi - \phi^* = \phi - \mathcal{A}_{PI}^{-1}(-w, y_r)$ , the closed-loop system (2.9) can be written as

$$(4.5) \quad \dot{\tilde{\phi}}(t) = \mathcal{A}_{PI}(\tilde{\phi}(t) + \phi^*) + (w, -y_r) = \mathcal{A}_{PI}\tilde{\phi}(t) + \mathcal{A}_{PI}\phi^* + (w, -y_r) = \mathcal{A}_{PI}\tilde{\phi}(t).$$

Consequently, the exponential stability of the closed-loop system (2.9) is equivalent to that of the semigroup  $S_{PI}(t)$ , independently of the perturbation  $w$ . The proof is complete.  $\square$

*Remark 4.1.*

1. As mentioned in the introduction, one of the advantages of introducing the proportional gain  $k_P$  in our control feedback law (contrary to the work [2] where  $k_P = 0$ ) is that this gain improves the stability and the regulation of the closed-loop system (1.1)–(1.2), where  $k_P \neq 0$ , in comparison with the

FIG. 5. Stability improvement for  $k_P > 0$ .

closed-loop system (1.1)–(1.2) with  $k_P = 0$ . To see how this goes, let us sketch the argument from the proof of Theorem 2.6. Suppose that  $k_P = 0$ . Then if  $m_1 < k_I < 0$  (the other cases can be treated similarly), the equation  $B_n(\lambda) = k_I$  has  $n + 1$  distinct negative real roots (see Figure 5), namely,  $\mu_i$ ,  $i = 1, \dots, n$ . Now, one can always choose  $k_P$  sufficiently small such that the new equation  $B_n(\lambda) = \lambda k_P + k_I$  has not only  $n + 1$  distinct negative real roots  $\eta_i$ ,  $i = 1, \dots, n$ , but also  $\max_i \{\eta_i\} < \max_i \{\mu_i\}$ , and hence the spectrum is moved to the left as shown in Figure 5.

- According to Proposition 4.1, one can claim that in order to recover all negative real eigenvalues of the operator  $\mathcal{A}_{PI}$ , it suffices to take both  $k_P$  and  $k_I$  negative and then to try adding further conditions on  $k_P$  and  $k_I$  to conclude the stability. Unfortunately, we have tried in this direction but without much success. This is due to the fact that when  $k_P$  and  $k_I$  are negative, the arguments of the proof of Theorem 2.6 fail. Indeed, one can easily check that for  $k_P, k_I < 0$  and for given  $\alpha, \beta$ , and  $\ell$ , the spectrum  $\sigma(\mathcal{A}_{PI})$  may contain many complex eigenvalues, and we cannot control their real parts by means of our approach. For instance, consider a river whose characteristics are  $\ell = 2700$ ,  $\alpha = 2000$ , and  $\beta = 0.9$  (see [31] for more details about this model). Then, let  $k_I = -0.01$  and  $k_P = -0.05$ . Using MAPLE, one can verify that  $\lambda = 0.001150641022 + i0.003238193679$  is an eigenvalue among others. This physical example shows that for  $k_P < 0$ , we may have complex eigenvalues with positive real part, and hence the closed-loop system is unstable. However, it is clear that this does not mean that the system is unstable whenever  $k_P < 0$ , but as mentioned above, this is a drawback of our approach. This is why we had to choose  $k_I < 0$  and  $k_P > 0$  in Theorem 2.6 to overcome this difficulty and conclude some results on the spectrum  $\sigma(\mathcal{A}_{PI})$ .

**5. Numerical applications.** Consider a river reach (1.1)–(1.2) with length  $\ell = 2000m$  and a reference discharge  $Q_0 = 2m^3/s$ . The coefficients are hence  $\alpha = 664m^2/s$  and  $\beta = 7.7854m/s$  (for more details about the model, the reader is referred to [18]). Now, assume the constant perturbation  $w = 1/2$  and the reference  $y_r = 1$ . Next, we apply the finite difference method for the space variable  $x$

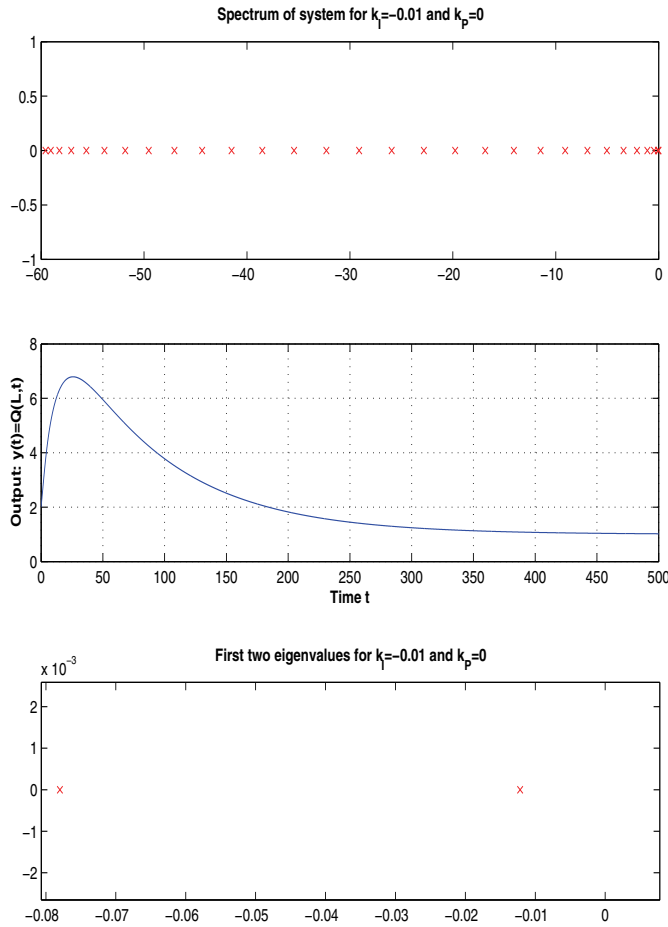

FIG. 6. Output regulation for  $K_I = -0.05$ ,  $K_P = 0$ .

to transform the distributed parameter system (1.1)–(1.2) to a first order system of differential equations and then use MATLAB. Taking the proportional gain  $k_P = 0$  and the integral gain  $k_I = -0.01$ , we observe that the system spectrum consists of negative real numbers, and the output  $y(t) = Q(\ell, t)$  is regulated to  $y_r = 1$  (see Figure 6). Furthermore, we notice that for sufficiently small values of  $k_P$ , the spectrum moves to the left in the sense that the first eigenvalue of the system is shifted to the left (see the third parts of Figures 6 and 7) and thus the regulation is guaranteed with smaller values of time  $t$  (see Figures 6 and 7). In other words, less time is needed to regulate the system, and hence both exponential stability and regulation are sped up. For  $k_P = 0.259$ , one complex conjugate pair, with negative real part, appears but we still have the stability as well as the regulation of the system (see Figure 8). However, although  $k_I$  is unchanged, i.e.,  $k_I = -0.01$ , if the proportional gain  $k_P$  is not “sufficiently small,” for instance,  $k_P = 0.9$ , there are two complex eigenvalues with positive real part, and hence neither the stability nor the output regulation is guaranteed (see Figure 9).

# APPROXIMATE FIXED POINT ITERATION WITH AN APPLICATION TO INFINITE HORIZON MARKOV DECISION PROCESSES\*

ANTHONY ALMUDEVAR†

**Abstract.** Many approximate iterative algorithms can be represented by the form  $V_n = TV_{n-1} + U_n$ ,  $n \geq 1$ , where  $V_{n-1}, U_n$ ,  $n \geq 1$ , are elements of a seminormed linear space  $(\mathcal{V}, \|\cdot\|)$  and  $T$  is a contractive operator. The objective is usually to calculate a fixed point  $V^*$  of  $T$ . Here, the quantities  $U_n$  may be interpreted as the errors obtained when the operator  $T$  can be evaluated only approximately. As is well known, in the absence of such an approximation error, the algorithm converges to a fixed point with a geometric rate under general conditions. In this article the convergence properties of such algorithms in the presence of an approximation error  $U_n$  are studied. It is shown that the error  $\|V_n - V^*\|$  is dominated by  $\|U_n\|$ , so that convergence of  $\|U_n\|$  to zero implies the convergence of  $\|V_n - V^*\|$  to zero, at a rate determined by  $\|U_n\|$ . The results are naturally extended to a relative error of the form  $\|U_n\|/\|V_{n-1}\|$ , as well as to  $J$ -stage contractions. The utility of this general theory is then demonstrated by an extended application to the problem of model-based approximate and adaptive control of Markov decision processes. The theory is shown to permit a sharpening of known convergence rates under more general conditions. Additionally, bounds on regret for adaptive controls with forced exploration are calculated in terms of a stagewise exploration rate. This permits the determination of an optimal choice of exploration rate within the class of certainty-equivalence adaptive control policies.

**1. Introduction.** Iterative algorithms play a central role in many areas of control theory, optimization, and numerical analysis. Such algorithms generate successive solutions  $V_n = TV_{n-1}$ ,  $n \geq 1$ , of a fixed point equation  $V = TV$  induced by a contractive operator  $T$ . Practical considerations often permit only an approximate evaluation of  $T$ , so characterizing the impact of such approximations is a problem of some importance. However, few general principles concerning this problem have emerged. The simplest case of a single uniform bound on approximations of  $T$  for one-dimensional real valued operators was considered in Isaacson and Keller [21]. More typically, the problem has been analyzed for specific applications. An important example is approximate value iteration for Markov decision processes (MDPs), discussed variously in Federgruen and Schweitzer [11], Hernández-Lerma [17], Moore and Atkeson [28], Bertsekas and Tsitsiklis [5], and Munos [29]. Additionally, approximate Monte Carlo schemes for iterative solutions of large linear and nonlinear systems of equations have been analyzed in Halton [14, 15].

The present article divides naturally into two parts. In the first, the basis for a general theory of approximate iterative algorithms is introduced. In the second, the utility of the approach is demonstrated with a detailed development of some

†Department of Biostatistics and Computational Biology, University of Rochester, Rochester, NY 14642 (anthony\_almudevar@urmc.rochester.edu).

problems associated with the approximate control of MDPs. In the remainder of this introduction a detailed outline is presented.

**1.1. General approximate iteration processes.** The general algorithm considered is of the form  $V_n = T_n V_{n-1} = TV_{n-1} + U_n$ , where  $V_{n-1}, U_n$  are elements of a seminormed linear space  $(\mathcal{V}, \|\cdot\|)$  on which the operator  $T$  is defined. It is assumed that  $T$  has a fixed point  $V^*$ , or an equivalence class of fixed points, to which the algorithm is designed to converge. This operator is assumed to be  $J$ -stage contractive of modulus  $\rho < 1$ . Then  $U_n$  may be interpreted as the error resulting from an approximate evaluation of  $TV_{n-1}$  in which  $T$  is replaced by an approximate operator  $T_n$ .

The main theoretical results are presented in section 2, consisting of a comprehensive study of the convergence properties of the general algorithm. In particular it is found that  $\|V_n - V^*\| \leq O(\max(\|U_n\|, (\rho + \epsilon)^n))$ ,  $\epsilon > 0$ , under general conditions. This result extends naturally to  $J$ -stage contractions and to the case of vanishing relative error  $\|U_n\|/\|V_{n-1}\| \rightarrow_n 0$ .

**1.2. Approximate and adaptive control of MDPs.** The remainder of the article consists of an application of the theoretical results to the problem of the approximate control of MDPs with infinite horizon and discounted costs. In the standard formulation, an MDP navigates indefinitely through a *state space*  $\mathcal{X}$  by discrete stages. At each state  $x$  an *action*  $a$  from *action space*  $\mathcal{A}$  is taken, resulting in *cost*  $R(x, a)$ . The process transfers to a subsequent state according to probability measure  $Q(\cdot | x, a)$ . The state-action space  $\mathcal{K} \subset \mathcal{X} \times \mathcal{A}$  consists of all state-action pairs  $(x, a)$  for which action  $a$  is available from state  $x$ . If  $\beta$  is the discount factor, we refer to the object  $\pi = (\mathcal{K}, Q, R, \beta)$  as a Markov control model (MCM). A *control policy*  $\Phi$  is a rule (which may be probabilistic) for choosing an action based on the current state and process history. An MCM  $\pi$  together with a control policy  $\Phi$  defines an MDP. The objective is to minimize the expected total discounted cost from any given initial state.

Calculation of an optimal control usually proceeds by considering the *value function*  $V_\pi^*$ , which gives the lowest achievable expected discounted cost  $V_\pi^*(x)$  for initial state  $x$  under MCM  $\pi$ . Under general conditions,  $V_\pi^*$  is the fixed point of the *Bellman operator*  $T_\pi$ , which is defined for a specific MCM  $\pi$ . Then  $V_\pi^*$  may be calculated by the iterative algorithm  $V_n = T_\pi V_{n-1}$ ,  $n \geq 1$ , usually referred to as the *value iteration* (VI), and it is easily established that the algorithm converges to  $V_\pi^*$ . The optimal control can then be derived by first calculating  $V_\pi^*$ , then implicitly through an evaluation of  $T_\pi V_\pi^*$ . Therefore,  $\pi$  must be known in order to optimize cost.

Often, the evaluation of  $T_\pi V$  is impossible or impractical. Two important cases may be identified. The first arises when the evaluation of  $T_\pi V$  is computationally unfeasible and is carried out using approximation methods [5]. The second case arises when the MCM  $\pi$  on which  $T_\pi$  depends is unknown but may be estimated (see, for example, Kumar and Varaiya [24] or Hernández-Lerma [17]). In each case, a VI algorithm may be carried out approximately, resulting in some estimate of  $V_\pi^*$ . What is needed is to first characterize the effect of the approximation on the evaluation of  $T_\pi V$  and then to deduce the behavior of the approximate VI algorithm.

New issues arise when considering *adaptive control policies*, definable as policies which refine the applied control using data collected while the MDP is active. Ideally, these policies approach optimal cost performance when  $\pi$  is unknown. The analytical object is to estimate *regret*, which is the excess in costs obtainable from the adaptive control over the optimal costs obtainable when  $\pi$  is known. Because many such

policies rely on sequential refinements of estimates of  $V_\pi^*$ , the theory of approximate VI has direct bearing on the estimation of regret. Thus, the problem of approximating the value function and the problem of adaptive control are naturally considered in sequence, as in Hernández-Lerma and Marcus [16] and Hernández-Lerma [17], and which is the approach taken here.

The overall strategy will be to consider approximate VI as a special case of the general algorithm discussed in section 2. If  $\hat{\pi}$  is an estimate of MCM  $\pi$ , then the Bellman operator  $T_\pi$  can be approximated by  $T_{\hat{\pi}}$ . The analysis then proceeds by first defining a distance between models  $\pi$  and  $\hat{\pi}$ , then bounding  $\|T_\pi V - T_{\hat{\pi}} V\|$  with this distance for a suitable norm. Once this is done, the properties of approximate VI algorithms, and of approximate and adaptive controls, may be deduced directly from the model estimation process. Because the main results follow from properties which may be characterized purely in terms of normed linear spaces, it becomes straightforward to define a single general model. In the development which follows,  $\mathcal{X}$  and  $\mathcal{A}$  will be general Borel spaces. We also permit the cost function  $R(x, a)$  to be unbounded. The essential condition is the existence of a norm with respect to which the Bellman operator  $T_\pi$  is  $J$ -stage contractive. In this article we employ the class of weighted supremum norms. Much of the technical details presented here follow approaches taken in previous work in the literature but are needed to accommodate the use of this type of norm, as well as the related model distance, as will now be discussed.

**1.2.1. Approximate VI with general bounds.** When VI can be implemented only approximately, this can be modelled by a sequence of approximate operators  $T_n$ ,  $n \geq 1$ , close to the Bellman operator  $T_\pi$  in some sense, which defines an *approximate value iteration* algorithm (AVIA)  $V_n = T_n V_{n-1}$ ,  $n \geq 1$ . The technical problem is then to bound  $\|V_n - V_\pi^*\|$  asymptotically, or for finite  $n$  as needed. Such a bound will follow from a uniform bound on evaluation error  $\|T_n V_{n-1} - T_\pi V_{n-1}\| \leq \epsilon$  as discussed in, for example, [5, 29].

Such uniform bounds may also be obtained directly from the theory in section 2, and they rely primarily on the contractive properties of  $T_\pi$ . The analysis may then be extended to nonstationary bounds  $\|T_n V_{n-1} - T_\pi V_{n-1}\| \leq \epsilon_n$ . When these bounds converge to zero, it follows that the AVIA converges to  $V_\pi^*$  with a rate determined by  $\epsilon_n$ . The result holds when only relative error  $\|T_n V_{n-1} - T_\pi V_{n-1}\|/\|V_{n-1}\| \leq \epsilon_n$  can be bounded. The results are easily extended to  $J$ -stage contractive operators.

**1.2.2. Approximate VI using model estimates.** In section 3 the general MDP model is defined, and the problem of approximate VI based on model estimation is considered. A model distance between  $\pi$  and  $\hat{\pi}$  is defined and used to bound evaluation error  $\|T_{\hat{\pi}} V - T_\pi V\|$ , allowing for weighted supremum norms.

If we are given a sequence of estimates  $\hat{\pi}_n$ ,  $n \geq 1$ , of a model  $\pi$ , then an AVIA can be defined by the approximate operators  $T_n = T_{\hat{\pi}_n}$ . In [11] it was shown for finite  $\mathcal{K}$  that if the model estimates are consistent, this AVIA will converge to  $V_\pi^*$ . A convergence rate was also determined, which depends directly on the rate of convergence of the model estimate. In [17] this result was extended to general (Borel) state-action spaces with bounded costs. We improve on these results in two ways, first by allowing unbounded costs and general state-action spaces, then by strictly improving the rates of convergence reported in [11, 17].

As an alternative to the AVIA, we may determine the fixed point of each operator  $T_{\hat{\pi}_n}$ , yielding a sequence of value functions  $V_n$  for each approximate MCM  $\hat{\pi}_n$ . We refer to this as a *certainty-equivalence* algorithm (CEA). Intuitively, this would seem to be

the superior approach, provided it is computationally feasible. Rates of convergence of  $V_n$  to  $V_\pi^*$  are reported in [17] for the CEA, and equivalent rates for the more general model are derived in section 3 below. Interestingly, the rates of convergence for the AVIA reported in [11, 17] are strictly slower than for the CEA, whereas the sharper rates derived in section 3 below are equivalent to those for the CEA, except that they are asymptotic.

**1.2.3. Adaptive control policies.** A model-based adaptive control policy generates a sequence of model estimates  $\hat{\pi}_n$ ,  $n \geq 1$ , typically using process history, while exploiting these estimates to approximate optimal control. One natural approach, known as the *principle of estimation and control* (PEC) [17] (alternatively, *certainty-equivalence* [24]), is to refine at regular intervals the applied control policy based on the most recent model estimate. This may be done using a synchronous AVIA or CEA.

In section 4, the problem of estimating the regret of an adaptive control policy is discussed. Here we follow the approach taken in Schäl [30], in which the concept of *asymptotic discount optimality* was introduced. If the initial state  $x$  of the MDP is fixed, we may consider the expected remaining discounted cost at stage  $n$  under a policy  $\Phi$  and compare it to the expected remaining discounted cost when  $\Phi$  is used up to stage  $n - 1$  and the optimal control is used subsequently. In [30] costs may be unbounded and the action space is Borel, whereas the state space is assumed to be countable. The concept has been extended to more general models in [17] and in Hernández-Lerma and Lasserre [18, 19]. In section 4, bounds are developed for the general model which employ the weighted supremum norm and the model distances developed in section 3.

In section 5, the parameterization of the MCM is discussed, with the objective of verifying that model distances developed in section 3 are Lipschitz continuous on the parameter space. Similar concepts are reported in, for example, [24, 17], but are here extended to accommodate weighted supremum norms.

**1.2.4. Forced exploration.** It is important to note that for a general PEC adaptive control policy there is no guarantee that the applied control approaches the optimal one, since the model estimate need not be consistent under these conditions [24]. The issue is a fundamental one, since if optimal control is not approached, the MDP will indefinitely accrue excess costs (i.e., nonzero regret). Technically, the issue is straightforward. Suppose  $\mathcal{K}$  is discrete. In the absence of additional structure, a consistent estimate of the MCM is not achievable unless each available action is selected from each state infinitely often, which is not guaranteed using a PEC policy.

When convergence of a PEC policy to optimal performance cannot be guaranteed, one alternative is the use of *forced exploration*, in which exploratory selection of actions alternates with the application of an approximately optimal policy. If the exploration frequency is decreased at a suitable rate, then consistency conditions may be met, while achieving convergence to optimal performance. Such policies have been proposed in Kumar and Varaiya [24] and Cybenko, Gray, and Moizumi [7], with convergence to optimality verified. In Kearns and Singh [23] a policy which directs the MDP to underexplored states was proposed, with reported regret bounds of order  $n^{-1/5}$  after the  $n$ th stage. This applies to a discounted and average cost criterion for finite  $\mathcal{K}$ .

In section 6 a form of adaptive control is presented which accommodates forced exploration in the form of scheduled randomized exploration. A rate of exploration  $\alpha_n$  is defined, interpreted as the frequency of exploratory stages near stage  $n$ . This rate

then determines the rate of convergence for model estimates. The theory of sections 3, 4, and 5 then permits a careful calculation of a bound on regret, which may be decomposed into regret due to suboptimal control and due to forced exploration. This in turn permits selection of an optimal rate of exploration. In particular, we find that among exploration rates proportional to  $n^{-r}$ , the optimal choice is  $r = 1/3$ , resulting in a bound on regret of order  $n^{-1/3}$ , whereas if forced exploration were not needed, a bound of order  $n^{-1/2}$  would be obtained.

**1.2.5. Model-free adaptive control policies.** Although the methods considered in this paper rely on model estimation, it is important to note that a number of model-free methods exist (see Sutton and Barto [31]). A well-known example is *Q-learning*, due to Watkins [37] (see also Watkins and Dayan [38]), which is a method of directly estimating the value function, and hence the optimal control, from online data. Conditions for convergence include visitation of each state-action pair  $(x, a)$  infinitely often so, as for a PEC policy, forced exploration may be necessary. See Tsitsiklis [34] for rigorous convergence criteria. Q-learning has a convergence rate that is strictly greater than the PEC policy. See Szepesvári [32], Kearns and Singh [22], or Evan-Dar and Mansour [10] for a discussion of this issue. On the other hand, the principal advantage of Q-learning is that value function estimates are updated without integration over  $\mathcal{X}$ . Thus Q-learning may be preferable to a PEC policy when updating the control using VI is not feasible online.

A bandit theory approach to the adaptive control of MDPs is proposed in Lai and Yakowitz [25]. This adaptive control policy proceeds by applying to the MDP in turn a sequence of control policies selected in random order. The selection procedure tends to remain longer in controls with lower observed costs. For general  $\mathcal{X}$  and countably many control policies, this approach achieves a growth in cumulative regret for undiscounted costs of  $O(a_n \log(n))$  for any increasing unbounded sequence  $a_n$ . This is equivalent to a stage  $n$  regret less than  $n^{-1+\epsilon}$ ,  $\epsilon > 0$ . However, exploratory randomization is applied over the entire space of control policies rather than the action space, which is the more common approach. Unless the set of control policies is of low dimension, the resulting performance will be subject to a high degree of variability attributable to the randomization scheme, an effect reported in [25]. Despite this, the much faster theoretical rate of convergence suggests that a careful comparison of this approach with the one described in section 6 is warranted.

**2. Approximate fixed point algorithms.** Suppose  $(\mathcal{V}, \|\cdot\|)$  is a seminormed linear space on which a mapping  $T : \mathcal{V} \rightarrow \mathcal{V}$  is given. Define the operator  $T^J : \mathcal{V} \rightarrow \mathcal{V}$  to be the  $J$ th iteration of  $T$  on any element of  $\mathcal{V}$ . Consider the following two assumptions:

- (A1) *Pseudocontraction.* There exists  $V^* \in \mathcal{V}$  with  $\|V^*\| < \infty$ , a positive integer  $J$ , and a constant  $\rho \in (0, 1)$  such that  $TV^* = V^*$  and  $\|T^J V - T^J V^*\| \leq \rho \|V - V^*\|$  for all  $V \in \mathcal{V}$ .
- (A2) *Lipschitz continuity.* There exists finite  $L$  such that  $\|TV_1 - TV_2\| \leq L\|V_1 - V_2\|$  for all  $V_1, V_2 \in \mathcal{V}$ .

If (A1) holds and  $\|\cdot\|$  is a true norm,  $V^*$  is the unique fixed point of  $T$ . If  $\|\cdot\|$  is a seminorm, any other fixed point is a member of an equivalence class  $\{V \in \mathcal{V} : \|V - V^*\| = 0\}$ . We will study convergence properties of sequences of the form  $\|V_n - V^*\|$  exclusively. Whether this implies convergence of  $V_n$  to  $V^*$  in some other sense depends on the particular structure of the seminorm.

For most of the theory presented in this article the *pseudocontraction* condition of (A1) suffices. The stronger conditions under which the Banach fixed point theorem

holds ( $T$  is ( $J$ -stage) contractive and  $(\mathcal{V}, \|\cdot\|)$  is closed and complete) imply (A1). In either case for the fixed point algorithm

$$(2.1) \quad \begin{aligned} V_0 &= v_0 \in \mathcal{V}, \\ V_n &= TV_{n-1}, \quad n \geq 1, \end{aligned}$$

$\|V_n - V^*\|$  converges to zero. Assumption (A2) will be employed in addition to (A1) when  $J > 1$ .

The purpose of this article is to study the related algorithm

$$(2.2) \quad \begin{aligned} V_0 &= v_0 \in \mathcal{V}, \\ V_n &= TV_{n-1} + U_n, \quad n \geq 1, \end{aligned}$$

where  $U_n \in \mathcal{V}$  is in some sense small and typically represents the error term of an approximate evaluation of  $TV_{n-1}$ . It will be natural to think of (2.2) as arising from the replacement of operator  $T$  with an approximate operator  $T_n$  for the  $n$ th iteration, setting  $T_n V_{n-1} = TV_{n-1} + U_n$ . We will generally impose the following assumption on any approximate algorithm (2.2).

(A3) In (2.2),  $\|v_0\| < \infty$  and  $\|U_n\| < \infty$  for  $n \geq 1$ .

Condition (A1) with  $J = 1$  and (A3) guarantees that each iterate has a finite seminorm, since

$$(2.3) \quad \begin{aligned} \|V_n\| &\leq \|V^*\| + \|V_n - V^*\| \leq \|V^*\| + \rho\|V_{n-1} - V^*\| + \|U_n\| \\ &\leq \rho\|V_{n-1}\| + (1 + \rho)\|V^*\| + \|U_n\|, \quad n \geq 1, \end{aligned}$$

and we have  $\|V_0\| < \infty$ . Conditions (A2) and (A3) also imply  $\|V_n\| < \infty$ ,  $n \geq 1$ , by the same argument with  $\rho$  replaced by  $L$ .

Our immediate objective is to show that  $\|U_n\| \rightarrow_n 0$  implies  $\|V_n - V^*\| \rightarrow_n 0$  in (2.2), or, when  $\|U_n\|$  does not converge to zero, to bound the quantity  $\|V_n - V^*\|$  in terms of the error magnitudes  $\|U_n\|$ .

**2.1. Introductory lemmas.** The results given in this section depend on the properties of summations of the form  $\sum_{i=1}^n \rho^{n-i} \alpha_i$ , where  $\rho \in (0, 1)$  and the sequence  $\alpha_1, \alpha_2, \dots$  is some representation of the magnitude of the error sequence  $U_1, U_2, \dots$ .

LEMMA 2.1. *If  $\alpha_1, \alpha_2, \dots$  is a sequence of real numbers in  $[0, \infty)$  and  $\rho \in (0, 1)$ , then*

$$(2.4) \quad \limsup_{n \rightarrow \infty} \sum_{i=1}^n \rho^{n-i} \alpha_i \leq \limsup_{n \rightarrow \infty} \frac{\alpha_n}{1 - \rho}.$$

*Proof.* We may assume  $\limsup_{n \rightarrow \infty} \alpha_n = K$  is finite; otherwise (2.4) holds trivially. Then for any  $\epsilon > 0$  we may select finite  $N_\epsilon$  such that  $\sup_{i > N_\epsilon} \alpha_i \leq K + \epsilon$ . Then for  $n > N_\epsilon$ ,

$$\sum_{i=1}^n \rho^{n-i} \alpha_i = \sum_{i=1}^{N_\epsilon} \rho^{n-i} \alpha_i + \sum_{i=N_\epsilon+1}^n \rho^{n-i} \alpha_i \leq \rho^n \sum_{i=1}^{N_\epsilon} \rho^{-i} \alpha_i + (K + \epsilon) \sum_{i=0}^n \rho^{n-i}.$$

The first term of this upper bound is  $\rho^n$  multiplied by a finite summation which does not depend on  $n$ ; hence this term vanishes as  $n \rightarrow \infty$ . The second term converges to  $(K + \epsilon)/(1 - \rho)$ . This is true for any  $\epsilon$ , from which (2.4) follows.  $\square$

The following lemma is a version of L'Hôpital's rule, the proof of which follows Theorem 9.1 in Fischer [13].

LEMMA 2.2. *Suppose  $\{a_n\}$ ,  $\{b_n\}$  are two real valued sequences such that  $b_{n+1} > b_n > 0$  for all  $n$ , and  $\lim_{n \rightarrow \infty} b_n = \infty$ . Then for any finite  $L$ ,*

$$(2.5) \quad \liminf_{n \rightarrow \infty} \frac{a_{n+1} - a_n}{b_{n+1} - b_n} \geq L \text{ implies } \liminf_{n \rightarrow \infty} \frac{a_n}{b_n} \geq L.$$

*Proof.* Suppose for each  $\epsilon > 0$  there exists  $N_\epsilon$  such that  $(a_{n+1} - a_n)/(b_{n+1} - b_n) > L - \epsilon$  for  $n \geq N_\epsilon$ . It follows that, for  $k > 0$ ,

$$\frac{a_{N_\epsilon+k} - a_{N_\epsilon}}{b_{N_\epsilon+k} - b_{N_\epsilon}} > L - \epsilon,$$

which is equivalent to

$$\frac{a_{N_\epsilon+k}}{b_{N_\epsilon+k}} > \frac{a_{N_\epsilon}}{b_{N_\epsilon+k}} + \left(1 - \frac{b_{N_\epsilon}}{b_{N_\epsilon+k}}\right)(L - \epsilon).$$

Letting  $k \rightarrow \infty$  gives

$$\liminf_{k \rightarrow \infty} \frac{a_{N_\epsilon+k}}{b_{N_\epsilon+k}} > L - \epsilon,$$

from which (2.5) follows.  $\square$

If  $\alpha_i$  converges at a well-defined rate, then we can express the convergent behavior of  $\sum_{i=1}^n \rho^{n-i} \alpha_i$  in terms of that of  $\alpha_i$ .

LEMMA 2.3. *Suppose  $\rho > 0$ . Let  $\{\alpha_n\}$  be a positive sequence of real numbers. Let*

$$r_u = \limsup_{n \rightarrow \infty} \frac{\alpha_{n-1}}{\alpha_n}.$$

*Suppose  $\sum_{i=1}^n \rho^{-i} \alpha_i = \infty$ . Then*

$$(2.6) \quad \liminf_{n \rightarrow \infty} \frac{\rho^{-n} \alpha_n}{\sum_{i=1}^n \rho^{-i} \alpha_i} \geq 1 - r_u \rho.$$

*Proof.* Using the notation of Lemma 2.2, set  $a_n = \rho^{-n} \alpha_n$  and  $b_n = \sum_{i=1}^n \rho^{-i} \alpha_i$ . Then

$$\frac{a_n - a_{n-1}}{b_n - b_{n-1}} = \frac{\rho^{-n} \alpha_n - \rho^{-(n-1)} \alpha_{n-1}}{\rho^{-n} \alpha_n} = 1 - \rho \frac{\alpha_{n-1}}{\alpha_n}.$$

Taking the limit supremum and applying Lemma 2.2 gives (2.6).  $\square$

We deal separately with the case of geometric rate  $\rho$ .

LEMMA 2.4. *If, for  $\rho \in (0, 1)$ ,*

$$\limsup_{n \rightarrow \infty} n^{-1} \log(\alpha_n) \leq \log(\rho),$$

*then*

$$(2.7) \quad \limsup_{n \rightarrow \infty} n^{-1} \log \left( \sum_{i=1}^n \rho^{n-i} \alpha_i \right) \leq \log(\rho).$$

*Proof.* By hypothesis, given  $\epsilon > 0$  there exists finite  $K_\epsilon$  such that  $\alpha_n \leq K_\epsilon(\rho + \epsilon)^n$  for all  $n$ . Then

$$\begin{aligned} n^{-1} \log \left( \sum_{i=1}^n \rho^{n-i} \alpha_i \right) &\leq n^{-1} \log \left( K_\epsilon \rho^n \sum_{i=1}^n (1 + \epsilon/\rho)^i \right) \\ &\leq \log(\rho) + n^{-1} \log \left( K_\epsilon \frac{(1 + \epsilon/\rho)^{n+1}}{\epsilon/\rho} \right) \\ &= \log(\rho) + \log(1 + \epsilon/\rho) + n^{-1} \log(K_\epsilon(\rho/\epsilon + 1)). \end{aligned}$$

Taking the limit supremum gives

$$\limsup_{n \rightarrow \infty} n^{-1} \log \left( \sum_{i=1}^n \rho^{n-i} \alpha_i \right) \leq \log(\rho) + \log(1 + \epsilon/\rho),$$

which gives (2.7) by making  $\epsilon$  arbitrarily small.  $\square$

**2.2. Single stage contractions.** The aim of this subsection is to study those convergence properties of  $\|V_n - V^*\|$  of (2.2) which follow from the convergence properties of  $U_n$ ,  $n \geq 1$ , when (A1) holds with  $J = 1$ . We additionally assume (A3) holds, which guarantees that the iterates have finite seminorm. We first show that the algorithmic accuracy  $\|V_n - V^*\|$  can be asymptotically bounded by the error magnitude  $\|U_n\|$ .

LEMMA 2.5. *If in (2.2) (A1) ( $J=1$ ) and (A3) hold, then*

$$(2.8) \quad \limsup_{n \rightarrow \infty} \|V_n - V^*\| \leq (1 - \rho)^{-1} \limsup_{n \rightarrow \infty} \|U_n\|.$$

*Proof.* Fix any initial point  $v_0 \in \mathcal{V}$ . Subtract  $V^*$  from each side of (2.2), giving for  $n \geq 1$ ,

$$(2.9) \quad \begin{aligned} \|V_n - V^*\| &= \|TV_{n-1} - V^* + U_n\| \leq \|TV_{n-1} - V^*\| + \|U_n\| \\ &= \|TV_{n-1} - TV^*\| + \|U_n\| \leq \rho \|V_{n-1} - V^*\| + \|U_n\|. \end{aligned}$$

Applying (2.9) iteratively gives

$$(2.10) \quad \|V_n - V^*\| \leq \rho^n \|V_0 - V^*\| + \sum_{i=1}^n \rho^{n-i} \|U_i\|.$$

Then (2.8) follows by applying Lemma 2.1 and noting that  $\rho < 1$ .  $\square$

By Lemma 2.5 the boundedness of (2.2) follows from the boundedness of the sequence  $\|U_n\|$ . In some applications it may be more natural to bound the relative error  $\|U_n\|/\|V_{n-1}\|$ . Lemma 2.6 deals with a somewhat more general case in which bounds are assumed on the sequence  $\|U_n\|/\max(s, \|V_{n-1}\|)$ , where  $s$  is a nonnegative constant.

LEMMA 2.6. *If in (2.2) (A1) ( $J = 1$ ) and (A3) hold, then for any  $s \geq 0$  and  $\delta \in [0, 1 - \rho)$ ,*

$$\limsup_{n \rightarrow \infty} \|U_n\|/\max(s, \|V_{n-1}\|) = \delta,$$

*then*

$$\limsup_{n \rightarrow \infty} \|V_n - V^*\| \leq \delta(1 - \rho - \delta)^{-1} \max(s, \|V^*\|).$$

*Proof.* Fix  $\epsilon > 0$  such that  $\rho + \delta + \epsilon < 1$ . Then there exists  $N_\epsilon$  such that  $\|U_n\| \leq (\delta + \epsilon) \max(s, \|V_{n-1}\|)$  for all  $n \geq N_\epsilon$ . Then

$$\begin{aligned}
 \|V_n - V^*\| &\leq \|TV_{n-1} - TV^*\| + \|U_n\| \\
 &\leq \rho\|V_{n-1} - V^*\| + (\delta + \epsilon) \max(s, \|V_{n-1}\|) \\
 &\leq \rho\|V_{n-1} - V^*\| + (\delta + \epsilon) \max(s, \|V_{n-1} - V^*\| + \|V^*\|) \\
 &= \max(\rho\|V_{n-1} - V^*\| + (\delta + \epsilon)s, (\rho + \delta + \epsilon)\|V_{n-1} - V^*\| + (\delta + \epsilon)\|V^*\|) \\
 (2.11) \quad &\leq (\rho + \delta + \epsilon)\|V_{n-1} - V^*\| + (\delta + \epsilon) \max(s, \|V^*\|), \quad n \geq N_\epsilon.
 \end{aligned}$$

Applying (2.11) iteratively,

$$\begin{aligned}
 \|V_{N_\epsilon+n} - V^*\| &\leq (\rho + \delta + \epsilon)^n \|V_{N_\epsilon} - V^*\| + (\delta + \epsilon) \sum_{i=0}^{n-1} (\rho + \delta + \epsilon)^i \max(s, \|V^*\|) \\
 &\leq (\rho + \delta + \epsilon)^n \|V_{N_\epsilon} - V^*\| + (\delta + \epsilon)(1 - \rho - \delta - \epsilon)^{-1} \max(s, \|V^*\|);
 \end{aligned}$$

hence

$$\limsup_{n \rightarrow \infty} \|V_n - V^*\| \leq (\delta + \epsilon)(1 - \rho - \delta - \epsilon)^{-1} \max(s, \|V^*\|),$$

which proves the theorem by making  $\epsilon$  arbitrarily small.  $\square$

The next lemma gives some conditions under which the rate of convergence of  $\|V_n - V^*\|$  may be bounded.

LEMMA 2.7. *If in (2.2) (A1) ( $J = 1$ ) and (A3) hold, then*

(i)  $\sum_{i=1}^{\infty} \rho^{-i} \|U_i\| < \infty$  *implies*

$$(2.12) \quad \limsup_{n \rightarrow \infty} \rho^{-n} \|V_n - V^*\| < \infty;$$

(ii)  $\limsup_{n \rightarrow \infty} n^{-1} \log(\|U_n\|) \leq \log(\rho)$  *implies*

$$(2.13) \quad \limsup_{n \rightarrow \infty} n^{-1} \log(\|V_n - V^*\|) \leq \log(\rho);$$

(iii) *for any sequence  $\{d_i\}$ ,  $d_i \in (0, \infty)$  satisfying  $\|U_i\| \leq d_i$ ,  $i \geq 1$ , if  $r_u < \rho^{-1}$ , where  $r_u = \limsup_{n \rightarrow \infty} d_{n-1}/d_n$ , then*

$$(2.14) \quad \limsup_{n \rightarrow \infty} d_n^{-1} \|V_n - V^*\| \leq (1 - r_u \rho)^{-1}.$$

*Proof.* We treat the three cases in order.

(i) If  $\sum_{i=1}^{\infty} \rho^{-i} \|U_i\| = K < \infty$ , then from (2.10) we have

$$\|V_n - V^*\| \leq \rho^n \|V_0 - V^*\| + \rho^n K,$$

from which (2.12) follows.

(ii) From (2.10) we may write

$$n^{-1} \log(\|V_n - V^*\|) \leq n^{-1} \log \left( \rho^n \|V_0 - V^*\| + \sum_{i=1}^n \rho^{n-i} \|U_i\| \right).$$

Apply Lemma 2.4 to the above inequality, setting  $\alpha_i = \|U_i\|$  for  $i > 1$  and  $\alpha_1 = \|U_1\| + \rho\|V_0 - V^*\|$ . This yields (2.13).

(iii) From (2.10) we may write

$$(2.15) \quad d_n^{-1} \|V_n - V^*\| \leq \frac{\|V_0 - V^*\| + \sum_{i=1}^n \rho^{-i} d_i}{\rho^{-n} d_n}.$$

Note that  $r_u < \rho^{-1}$  implies  $\sum_{i=1}^{\infty} \rho^{-i} d_i = \infty$ ; hence taking the limit supremum of (2.15) while applying Lemma 2.3, noting that  $(1 - r_u \rho) > 1$ , yields (2.14).  $\square$

*Remark 2.1.* The sequence  $\{d_i\}$  in Lemma 2.7(iii) may be chosen so as to readily calculate  $r_u$ . If  $r_u = \rho^{-1}$ , then part (ii) is used, since the upper bound in (2.14) is  $\infty$ . As an example, if the sequence  $\{U_n\}$  is a mapping of independent and identically distributed (i.i.d.) sequences we may be able to deduce from the law of the iterated logarithm  $\|U_n\| \leq d_n = Kn^{-1/2} \log \log n$  for some finite  $K$ , in which case  $r_u = 1$ .

Conversely, we may devise a bounding sequence  $\{d_i\}$  which converges to zero, but which can't be used in Lemma 2.7 to obtain a meaningful rate under the assumption that  $\|U_n\| \leq d_n$ . For some  $\rho \in (0, 1)$  let  $d_n = \sup\{\rho^i : \rho^i \leq 1/n, i \in \mathbb{Z}^+\}$ . For large enough  $n$ ,  $d_n > \rho^n$  and so  $\sum_{i=1}^{\infty} \rho^{-i} d_i = \infty$ ; thus condition (i) is not applicable. Then note that there is an increasing subsequence  $n_i$ ,  $i \geq 1$ , such that  $d_{n_i} > 1/(n_i + 1)$ , from which it follows that  $\limsup_{n \rightarrow \infty} n^{-1} \log(d_n) = 0$ , so that condition (ii) is not applicable. In addition,  $r_u = \rho^{-1}$  so condition (iii) is not applicable. The situation is easily remedied by noting that  $d_n \leq 1/n$ , for which  $r_u = 1$ , so that a finite rate can be deduced using Lemma 2.7(iii). In general, if a sequence does not satisfy  $r_u < \rho^{-1}$ , it may be dominated by one that does.

Clearly, algorithm (2.2) will not converge more quickly than the error term. This is expressed formally in the next theorem. Note that in the following theorem  $T$  need not be a contraction map. In place, a weaker form of (A2) suffices.

**THEOREM 2.8.** *In algorithm (2.2) let*

$$d_n = \sup_{n' \geq n} \|U_{n'}\|$$

for  $n \geq 1$ . If  $V^*$  is a fixed point of  $T$ , and there exists a finite constant  $L$  such that  $\|TV - TV^*\| \leq L\|V - V^*\|$  for all  $V \in \mathcal{V}$ , then

$$(2.16) \quad \limsup_{n \rightarrow \infty} \frac{\|V_{n-1} - V^*\|}{d_n} > 0.$$

*Proof.* Suppose (2.16) does not hold. Fix  $\epsilon > 0$ . Then there exists  $N$  such that

$$(2.17) \quad \|V_{n-1} - V^*\| \leq \epsilon d_n \quad \forall n \geq N.$$

Let  $N_1$  be the smallest integer not less than  $N$  such that  $\|U_{N_1}\| \geq (1 - \epsilon)d_N$ , which exists by the definition of  $d_n$ . This implies  $\|U_{N_1}\| \geq (1 - \epsilon)d_{N_1}$ . Applying (2.17) gives

$$\begin{aligned} \|U_{N_1}\| &= \|(V_{N_1} - V^*) - (TV_{N_1-1} - TV^*)\| \\ &\leq \|V_{N_1} - V^*\| + \|TV_{N_1-1} - TV^*\| \\ &\leq \|V_{N_1} - V^*\| + L\|V_{N_1-1} - V^*\| \\ &\leq \epsilon d_{N_1+1} + L\epsilon d_{N_1} \\ &\leq (1 + L)\epsilon d_{N_1}. \end{aligned}$$

We can always set  $\epsilon$  small enough to force  $(1 + L)\epsilon d_{N_1} < (1 - \epsilon)d_{N_1}$ , in which case (2.17) leads to a contradiction, since  $\|U_{N_1}\| \geq (1 - \epsilon)d_{N_1}$ . Hence (2.16) follows.  $\square$

**2.3.  $J$ -stage contractions.** The results of the previous subsection extend naturally to  $J$ -stage contractions with the additional assumption that the operator is first order Lipschitz. Note that if  $L < 1$  in (A2), then  $T$  is contractive, and the previous results apply directly.

Consider the  $J$ -stage error term of (2.2),

$$W_n^J = V_n - T^J V_{n-J}, \quad n \geq J.$$

Under assumptions (A2) and (A3),  $\|V_n\|$  and  $\|T^J V_n\|$  are finite; hence so is  $\|W_n^J\|$ . The subsequence

$$(2.18) \quad V_{mJ+k} = T^J V_{(m-1)J+k} + W_{mJ+k}^J, \quad m \geq 1,$$

is then of type (2.2) with operator  $T^J$  satisfying (A1) and (A3) for  $J = 1$ , after a suitable relabelling, and the results of the previous subsection apply directly. However, bounds may be more naturally obtained for  $U_n$  as originally defined in (2.2). Hence the strategy in this subsection will be to derive generalizations of Lemmas 2.5–2.7 to the general  $J$ -stage contraction operator (Theorems 2.10, 2.11, and 2.12, respectively) while maintaining bounding conditions expressed in terms of the single stage error  $U_n$ . Note that Theorem 2.8 already applies to the general case.

We will need the following lemma.

LEMMA 2.9. *For algorithm (2.2) if (A2) holds, then for any  $I \geq 1$ ,  $n \geq 0$ ,*

$$(2.19) \quad \|V_{n+I} - T^I V_n\| \leq \sum_{i=1}^I L^{I-i} \|U_{n+i}\|.$$

*Proof.* We proceed by induction. Suppose (2.19) holds for some  $I \geq 1$ ; then

$$\begin{aligned} \|V_{n+I+1} - T^{I+1} V_n\| &= \|TV_{n+I} - T^{I+1} V_n + U_{n+I+1}\| \\ &\leq \|TV_{n+I} - T^{I+1} V_n\| + \|U_{n+I+1}\| \\ &\leq L\|V_{n+I} - T^I V_n\| + \|U_{n+I+1}\| \\ &\leq L \sum_{i=1}^I L^{I-i} \|U_{n+i}\| + \|U_{n+I+1}\| \\ &\leq \sum_{i=1}^{I+1} L^{I+1-i} \|U_{n+i}\|, \end{aligned}$$

and (2.19) holds for  $I+1$ . That (2.19) holds for  $I = 1$  follows directly from (2.2).  $\square$

By Lemma 2.9  $\|U_n\| \rightarrow_n 0$  directly implies  $\|W_n^J\| \rightarrow_m 0$  and therefore  $\|V_{mJ+k} - V^*\| \rightarrow_m 0$ . This holds for  $k = 0, \dots, J-1$ , from which it follows that  $\|V_n - V^*\| \rightarrow_n 0$ .

Define a *block error*

$$B_n^{J,L} = \sum_{j=1}^J L^{J-j} \|U_{n-J+j}\|, \quad n \geq J \text{ and } B_n^{J,L} = 0, \quad n < J,$$

for  $J \geq 1$ ,  $L \in \mathbb{R}^+$ . Note that for  $J = 1$ ,  $B_n^{J,L} = \|U_n\|$  for any value of  $L$ . Directly from Lemma 2.9, the error term in (2.18) can be bounded by

$$(2.20) \quad \|W_{mJ+k}^J\| \leq B_{mJ+k}^{J,L}, \quad m \geq 1.$$

Theorem 2.10 generalizes Lemma 2.5 to  $J$ -stage contractions.

THEOREM 2.10. *If in (2.2) (A1) and (A3) hold, and (A2) holds when  $J > 1$ , then*

$$(2.21) \quad \limsup_{n \rightarrow \infty} \|V_n - V^*\| \leq (1 - \rho)^{-1} \limsup_{n \rightarrow \infty} B_n^{J,L}.$$

*Proof.* If  $J = 1$ , set  $L$  to be any positive number. Then by (2.20) and Lemma 2.5 applied to (2.18) for some fixed  $k \geq 0$ ,

$$\limsup_{m \rightarrow \infty} \|V_{mJ+k} - V^*\| \leq \limsup_{m \rightarrow \infty} B_{mJ+k}^{J,L},$$

which holds for  $k = 0, \dots, J-1$ , from which (2.21) follows.  $\square$

Similarly, Theorem 2.11 generalizes Lemma 2.6.

THEOREM 2.11. *If in (2.2) (A1) and (A3) hold, and (A2) holds when  $J > 1$ , then for any  $s \geq 0$ ,  $\delta \in [0, 1 - \rho)$ ,*

$$(2.22) \quad \limsup_{n \rightarrow \infty} B_{n+J}^{J,L} / \max(s, \|V_n\|) = \delta$$

*implies*

$$\limsup_{n \rightarrow \infty} \|V_n - V^*\| \leq \delta(1 - \rho - \delta)^{-1} \max(s, \|V^*\|).$$

*Proof.* If  $J = 1$ , set  $L$  to be any positive number. For algorithm (2.18) for fixed  $k \geq 0$ , using (2.20), then (2.22), we obtain

$$\begin{aligned} \limsup_{m \rightarrow \infty} \|W_{mJ+k}^J\| / \max(s, \|V_{(m-1)J+k}\|) &\leq \limsup_{m \rightarrow \infty} B_{mJ+k}^{J,L} / \max(s, \|V_{(m-1)J+k}\|) \\ &= \limsup_{m \rightarrow \infty} B_{mJ+k}^{J,L} / \max(s, \|V_{(m-1)J+k}\|) \\ &\leq \delta. \end{aligned}$$

We may therefore apply Lemma 2.6 to (2.18), yielding

$$\limsup_{m \rightarrow \infty} \|V_{mJ+k} - V^*\| \leq \delta(1 - \rho - \delta)^{-1} \max(s, \|V^*\|).$$

Letting  $k = 0, \dots, J-1$  completes the proof.  $\square$

Finally, Theorem 2.12 generalizes Lemma 2.7. It will be convenient to define the function

$$\sigma(r, J) = \begin{cases} \frac{1-r^J}{1-r}; & r \neq 1, \\ J; & r = 1, \end{cases}$$

which is continuous in  $r \in \Re$  for any fixed  $J$ .

THEOREM 2.12. *If for algorithm (2.2) (A1) and (A3) hold and (A2) holds when  $J > 1$ , then*

(i)  $\sum_{i=1}^{\infty} (\rho^{1/J})^{-i} \|U_i\| < \infty$  *implies*

$$(2.23) \quad \limsup_{n \rightarrow \infty} (\rho^{1/J})^{-n} \|V_n - V^*\| < \infty;$$

(ii)  $\limsup_{n \rightarrow \infty} n^{-1} \log(\|U_n\|) \leq \log(\rho^{1/J})$  *implies*

$$(2.24) \quad \limsup_{n \rightarrow \infty} n^{-1} \log(\|V_n - V^*\|) \leq \log(\rho^{1/J});$$

(iii) for any sequence  $\{d_i\}$ ,  $d_i \in (0, \infty)$ , satisfying  $\|U_i\| \leq d_i$ ,  $i \geq 1$ , if  $r_u < \rho^{-1/J}$ , where  $r_u = \limsup_{n \rightarrow \infty} d_{n-1}/d_n$ , then

$$(2.25) \quad \limsup_{n \rightarrow \infty} d_n^{-1} \|V_n - V^*\| \leq \sigma(Lr_u, J)(1 - r_u^J \rho)^{-1}.$$

*Proof.* For case (i) fix  $k \geq 0$  in algorithm (2.18). Consider the series

$$(2.26) \quad \begin{aligned} \sum_{m=1}^{\infty} \rho^{-m} \|W_{mJ+k}^J\| &\leq \sum_{m=1}^{\infty} \rho^{-m} B_{mJ+k}^{J,L} \\ &\leq \max(L^J, 1) \rho^{-1} \sum_{i=1}^{\infty} (\rho^{1/J})^{-i} \|U_i\| \\ &< \infty, \end{aligned}$$

where the inequalities follow from (2.20) and condition (i). Then given (2.26) we may apply Lemma 2.7(i) to (2.18), giving

$$\limsup_{m \rightarrow \infty} \rho^{-m} \|V_{mJ+k} - V^*\| < \infty,$$

which then implies (2.23) after taking  $k = 0, \dots, J-1$ , noting that

$$(\rho^{1/J})^{-(Jm+k)} \|V_{mJ+k} - V^*\| = (\rho^{-k/J}) \rho^{-m} \|V_{mJ+k} - V^*\|.$$

For case (ii) fix  $k \geq 0$  in algorithm (2.18). Then by (2.20),

$$(2.27) \quad \begin{aligned} m^{-1} \log(\|W_{mJ+k}^J\|) &\leq m^{-1} \log(B_{mJ+k}^{J,L}) \\ &\leq m^{-1} \max_{(m-1)J+k+1 \leq n \leq mJ+k} (\log(\|U_n\|) + \log(J \max(L^J, 1))) \\ &\leq (J + km^{-1}) \left( \sup_{n \geq (m-1)J+k+1} n^{-1} \log(\|U_n\|) \right) \\ &\quad + m^{-1} \log(J \max(L^J, 1)), \quad m \geq 1. \end{aligned}$$

Taking the limit supremum of (2.27) with condition (ii) gives

$$\limsup_{m \rightarrow \infty} m^{-1} \log(\|W_{mJ+k}^J\|) \leq J \log(\rho^{1/J}) = \log(\rho).$$

This allows us to apply Lemma 2.7(ii) to (2.18), giving

$$\limsup_{m \rightarrow \infty} m^{-1} \log(\|V_{mJ+k} - V^*\|) \leq \log(\rho),$$

or equivalently,

$$\begin{aligned} \limsup_{m \rightarrow \infty} \frac{(J + km^{-1})}{(mJ + k)} \log(\|V_{mJ+k} - V^*\|) &= J \limsup_{m \rightarrow \infty} (mJ + k)^{-1} \log(\|V_{mJ+k} - V^*\|) \\ &\leq \log(\rho), \end{aligned}$$

which then implies (2.24) after taking  $k = 0, \dots, J-1$ .

For case (iii) fix  $k \geq 0$  in algorithm (2.18). From (2.20) we have

$$\|W_{mJ+k}^J\| \leq B_{mJ+k}^{J,L} \leq D_{mJ+k}^{J,L}, \quad m \geq 1,$$

where

$$D_n^{J,L} = \sum_{j=1}^J L^{J-j} d_{n-J+j}, \quad n \geq J, \text{ and } D_n^{J,L} = 0, \quad n < J.$$

Then

$$\begin{aligned} \sum_{m=1}^{\infty} \rho^{-m} D_{mJ+k}^{J,L} &\geq \min(1, L^J) \sum_{m=1}^{\infty} \rho^{-m} \sum_{j=1}^J d_{(m-1)J+k+j} \\ (2.28) \qquad \qquad \qquad &\geq \min(1, L^J) \rho \sum_{i=k}^{\infty} (\rho^{1/J})^{-i} d_i = \infty \end{aligned}$$

by applying condition (iii). Then for any  $\epsilon > 0$  there is  $N_\epsilon$  such that  $d_n \leq (r_u + \epsilon)d_{n+1}$  when  $n > N_\epsilon$ , and hence  $d_n \leq (r_u + \epsilon)^j d_{n+j}$ . Then, for all large enough  $m$ ,

$$\begin{aligned} D_{(m-1)J+k}^{J,L} &= \sum_{j=1}^J L^{J-j} d_{(m-2)J+k+j} \leq (r_u + \epsilon)^J \sum_{j=1}^J L^{J-j} d_{(m-1)J+k+j} \\ &= (r_u + \epsilon)^J D_{mJ+k}^{J,L} \end{aligned}$$

so that taking the limit supremum in  $m$  and letting  $\epsilon$  approach zero gives

$$(2.29) \qquad \qquad \qquad \limsup_{m \rightarrow \infty} \frac{D_{(m-1)J+k}^{J,L}}{D_{mJ+k}^{J,L}} = r_u^J.$$

We may then apply Lemma 2.7(iii) to (2.18) using bounding sequence  $D_{mJ+k}^{J,L}, m \geq 1$ , which with (2.28) and (2.29) yields

$$(2.30) \qquad \qquad \qquad \limsup_{m \rightarrow \infty} (D_{mJ+k}^{J,L})^{-1} \|V_{mJ+k} - V^*\| \leq (1 - r_u^J \rho)^{-1}.$$

Then for large enough  $m$ ,

$$\begin{aligned} D_{mJ+k}^{J,L} &= \sum_{j=1}^J L^{J-j} d_{(m-1)J+k+j} \leq \sum_{j=1}^J L^{J-j} (r_u + \epsilon)^{J-j} d_{mJ+k} \\ (2.31) \qquad \qquad &= d_{mJ+k} \sigma(L(r_u + \epsilon), J), \end{aligned}$$

which, with (2.30), letting  $\epsilon$  approach zero, gives

$$(2.32) \qquad \qquad \qquad \limsup_{m \rightarrow \infty} d_{mJ+k}^{-1} \|V_{mJ+k} - V^*\| \leq \sigma(r_u L, J) (1 - r_u^J \rho)^{-1}.$$

Then (2.25) follows by setting  $k = 0, \dots, J-1$ .  $\square$

**2.4. A general error model.** The structure of (2.2) suggests that a bound on  $\|U_n\|$  which directly depends on  $\|V_{n-1}\|$  may be available. This motivates a general error model, given as the following assumption:

(A4) In (2.2),

$$\|U_n\| \leq a_n + b_n \|V_{n-1}\|, \quad n \geq 1,$$

for some sequence of nonnegative finite constants  $\{a_n; n \geq 1\}$ ,  $\{b_n; n \geq 1\}$ .

It will be convenient to define, for a constant  $L$ , a sequence  $\{b_n; n \geq 1\}$  and integers  $n_2, n_1$ ,

$$(2.33) \quad \bar{L}_{n_1}^{n_2} = \begin{cases} \prod_{n=n_1}^{n_2} (L + b_n); & n_2 \geq n_1, \\ 1; & n_2 < n_1. \end{cases}$$

Theorem 2.11 can be used to establish the convergence of (2.2) given the error model in (A4). We will first need the following lemma.

LEMMA 2.13. *If (A4) holds for (2.2), in addition to (A1), and (A2) if  $J > 1$ , then*

$$(2.34) \quad \|V_{n+I} - V^*\| \leq \bar{L}_{n+1}^{n+I} \|V_n - V^*\| + \sum_{i=1}^I \bar{L}_{n+i+1}^{n+I} (a_{n+i} + b_{n+i} \|V^*\|)$$

for  $n \geq 1$ ,  $I \geq 1$ , with  $\bar{L}_{n_1}^{n_2}$  defined as in (2.33) for sequence  $\{b_n; n \geq 1\}$  and constant  $L$  satisfying  $\|TV - V^*\| \leq L\|V - V^*\|$ .

*Proof.* We proceed by induction. Fix  $n \geq 1$  and suppose (2.34) holds for  $I$ . Then directly from (2.2),

$$\|V_{n+I+1} - V^*\| \leq \|TV_{n+I} - V^*\| + \|U_{n+I+1}\|.$$

Applying (A4) gives

$$(2.35) \quad \begin{aligned} \|V_{n+I+1} - V^*\| &\leq L\|V_{n+I} - V^*\| + a_{n+I+1} + b_{n+I+1}\|V_{n+I}\| \\ &\leq (L + b_{n+I+1})\|V_{n+I} - V^*\| + a_{n+I+1} + b_{n+I+1}\|V^*\|; \end{aligned}$$

then applying the induction hypothesis to  $\|V_{n+I} - V^*\|$  gives

$$\begin{aligned} \|V_{n+I+1} - V^*\| &\leq (L + b_{n+I+1})\bar{L}_{n+1}^{n+I}\|V_n - V^*\| \\ &\quad + (L + b_{n+I+1}) \sum_{i=1}^I \bar{L}_{n+i+1}^{n+I} (a_{n+i} + b_{n+i}\|V^*\|) \\ &\quad + a_{n+I+1} + b_{n+I+1}\|V^*\| \\ &= \bar{L}_{n+1}^{n+I+1}\|V_n - V^*\| + \sum_{i=1}^{I+1} \bar{L}_{n+i+1}^{n+I+1} (a_{n+i} + b_{n+i}\|V^*\|) \end{aligned}$$

so that if (2.34) holds for  $I$ , it holds for  $I + 1$ . That (2.34) holds for  $I = 1$  follows from a simple relabelling of (2.35).  $\square$

Remark 2.2. In the proof of Lemma 2.13 the Lipschitz condition (A2) is used only in inequalities of the form  $\|TV - V^*\| \leq L\|V - V^*\|$ , (i.e., involving fixed point  $V^*$ ) so that (A2) may be replaced with a weaker condition.

We can now establish convergence properties of (2.2) under (A4).

THEOREM 2.14. *If (A1) and (A3) hold, with (A2) holding when  $J > 1$ , and if (A4) holds with  $a_n \rightarrow_n 0$  and  $b_n \rightarrow_n 0$ , then for algorithm (2.2)  $\|V_n - V^*\| \rightarrow_n 0$ .*

*Proof.* Suppose  $J = 1$ . Then

$$\begin{aligned} \limsup_{n \rightarrow \infty} \frac{\|U_{n+1}\|}{\max(1, \|V_n\|)} &\leq \limsup_{n \rightarrow \infty} \frac{a_{n+1} + b_{n+1}\|V_n\|}{\max(1, \|V_n\|)} \\ &\leq \limsup_{n \rightarrow \infty} a_{n+1} + b_{n+1} = 0. \end{aligned}$$

Noting that  $B_n^{J,L} = \|U_n\|$  for  $J = 1$ , and setting  $s = 1$ , the theorem is proved directly from Theorem 2.11.

Now suppose  $J > 1$ . For  $I > 1$  we have, using (A4) and Lemma 2.13,

$$\begin{aligned}
 \|U_{n+I}\| &\leq a_{n+I} + b_{n+I}\|V_{n+I-1}\| \\
 &\leq a_{n+I} + b_{n+I}\|V^*\| + b_{n+I}\|V_{n+I-1} - V^*\| \\
 &\leq a_{n+I} + b_{n+I}\|V^*\| + b_{n+I}\bar{L}_{n+1}^{n+I-1}\|V_n - V^*\| \\
 (2.36) \quad &\quad + b_{n+I} \sum_{i=1}^{I-1} \bar{L}_{n+i+1}^{n+I-1} (a_{n+i} + b_{n+i}\|V^*\|).
 \end{aligned}$$

Additionally, (2.36) is also true for  $I = 1$  (directly by (A4) and the triangular inequality) if the final summation is interpreted as zero. Note that  $\lim_{n \rightarrow \infty} \bar{L}_{n+n_1}^{n+n_2} = L^{\max(0, n_2 - n_1 + 1)}$ . Examining the terms of the upper bound of (2.36) and dividing by  $\max(1, \|V_n\|)$  gives

$$\frac{\|U_{n+I}\|}{\max(1, \|V_n\|)} \leq a_{n+I} + b_{n+I}(K_1\|V^*\| + K_2)$$

for some finite constants  $K_1, K_2$  which do not depend on  $n$ ; hence,

$$(2.37) \quad \limsup_{n \rightarrow \infty} \frac{\|U_{n+I}\|}{\max(1, \|V_n\|)} = 0.$$

Then consider

$$(2.38) \quad \frac{\|B_{n+J}^{J,L}\|}{\max(1, \|V_n\|)} = \sum_{j=1}^J L^{J-j} \frac{\|U_{n+j}\|}{\max(1, \|V_n\|)}.$$

We may then use (2.37) to conclude that the limit supremum of each term on the right-hand side of (2.38) is zero. The theorem is proved following a direct application of Theorem 2.11.  $\square$

**2.5. Finite bounds.** The convergence results given above are based on asymptotic bounds. However, inequality (2.10) provides a means to calculate finite upper bounds on  $\|V_n - V^*\|$ . In this section we suppose we may bound errors with constants  $\|U_n\| \leq d_n$ , where we assume  $d_n > 0$ .

We first deal with the single stage contraction of modulus  $\rho$ . The first term in the upper bound is composed of the exponentially decreasing error of the exact algorithm. The second term may be bounded by

$$\sum_{i=1}^n \rho^{n-i} \|U_i\| \leq d_n I_n, \quad n \geq 1,$$

where  $I_n = \sum_{i=1}^n \rho^{n-i} d_i / d_n$ . If we assume  $r_u < \rho^{-1}$ , then from Lemma 2.3 we have

$$\limsup_{n \rightarrow \infty} I_n \leq (1 - r_u \rho)^{-1};$$

hence we rewrite (2.10) as

$$\|V_n - V^*\| \leq \|V_0 - V^*\| \rho^n + d_n I_n, \quad n \geq 1,$$

and consider the problem of usefully bounding  $I_n$ . If  $d_n$  has a tractable form, we may simply calculate  $I_n$  numerically. In this case, it will be useful to know something of the iterative properties of  $I_n$ . We show in the following lemma that, under a type of convexity assumption on the sequence  $d_n$ , once  $I_n$  decreases in  $n$ , it decreases indefinitely.

LEMMA 2.15. *If a positive sequence  $\{d_n; n \geq 1\}$  satisfies*

$$(2.39) \quad d_{n+1}/d_{n+2} \leq d_n/d_{n+1}, \quad n \geq 1,$$

*then  $I_{n+1} < I_n$  implies  $I_{n+2} < I_{n+1}$ .*

*Proof.* We may write

$$I_{n+1} - I_n = 1 + \left( \rho \frac{d_n}{d_{n+1}} - 1 \right) I_n, \quad n \geq 1,$$

from which it follows that

$$(2.40) \quad I_{n+1} - I_n < 0 \text{ if and only if } \left( 1 - \rho \frac{d_n}{d_{n+1}} \right) I_n > 1.$$

Then if  $I_{n+1} - I_n < 0$ , we have  $(1 - \rho \frac{d_n}{d_{n+1}}) > 0$  and hence  $(1 - \rho \frac{d_{n+1}}{d_{n+2}}) > 0$  from condition (2.39). This in turn implies by (2.40) that

$$\begin{aligned} \left( 1 - \rho \frac{d_{n+1}}{d_{n+2}} \right) I_{n+1} &= \left( 1 - \rho \frac{d_{n+1}}{d_{n+2}} \right) \left( 1 + \rho \frac{d_n}{d_{n+1}} I_n \right) \\ &> \left( 1 - \rho \frac{d_{n+1}}{d_{n+2}} \right) \left( 1 - \rho \frac{d_n}{d_{n+1}} \right)^{-1} \geq 1, \end{aligned}$$

which proves the lemma.  $\square$

*Remark 2.3.* Condition (2.39) is quite general and is satisfied by any polynomially decreasing bound  $1/n^k$ .

The same calculation can be made in the case of a general  $J$ -stage contraction of modulus  $\rho$ . Combining Lemma 2.9 with (2.10) gives

$$\|V_n - V^*\| \leq K \sum_{i=1}^n (\rho^{1/J})^{n-i} d_i + O\left((\rho^{1/J})^n\right), \quad n \geq 1,$$

for some finite constant  $K$  which does not depend on  $n$ . The finite bound may be treated in the same way as for the single stage contraction.

**2.6. Stochastic error terms.** The convergence results obtained in this section depend only on the properties of  $U_n$ , which can be defined in terms of the underlying seminormed linear space. If in (2.2), under (A1),  $U_n$  is stochastic, then almost sure convergence properties of  $\|V_n - V^*\|$  are deduced from those of  $\|U_n\|$ , and no other stochastic properties are needed.

To obtain  $L_p$  convergence or bounds, we need to regard  $\|U_n\|$  as a stochastic quantity. We start with the original seminormed linear space  $(\mathcal{V}, \|\cdot\|)$ , with contractive operator  $T$  as defined in (A1). We then define a new seminormed linear space based on  $(\mathcal{V}, \|\cdot\|)$ . Suppose we have a probability space  $(\Omega, \mathcal{F}, \mathcal{P})$  and can define a measurable space on  $\mathcal{V}$ . Let  $\mathcal{V}_\Omega$  be the linear space under the convolution operation of measurable mappings  $V : \Omega \rightarrow \mathcal{V}$ . Let  $\mathcal{U}$  be the space of random variables on  $(\Omega, \mathcal{F}, \mathcal{P})$ . Then for

$V \in \mathcal{V}_\Omega$  we have  $\|V\| \in \mathcal{U}$ . If  $\|\cdot\|_p$  is an  $L_p$  norm on random variables  $\mathcal{U}$ , we define a new seminorm  $\|V\|_\Omega = \|(\|V\|)\|_p$ . Then define the operators  $T_\Omega^I : \mathcal{V}_\Omega \rightarrow \mathcal{V}_\Omega$  by  $(T_\Omega^I V)(\omega) = T^I(V(\omega))$  for  $I \geq 1$ . Set  $V^*(\omega) \equiv v^*$ , where  $v^*$  is a fixed point of  $T$  in  $\mathcal{V}$ . Then  $(T_\Omega V^*)(\omega) = T(V^*(\omega)) \equiv T v^* = v^*$ , so that  $V^*$  is a fixed point of  $T_\Omega$ . For any  $V \in \mathcal{V}_\Omega$  we have  $\|T_\Omega^J V - V^*\|(\omega) = \|T^J(V(\omega)) - v^*\| \leq \rho \|V(\omega) - v^*\| = \rho \|V - V^*\|(\omega)$ . This leads to  $\|T_\Omega^J V - V^*\|_\Omega = \| \|T_\Omega^J V - V^*\| \|_p \leq \|\rho\| V - V^* \|_p = \rho \|V - V^*\|_\Omega$ , so that the seminormed linear space  $(\mathcal{V}_\Omega, \|\cdot\|_\Omega)$  also satisfies (A1) for  $J$ , modulus  $\rho$ , and operator  $T_\Omega$ .

To summarize, convergence with probability one (w.p.1) (or in  $L_p$ ) of  $\|V_n - V^*\|$  in (2.2) is a consequence of convergence w.p.1 (or in  $L_p$ ) of  $\|U_n\|$ .

**3. The dynamic programming operator for MDPs.** Following section 1.2, calculation of the optimal control of discrete time MDPs usually reduces to a VI algorithm based on the Bellman operator  $T_\pi$  associated with MCM  $\pi$ . In practice, exact knowledge of  $\pi$  is a special case, but it may be possible to construct an estimate  $\hat{\pi}$  of  $\pi$ , or a sequence of estimates  $\hat{\pi}_1, \hat{\pi}_2, \dots$ . In such a case, it is natural to consider substituting within a VI algorithm the estimates for the actual model  $\pi$ . The expectation would then be that the resulting value function solution would be close to the true one, to the degree that the model estimates are close to  $\pi$ . In this section we apply the theory of section 2 to this problem, with the objective of describing the behavior of approximate VI algorithms in terms of model estimates.

The general MDP considered is defined in section 3.1. It is important to emphasize that, because the theory is given largely in terms of the properties of normed linear spaces, the structure of the MDP can be left quite general. The essential condition is the existence of a well-behaved contractive VI algorithm coupled with a suitable norm. In the presence of unbounded costs, the weighted supremum norm may be used, which may be reduced to the standard supremum norm for bounded costs. See [19] for extensive discussion on this topic. We will employ this norm after some further discussion in section 3.1.

Section 3.2 will deal with two issues. A model distance is first defined. This distance incorporates the weight function used to define the weighted supremum norm. This permits a bound on the error due to the approximate evaluation of Bellman's operator to be given in terms of model distance.

We then note that one of the advantages of the general theory is that contractive properties need to be verified only for the exact operator  $T_\pi$ . However, it still needs to be verified that the approximate operators  $T_n$  are closed on the set of elements of finite norm, which will then imply assumption (A3). Theorem 3.5 below allows this question to be resolved on the basis of model distances. As a general rule, regularity conditions need only be verified for the exact model  $\pi$ . They follow for any model estimate  $\hat{\pi}$  as long as the model distance is finite.

Sections 3.3 and 3.4 then present the main results for, respectively, the AVIA and CEA forms of approximate VI as discussed in section 1.2.2.

**3.1. Model definition.** We adopt the following conventions. For any Borel space  $\mathcal{U}$ ,  $\mathcal{B}(\mathcal{U})$  is the class of Borel sets, and  $\mathcal{M}(\mathcal{U})$  is the set of probability measures on  $(\mathcal{U}, \mathcal{B}(\mathcal{U}))$ . Then  $F(\mathcal{U})$  is the set of measurable real valued functions on  $\mathcal{U}$ . If  $\|\cdot\|$  is a seminorm defined on  $F(\mathcal{U})$ , then  $F(\mathcal{U}, \|\cdot\|) = \{V \in F(\mathcal{U}) : \|V\| < \infty\}$ . Let  $\sigma(H)$  denote the  $\sigma$ -algebra generated by a mapping  $H$  defined on a probability space.

A Markov decision process will be made of the following elements (see, for example, [18, 19]):

(M1) A Borel space  $\mathcal{X}$ . We refer to  $\mathcal{X}$  as the *state space*.

- (M2) A Borel space  $\mathcal{A}$ . We refer to  $\mathcal{A}$  as the *action space*.
- (M3) With each  $x \in \mathcal{X}$  associate  $\mathcal{K}_x \in \mathcal{B}(\mathcal{A})$  with  $\mathcal{K}_x \neq \emptyset$ . The *state-action space*  $\mathcal{K} = \{(x, a) \in \mathcal{X} \times \mathcal{A} : a \in \mathcal{K}_x\}$  is assumed to be a measurable subset of  $\mathcal{X} \times \mathcal{A}$ .
- (M4) A *transition kernel*  $Q : \mathcal{K} \rightarrow \mathcal{M}(\mathcal{X})$ . We assume for each fixed  $E_x \in \mathcal{B}(\mathcal{X})$  that  $Q(E_x \mid \cdot)$  is a measurable function from  $\mathcal{K}$  to  $\mathfrak{R}$ . Furthermore, we assume there is a measure  $\mu_Q$  on  $\mathcal{X}$  with respect to which  $Q(\cdot \mid x, a)$  has a density  $f(\cdot \mid x, a)$  for each  $(x, a) \in \mathcal{K}$ .
- (M5) A measurable mapping  $R : \mathcal{K} \rightarrow (-\infty, \infty)$ , referred to as the *cost function*.
- (M6) A *discount factor*  $\beta \geq 0$ .

A reference to state-action space  $\mathcal{K}$  will implicitly include  $(\mathcal{X}, \mathcal{A})$ . A reference to the stochastic kernel  $Q$ , defined on  $\mathcal{K}$ , will implicitly include  $\mu_Q$ . An MCM will be the object  $\pi = (\mathcal{K}, Q, R, \beta)$ . Let  $\mathcal{K}^f$  be the set of all measurable mappings  $f : \mathcal{X} \rightarrow \mathcal{A}$  for which  $f(x) \in \mathcal{K}_x$  for all  $x \in \mathcal{X}$ . Assume  $\mathcal{K}^f$  is not empty.

An MDP will consist of an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  coupled with a control policy.

**DEFINITION 3.1.** A control policy consists of a sequence of measurable mappings  $\Phi = \{\Phi_n, n \geq 1\}$  of the form  $\Phi_n : (\mathcal{K})^{n-1} \times \mathcal{X} \rightarrow \mathcal{M}(\mathcal{A})$ . We assume  $\Phi_n(\mathcal{K}_{x_n} \mid x_1, a_1, \dots, x_{n-1}, a_{n-1}, x_n) = 1$  for  $n \geq 1$ .

Intuitively, the MDP is realized as a random process  $(X_1, A_1, X_2, A_2, \dots)$  on the Borel space  $\mathcal{K}^\infty$ . Stage  $n$  is taken to refer to  $(X_n, A_n)$ , and the history at stage  $n$  up to state  $X_n$  is denoted  $H_n^x = (X_1, A_1, \dots, X_n) \in \mathcal{K}^{n-1} \times \mathcal{X}$ . Similarly, the history at stage  $n$  up to action  $A_n$  is denoted  $H_n^a = (X_1, A_1, \dots, X_n, A_n) \in \mathcal{K}^n$ . The stage  $n$  cost is taken to be  $R(X_n, A_n)$ . It has been shown (see [17]) that for each  $x \in \mathcal{X}$  there exists a unique probability measure  $P_x^\Phi$  on  $\mathcal{K}^\infty$  which satisfies

$$\begin{aligned} P_x^\Phi(X_1 = x) &= 1, \\ P_x^\Phi(A_n \in E_a \mid H_n^x) &= \Phi_n(E_a \mid H_n^x) \quad \forall E_a \in \mathcal{B}(\mathcal{A}), H_n^x \in \mathcal{K}^{n-1} \times \mathcal{X}, \\ (3.1) \quad P_x^\Phi(X_{n+1} \in E_x \mid H_n^a) &= Q(E_x \mid X_n, A_n) \quad \forall E_x \in \mathcal{B}(\mathcal{X}), H_n^a \in \mathcal{K}^n, \end{aligned}$$

for  $n \geq 1$  and each admissible history  $H_n^x, H_n^a$ . The criterion for choosing a policy  $\Phi$  is given as a  $\beta$ -discounted cost from initial point  $X_1 = x$ ,

$$V^\Phi(x) = E_x^\Phi \left[ \sum_{n=1}^{\infty} \beta^{n-1} R(X_n, A_n) \right], \quad x \in \mathcal{X},$$

where  $E_x^\Phi$  is the expectation operator of  $P_x^\Phi$ . In this case interest is in control processes, which assume finite total expected cost. The *value function* is

$$V^*(x) = \inf_{\Phi} V^\Phi(x), \quad x \in \mathcal{X},$$

and any policy  $\Phi^*$  satisfying  $V^{\Phi^*}(x) = V^*(x)$  for all  $x \in \mathcal{X}$  is the minimum  $\beta$ -discounted cost policy. Of special interest will be deterministic policies.

**DEFINITION 3.2.** Given a sequence of policy functions  $\tilde{\phi} = \{\phi_n \in \mathcal{K}^f; n \geq 1\}$ , where  $\phi_n \equiv \phi_n(x \mid H_n^x)$  may depend on  $H_n^x$ ,  $\Phi$  is a deterministic policy based on  $\tilde{\phi}$  if  $\Phi_n(E_a \mid H_n^x) = I\{\phi_n(X_n \mid H_n^x) \in E_a\}$  for all  $n \geq 1$ . If  $\phi_n(\cdot \mid H_n^x) \equiv \phi(\cdot)$  for some single  $\phi \in \mathcal{K}^f$ , then  $\Phi$  is a stationary deterministic policy.

For a stochastic kernel  $Q$  on  $\mathcal{K}$  let  $\mathcal{L}_Q$  be the set of functions  $V \in F(\mathcal{X})$  for which the integral  $\int_{y \in \mathcal{X}} V(y) dQ(y \mid x, a)$  exists and is finite for all  $(x, a) \in \mathcal{K}$ . The set of *weight functions*  $\mathcal{W}(\mathcal{X}) \subset F(\mathcal{X})$  is taken to be the set of all measurable functions

$w : \mathcal{X} \rightarrow (0, \infty)$ . For any weight function  $w$  we define the weighted supremum norm  $\|\cdot\|_w$  on  $F(\mathcal{X})$  by  $\|V\|_w = \sup_{x \in \mathcal{X}} w^{-1}(x)|V(x)|$ . Then define quantities

$$\eta_Q^w(x, a) = w(x)^{-1} \int_{y \in \mathcal{X}} w(y) dQ(y | x, a), \quad (x, a) \in \mathcal{K},$$

$$\eta_Q^w = \sup_{(x, a) \in \mathcal{K}} \eta_Q^w(x, a).$$

We next define for an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  the Bellman operator, or dynamic programming operator (DPO),  $T_\pi : \mathcal{L}_Q \rightarrow F(\mathcal{X})$ ,

$$(3.2) \quad T_\pi V(x) = \inf_{a \in \mathcal{K}_x} R(x, a) + \beta \int_{y \in \mathcal{X}} V(y) dQ(y | x, a).$$

Removing the infimum operation in (3.2) gives the quantity

$$(3.3) \quad T_\pi^a V(x, a) = R(x, a) + \beta \int_{y \in \mathcal{X}} V(y) dQ(y | x, a),$$

also defined for all  $V \in \mathcal{L}_Q$ . Let  $V_\pi^*$  denote the value function for  $\pi$ .

This leads to the definition of a solution space for an MCM.

**DEFINITION 3.3.** A solution space for MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  consists of vector space  $\mathcal{V} \subset F(\mathcal{X})$  and a weight function  $w$  which defines norm  $\|\cdot\|_w$ , together denoted  $\mathcal{V}^w = (\mathcal{V}, w)$ , which satisfies

- (i)  $\mathcal{V} \subset \mathcal{L}_Q$ ,
- (ii)  $T_\pi \mathcal{V} \subset \mathcal{V}$  for DPO  $T_\pi$ , and
- (iii)  $V_\pi^* \in \mathcal{V}$ .

Additionally,  $\mathcal{V}^w$  is a contractive solution space if  $T_\pi V_\pi^* = V_\pi^*$  and if  $(\mathcal{V}, \|\cdot\|_w, T_\pi, V_\pi^*, \rho, J)$  satisfies (A1) and (A2) if  $J > 1$ .

**Remark 3.1.** We may have  $\rho \neq \beta$ . This will generally be the case for unbounded costs. See Lippman [27], Van Nunen and Wessels [35] or Hernández-Lerma and Lasserre [19].

The solution to the MCM control problem is ideally of the following form.

**DEFINITION 3.4.** MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  possesses an optimal stationary deterministic policy (OSDP) if

- (i) there exists  $\phi_\pi^* \in \mathcal{K}^f$  such that

$$(3.4) \quad \phi_\pi^*(x) = \arg \min_{a \in \mathcal{K}_x} R(x, a) + \beta \int_{y \in \mathcal{X}} V_\pi^*(y) dQ(y | x, a);$$

- (ii) the stationary deterministic policy implied by  $\phi_\pi^*$  is a minimum  $\beta$ -discounted cost policy.

The existence of a solution space and an OSDP can be guaranteed under a wide variety of conditions, which are discussed in detail in, for example, Bertsekas and Shreve [4] and Hernández-Lerma and Lasserre [18, 19]. Typically  $R(x, a)$  is assumed to be nonnegative and lower semicontinuous, and the action space projection  $\mathcal{K}_x$  is assumed to possess some compactness property. Additionally, a continuity condition on the kernel  $Q$  on  $\mathcal{K}$  is usually imposed. The contraction property for  $T$  is easy to verify when  $\beta < 1$  and  $R$  is bounded, in which case the unweighted supremum norm (i.e.,  $w \equiv 1$ ) suffices. On the other hand, if  $R$  is unbounded, the supremum norm is usually unsuitable, but may be replaced with a weighted supremum norm

with respect to which  $T$  is contractive. Conditions under which this is the case are given in [27], and in fact these conditions also imply (A2). Informally, the weight function  $w$  is required to bound  $R$  in some sense. See also Van Nunen and Wessels [35], Bhattacharya and Majumdar [6], and Hernández-Lerma and Lesserre [19].

For  $\beta \geq 1$ , it will generally be required that the process terminate after some finite time. In this case a weighted supremum norm which induces contractivity may exist. Some conditions are given in Bertsekas [3]. In general, if the process may terminate at any stage with a probability bounded away from zero, then it is easily established that  $T$  is contractive in the unweighted supremum norm under bounded costs (see Almedevar [1]).

It is important to note that there will be no advantage in specifying any single set of regularity conditions on the model elements (M1)–(M6). The existence of a contractive solution space and an OSDP will be our point of departure.

**3.2. Approximate evaluation of the DPO.** If MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  possesses a contractive solution space  $\mathcal{V}^w$ , we may define a VI algorithm to be a sequence of the form

$$(3.5) \quad \begin{aligned} V_0 &= v_0 \in \mathcal{V}, \\ V_n &= T_\pi V_{n-1}, \quad n \geq 1, \end{aligned}$$

for which we may easily conclude  $\|V_n - V_\pi^*\|_w \rightarrow_n 0$  at a geometric rate. If the model pair  $(Q, R)$  is unknown, but we have an estimate  $\hat{\pi} = (\mathcal{K}, \hat{Q}, \hat{R}, \beta)$ , we may construct an approximate DPO  $T_{\hat{\pi}}$  to use in place of  $T_\pi$ . In this case we will need to define some notion of distance between two models. Additionally, we need to establish that the approximate DPO possesses a suitable range and domain, and that any evaluation  $T_{\hat{\pi}}V$  is close to  $T_\pi V$ , with the evaluation error expressed naturally in terms of model distance.

Recall that the definition of a stochastic kernel in (M4) includes a notion of a density on a common measure over state-action space  $\mathcal{K}$ . Distances between probability measures will ultimately be derived from these densities, so stochastic kernels must be absolutely continuous with respect to some common measure to be comparable. Accordingly, we give the following definition.

**DEFINITION 3.5.** *Two stochastic kernels  $Q_1$  and  $Q_2$  of type (M4) defined on a common state-action space conform if  $\mu_{Q_1} = \mu_{Q_2}$ .*

The distance between two conforming stochastic kernels on  $\mathcal{K}$  with weight function  $w$  will be defined as

$$D_q^w(Q_1, Q_2) = \sup_{(x,a) \in \mathcal{K}} w^{-1}(x) \int_{y \in \mathcal{X}} w(y) |f_1(y | x, a) - f_2(y | x, a)| d\mu_Q(y),$$

where  $f_1(y | x, a)$ ,  $f_2(y | x, a)$  are the densities of  $Q_1(\cdot | x, a)$  and  $Q_2(\cdot | x, a)$  with respect to common measure  $\mu_Q$ . Similarly, the distance between two cost functions  $R_1, R_2$  of type (M5) will be defined as

$$D_r^w(R_1, R_2) = \sup_{(x,a) \in \mathcal{K}} w(x)^{-1} |R_1(x, a) - R_2(x, a)|.$$

If the model distances  $D_r^w(R, \hat{R}), D_q^w(Q, \hat{Q})$  between actual and approximate models  $\pi = (\mathcal{K}, Q, R, \beta)$  and  $\hat{\pi} = (\mathcal{K}, \hat{Q}, \hat{R}, \beta)$  can be bounded, then it suffices to verify contractive, Lipschitz, or ergodic properties for  $\pi$  alone. This idea is developed in the following four lemmas and Theorem 3.5.

LEMMA 3.1. Suppose for stochastic kernel  $Q$  on  $\mathcal{K}$  and weight function  $w \in \mathcal{W}(\mathcal{X})$  we have  $\eta_Q^w(x, a) < \infty$  for all  $(x, a) \in \mathcal{K}$ . Then  $F(\mathcal{X}, \|\cdot\|_w) \subset \mathcal{L}_Q$ .

*Proof.* Note that  $|V(y)| \leq \|V\|_w w(y)$  for each  $y \in \mathcal{X}$ . For  $V \in F(\mathcal{X}, \|\cdot\|_w)$ ,  $\|V\|_w < \infty$ . By hypothesis,  $\|V\|_w w \in \mathcal{L}_Q$ , and hence so is  $V$ .  $\square$

LEMMA 3.2. Suppose we have some MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  and weight function  $w \in \mathcal{W}(\mathcal{X})$  such that  $\eta_Q^w(x, a) < \infty$  for all  $(x, a) \in \mathcal{K}$ . If  $\hat{Q}$  is a stochastic kernel on  $\mathcal{K}$  which conforms to  $Q$ , and if  $D_q^w(Q, \hat{Q}) < \infty$ , then

- (i)  $\eta_{\hat{Q}}^w(x, a) \leq \eta_Q^w(x, a) + D_q^w(Q, \hat{Q}) < \infty$  for all  $(x, a) \in \mathcal{K}$ ,
- (ii)  $\eta_{\hat{Q}}^w \leq \eta_Q^w + D_q^w(Q, \hat{Q})$ , and
- (iii)  $F(\mathcal{X}, \|\cdot\|_w) \subset \mathcal{L}_{\hat{Q}}$ .

*Proof.* Denote the density kernels for  $Q, \hat{Q}$  by  $f, \hat{f}$ . We have

$$(3.6) \quad w(y)\hat{f}(y | x, a) \leq w(y)f(y | x, a) + w(y)|f(y | x, a) - \hat{f}(y | x, a)|, \quad y \in \mathcal{X}.$$

Integrating with respect to  $y$  over measure  $\mu_Q$ , multiplying by  $w^{-1}(x)$ , then taking the supremum of the final term over  $\mathcal{K}$  gives (i), from which (ii) follows by taking the supremum of the remaining terms over  $\mathcal{K}$ . Then (iii) follows by applying Lemma 3.1.  $\square$

LEMMA 3.3. Let  $f_1, f_2$  be real valued functions on a set  $E$ . Suppose  $\inf_x f_2(x) > -\infty$  and  $|f_2(x)| < \infty$  for all  $x \in E$ . Then  $|\inf_x f_1(x) - \inf_x f_2(x)| \leq \sup_x |f_1(x) - f_2(x)|$ .

*Proof.* First, note that since  $f_2$  is everywhere finite,  $\sup_x |f_1(x) - f_2(x)|$  is well defined. If  $|\inf_x f_1(x)| = \infty$ , it follows that  $\sup_x |f_1(x) - f_2(x)| = \infty$ . Then suppose  $\inf_x f_1(x)$  is finite. For any  $\epsilon > 0$  there exists  $x^* \in E$  such that  $f_2(x^*) \leq \inf_x f_2(x) + \epsilon$ . Then

$$\inf_x f_1(x) - \inf_x f_2(x) \leq f_1(x^*) - f_2(x^*) + \epsilon \leq \sup_x |f_1(x) - f_2(x)| + \epsilon.$$

A similar argument gives  $\inf_x f_2(x) - \inf_x f_1(x) \leq \sup_x |f_1(x) - f_2(x)| + \epsilon$ . The lemma follows by letting  $\epsilon$  approach 0.  $\square$

Remark 3.2. This lemma is similar to one in Hinderer [20, p. 17].

LEMMA 3.4. Suppose we have an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  with solution space  $\mathcal{V}^w$ , and an MCM  $\hat{\pi} = (\mathcal{K}, \hat{Q}, \hat{R}, \beta)$  for which  $\hat{Q}$  conforms to  $Q$ . Furthermore, suppose  $T_\pi : \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w) \rightarrow \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ . Then

$$(3.7) \quad \|T_{\hat{\pi}}V - T_\pi V\|_w \leq D_r^w(R, \hat{R}) + \beta\|V\|_w D_q^w(Q, \hat{Q})$$

for any  $V \in \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w) \cap \mathcal{L}_{\hat{Q}}$ .

*Proof.* Denote the density kernels for  $Q, \hat{Q}$  by  $f, \hat{f}$ . By assumption,  $T_\pi V(x)$  is finite and  $V \in \mathcal{L}_Q$ , so for fixed  $x$ ,  $T_\pi^a V(x, a)$  as a function of  $a$  satisfies the conditions imposed on  $f_2$  in Lemma 3.3, so that

$$\begin{aligned} & w(x)^{-1} |T_{\hat{\pi}}V(x) - T_\pi V(x)| \\ & \leq \sup_{a \in \mathcal{K}_x} w(x)^{-1} \left| \hat{R}(x, a) - R(x, a) \right| \\ & \quad + \sup_{a \in \mathcal{K}_x} w(x)^{-1} \left| \beta \int_{y \in \mathcal{X}} w(y)^{-1} V(y) w(y) \left( \hat{f}(y|x, a) - f(y|x, a) \right) d\mu_Q(y) \right| \\ & \leq D_r^w(R, \hat{R}) + \beta\|V\|_w D_q^w(Q, \hat{Q}). \end{aligned}$$

Then taking the supremum over  $\mathcal{X}$  gives (3.7).  $\square$

The required properties of an approximate DPO are established in the next theorem.

**THEOREM 3.5.** *Suppose we have an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  with solution space  $\mathcal{V}^w$ , and an MCM  $\hat{\pi} = (\mathcal{K}, \hat{Q}, \hat{R}, \beta)$  for which  $\hat{Q}$  conforms to  $Q$ . Furthermore, suppose*

- (a)  $\eta_Q^w(x, a) < \infty$ ,
- (b)  $T_\pi : \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w) \rightarrow \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ ,
- (c)  $D_q^w(Q, \hat{Q})$ ,  $D_r^w(R, \hat{R})$  are finite, and
- (d)  $T_{\hat{\pi}} : \mathcal{V} \cap \mathcal{L}_{\hat{Q}} \rightarrow \mathcal{V}$ .

Then  $T_{\hat{\pi}} : \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w) \rightarrow \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ .

*Proof.* By Lemma 3.2, noting (a) and (c) we have  $F(\mathcal{X}, \|\cdot\|_w) \subset \mathcal{L}_{\hat{Q}}$ , and hence  $T_{\hat{\pi}} : \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w) \rightarrow \mathcal{V}$ . Then suppose  $V \in \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ . By Lemma 3.4  $\|T_{\hat{\pi}}V - T_\pi V\|_w < \infty$ . Condition (b) implies  $\|T_\pi V\|_w < \infty$ , hence  $\|T_{\hat{\pi}}V\|_w < \infty$ , which completes the proof.  $\square$

**Remark 3.3.** If  $\mathcal{V}^w$  is a contractive solution space, then condition (b) is easily verified.

**3.3. AVIAs.** We are now in a position to investigate the convergence properties of iterative algorithms based on approximate DPOs. We begin with the following definition.

**DEFINITION 3.6.** *Given an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  with solution space  $\mathcal{V}^w$ , and a sequence of MCMs  $\hat{\pi}_n = (\mathcal{K}, \hat{Q}_n, \hat{R}_n, \beta)$  for which  $(\pi, \mathcal{V}^w)$  and  $\hat{\pi}_n$  satisfy the conditions of Theorem 3.5 for each  $n \geq 1$ , an AVIA associates with each  $v_0 \in \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$  a sequence*

$$\begin{aligned} V_0 &= v_0, \\ V_n &= T_{\hat{\pi}_n} V_{n-1}, \quad n \geq 1. \end{aligned}$$

**Remark 3.4.** Theorem 3.5 ensures that the sequence of an AVIA is well defined and exists in  $\mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ .

This is the type of algorithm considered in [11] for finite state-action spaces. See also [17] for a more general model with bounded costs. In that work an AVIA is referred to as a type of *nonstationary VI*.

The following theorem summarizes the convergence properties of an AVIA and is a direct application of Theorems 2.12 and 2.14. The notation conforms by setting  $U_n = T_{\hat{\pi}_n} V_{n-1} - T_\pi V_{n-1}$ .

**THEOREM 3.6.** *Suppose we have some MCM  $(\mathcal{K}, Q, R, \beta)$  with contractive solution space  $\mathcal{V}^w$  with an AVIA (Definition 3.6). Suppose there exist two sequences of positive constants  $a_n, b_n$ ,  $n \geq 1$ , such that*

$$\begin{aligned} D_r^w(R, \hat{R}_n) &\leq a_n, \\ D_q^w(Q, \hat{Q}_n) &\leq b_n, \quad n \geq 1, \end{aligned}$$

with  $\lim_{n \rightarrow \infty} a_n = 0$  and  $\lim_{n \rightarrow \infty} b_n = 0$ . Then

$$(3.8) \quad \lim_{n \rightarrow \infty} \|V_n - V_\pi^*\|_w = 0.$$

Additionally, define  $d_n = a_n + b_n \beta \|V_{n-1}\|$ ,  $n \geq 1$ . Then

- (i) if  $\sum_{n=1}^\infty (\rho^{1/J})^{-i} d_n < \infty$ , then

$$(3.9) \quad \limsup_{n \rightarrow \infty} (\rho^{1/J})^{-n} \|V_n - V_\pi^*\|_w < \infty;$$

(ii) if  $\limsup_{n \rightarrow \infty} n^{-1} \log(d_n) \leq \log(\rho^{1/J})$ , then

$$(3.10) \quad \limsup_{n \rightarrow \infty} n^{-1} \log(\|V_n - V_\pi^*\|_w) \leq \log(\rho^{1/J});$$

(iii) if  $r_u = \limsup_{n \rightarrow \infty} d_{n-1}/d_n < \rho^{-1/J}$ , then

$$(3.11) \quad \limsup_{n \rightarrow \infty} d_n^{-1} \|V_n - V_\pi^*\|_w < (1 - r_u^J \rho)^{-1}.$$

*Proof.* Assumption (A3) follows from Definition 3.6 and the contractive property of  $T_\pi$ . By Lemma 3.4 we directly conclude that assumption (A4) holds. Since  $D_q^w(Q, \hat{Q}_n)$  and  $D_q^w(Q, \hat{Q}_n)$  converge to zero, (3.8) follows directly from Theorem 2.14. Then by Lemma 3.4  $\|U_n\|_w \leq d_n$ , and (3.9)–(3.11) follow by applying Theorem 2.12.  $\square$

*Remark 3.5.* If  $\|V_\pi^*\| > 0$ , we may replace  $d_n$  in Theorem 3.6 with  $d'_n = a_n + b_n \beta \|V_\pi^*\|$ . In this case there exists finite  $K$  such that  $d'_n \leq K d_n$  with  $\lim_{n \rightarrow \infty} d_n/d'_n = 1$ . It is easily shown that the conditions and results for cases (i), (ii), and (iii) hold for  $d_n$  if and only if they hold for  $d'_n$ .

*Remark 3.6.* If  $D_q^w(Q, \hat{Q}_n)$  or  $D_r^w(R, \hat{R}_n)$  do not converge to zero but can be bounded, and if  $\|V_n\|_w$  can be bounded (assuming, for example, that  $R(x, a)$  can be bounded), Lemma 3.4 and Theorem 2.10 can be used directly to bound  $\limsup_{n \rightarrow \infty} \|V_n - V_\pi^*\|_w$ .

A different bound for an AVIA is obtained in [17] for the discounted ( $\beta < 1$ ) model with cost bounded by  $R^b < \infty$  and supremum norm (see also [11]) in addition to some other model regularity conditions. Using the notation of Theorem 3.6 the reported bound (obtained from the proof in Theorem 4.8, Chapter 2 of [17]) is

$$(3.12) \quad \|V_n - V_\pi^*\|_w \leq \frac{a_{[n/2]} + \beta R^b (1 - \beta)^{-1} b_{[n/2]}}{1 - \beta} + \frac{2R^b \beta^{[n/2]}}{1 - \beta}, \quad n \geq 1,$$

where  $[t]$  is the largest integer less than or equal to  $t$ . The asymptotic bound from Theorem 3.6 is

$$(3.13) \quad \|V_n - V_\pi^*\|_w \leq \frac{a_n + \beta \|V_\pi^*\|_w b_n}{1 - \beta} + o(a_n + b_n), \quad n \geq 1,$$

when  $a_n$  and  $b_n$  decrease nongeometrically (i.e.,  $r_u = 1$  in Theorem 3.6). If we then follow [17] by bounding  $\|V_\pi^*\|_w$  with  $R^b(1 - \beta)^{-1}$ , the asymptotic bound in (3.12) is obtained by replacing  $(a_n, b_n)$  in (3.13) with  $(a_{[n/2]}, b_{[n/2]})$ . This will result in a faster rate of convergence for (3.13). Additionally, this implies that the finite bound obtained in section 2.5 will be uniformly smaller than (3.12) for all large enough  $n$ .

**3.4. Certainty-equivalence methods.** We have not assumed that the approximate DPOs of Definition 3.6 are contractive. If we may verify that repeated iteration of  $T_{\hat{\pi}_n}$  in a suitable starting point for any  $n$  results in some limit  $V_{\hat{\pi}_n}^*$ , we may wish to investigate whether  $V_{\hat{\pi}_n}^*$  converges to  $V_\pi^*$ . Such an algorithm differs from the AVIA, and we reserve the term *certainty-equivalence* for this approach. In effect, the MDP is controlled as though the current model estimate is correct. See [24] or [17] for further discussion.

**DEFINITION 3.7.** Suppose we are given an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  with solution space  $\mathcal{V}^w$ , and a sequence of MCMs  $\hat{\pi}_n = (\mathcal{K}, \hat{Q}_n, \hat{R}_n, \beta)$  for which  $(\pi, \mathcal{V}^w)$  and  $\hat{\pi}_n$  satisfy the conditions of Theorem 3.5 for each  $n \geq 1$ . Suppose there exists a sequence

$v_{0,n} \in \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ ,  $n \geq 1$ , such that for each  $n$  we have  $\lim_{i \rightarrow \infty} \|T_{\hat{\pi}_n}^i v_{0,n} - V_{\hat{\pi}_n}^*\|_w = 0$  for some  $V_{\hat{\pi}_n}^* \in \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ . Then a CEA is defined as an algorithm which calculates the sequence  $(V_{\hat{\pi}_1}^*, V_{\hat{\pi}_2}^*, \dots)$ .

Conditions for the convergence of a CEA are given in the next theorem.

**THEOREM 3.7.** *Suppose for a CEA (Definition 3.7)  $\mathcal{V}^w$  is a contractive solution space. Then for  $n \geq 1$ ,*

$$(3.14) \quad \|V_{\hat{\pi}_n}^* - V_{\pi}^*\|_w \leq \frac{\sigma(L, J)}{(1 - \rho)} (D_r^w(R, \hat{R}_n) + \beta \|V_{\hat{\pi}_n}^*\|_w D_q^w(Q, \hat{Q}_n)).$$

If in addition  $D_r^w(R, \hat{R}_n) \rightarrow_n 0$  and  $D_q^w(Q, \hat{Q}_n) \rightarrow_n 0$ , then  $\sup_n \|V_{\hat{\pi}_n}^*\|_w < \infty$ , and hence  $\|V_{\hat{\pi}_n}^* - V_{\pi}^*\|_w \rightarrow_n 0$ .

*Proof.* Fix  $n \geq 1$  and apply the VI algorithm for operator  $T_{\hat{\pi}_n}$  with starting value  $v_{0,n}$ ; that is, define algorithm

$$\begin{aligned} V_0 &= v_{0,n}, \\ V_i &= T_{\hat{\pi}_n} V_{i-1}, \quad i \geq 1. \end{aligned}$$

This is an AVIA satisfying Definition 3.6 with  $(\hat{R}_i, \hat{Q}_i) \equiv (R, \hat{Q}_n)$ . The conditions of Lemma 3.4 apply, giving

$$\|T_{\hat{\pi}_n} V_{i-1} - T_{\pi} V_{i-1}\| \leq D_r^w(R, \hat{R}_n) + \beta \|V_{i-1}\| D_q^w(Q, \hat{Q}_n), \quad i \geq 1.$$

Using Theorem 2.10, and noting (2.31) in the proof of Theorem 2.12, we obtain

$$\begin{aligned} \|V_{\hat{\pi}_n}^* - V_{\pi}^*\|_w &= \limsup_{i \rightarrow \infty} \|V_i - V^*\| \\ &\leq \frac{\sigma(L, J)}{(1 - \rho)} \limsup_{i \rightarrow \infty} D_r^w(R, \hat{R}_n) + \beta \|V_i\| D_q^w(Q, \hat{Q}_n), \end{aligned}$$

where  $L = 1$  for  $J = 1$ . Under the assumption  $\|V_i - V_{\hat{\pi}_n}^*\|_w \rightarrow_i 0$  the above inequality evaluates to (3.14).

Then assume  $D_r^w(R, \hat{R}_n) \rightarrow_n 0$  and  $D_q^w(Q, \hat{Q}_n) \rightarrow_n 0$ . Suppose there is an increasing sequence of integers  $n_1, n_2, \dots$  such that  $\|V_{\hat{\pi}_{n_i}}^*\|_w$  is increasing and unbounded as  $i \rightarrow \infty$ . For any  $\epsilon > 0$  we have  $I_\epsilon$  such that  $i > I_\epsilon$  implies

$$(3.15) \quad \frac{\|V_{\hat{\pi}_{n_i}}^* - V_{\pi}^*\|_w}{\|V_{\hat{\pi}_{n_i}}^*\|_w} \geq \frac{\|V_{\hat{\pi}_{n_i}}^*\|_w - \|V_{\pi}^*\|_w}{\|V_{\hat{\pi}_{n_i}}^*\|_w} \geq 1 - \epsilon$$

after applying the triangle inequality. Divide (3.14) for  $n = n_i$  by  $\|V_{\hat{\pi}_{n_i}}^*\|_w$ . As  $i \rightarrow \infty$ , the upper bound of the resulting inequality approaches 0, which combined with (3.15) leads to a contradiction. Hence  $\|V_{\hat{\pi}_n}^*\|_w$  must remain bounded. The boundedness of  $\|V_{\hat{\pi}_n}^*\|_w$  then implies  $\|V_{\hat{\pi}_n}^* - V_{\pi}^*\|_w \rightarrow_n 0$ .  $\square$

Clearly, the AVIA has the advantage that only a single VI algorithm is involved while achieving the same convergence rate. On the other hand, if an efficient specialized algorithm for calculating  $V_{\hat{\pi}_n}^*$  is available, a CEA may be preferable. Of course, intermediate options are available. We may modify an AVIA so that some number of VIs greater than one are performed using  $T_{\hat{\pi}_n}$  once  $(\hat{Q}_n, \hat{R}_n)$  is available. In this case, let  $j_n$  be the highest model index available for the approximate operator  $T_{\hat{\pi}_n}$ . The convergence rate is given in terms of  $(\hat{Q}_{j_n}, \hat{R}_{j_n})$  as given in Theorem 3.6, with the results remaining otherwise directly applicable.

**4. Value functions for approximate optimal policies.** The methods of section 3 are used to estimate the optimal achievable cost of an MDP but do not explicitly describe the properties of any particular control. Of course, the process of evaluating an approximate DPO on value function  $V$  yields a control function  $\phi(x) = \arg \min_{a \in \mathcal{K}_x} T_\pi^a V(x, a)$ , and we would expect that if  $\hat{\pi}$  is close to the true model  $\pi$ , and if  $V$  is close to the value function  $V_\pi^*$ , then  $\phi$  would be close to the optimal control function  $\phi_\pi^*$  in some sense. The purpose of this section is to formalize this idea.

Given an MDP  $(\mathcal{K}, Q, R, \beta, \Phi)$  with measure (3.1), construct, when well defined, the sequence

$$(4.1) \quad \Lambda_n^\Phi(H_n^x) = E_x^\Phi \left[ \sum_{i=n}^{\infty} \beta^{i-n} R(X_n, A_n) \mid H_n^x \right], \quad n \geq 1,$$

which can be interpreted as the expected remaining discounted cost calculated from stage  $n$  given history  $H_n^x$ . We wish to show that  $\Lambda_n^\Phi(H_n^x)$  exists, is finite, and is bounded from below by  $V_\pi^*(X_n)$ . This gives us a method of evaluating directly the consequence of using a suboptimal control and allows us to develop some notion of the convergence of a control to optimality. This approach is similar to that used in [30], in which the deviation from optimality at stage  $n$  is taken to be  $|E_x^\Phi[\Lambda_n^\Phi(H_n^x)] - E_x^\Phi[V_\pi^*(X_n)]|$ . In that terminology, a control policy is described as *asymptotically discount optimal* if this deviation vanishes as  $n \rightarrow \infty$  for all  $x \in \mathcal{X}$ . In this article, we do not employ the expectation but describe convergence directly in terms of  $\Lambda_n^\Phi(H_n^x)$ .

The measure of deviation of a control from optimality will be given by the following quantity. Define for MCM  $\pi$  and  $(x, a) \in \mathcal{K}$ ,

$$(4.2) \quad \lambda_\pi(x, a) = T_\pi^a V_\pi^*(x, a) - V_\pi^*(x).$$

This quantity is also employed in [30]. Note that if  $V_\pi^*$  is a fixed point of  $T_\pi$ , then it is easily verified that  $\lambda_\pi(x, a) \geq 0$ . We will need to impose the following conditions on MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  with solution space  $\mathcal{V}^w$ :

(B1) There exists a finite constant  $b_Q$  such that  $\int_{y \in \mathcal{X}} w(y) dQ(y \mid x, a) \leq w(x) + b_Q$  for all  $(x, a) \in \mathcal{K}$ .

(B2) There exists a finite constant  $b_\pi$  such that  $\lambda_\pi(x, a) \leq b_\pi w(x)$  for all  $(x, a) \in \mathcal{K}$ .

Condition (B1) is similar to regularity conditions developed for MCMs with unbounded rewards in, for example, [27, 35]. See also [6] for further discussion. Condition (B2) follows from (B1),  $\|V_\pi^*\| < \infty$ , and a suitable restriction on cost function  $R$  and state-action projection  $\mathcal{K}_x$ .

The important properties of (4.1) are given in the following theorem.

**THEOREM 4.1.** *Suppose an MDP  $\pi = (\mathcal{K}, Q, R, \beta)$  with control  $\Phi$  has contractive solution space  $\mathcal{V}^w$ . Suppose additionally that (B1) holds and  $\beta < 1$ . Then the quantity  $\Lambda_n^\Phi(H_n^x)$  of (4.1) is well defined, and*

$$(4.3) \quad \Lambda_n^\Phi(H_n^x) = V_\pi^*(X_n) + E_x^\Phi \left[ \sum_{i=0}^{\infty} \beta^i \lambda_\pi(X_{n+i}, A_{n+i}) \mid H_n^x \right].$$

*If, in addition, (B2) holds, then  $\Lambda_n^\Phi(H_n^x) < \infty$  w.p.1.*

*Proof.* Fix  $n$ , and note that

$$E_x^\Phi[w(X_{n+1}) \mid H_n^x] \leq w(X_n) + b_Q$$

by condition (B1). Then for any  $m \geq 1$ ,

$$\begin{aligned} E_x^\Phi[w(X_{n+m}) \mid H_n^x] &= E_x^\Phi[E_x^\Phi[w(X_{n+m}) \mid H_{n+m-1}^x] \mid H_n^x] \\ &\leq E_x^\Phi[w(X_{n+m-1}) + b_Q \mid H_n^x]. \end{aligned}$$

Repeated application of this argument gives

$$(4.4) \quad E_x^\Phi[w(X_{n+m}) \mid H_n^x] \leq w(X_n) + mb_Q.$$

Under the assumption that  $\mathcal{V}^w$  is a contractive solution space,  $V_\pi^*$  is a fixed point of  $T_\pi$ , and hence  $\lambda_\pi(x, a) \geq 0$ , so that the expectation  $E_x^\Phi[\sum_{i=0}^\infty \beta^i \lambda_\pi(X_{n+i}, A_{n+i}) \mid H_n^x]$  is well defined. Then

$$\begin{aligned} \lambda_\pi(X_{n+i}, A_{n+i}) &= R(X_{n+i}, A_{n+i}) + \beta \int_{y \in \mathcal{X}} V_\pi^*(y) dQ(y \mid X_{n+i}, A_{n+i}) - V_\pi^*(X_{n+i}) \\ &= R(X_{n+i}, A_{n+i}) + \beta E_x^\Phi[V_\pi^*(X_{n+i+1}) \mid H_{n+i}^a] - V_\pi^*(X_{n+i}), \end{aligned}$$

which, using the monotone convergence theorem and noting that  $\sigma(H_n^x) \subset \sigma(H_{n+i}^a)$  for  $i \geq 0$ , leads to

$$\begin{aligned} E_x^\Phi \left[ \sum_{i=0}^\infty \beta^i \lambda_\pi(X_{n+i}, A_{n+i}) \mid H_n^x \right] &= \lim_{N \rightarrow \infty} E_x^\Phi \left[ \sum_{i=0}^N \beta^i \lambda_\pi(X_{n+i}, A_{n+i}) \mid H_n^x \right] \\ &= \lim_{N \rightarrow \infty} E_x^\Phi \left[ \sum_{i=0}^N \beta^i R(X_{n+i}, A_{n+i}) \mid H_n^x \right] \\ (4.5) \quad &\quad -V_\pi^*(X_n) + E_x^\Phi[\beta^N \beta V_\pi^*(X_{n+N}) \mid H_n^x]. \end{aligned}$$

By assumption,  $\|V_\pi^*\|_w < \infty$ , so that

$$\begin{aligned} E_x^\Phi[\beta^N V_\pi^*(X_{n+N}) \mid H_n^x] &\leq \beta^N \|V_\pi^*\|_w E_x^\Phi[w(X_{n+N}) \mid H_n^x] \\ &\leq \beta^N \|V_\pi^*\|_w (w(X_n) + Nb_Q) \end{aligned}$$

using (4.4). This upper bound approaches 0 as  $N \rightarrow \infty$ . From (4.5) this implies that  $\Lambda_n^\Phi(H_n^x)$  of (4.1) is well defined, from which (4.3) follows. Applying (4.4) and condition (B2) gives

$$\begin{aligned} E_x^\Phi \left[ \sum_{i=0}^\infty \beta^i \lambda_\pi(X_{n+i}, A_{n+i}) \mid H_n^x \right] &\leq E_x^\Phi \left[ \sum_{i=0}^\infty \beta^i b_\pi w(X_{n+i}) \mid H_n^x \right] \\ (4.6) \quad &\leq \sum_{i=0}^\infty \beta^i (b_\pi w(X_n) + i b_\pi b_Q), \end{aligned}$$

the upper bound of which is finite, which completes the proof.  $\square$

The following theorem bounds the control error defined in (4.2) for a control function calculated (perhaps approximately) by

$$\phi(x) = \arg \min_{a \in \mathcal{K}_x} T_{\hat{\pi}}^a V(x, a)$$

when  $\hat{\pi}$  approximates true model  $\pi$  and  $V$  approximates value function  $V_\pi^*$ .

**THEOREM 4.2.** *Suppose we are given an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  with contractive solution space  $\mathcal{V}^w$  for which  $\eta_Q^w < \infty$ . Suppose we are given a second MCM  $\hat{\pi} =$*

$(\mathcal{K}, \hat{Q}, \hat{R}, \beta)$  such that  $\hat{Q}$  conforms to  $Q$ ,  $D_r^w(\hat{R}, R), D_q^w(\hat{Q}, Q)$  are finite, and  $T_{\hat{\pi}} : \mathcal{V} \rightarrow \mathcal{V}$ . For any  $V \in \mathcal{V}$  and  $\phi \in \mathcal{K}^f$  let

$$\varepsilon_V(x) = T_{\hat{\pi}}^a V(x, \phi(x)) - T_{\hat{\pi}} V(x)$$

when well defined, and set  $\varepsilon_V(x) \equiv 0$  otherwise. Then,

$$(4.7) \quad \begin{aligned} w^{-1}(x) \lambda_{\pi}(x, \phi(x)) / 2 &\leq \|V - V_{\pi}^*\|_w (\eta_Q^w + D_q^w(\hat{Q}, Q)) \\ &+ D_r^w(\hat{R}, R) + \|V_{\pi}^*\|_w D_q^w(\hat{Q}, Q) + \|\varepsilon_V\|_w / 2. \end{aligned}$$

*Proof.* If  $V \notin F(\mathcal{X}, \|\cdot\|_w)$ , then the upper bound in (4.7) is equal to  $\infty$ . Otherwise, assume  $V \in F(\mathcal{X}, \|\cdot\|_w)$ . By definition,  $V \in \mathcal{L}_Q$ , and by Lemma 3.2,  $V \in \mathcal{L}_{\hat{Q}}$ . This means the quantities  $T_{\pi} V_{\pi}^*(x)$ ,  $T_{\pi}^a V_{\pi}^*(x, a)$ ,  $T_{\hat{\pi}} V(x)$ ,  $T_{\hat{\pi}}^a V(x, a)$  are all well defined. We may write

$$(4.8) \quad \begin{aligned} w(x)^{-1} |T_{\hat{\pi}}^a V(x, a) - T_{\pi}^a V_{\pi}^*(x, a)| &\leq w(x)^{-1} |\hat{R}(x, a) - R(x, a)| \\ &+ w(x)^{-1} \beta \int w(y)^{-1} |V(y) - V_{\pi}^*(y)| w(y) f(y|x, a) d\mu_Q(y) \\ &+ w(x)^{-1} \beta \int w(y)^{-1} |V(y) - V_{\pi}^*(y)| w(y) |\hat{f}(y|x, a) - f(y|x, a)| d\mu_Q(y) \\ &+ w(x)^{-1} \beta \int w(y)^{-1} V_{\pi}^*(y) w(y) |\hat{f}(y|x, a) - f(y|x, a)| d\mu_Q(y) \\ &\leq \|V - V_{\pi}^*\|_w (\eta_Q^w + D_q^w(\hat{Q}, Q)) + D_r^w(\hat{R}, R) + \|V_{\pi}^*\|_w D_q^w(\hat{Q}, Q). \end{aligned}$$

Using the triangle inequality gives

$$\begin{aligned} w(x)^{-1} |T_{\pi}^a V^*(x, \phi(x)) - V_{\pi}^*(x)| &\leq w(x)^{-1} |T_{\pi}^a V^*(x, \phi(x)) - T_{\hat{\pi}}^a V(x, \phi(x))| \\ &+ w(x)^{-1} |T_{\hat{\pi}}^a V(x, \phi(x)) - T_{\hat{\pi}} V(x)| \\ &+ w(x)^{-1} |T_{\hat{\pi}} V(x) - V_{\pi}^*(x)| \\ &= K_1 + K_2 + K_3. \end{aligned}$$

Note that  $K_1$  can be bounded by (4.8) and  $K_2$  is equivalent to  $w(x)^{-1} \varepsilon_V(x)$ . By assumption,  $V_{\pi}^*(x)$  is finite and  $V_{\pi}^* \in \mathcal{L}_Q$ , so Lemma 3.3 applied to  $T_{\hat{\pi}}^a V(x, a)$  and  $T_{\pi}^a V_{\pi}^*(x, a)$  for fixed  $x$  may be used to bound  $K_3$  as follows:

$$\begin{aligned} w(x)^{-1} |T_{\hat{\pi}} V(x) - V_{\pi}^*(x)| &\leq w(x)^{-1} \sup_{a \in \mathcal{A}_x} |T_{\hat{\pi}}^a V(x, a) - T_{\pi}^a V_{\pi}^*(x, a)| \\ &\leq \sup_{(x, a) \in \mathcal{K}} w(x)^{-1} |T_{\hat{\pi}}^a V(x, a) - T_{\pi}^a V_{\pi}^*(x, a)|, \end{aligned}$$

which may be bounded using (4.8). Then (4.7) follows.  $\square$

We have shown that the realized cost of a policy may be estimated using two steps. First, the deviation of a particular control function  $\lambda_{\pi}(x, \phi(x))$  is bounded using Theorem 4.2. This bound is then incorporated into the expression (4.3) given in Theorem 4.1. We will illustrate this procedure on a type of adaptive control in section 6.

**5. Parametric models.** In this section we consider parametric representations of model approximations. A class of model elements  $(Q^{\theta}, R^{\theta})$  is indexed by a parameter  $\theta \in \Theta$  for some metric space  $\Theta$ . A model approximation assumes the form

$\hat{\pi} = (\mathcal{K}, \hat{Q}, \hat{R}, \beta) = (\mathcal{K}, Q^{\hat{\theta}}, R^{\hat{\theta}}, \beta)$  for some  $\hat{\theta} \in \Theta$ . Model identification then reduces to an estimation problem on  $\Theta$ , which is especially advantageous when  $\Theta$  is naturally a finite-dimensional space. Of course, any model with finite  $\mathcal{K}$  may be represented this way. This approach is especially suitable when the source of randomness of the MCM is a single underlying stochastic process, for example, some finite collection of arrival processes.

We proceed by first defining a parametric family of models, and then imposing some notion of Lipschitz continuity for model distance terms  $(D_q^w(Q^{\theta_1}, Q^{\theta_2}), D_r^w(R^{\theta_1}, R^{\theta_2}))$  with respect to  $\Theta$ . We will show that this is easily done for densities of the exponential family type, which includes many commonly used densities such as the Poisson, gamma, and Gaussian. It is important to note that little reference is made in this section to any specific MCM. The objective is rather to define a useful class of putative models from which  $(\hat{Q}, \hat{R})$  may be selected, and which permit a convenient calculation of model distances. Once this is done, the theory of sections 3 and 4 applies.

DEFINITION 5.1. *Given the state-action space  $\mathcal{K}$ , a parametric model (PM) consists of*

- (i) *a parameter space  $\Theta$  with metric  $d(\cdot, \cdot)$ ,*
- (ii) *a measure  $\mu_{\Theta} \in \mathcal{M}(\mathcal{X})$ , and*
- (iii) *a set  $M_{qr}^{\Theta} = \{(Q^{\theta}, R^{\theta}) : \theta \in \Theta\}$  of pairs in which  $Q^{\theta}$  satisfies (M4) with respect to measure  $\mu_{\Theta}$  and  $R^{\theta}$  satisfies (M5).*

*The PM is denoted  $M^{\Theta} = (\Theta, d, M_{qr}^{\Theta}, \mu_{\Theta})$ . Additionally, the PM conforms to an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  with solution space  $\mathcal{V}^w$  if  $\mu_{\Theta} = \mu_Q$ , if there exists  $\theta' \in \Theta$  such that  $(Q^{\theta'}, R^{\theta'}) = (Q, R)$ , and if the DPO for MCM  $\pi^{\theta} = (\mathcal{K}, Q^{\theta}, R^{\theta}, \beta)$  satisfies  $T_{\pi^{\theta}} : \mathcal{V} \cap \mathcal{L}_{Q^{\theta}} \rightarrow \mathcal{V}$  for each  $\theta \in \Theta$ .*

Remark 5.1. That  $T_{\pi^{\theta}} : \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w) \rightarrow \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$  may be established under the conditions of Theorem 3.5. For the types of problems considered in this article, it will generally suffice to replace  $\mathcal{V}$  with  $\mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ .

For convenience we denote the density of  $Q^{\theta}(\cdot \mid x, a)$  with respect to  $\mu_{\Theta}$  by  $f^{\theta}(\cdot \mid x, a)$  for which  $E_{x,a}^{\theta}$  is the expectation operator.

**5.1. Lipschitz continuity.** Given a natural PM, we would like to establish a form of Lipschitz continuity which will allow us to express model distance measures  $D_q^w(Q^{\theta_1}, Q^{\theta_2})$  and  $D_r^w(R^{\theta_1}, R^{\theta_2})$  in terms of  $d(\theta_1, \theta_2)$ . In practice, this will have to incorporate the weight function  $w$  used in Definition 3.3 of solution space  $\mathcal{V}^w$ . We begin with the following definition.

DEFINITION 5.2. *For a given metric space  $(\Theta, d)$ , Borel space  $\mathcal{U}$ , and a measurable function  $t : \mathcal{U} \rightarrow \mathbb{R}$ , we say a parametric family  $\{g^{\theta} : \theta \in \Theta\}$  of density functions on  $\mathcal{U}$  is  $t$ -weighted Lipschitz on  $B \subset \Theta$  if*

$$(5.1) \quad |g^{\theta_1}(u) - g^{\theta_2}(u)| \leq d(\theta_1, \theta_2)t(u) (g^{\theta_1}(u) + g^{\theta_2}(u)) \quad \forall u \in \mathcal{U}$$

*for any  $\theta_1, \theta_2 \in B$ .*

Given  $M^{\Theta} = (\Theta, d, M_{qr}^{\Theta}, \mu_{\Theta})$  defined for state-action space  $\mathcal{K}$ , a weight function  $w \in \mathcal{W}(\mathcal{X})$  and a subset  $B \in \Theta$ , define the following conditions:

- (C1) There exists a finite constant  $C_B^r$  such that

$$w(x)^{-1}|R^{\theta_1}(x, a) - R^{\theta_2}(x, a)| \leq C_B^r d(\theta_1, \theta_2)$$

for all  $(x, a) \in \mathcal{K}$ ,  $\theta_1, \theta_2 \in B$ .

- (C2) There exists a finite constant  $C_B^q$  and a measurable mapping  $t(y|x, a) : \mathcal{X} \times \mathcal{K} \rightarrow (0, \infty)$  such that for each  $(x, a) \in \mathcal{K}$  the parametric family  $\{f^\theta(\cdot|x, a) : \theta \in \Theta\}$  is  $t(\cdot|x, a)$ -weighted Lipschitz on  $B$ , with

$$(5.2) \quad \sup_{\theta \in B} \sup_{(x, a) \in \mathcal{K}} w(x)^{-1} E_{x, a}^\theta [w(Y)t(Y|x, a)] \leq C_B^q.$$

That (C1) and (C2) imply Lipschitz continuity of  $M^\Theta$  is verified in the following theorem.

**THEOREM 5.1.** *Suppose conditions (C1)–(C2) hold for a PM  $M^\Theta = (\Theta, d, M_{qr}^\Theta, \mu_\Theta)$  defined on a state-action space  $\mathcal{K}$ , a weight function  $w \in \mathcal{W}(\mathcal{X})$ , and a subset  $B \subset \Theta$ . Then*

$$(5.3) \quad D_q^w(Q^{\theta_1}, Q^{\theta_2}) \leq 2C_B^q d(\theta_1, \theta_2),$$

$$(5.4) \quad D_r^w(R^{\theta_1}, R^{\theta_2}) \leq C_B^r d(\theta_1, \theta_2)$$

for all  $\theta_1, \theta_2 \in B$ .

*Proof.* For any  $\theta_1, \theta_2 \in B$ ,  $(x, a) \in \mathcal{K}$  we have by (C2),

$$\begin{aligned} & \int_{\mathcal{X}} w(y) |f^{\theta_1}(y|x, a) - f^{\theta_2}(y|x, a)| d\mu_\Theta(y) \\ & \leq d(\theta_1, \theta_2) \int_{\mathcal{X}} w(y) t(y|x, a) (f^{\theta_1}(y|x, a) + f^{\theta_2}(y|x, a)) d\mu_\Theta(y) \\ & = d(\theta_1, \theta_2) (E_{x, a}^{\theta_1} [w(Y)t(Y|x, a)] + E_{x, a}^{\theta_2} [w(Y)t(Y|x, a)]), \end{aligned}$$

where we employ inequality (5.1). Inequality (5.3) follows by applying (5.2). Then (5.4) follows directly from assumption (C1).  $\square$

**5.2. Exponential family densities.** It is important to establish that the form of the inequality (5.1) is one that might be encountered in practice, with some natural choice of weighting function  $t(u)$ . It will, in fact, hold under general conditions for an exponential family type of density commonly employed in statistical inference. This form of density usually provides a natural relationship between a parameter space and a probability measure. See, for example, Lehmann and Casella [26].

**DEFINITION 5.3.** *An exponential family of densities on  $\mathcal{U} \subset \mathbb{R}^p$  (with respect to the Lebesgue measure) with parameter space  $\Theta \subset \mathbb{R}^k$  takes the form*

$$g^\theta(u) = \exp(v(u, \theta) - b(\theta) + h(u)), \quad u \in \mathcal{U},$$

where

$$v(u, \theta) = \sum_{i=1}^k \theta_i v_i(u),$$

for real valued functions  $v_1, \dots, v_k, h$  defined on  $\mathcal{U}$  and  $b$  defined on  $\Theta$ .

Definition 5.2 is motivated by the following theorem.

**THEOREM 5.2.** *Suppose we have an exponential family of densities given in Definition 5.3. Define metric  $d(x, y) = \|x - y\|_1$  on  $\mathbb{R}^k$ , where  $\|\cdot\|_1$  is  $\ell^1$  norm, and suppose  $b(\theta)$  is locally Lipschitz. Let  $B$  be a compact subset of  $\Theta$ . Then the exponential family is  $t$ -weighted Lipschitz on  $B$  with respect to  $d$ , with  $t(u) = \|(v_1(u), \dots, v_k(u))\|_1 + M_B$  for some finite constant  $M_B$ .*

*Proof.* We will make use of the inequality

$$(5.5) \quad |e^x - 1| \leq |x|e^{\max(0,x)} \leq |x|(1 + e^x), \quad x \in \mathbb{R}.$$

Let  $\theta_1, \theta_2 \in B$ . Setting  $\delta = \theta_2 - \theta_1$ ,  $b^\delta = b(\theta_2) - b(\theta_1)$ , we may write directly

$$|g^{\theta_2}(u) - g^{\theta_1}(u)| = |\exp(v(u, \delta) - b^\delta) - 1| |g^{\theta_1}(u)|,$$

and then using (5.5) gives

$$\begin{aligned} |g^{\theta_2}(u) - g^{\theta_1}(u)| &\leq |v(u, \delta) - b^\delta| (1 + \exp(v(u, \delta) - b^\delta)) |g^{\theta_1}(u)| \\ &= |v(u, \delta) - b^\delta| (g^{\theta_2}(u) + g^{\theta_1}(u)). \end{aligned}$$

Finally, if  $b$  is locally Lipschitz, there exists a constant  $M_B$  such that  $|b(\theta_2) - b(\theta_1)| \leq M_B d(\theta_1, \theta_2)$  for  $\theta_1, \theta_2 \in B$ . Also,  $|v(u, \delta)| \leq \|(v_1(u), \dots, v_k(u))\|_1 d(\theta_1, \theta_2)$ , giving

$$|g^{\theta_2}(u) - g^{\theta_1}(u)| \leq d(\theta_1, \theta_2) (\|(v_1(u), \dots, v_k(u))\|_1 + M_B) (g^{\theta_1}(u) + g^{\theta_2}(u))$$

for all  $u \in \mathcal{U}$ ,  $\theta_1, \theta_2 \in B$ , which concludes the proof.  $\square$

This result would be used to establish the property given in Definition 5.2, after which it would remain to be verified that the expectations in condition (C2) can be suitably bounded.

**6. Adaptive control.** We now consider the problem of adaptive control. Suppose an MDP operates indefinitely according to an MCM with unknown  $(Q, R)$ . The process history is available for constructing a sequence of model estimates  $\{\hat{Q}_n, \hat{R}_n; n \geq 1\}$ , synchronized with the stages of the MDP, which are in turn used to refine the control policy using the methods discussed in sections 3 and 4. Estimation is based on a PM of the form discussed in section 5, with parameter space  $\Theta \subset \mathbb{R}^k$ . If we cannot guarantee that statistical information regarding each component of the parameter is available at each stage, then we resort to forced exploration.

This, however, leaves us with two sources of regret. The *estimation regret* is that inherent in using a model estimate instead of the true model to calculate a control policy, which can be bounded using the methods of sections 3 and 4. The second source, *exploratory regret*, is that attributable to exploration. We take as given that a nonzero regret accrues from any exploratory behavior. We also note that by using Theorems 4.1 and 4.2 an upper bound can be placed on exploratory regret. Hence, we may place a bound on the rate at which exploratory regret is accrued by characterizing the exploration rate itself, which we take to be the rate (expressed as a proportion of stages) at which the MDP adopts an exploratory control.

Clearly, these two forms of regret represent a type of trade-off. A higher exploration rate results in lower estimation regret at the cost of higher exploration regret. The purpose of this section is to give an analytical bound for the combined regret in terms of the exploration rate. This can then be used to design an efficient exploratory control policy.

We will need to accomplish three preliminary tasks. We first need to expand our definition of an MDP in order to accommodate exploratory behavior (section 6.1). Fortunately, we can leave the basic definition given in section 3.1 essentially unaltered. We then need to develop a notion of model estimation in an online setting using process history (section 6.2). We will assume a finite-dimensional PM of the type defined in section 5. The objective will be to develop regularity conditions which permit a well-defined rate of model estimate convergence. We will also need to define precisely an exploration rate, which will permit direct calculation of estimation and exploratory regret (section 6.3).

**6.1. Definition of an adaptive MDP.** We will need to expand on the definition of an MDP to include exploratory behavior, as well as observable data available for model estimation. Throughout this section we assume the existence of an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  which possesses a contractive solution space  $\mathcal{V}^w = (\mathcal{V}, w)$  as well as an OSDP based on control function  $\phi_\pi^* \in \mathcal{K}^f$  with value function  $V_\pi^*$ . We add two new elements as follows:

- (M7) A Borel space  $\mathcal{O}$ , called the *observation space*, and a stochastic kernel  $Q^{o,x} : \mathcal{K} \rightarrow \mathcal{M}(\mathcal{O} \times \mathcal{X})$  for which  $Q^{o,x}(\mathcal{O} \times E_x \mid x, a) = Q(E_x \mid x, a)$  for all  $E_x \in \mathcal{B}(\mathcal{X})$ ,  $(x, a) \in \mathcal{K}$ .
- (M8) A binary outcome  $\mathcal{Z} = \{0, 1\}$  and a sequence of measurable mappings  $p_n^e : (\mathcal{X}\mathcal{Z}\mathcal{A}\mathcal{O})^{n-1} \times \mathcal{X} \rightarrow [0, 1]$ .

We will let  $E_{x,a}^{Q^{o,x}}$  be the expectation operator associated with  $Q^{o,x}(\cdot \mid x, a)$ . In addition to the state-action pair  $(X_n, A_n)$  and cost  $R(X_n, A_n)$ , we associate with stage  $n$  two new quantities. First, we include a random observation  $O_n$  defined on  $\mathcal{O}$ , with distribution calculable from  $Q^{o,x}(\cdot \mid X_n, A_n)$  according to (M7). This represents the information available to the controller pertaining to the  $n$ th stage transition from  $X_n$  to  $X_{n+1}$  and the realization of the  $n$ th stage cost. This is assumed to be available in time to influence the control applied at the  $n + 1$ st stage. Estimates are assumed to be sample averages of functions of  $O_n$ . This formulation suffices, for example, when the parameter represents a state transition rate, in which case  $O_n = (X_n, X_{n+1})$ . Alternatively, if the parameters represent arrival rates, then  $O_n$  may be a set of arrival counts coupled with an interobservation time. Additionally,  $O_n$  may include an observation of  $R(X_n, A_n)$ , and may incorporate observation error, although some conditions on state observability are necessary for the adaptive control policy defined below. It should be pointed out, however, that this construction does not accommodate many important recursive estimation procedures. Additional discussion of this topic will be deferred to section 6.7.

Given state  $X_n$ , a binary randomization quantity  $Z_n \in \mathcal{Z} = \{0, 1\}$  is observed, then an action  $A_n$  is selected according to a distribution dependent on the process history up to that point (including  $X_n$  and  $Z_n$ ). The role of  $Z_n$  is to define an *exploration schedule* (that is, exploratory behavior is forced when  $Z_n = 1$ ), and will be controlled by  $p_n^e$  given in (M8). It will be helpful to think of the order of realization of the random quantities as  $X_n \rightarrow Z_n \rightarrow A_n \rightarrow O_n \rightarrow X_{n+1} \rightarrow Z_{n+1} \rightarrow \dots$ . We accordingly define the Borel space  $\mathcal{S} \subset \mathcal{X}\mathcal{Z}\mathcal{A}\mathcal{O}$  to be all elements  $(x, w, a, o) \in \mathcal{X}\mathcal{Z}\mathcal{A}\mathcal{O}$  for which  $(x, a) \in \mathcal{K}$ .

It will be convenient to redefine the history vectors

$$\begin{aligned} H_n^a &= (X_1, Z_1, A_1, O_1, \dots, X_n, Z_n, A_n), \\ H_n^z &= (X_1, Z_1, A_1, O_1, \dots, X_n, Z_n), \\ H_n^x &= (X_1, Z_1, A_1, O_1, \dots, X_n). \end{aligned} \tag{6.1}$$

The adaptive control will be a mixture of two policies,  $\Phi^e = (\Phi_1^e, \Phi_2^e, \dots)$  and  $\Phi^o = (\Phi_1^o, \Phi_2^o, \dots)$ , where  $\Phi_n^e$  and  $\Phi_n^o$  are measurable mappings of  $H_n^x$  to  $\mathcal{M}(\mathcal{A})$ . The randomization variable  $Z_n$  is used to select the policy according to the form

$$\Phi_n(E_a \mid H_n^z) = (1 - Z_n)\Phi_n^o(E_a \mid H_n^x) + Z_n\Phi_n^e(E_a \mid H_n^x), \quad E_a \in \mathcal{B}(\mathcal{A}). \tag{6.2}$$

Essentially the purpose of  $\Phi^e$  is to explore, while  $\Phi^o$  in some sense converges to the OSDP. By regarding the action space as incorporating the randomization variable  $Z_n$  and the state space incorporating the observation variable  $O_n$  (while keeping  $R$  and

$Q$  independent of  $Z_n$  and  $O_n$ ), we retain the original definition of an MCM of the type defined in section 3, for which, given starting state  $X_1 = x$ , a unique measure  $P_x^\Phi$  exists on the Borel space  $\mathcal{S}^\infty$  satisfying

$$\begin{aligned} P_x^\Phi(X_1 = x) &= 1, \\ P_x^\Phi((O_n, X_{n+1}) \in E_{ox} \mid H_n^a) &= Q^{o,x}(E_{ox} \mid X_n, A_n), \quad E_{ox} \in \mathcal{B}(\mathcal{OX}), \\ P_x^\Phi(X_{n+1} \in E_x \mid H_n^a) &= Q(E_x \mid X_n, A_n), \quad E_x \in \mathcal{B}(\mathcal{X}), \\ P_x^\Phi(Z_n = 1 \mid H_n^x) &= p_n^e(H_n^x), \\ (6.3) \quad P_x^\Phi(A_n \in E_a \mid H_n^z) &= \Phi_n(E_a \mid H_n^z), \quad E_a \in \mathcal{B}(\mathcal{A}), \end{aligned}$$

for  $n \geq 1$  and each admissible history  $H_n^x, H_n^z, H_n^a$ . As above, we let  $E_x^\Phi$  be the expectation operator of  $P_x^\Phi$ , and  $x$  may be any initial state.

We additionally assume we have a PM  $M^\Theta$  which conforms to  $\pi = (\mathcal{K}, Q, R, \beta)$ , where  $\Theta \subset \mathbb{R}^k$  and the metric  $d$  on  $\Theta$  is taken to be  $d(\theta, \theta') = \|\theta - \theta'\|_1$ , where  $\|\cdot\|_1$  is  $\ell_1$  norm in  $\mathbb{R}^k$ . The true parameter is denoted  $\theta'$ , that is,  $(Q, R) = (Q^{\theta'}, R^{\theta'})$ . Estimates  $(\hat{\theta}_n, \hat{\phi}_n)$  of parameter  $\theta'$  and optimal control function  $\phi_\pi^*$  will be associated with each stage  $n$ . We therefore assume that  $(\hat{\theta}_n, \hat{\phi}_n)$  can be calculated by the end of stage  $n$ .

**6.2. Online parameter estimation.** We now consider the problem of constructing the estimators  $\hat{\theta}_n$ . It may be that a specific observation  $O_n$  contains statistical information about some, but not all, parameter components  $(\theta_1, \dots, \theta_k)$ . This will depend on the current state-action pair  $(X_n, A_n)$  through the measure  $Q^{o,x}(\cdot \mid x, a)$ . We may therefore associate with each parameter component  $\theta_j$  the elements of  $\mathcal{K}$  which admit estimation.

**DEFINITION 6.1.** Suppose we have an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$ , observation space  $\mathcal{O}$ , kernel  $Q^{o,x}$  as defined in (M7), and a conforming PM  $M^\Theta$  with  $\Theta \subset \mathbb{R}^k$  and  $(Q, R) = (Q^{\theta'}, R^{\theta'})$ . The informative subset of  $\mathcal{K}$  for component  $\theta_j$  of  $\theta = (\theta_1, \dots, \theta_k)$ , which we denote  $\mathcal{K}(\theta_j)$ , consists of all  $(x, a) \in \mathcal{K}$  for which a measurable estimator  $\bar{\theta}_j(O)$ ,  $O \in \mathcal{O}$ , exists satisfying

$$(6.4) \quad E_{x,a}^{Q^{o,x}}[\bar{\theta}_j(O)] = \theta'_j \text{ and } E_{x,a}^{Q^{o,x}}[(\bar{\theta}_j(O) - \theta'_j)^2] \leq \nu$$

for some constant  $0 \leq \nu < \infty$ , where  $\theta' = (\theta'_1, \dots, \theta'_k)$  is the true parameter.

For convenience set  $I_n(\theta_j) = I\{(X_n, A_n) \in \mathcal{K}(\theta_j)\}$ . Given measure (6.3) consider the quantities

$$W_n(\theta_j) = \sum_{i=1}^n (\bar{\theta}_j(O_i) - \theta'_j) I_i(\theta_j), \quad n \geq 1.$$

Note that the process  $(W_1(\theta_j), W_2(\theta_j), \dots)$  is adapted to the filtration  $(\sigma(H_2^a), \sigma(H_3^a), \dots)$ . From (6.3) and (6.4) we have

$$\begin{aligned} E_x^\Phi[W_n(\theta_j) \mid H_n^a] &= E_x^\Phi[(\bar{\theta}_j(O_n) - \theta'_j) I_n(\theta_j) \mid H_n^a] + W_{n-1}(\theta_j) \\ &= E_x^\Phi[(\bar{\theta}_j(O_n) - \theta'_j) I_n(\theta_j) \mid X_n, A_n] + W_{n-1}(\theta_j) \\ &= W_{n-1}(\theta_j), \quad n \geq 1, \end{aligned}$$

so that  $\{W_n(\theta_j); n \geq 0\}$  is a martingale, where we set  $W_0(\theta_j) = 0$ . Similarly define

$$\begin{aligned} \Delta_n(\theta_j) &= E_x^\Phi[(W_n(\theta_j) - W_{n-1}(\theta_j))^2 \mid H_n^a] \\ &= E_x^\Phi[(\bar{\theta}_j(O_n) - \theta'_j)^2 I_n(\theta_j) \mid H_n^a] \\ &\leq \nu I_n(\theta_j), \quad n \geq 1. \end{aligned}$$

Let  $S_n(\theta_j) = \sum_{i=1}^n \Delta_i(\theta_j)$  and define the counting process

$$M_n(\theta_j) = \sum_{i=1}^n I_i(\theta_j), \quad n \geq 1,$$

and set  $M_0(\theta_j) = 0$ . It follows that  $S_n(\theta_j) \leq \nu M_n(\theta_j)$ . Since  $\{W_n(\theta_j); n \geq 1\}$  is clearly square-integrable, we may apply a suitable martingale law of large numbers (for example, Theorem 1.3.15 in Duflo [9]) to conclude

$$\left| \frac{W_n(\theta_j)}{S_n(\theta_j)} \right| = o\left(S_n(\theta_j)^{-1/2+\epsilon}\right),$$

or equivalently,

$$(6.5) \quad \left| \frac{W_n(\theta_j)}{M_n(\theta_j)} \right| = o\left((S_n(\theta_j)/M_n(\theta_j))^{1/2+\epsilon} M_n(\theta_j)^{-1/2+\epsilon}\right) \leq o\left(M_n(\theta_j)^{-1/2+\epsilon}\right)$$

for any small  $\epsilon > 0$ . This leads to component estimates

$$(6.6) \quad \hat{\theta}_{n,j} = \begin{cases} M_n(\theta_j)^{-1} \sum_{i=1}^n \bar{\theta}_j(O_i) I_i(\theta_j); & M_n(\theta_j) \geq 1, \\ \hat{\theta}_{0,j}; & M_n(\theta_j) = 0 \end{cases}$$

for  $n \geq 1, j = 1, \dots, k$ , where  $\hat{\theta}_0 = (\hat{\theta}_{0,1}, \dots, \hat{\theta}_{0,k})$  is a suitably chosen starting value. The parameter estimate sequence is then  $\hat{\theta}_n = (\hat{\theta}_{n,1}, \dots, \hat{\theta}_{n,k})$ . From (6.5) we have

$$(6.7) \quad \begin{aligned} |\hat{\theta}_{n,j} - \theta'_j| &= o\left(M_n(\theta_j)^{-1/2+\epsilon}\right), \\ d(\hat{\theta}_n, \theta') &= o\left(M_n(\theta)^{-1/2+\epsilon}\right) \end{aligned}$$

for any  $\epsilon > 0$ , where

$$M_n(\theta) = \min_{1 \leq j \leq k} M_n(\theta_j), \quad n \geq 1.$$

Hence, convergence of  $\hat{\theta}_n$  to  $\theta'$  follows from  $M_n(\theta) \rightarrow \infty$  at a rate implied by  $M_n(\theta)$ .

Finally, the following lemma will be useful in establishing a rate of convergence for an adaptive control. We will need to impose the following condition:

(D1) For a given weight function  $w \in \mathcal{W}(\mathcal{X})$ ,

$$E_{x,a}^{Q^{o,x}}[w(X)|\bar{\theta}_j(O) - \theta'_j|] \leq \tau w(x)$$

for a finite constant  $\tau$  when  $(x, a) \in \mathcal{K}(\theta_j)$ , for each  $j = 1, \dots, k$ .

This condition supplements (B1).

LEMMA 6.1. *Suppose, under the conditions of Definition 6.1, given a weight function  $w \in \mathcal{W}(\mathcal{X})$ , conditions (B1) and (D1) hold. Then*

$$(6.8) \quad \begin{aligned} E_x^\Phi[w(X_{n+m})|\hat{\theta}_{n+m-1,j} - \theta'_j| \mid H_n^a] &\leq (w(X_n) + mb_Q)|\hat{\theta}_{n-1,j} - \theta'_j| \\ &\quad + \frac{m\tau w(X_n) + b_Q(\nu^{1/2} + \tau)m(m-1)/2}{M_n(\theta_j)} \end{aligned}$$

for  $m \geq 0, n \geq 1$ .

*Proof.* First note that  $X_n$  and  $\theta'_j$  are both  $\sigma(H_n^a)$ -measurable, so that (6.8) is easily verified for  $m = 0$ . Next assume  $m \geq 1$ . For  $n \geq 1$ , if  $M_n(\theta_j) \geq 1$  we may write

$$\begin{aligned} |\hat{\theta}_{n,j} - \theta'_j| &= \frac{|\sum_{i=1}^n (\bar{\theta}_j(O_i) - \theta'_j) I_i(\theta_j)|}{M_n(\theta_j)} \\ &\leq \frac{|(\bar{\theta}_j(O_n) - \theta'_j) I_n(\theta_j)|}{M_n(\theta_j)} + \frac{|\sum_{i=1}^{n-1} (\bar{\theta}_j(O_i) - \theta'_j) I_i(\theta_j)|}{M_n(\theta_j)}. \end{aligned}$$

Note that  $M_n(\theta_j) \geq M_{n-1}(\theta_j)$ , and that the second term of this upper bound is zero if  $M_{n-1}(\theta_j) = 0$ . We may therefore write

$$(6.9) \quad |\hat{\theta}_{n,j} - \theta'_j| \leq \frac{|(\bar{\theta}_j(O_n) - \theta'_j) I_n(\theta_j)|}{M_n(\theta_j)} + |\hat{\theta}_{n-1,j} - \theta'_j|.$$

We will need the following three inequalities:

$$(6.10) \quad E_x^\Phi \left[ w(X_{n+1}) |\hat{\theta}_{n,j} - \theta'_j| \mid H_n^a \right] \leq \frac{\tau w(X_n)}{M_n(\theta_j)} + (w(X_n) + b_Q) |\hat{\theta}_{n-1,j} - \theta'_j|,$$

$$(6.11) \quad E_x^\Phi \left[ |\hat{\theta}_{n,j} - \theta'_j| \mid H_n^a \right] \leq \frac{\nu^{1/2}}{M_n(\theta_j)} + |\hat{\theta}_{n-1,j} - \theta'_j|,$$

$$(6.12) \quad E_x^\Phi \left[ w(X_{n+1}) \mid H_n^a \right] \leq w(X_n) + b_Q.$$

Inequalities (6.10) and (6.11) make use of (6.9) and the fact that  $\hat{\theta}_{n-1,j}$  and  $M_n(\theta_j)$  are  $\sigma(H_n^a)$ -measurable. Then, in particular, (6.10) follows from (D1) and (B1), (6.11) follows from Definition 6.1 with Jensen's inequality, and (6.12) follows from (B1). Note that (6.10)–(6.12) hold trivially for  $M_n(\theta_j) = 0$ .

We then complete the argument by induction. Suppose (6.8) holds for  $n \geq 1$  for some  $m \geq 1$ . Then, considering  $m + 1$ , we write

$$\begin{aligned} &E_x^\Phi \left[ w(X_{n+m+1}) |\hat{\theta}_{n+m,j} - \theta'_j| \mid H_n^a \right] \\ &= E_x^\Phi \left[ E_x^\Phi [w(X_{n+m+1}) |\hat{\theta}_{n+m,j} - \theta'_j| \mid H_{n+1}^a] \mid H_n^a \right] \\ &\leq E_x^\Phi \left[ (w(X_{n+1}) + mb_Q) |\hat{\theta}_{n,j} - \theta'_j| + \frac{m\tau w(X_{n+1}) + b_Q(\nu^{1/2} + \tau)m(m-1)/2}{M_{n+1}(\theta_j)} \mid H_n^a \right] \\ &\leq E_x^\Phi \left[ (w(X_{n+1}) + mb_Q) |\hat{\theta}_{n,j} - \theta'_j| \mid H_n^a \right] \\ &\quad + \frac{E_x^\Phi [m\tau w(X_{n+1}) + b_Q(\nu^{1/2} + \tau)m(m-1)/2 \mid H_n^a]}{M_n(\theta_j)} \end{aligned}$$

after applying the induction hypothesis and using the fact that  $M_{n+1}(\theta_j) \geq M_n(\theta_j)$  and that  $M_n(\theta_j)$  is  $\sigma(H_n^a)$ -measurable. Direct application of inequalities (6.10)–(6.12) yields, after some algebra, (6.8) with  $m$  incremented to  $m + 1$ . The proof follows by noting that for  $m = 1$ , (6.8) follows directly from (6.10).  $\square$

**6.3. Exploration rates.** In order to verify convergence of  $\hat{\theta}_n$  to  $\theta'$  we must have each informative subset  $\mathcal{K}(\theta_j)$  visited infinitely often. This is not problematic if  $\mathcal{K}(\theta_j) \equiv \mathcal{K}$  for each  $\theta_j$ , or if we may otherwise verify that  $M_n(\theta) \rightarrow_n \infty$  for a sufficiently rich class of control policies. In the absence of any such guarantee, one

method of ensuring sufficient exploration is to employ blocks of exploratory control, which is the motivation for the mixed policy defined in (6.2). Define

$$\begin{aligned} B_n &= I\{Z_n = 1\}I\{Z_{n-1} = 0\}, \quad n \geq 1, \\ S_n &= \sum_{i=1}^n B_i, \quad n \geq 1, \\ J_k &= \inf\{j : S_j = k\}, \quad k \geq 1, \\ I_k &= \inf\{m \geq 1 : Z_{J_k+m} = 0\}I\{J_k < \infty\}, \quad k \geq 1, \end{aligned}$$

setting for convenience  $Z_0 = 0$ . A block begins at stage  $n$  if  $B_n = 1$ ,  $S_n$  is the number of blocks begun by stage  $n$ ,  $J_k$  is the stage at which the  $k$ th block begins, and  $I_k$  is the duration of the  $k$ th block. We will employ the following conditions:

- (D2)  $S_n \rightarrow_n \infty$ .
- (D3) For some constant  $\delta > 0$ , for each  $\theta_j$  of  $\theta$ ,

$$P_x^\Phi(K_n(\theta_j)I\{B_n = 1\} \mid H_n^z) \geq \delta I\{B_n = 1\},$$

where

$$K_n(\theta_j) = \cup_{j=1}^{I_{S_n}} \{(X_{n+j-1}, A_{n+j-1}) \in \mathcal{K}(\theta_j)\},$$

for  $n \geq 1$ .

*Remark 6.1.* Under (D2) the sequence  $\{J_k : k \geq 1\}$  satisfies  $J_k < \infty$  and forms an increasing sequence of stopping times.

*Remark 6.2.* Condition (D3) states that given that a block begins at stage  $n$ , conditional on the history up to that block, the probability of visiting  $\mathcal{K}(\theta_j)$  within the block is at least  $\delta$ . It holds uniformly over all  $X_n$  and  $\theta_j$ . This requirement was devised primarily for mathematical convenience, and in practice may need to be relaxed. The use of an exploratory control in an actual control setting would presumably be subject to many practical constraints. See Thrun [33] for an interesting discussion of this issue.

We make use of the following theorem due to Dubins and Freedman [8].

**THEOREM 6.2.** *Suppose a sequence of events  $E_j$  is adapted to filtration  $\mathcal{F}_j$ ,  $j \geq 0$ , defined on probability measure  $P$ ; then*

$$L_n = \frac{\sum_{j=1}^n I\{E_j\}}{\sum_{j=1}^n P(E_j|\mathcal{F}_{j-1})}$$

*converges to a finite limit  $L$  w.p.1, with  $L = 1$  on  $\{\sum_{j \geq 1} P(E_j|\mathcal{F}_{j-1}) = \infty\}$ .*

Under conditions (D2) and (D3), the exploration rate follows from the counting process  $S_n$ , as formalized in the following theorem.

**THEOREM 6.3.** *Given an MDP with measure (6.3), if (D2)–(D3) hold, then*

$$\liminf_{n \rightarrow \infty} \frac{M_n(\theta_j)}{S_n} \geq \delta$$

*w.p.1 for all  $\theta_j$ .*

*Proof.* By (D2)  $J_1, J_2, \dots$  forms a sequence of increasing, finite stopping times. We may define the  $\sigma$ -algebra  $\mathcal{F}_k^J \subset \mathcal{S}^\infty$  to be that generated by Borel sets resolvable

by  $(X_1, Z_1, A_1, O_1, \dots, X_{J_k}, Z_{J_k})$ . This defines filtration  $\mathcal{F}^J = (\mathcal{F}_1^J, \mathcal{F}_2^J, \dots)$ . We then have

$$(6.13) \quad M_n(\theta_j) \geq \sum_{k=1}^{S_n-1} I\{K_{J_k}(\theta_j)\}, \quad n \geq 1,$$

where we set the summation to be zero for  $S_n - 1 < 1$ . We then argue that  $K_{J_k}(\theta_j) \in \mathcal{F}_{k+1}^J$ , since the occurrence of  $K_{J_k}(\theta_j)$  is resolved before stopping time  $J_{k+1}$ . On the other hand, by (D3) we have  $P_x^\Phi(K_{J_k}(\theta_j) \mid \mathcal{F}_k^J) \geq \delta$ ,  $k \geq 1$ . Applying Theorem 6.2 and noting (D2) and (6.13) gives

$$1 = \lim_{n \rightarrow \infty} \frac{\sum_{k=1}^{S_n-1} I\{K_{J_k}(\theta_j)\}}{\sum_{k=1}^{S_n-1} P_x^\Phi(K_{J_k}(\theta_j) \mid \mathcal{F}_k^J)} \leq \liminf_{n \rightarrow \infty} \frac{M_n(\theta_j)}{\delta(S_n - 1)} \quad \text{w.p.1,}$$

which proves the theorem.  $\square$

The consequence of Theorem 6.3 is that under conditions (D2)–(D3), given (6.7), the exploration schedule will guarantee

$$d(\hat{\theta}_n, \theta') = o\left(S_n^{-1/2+\epsilon}\right)$$

for any  $\epsilon > 0$ .

**6.3.1. Randomized exploration schedules.** It is straightforward to devise a completely deterministic schedule that satisfies condition (D2). Alternatively, the exploration schedule may be randomized, in which case it remains to define conditions on block transition probabilities which ensure (D2). Define the sequence of mappings  $\alpha_n(H_n^x)$  by

$$P_x^\Phi(B_n = 1 \mid H_n^x) = \alpha_n(H_n^x) I\{Z_{n-1} = 0\}, \quad n \geq 1.$$

We may interpret  $\alpha_n(H_n^x)$  as the probability of entering an exploration block at stage  $n$ , given that the MDP was not in an exploration block at stage  $n-1$ . In fact,  $\alpha_n(H_n^x)$  follows from  $p_n^e$  by  $\alpha_n(H_n^x) I\{Z_{n-1} = 0\} = p_n^e(H_n^x) I\{Z_{n-1} = 0\}$ . The following theorem gives a well-defined rate for  $S_n$  in terms of  $\alpha_n(H_n^x)$ .

**THEOREM 6.4.** *Given an MDP with measure (6.3), if w.p.1*

- (i)  $\sum_{i=1}^n \alpha_i(H_i^x) \rightarrow_n \infty$ ,
- (ii)  $\alpha_n(H_n^x) \rightarrow_n 0$ , and
- (iii)  $\limsup_{k \rightarrow \infty} k^{-1}(I_1 + \dots + I_k) = \mu_I < \infty$ ,

then

$$\lim_{n \rightarrow \infty} \frac{S_n}{\sum_{i=1}^n \alpha_i(H_i^x)} = 1.$$

*Proof.* Suppose  $S_n$  is bounded. Then either  $Z_n = 1$  for all large enough  $n$ , or  $Z_n = 0$  for all large enough  $n$ . The first case contradicts (iii), since  $I_k = \infty$  for some finite  $k$ . For the second case, there exists  $N$  such that for  $n > N$ , we have

$$\sum_{i=1}^n P_x^\Phi(B_i = 1 \mid H_i^x) = \sum_{i=1}^n \alpha_n(H_i^x) I\{Z_{n-1} = 0\} \geq \sum_{i=N}^n \alpha_i(H_i^x).$$

The lower bound approaches  $\infty$  as  $n \rightarrow \infty$  by (i). Noting that the process  $(B_1, B_2, \dots)$  is adapted to  $(\sigma(H_2^x), \sigma(H_3^x), \dots)$  we may use Theorem 6.2 to conclude that  $S_n \rightarrow \infty$ ,

leading to a contradiction. We must therefore have  $S_n \rightarrow_n \infty$ , which in turn implies  $\sum_{i=1}^{\infty} P_x^\Phi(B_i = 1 \mid H_i^x) = \infty$ . We then have

$$(6.14) \quad \begin{aligned} \sum_{i=1}^n P_x^\Phi(B_i = 1 \mid H_i^x) &= \sum_{i=1}^n \alpha_i(H_i^x) I\{Z_{i-1} = 0\} \\ &= \sum_{i=1}^n \alpha_i(H_i^x) - \sum_{i=1}^n \alpha_i(H_i^x) I\{Z_{i-1} = 1\}. \end{aligned}$$

Fix  $\epsilon > 0$ . From (ii), (iii) there is  $N_\epsilon$  such that  $S_n^{-1} \sum_{i=1}^n I\{Z_i = 1\} < \mu_I + \epsilon$  and  $\alpha_n(H_n^x) < \epsilon$  for  $n > N_\epsilon$ . The final summation in (6.14) satisfies

$$\sum_{i=1}^n \alpha_i(H_i^x) I\{Z_{i-1} = 1\} < K_\epsilon + \epsilon(\mu_I + \epsilon)S_n$$

for  $n > N_\epsilon$  and some finite  $K_\epsilon$ . Dividing (6.14) by  $S_n$  and letting  $n \rightarrow \infty$  gives

$$\limsup_{n \rightarrow \infty} \left| \frac{\sum_{i=1}^n P_x^\Phi(B_i \mid H_i^x)}{S_n} - \frac{\sum_{i=1}^n \alpha_i(H_i^x)}{S_n} \right| < \epsilon(\mu_I + \epsilon),$$

which proves the theorem using Theorem 6.2, letting  $\epsilon \rightarrow 0$ .  $\square$

It will be convenient to define a class of *randomized* exploration schedules. The essential feature is that transitions into and out of exploration blocks conditioned on the current history remain essentially random.

DEFINITION 6.2. An exploration schedule  $\{p_n^e(H^x); n \geq 1\}$  is randomized if

- (i) there exists a constant  $\gamma < 1$  such that  $p_n^e(H_n^x) \leq \gamma$ ,  $n \geq 1$ , w.p.1;
- (ii) there exists a sequence of constants  $\alpha_n^u$  such that  $\alpha_n(H_n^x) \leq \alpha_n^u$ , and we have

$$\liminf_{n \rightarrow \infty} \frac{\sum_{i=1}^n \alpha_i(H_i^x)}{\sum_{i=1}^n \alpha_i^u} = K_\alpha$$

w.p.1 for a finite constant  $K_\alpha > 0$ .

For convenience set

$$\xi_n = \sum_{i=1}^n \alpha_i^u \text{ and } \bar{\alpha}_n^u = \sup_{m \geq 0} \alpha_{n+m}^u, \quad n \geq 1.$$

The advantages of a randomized exploration schedule might be considered largely mathematical. It easily guarantees sufficient variety of state-action pairs while obeying a well-defined exploration rate. But Remark 6.2 may be equally relevant here. We summarize the rate of a randomized exploration schedule in the following theorem.

THEOREM 6.5. Suppose a randomized exploration schedule (Definition 6.2) satisfies  $\alpha_n^u \rightarrow_n 0$  and  $\xi_n \rightarrow_n \infty$ . Then w.p.1,

$$(6.15) \quad \liminf_{n \rightarrow \infty} \frac{S_n}{\xi_n} > 0$$

and

$$(6.16) \quad \liminf_{n \rightarrow \infty} \frac{\alpha_n^u}{P_x^\Phi(Z_n = 1)} \geq (1 - r_u \gamma),$$

where  $r_u = \limsup_{n \rightarrow \infty} \alpha_{n-1}^u / \alpha_n^u$ .

*Proof.* By hypothesis, and condition (ii) of Definition 6.2, conditions (i)–(ii) of Theorem 6.4 are satisfied. Additionally, condition (i) of Definition 6.2 implies condition (iii) of Theorem 6.4 for some  $\mu_I < \infty$ . Then (6.15) follows directly from Theorem 6.4.

We may then write for  $n \geq 1$ , under Definition 6.2,

$$\begin{aligned} P_x^\Phi(Z_n = 1) &= P_x^\Phi(Z_n = 1 \mid Z_{n-1} = 0)P_x^\Phi(Z_{n-1} = 0) \\ &\quad + P_x^\Phi(Z_n = 1 \mid Z_{n-1} = 1)P_x^\Phi(Z_{n-1} = 1) \\ &\leq \alpha_n^u P_x^\Phi(Z_{n-1} = 0) + \gamma P_x^\Phi(Z_{n-1} = 1) \\ &\leq \alpha_n^u + \gamma P_x^\Phi(Z_{n-1} = 1), \end{aligned}$$

which, applied iteratively, gives

$$(6.17) \quad P_x^\Phi(Z_n = 1) \leq \sum_{i=1}^n \gamma^{n-i} \alpha_i^u.$$

Then (6.16) follows from a direct application of Lemma 2.3 to the upper bound of (6.17).  $\square$

An example of a randomized exploration schedule is easy to construct. We may generate a production schedule  $Z_1, Z_2, \dots$  with  $Z_0 = 0$  from a nonhomogenous Markov chain with transition matrix

$$K_n = \begin{bmatrix} 1 - \alpha_n & \alpha_n \\ 1 - \gamma & \gamma \end{bmatrix}$$

with suitably chosen  $\alpha_n, \gamma$ , governing the transition from  $Z_{n-1}$  to  $Z_n$ , and assume transitions occur independently of process history.

Finally, we will make use of the following lemma.

LEMMA 6.6. *Given an MDP (6.3), if a weight function  $w \in \mathcal{W}(\mathcal{X})$  satisfies (B1), for a randomized exploration schedule (Definition 6.2) we have for  $n \geq 1$ ,  $m \geq 0$ ,*

$$(6.18) \quad \begin{aligned} &E_x^\Phi[w(X_{n+m})I\{Z_{n+m} = 1\} \mid H_n^x] \\ &\leq (w(X_n) + mb_Q)I\{Z_{n-1} = 1\} + \bar{\alpha}_n^u(m+1)(w(X_n) + mb_Q). \end{aligned}$$

*Proof.* We have

$$\{Z_{n+m} = 1\} \subset \{Z_{n-1} = 1\} \cup \left(\bigcup_{j=0}^m \{B_{n+j} = 1\}\right),$$

which implies

$$(6.19) \quad \begin{aligned} E_x^\Phi[w(X_{n+m})I\{Z_{n+m} = 1\} \mid H_n^x] &\leq E_x^\Phi[w(X_{n+m}) \mid H_n^x]I\{Z_{n-1} = 1\} \\ &\quad + \sum_{j=0}^m E_x^\Phi[w(X_{n+m})I\{B_{n+j} = 1\} \mid H_n^x]. \end{aligned}$$

To analyze the terms in (6.19), we write, for  $j \geq 0$ ,

$$(6.20) \quad \begin{aligned} E_x^\Phi[w(X_{n+j})I\{B_{n+j} = 1\} \mid H_n^x] &= E_x^\Phi[E_x^\Phi[w(X_{n+j})I\{B_{n+j} = 1\} \mid H_{n+j}^x] \mid H_n^x] \\ &= E_x^\Phi[E_x^\Phi[I\{B_{n+j} = 1\} \mid H_{n+j}^x]w(X_{n+j}) \mid H_n^x] \\ &\leq E_x^\Phi[\alpha_{n+j}^u w(X_{n+j}) \mid H_n^x] \end{aligned}$$

from Definition 6.2. First suppose  $m = 0$ . Then (6.18) follows by applying (6.20), with  $j = 0$ , to (6.19) and then noting that  $X_n$  is  $\sigma(H_n^x)$ -measurable and that  $\alpha_n^u \leq \bar{\alpha}_n^u$ . Then suppose  $m \geq 1$ . Setting  $j = 0, \dots, m-1$ , we have

$$\begin{aligned} E_x^\Phi[w(X_{n+m})I\{B_{n+j} = 1\} \mid H_n^x] &= E_x^\Phi[E^\Phi[w(X_{n+m})I\{B_{n+j} = 1\} \mid H_{n+m-1}^a] \mid H_n^x] \\ &= E_x^\Phi[E^\Phi[w(X_{n+m}) \mid H_{n+m-1}^a]I\{B_{n+j} = 1\} \mid H_n^x] \\ (6.21) \qquad \qquad \qquad &\leq E_x^\Phi[(w(X_{n+m-1}) + b_Q)I\{B_{n+j} = 1\} \mid H_n^x] \end{aligned}$$

by (B1), noting that  $B_{n+j}$  is  $\sigma(H_{n+m-1}^a)$ -measurable if  $j \leq m-1$ . Iterating (6.21) and applying (6.20) gives

$$\begin{aligned} E_x^\Phi[w(X_{n+m})I\{B_{n+j} = 1\} \mid H_n^x] &\leq E_x^\Phi[(w(X_{n+j}) + (m-j)b_Q)I\{B_{n+j} = 1\} \mid H_n^x] \\ &\leq E_x^\Phi[\alpha_{n+j}^u(w(X_{n+j}) + (m-j)b_Q) \mid H_n^x]; \end{aligned}$$

hence (6.19) implies

$$\begin{aligned} E_x^\Phi[w(X_{n+m})I\{Z_{n+m} = 1\} \mid H_n^x] &\leq E_x^\Phi[w(X_{n+m}) \mid H_n^x]I\{Z_{n-1} = 1\} \\ (6.22) \qquad \qquad \qquad &+ \sum_{j=0}^m \alpha_{n+j}^u (E_x^\Phi[w(X_{n+j}) \mid H_n^x] + (m-j)b_Q). \end{aligned}$$

Then apply (4.4) to (6.22), which yields (6.18).  $\square$

**6.4. Control policy definition.** We are now in a position to define an adaptive control policy for which a bound on total regret may be calculated, which consists of the following elements:

- (E1) *Control model.* We have an MCM  $\pi = (\mathcal{K}, Q, R, \beta)$  with  $\beta < 1$ . There is a contractive solution space  $\mathcal{V}^w$  and an OSDP based on control function  $\phi_\pi^* \in \mathcal{K}^f$ . The definition includes the observation process defined in (M7) and an exploration schedule defined in (M8). The policy  $\Phi$  assumes the form given in (6.2), and hence the process is governed by the measure defined by (6.3).
- (E2) *Weight function.* The weight function associated with  $\mathcal{V}^w$  satisfies (B1)–(B2). We will further assume that  $\inf_x w(x) > 0$ . If not, we may add a positive constant to  $w(x)$ , after which (B1)–(B2) will still hold. In this case (B1) implies  $\eta_Q^w < \infty$ .
- (E3) *PM.* We assume the existence of a PM  $M^\Theta$  which conforms to  $\pi$  and  $\mathcal{V}^w$ . We assume that  $\Theta \subset \mathbb{R}^k$  for finite dimension  $k$  and take the metric  $d$  to be based on the  $\ell_1$  norm. The true parameter is denoted by  $\theta' = (\theta'_1, \dots, \theta'_k)$ . We further assume that  $D_r^w(R, R^\theta) < \infty$  and  $D_q^w(Q, Q^\theta) < \infty$  for all  $\theta \in \Theta$ . In addition, we assume that Lipschitz continuity conditions (5.3) and (5.4) hold for finite constants  $C_B^q, C_B^r$ . By Theorem 5.1, this follows from (C1)–(C2).
- (E4) *CEA.* For each  $\theta \in \Theta$ , the conditions of Theorem 3.5 follow from (E1)–(E3), so we may assert  $T_{\pi^\theta} : \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w) \rightarrow \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$ . Suppose for each  $\theta \in \Theta$  there exists elements  $v_{0,\theta}, V_{\pi^\theta}^* \in \mathcal{V} \cap F(\mathcal{X}, \|\cdot\|_w)$  for which  $\|T_{\pi^\theta}^i v_{0,\theta} - V_{\pi^\theta}^*\|_w \rightarrow_i 0$ . Then we may construct a CEA (Definition 3.7) from any sequence  $\hat{\theta}_1, \hat{\theta}_2, \dots$ .
- (E5) *Parametric estimation.* Assume that the informative subset  $\mathcal{K}(\theta_j)$  is nonempty for each  $\theta_j$ . At stage  $n$  we may calculate estimate  $\hat{\theta}_n = (\hat{\theta}_{n,1}, \dots, \hat{\theta}_{n,k})$ , using the estimators defined by (6.6). We also assume that condition (D1) holds.

- (E6) *Exploratory control.* We assume  $p_n^e$  is a randomized exploration schedule (Definition 6.2) which satisfies the conditions of Theorem 6.5, from which (D2) follows. We assume  $\Phi^e$  satisfies condition (D3), hence Theorem 6.3 applies, so that given (6.7) we may conclude

$$d(\hat{\theta}_n, \theta') = o\left(S_n^{-1/2+\epsilon}\right)$$

for any  $\epsilon > 0$ . We further assume that in Theorem 6.5  $(1 - r_u \gamma) > 0$ .

- (E7) *Optimal control.* At stage  $n$  an estimate  $\hat{\phi}_n$  of  $\phi_\pi^*$  is calculated based on model  $\hat{\pi}_n = \pi^{\hat{\theta}_{n-1}}$ . The lag of one stage is due to the fact that  $\hat{\theta}_n$  is dependent on observation  $O_n$ , which is observed after control  $A_n$  is applied, while  $\hat{\theta}_{n-1}$  may be observed before. A default estimate for  $\hat{\theta}_0$  is assumed to be available. The value function  $V_{\hat{\pi}_n}^*$  given in (E4) is calculated. For each  $x \in \mathcal{X}$  a minimization operation is undertaken for  $T_{\hat{\pi}_n}^a V_{\hat{\pi}_n}^*(x, a)$  over  $a \in \mathcal{K}_x$ , with  $\hat{\phi}_n(x)$  set to the solution. The actual minimum may or may not be achievable. In either case we set

$$\varepsilon_n(x) = T_{\hat{\pi}_n}^a V_{\hat{\pi}_n}^*(x, \hat{\phi}_n(x)) - T_{\hat{\pi}_n} V_{\hat{\pi}_n}^*(x).$$

In principle, this quantity may be made arbitrarily small if the minimization cannot be exact. The optimal component of the control  $\Phi$  is then given by

$$\Phi_n^o(E_a \mid H_n^x) = I\{\hat{\phi}_n(X_n) \in E_a\}$$

for any  $E_a \in \mathcal{B}(\mathcal{A})$ .

Our final task is to estimate the combined regret of the MDP defined by (E1)–(E7). This is done in the form of an upper bound on  $\Lambda_n^\Phi(H_n^x)$ . In the discussion which follows,  $c_1, \dots, c_{12}$  are finite positive constants which do not depend on  $n$ . Their exact values are omitted for the sake of clarity.

For any MDP with a contractive solution space satisfying (B1)–(B2), an upper bound is directly obtainable from (4.3) and (4.6) of Theorem 4.1 and its proof. In particular, there exist constants  $c_1, c_2$  for which

$$(6.23) \quad \Lambda_n^\Phi(H_n^x) \leq V_\pi^*(X_n) + c_1 w(X_n) + c_2 \leq V_\pi^*(X_n) + \left(c_1 + \frac{c_2}{w^*}\right) w(X_n),$$

where  $w^* = \inf_x w(x)$ . A refinement of this bound for the adaptive policy discussed here follows.

**THEOREM 6.7.** *For the MDP defined in (E1)–(E7) the following bound on regret holds:*

$$(6.24) \quad \begin{aligned} \Lambda_x^\Phi(H_n^x) \leq & V_\pi^*(X_n) + (w(X_n) + 1)(c_9 I\{Z_{n-1} = 1\} + c_{10} \bar{\alpha}_n^u \\ & + c_{11} d(\hat{\theta}_{n-1}, \theta') + c_{12} (M_{n-1}(\theta))^{-1}) \end{aligned}$$

for some finite constants  $c_9, c_{10}, c_{11}, c_{12}$ .

*Proof.* First, bound the error of the value function estimate of the CEA. Under the Lipschitz property of  $M^\Theta$  we have

$$(6.25) \quad \max\left(D_q^w(Q^{\hat{\theta}_n}, Q), D_r^w(R^{\hat{\theta}_n}, R)\right) \leq C_B d(\hat{\theta}_n, \theta'), \quad n \geq 1,$$

for some finite  $C_B$ . Then Theorem 3.7 may be re-expressed as

$$(6.26) \quad \begin{aligned} & \|V_{\hat{\pi}_n}^* - V_{\pi}^*\|_w \left(1 - c_3 D_q^w(Q^{\hat{\theta}_{n-1}}, Q)\right) \\ & \leq c_4 \max \left(D_r^w(R^{\hat{\theta}_{n-1}}, R), D_q^w(Q^{\hat{\theta}_{n-1}}, Q)\right), \quad n \geq 1, \end{aligned}$$

for finite positive constants  $c_3, c_4$ , making use of the inequality  $\|V_{\hat{\pi}_n}^*\|_w \leq \|V_{\hat{\pi}_n}^* - V_{\pi}^*\|_w + \|V_{\pi}^*\|_w$ , and the fact that  $\|V_{\pi}^*\|_w < \infty$ . Given (6.25) and (6.26) we may then identify constants  $c_5, c_6$  such that

$$(6.27) \quad \|V_{\hat{\pi}_n}^* - V_{\pi}^*\|_w \leq c_5 d(\hat{\theta}_{n-1}, \theta') \quad \text{when } d(\hat{\theta}_{n-1}, \theta') \leq c_6.$$

With sufficient regularity conditions we can set the quantity  $\varepsilon_n \equiv 0$  defined in (E7); otherwise, we assume that  $\varepsilon_n$  may be made as small as we wish. Then by Theorem 4.2 and (6.27) there is a constant  $c_7$  such that

$$\lambda_{\pi}(x, \hat{\phi}_n(x)) \leq c_7 w(x) d(\hat{\theta}_{n-1}, \theta') \quad \text{when } d(\hat{\theta}_{n-1}, \theta') \leq c_6$$

if we may ensure, say, that  $\|\varepsilon_n\|_w \leq d(\hat{\theta}_{n-1}, \theta')$ . Then for fixed  $n$ ,  $m \geq 0$  consider a term of the form

$$(6.28) \quad \begin{aligned} \lambda_{\pi}(X_{n+m}, A_{n+m}) & \leq \lambda_{\pi}(X_{n+m}, A_{n+m}) I\{Z_{n+m} = 1\} \\ & + \lambda_{\pi}(X_{n+m}, A_{n+m}) I\{Z_{n+m} = 0 \wedge d(\hat{\theta}_{n+m-1}, \theta') \leq c_6\} \\ & + \lambda_{\pi}(X_{n+m}, A_{n+m}) I\{d(\hat{\theta}_{n+m-1}, \theta') > c_6\} \\ & = B_{n+m}^1 + B_{n+m}^2 + B_{n+m}^3 \end{aligned}$$

and consider the problem of estimating  $E_x^{\Phi}[\lambda_{\pi}(X_{n+m}, A_{n+m}) \mid H_n^x]$ . For term  $B_{n+m}^1$ , by condition (B2) and Lemma 6.6 we may write

$$(6.29) \quad \begin{aligned} E_x^{\Phi}[B_{n+m}^1 \mid H_n^x] & \leq b_{\pi} E_x^{\Phi}[w(X_{n+m}) I\{Z_{n+m} = 1\} \mid H_n^x] \\ & \leq b_{\pi} ((w(X_n) + mb_Q) I\{Z_{n-1} = 1\} + \bar{\alpha}_n^u(m+1)(w(X_n) + mb_Q)). \end{aligned}$$

For term  $B_{n+m}^2$  note that  $Z_{n+m} = 0$  implies  $A_{n+m} = \hat{\phi}_{n+m}(X_{n+m})$ , so that

$$(6.30) \quad B_{n+m}^2 \leq c_7 w(X_{n+m}) d(\hat{\theta}_{n+m-1}, \theta').$$

Finally, we may write

$$(6.31) \quad B_{n+m}^3 \leq b_{\pi} c_6^{-1} w(X_{n+m}) d(\hat{\theta}_{n+m-1}, \theta').$$

By applying Lemma 6.1 to each of the  $k$  terms of  $d(\hat{\theta}_{n+m-1}, \theta')$  we have, for  $m \geq 0$ ,

$$(6.32) \quad \begin{aligned} E_x^{\Phi}[w(X_{n+m}) d(\hat{\theta}_{n+m-1}, \theta') \mid H_n^x] & = E_x^{\Phi}[E_x^{\Phi}[w(X_{n+m}) d(\hat{\theta}_{n+m-1}, \theta') \mid H_n^a] \mid H_n^x] \\ & \leq E_x^{\Phi} \left[ (w(X_n) + mb_Q) d(\hat{\theta}_{n-1}, \theta') \right. \\ & \quad \left. + \frac{m\tau w(X_n) + b_Q(\nu^{1/2} + \tau)m(m-1)/2}{M_n(\theta)} \mid H_n^x \right] \\ & \leq (w(X_n) + mb_Q) d(\hat{\theta}_{n-1}, \theta') \\ & \quad + \frac{m\tau w(X_n) + b_Q(\nu^{1/2} + \tau)m(m-1)/2}{M_{n-1}(\theta)}, \end{aligned}$$

noting that  $M_{n-1}(\theta) \leq M_n(\theta) \leq M_n(\theta_j)$  and that  $X_n, \hat{\theta}_{n-1}$  and  $M_{n-1}(\theta)$  are each  $\sigma(H_n^x)$ -measurable.

Combining (6.28)–(6.32) gives, for some finite constant  $c_8$ ,

$$(6.33) \quad \begin{aligned} E_x^\Phi[\lambda_\pi(X_{n+m}, A_{n+m}) \mid H_n^x] &\leq b_\pi(w(X_n) + mb_Q)I\{Z_{n-1} = 1\} \\ &\quad + b_\pi \bar{\alpha}_n^u(m+1)(w(X_n) + mb_Q) \\ &\quad + c_8(w(X_n) + mb_Q)d(\hat{\theta}_{n-1}, \theta') \\ &\quad + c_8 \frac{m\tau w(X_n) + b_Q(\nu^{1/2} + \tau)m(m-1)/2}{M_{n-1}(\theta)}. \end{aligned}$$

Applying Theorem 4.1 to inequality (6.33) yields after taking suitable summations (6.24).  $\square$

The importance of (6.24) is that it decomposes the bound on regret into that attributable to exploration and estimation. Furthermore, each source of regret can be explicitly related to the exploration rate, permitting selection of that rate. By Theorems 6.3 and 6.5 we have, for  $\epsilon > 0$ ,

$$(6.34) \quad d(\hat{\theta}_n, \theta') = o\left(\xi_n^{-1/2+\epsilon}\right).$$

For the sake of argument, suppose  $\alpha_n^u \propto n^{-r}$  for  $0 < r \leq 1$ . Then  $\xi_n \propto n^{1-r}$  for  $r < 1$  and  $\xi_n \propto \log(n)$  for  $r = 1$ . This gives  $d(\hat{\theta}_{n-1}, \theta') = o(n^{(r-1)/2+\epsilon})$ , and  $M_n(\theta)^{-1} = O(n^{r-1})$  for  $r < 1$  and  $d(\hat{\theta}_{n-1}, \theta') = o(\log(n)^{-1/2+\epsilon})$ , and  $M_n(\theta)^{-1} = O(\log(n)^{-1})$  for  $r = 1$ , which yields

$$\Lambda^\Phi(H_n^x) = V_\pi^*(X_n) + (w(X_n) + 1) \left( c_9 I\{Z_{n-1} = 1\} + O(n^{-r}) + o(n^{(r-1)/2+\epsilon}) \right)$$

for  $r < 1$  and

$$\Lambda^\Phi(H_n^x) = V_\pi^*(X_n) + (w(X_n) + 1) \left( c_9 I\{Z_{n-1} = 1\} + O(n^{-1}) + o(\log(n)^{-1/2+\epsilon}) \right)$$

for  $r = 1$ . By Theorem 6.5 we have  $P_x^\Phi(Z_n = 1) = O(\alpha_n^u) = O(n^{-r})$ ; thus we may take the overall contribution to regret due to exploration to be  $O(n^{-r})$ , and that due to estimation to be  $o(n^{(r-1)/2+\epsilon})$  for  $r < 1$  or  $o(\log(n)^{-1/2+\epsilon})$  for  $r = 1$ . The upper bound is optimized by setting  $r = 1/3$ ; that is, we may devise an adaptive policy at which regret is accrued at rate  $o(n^{-1/3+\epsilon})$ .

**7. Conclusion and further work.** We have formulated the basis for a general theory of approximate iterative algorithms, giving a comprehensive set of convergence results following from properties given in terms of normed linear spaces.

The value of such a theory was illustrated by an extended application to the problem of model-based approximate and adaptive control of Markov decision processes. The theory permitted a sharpening of known convergence rates, applied to a more general model. Additionally, bounds on regret for adaptive controls with forced exploration are calculated in terms of a stagewise exploration rate. This permits the determination of an optimal choice of exploration rate.

Although this work establishes a number of important mathematical principles, there are a number of areas in which further refinement would make the theory more relevant to the practical design of control policies.

Attention was restricted to discounted cost models. Alternative norms or operators which induce the contraction property have been developed for the average cost

criterion control model (see, for example, [18, 19, 3, 36]). Application of this theory to average cost models would seem to be a logical extension.

In this work, parametric estimators have been restricted to a class of sample averages, whereas a much broader class of recursive estimators is required for general applications. A suitable extension should be possible for estimators with martingale properties, permitting natural conditions under which (6.7) will hold. The next task would be to derive a result comparable to Lemma 6.1. Once these conditions are met, Theorem 6.7 could then be argued as before. The theory could then conform more to the standard *partially observed control model* discussed in [17, 12, 2].

We briefly reiterate a number of points made earlier. The exploratory control presented here is mathematically convenient, but in practice one would expect any number of stringent constraints or specialized structures. For example, in [12] estimation of an unknown parameter within a repair system model is made specifically at replacement times, providing a natural example of the informative subset discussed in section 6.2. It is hoped that the present theory can be used to carefully analyze alternative exploratory controls of a variety of structures.

The rate for regret reported in section 6.4 is optimal for the type of adaptive control considered here. The fact that a strictly better cumulative regret of order  $a_n \log(n)$ , for any  $a_n \rightarrow \infty$ , can be achieved for some models using a bandit theory approach [25] suggests a number of possibilities. Perhaps the regret rate reported here can be further sharpened for some subset of the models presented. Failing that, it would still be of interest to consider the possibility that an alternative model-based control can be designed which approaches the faster bandit theory rate. It could be expected that such a control would be more stable than one based on randomization over control policies.

**Acknowledgments.** The author wishes to thank the referees for their careful reading of the manuscript and for their guidance during the revision process. The author also wishes to thank Ronald Shonkwiler and Franklin Mendivil for their generous advice.

## DIRICHLET PROBLEMS FOR SOME HAMILTON–JACOBI EQUATIONS WITH INEQUALITY CONSTRAINTS\*

JEAN-PIERRE AUBIN<sup>†</sup>, ALEXANDRE M. BAYEN<sup>‡</sup>, AND PATRICK SAINT-PIERRE<sup>§</sup>

**Abstract.** We use viability techniques for solving Dirichlet problems with inequality constraints (obstacles) for a class of Hamilton–Jacobi equations. The hypograph of the “solution” is defined as the “capture basin” under an auxiliary control system of a target associated with the initial and boundary conditions, viable in an environment associated with the inequality constraint. From the tangential condition characterizing capture basins, we prove that this solution is the unique “upper semicontinuous” solution to the Hamilton–Jacobi–Bellman partial differential equation in the Barron–Jensen/Frankowska sense. We show how this framework allows us to translate properties of capture basins into corresponding properties of the solutions to this problem. For instance, this approach provides a representation formula of the solution which boils down to the Lax–Hopf formula in the absence of constraints.

**Key words.** Hamilton–Jacobi equations, viability theory, optimal control, traffic modeling

### 1. Introduction.

**1.1. Motivation.** This article is motivated by macroscopic fluid models of highway traffic, following the pioneering work of Lighthill and Whitham [64] and Richards [78]. In their original work, the authors modeled highway traffic flow with a first order hyperbolic *partial differential equation* with concave flux function, called the Lighthill–Whitham–Richards (partial differential) equation. This model is the seminal model for numerous highway traffic flow studies available in the literature today [2, 45, 46, 63, 33, 87, 31]. It models the evolution of the density of vehicles on a highway by a conservation law, in which the mathematical model of the flux function inside the conservation law results from empirical measurements [60].

Solutions to such equations may have shocks (they are set-valued maps), which model abrupt changes in vehicle density on the highway [2], and only model physical phenomena to a certain degree. Hence discontinuous selections of these solutions are investigated, for instance, the *entropy solution* [2] of Oleinik [73], which is acknowledged to be the proper weak solution of this problem. There has been an extensive literature on this problem, of which we single out the work of Bardos, Leroux, and Nédélec [24]; see also Strub and Bayen [83].

Very few results applicable to highway traffic are available for control of first order hyperbolic conservation laws. Differential flatness [50] has been successfully applied to the Burgers equation (and therefore to the Lighthill–Whitham–Richards equation) in [75] order to avoid the formation of such shockwaves. This analysis does not so far

extend to the presence of shocks. Lyapunov-based techniques have also been applied to the Burgers equation [62]. Adjoint-based methods have been successfully applied to networks of Lighthill–Whitham–Richards equations in [57]; these results seem so far the most promising, but they do not have guarantees to provide an optimal control policy. Questions of interest in controlling first order partial differential equations [66, 74, 82, 86], and in particular, Lighthill–Whitham–Richards equations, are still open and difficult to solve due to the presence of shocks occurring in the solutions of these partial differential equations [3, 20, 21, 32, 36, 42, 47, 48, 49, 58, 59, 61].

In order to alleviate the technical difficulties resulting from shocks present in solutions of the Lighthill–Whitham–Richards equation, an alternate formulation consists in considering the *cumulated number of vehicles*, widely used in the transportation literature as well [70, 71, 72]. The cumulative number of vehicles can be thought of as a primitive of the density over space. Formally, the evolution of the cumulated number  $\mathbf{N}(t, x)$  of vehicles is the solution of a *Hamilton–Jacobi (partial differential) equation* of the form

$$\frac{\partial \mathbf{N}(t, x)}{\partial t} + \psi \left( \frac{\partial \mathbf{N}(t, x)}{\partial x} \right) = \psi(v(t)),$$

where the flux function  $\psi$  appearing in this Hamilton–Jacobi equation is in fact concave as shown by the empirically measured flux function of the Lighthill–Whitham–Richards equation [64, 78, 24, 83]. The function  $v(\cdot)$  will be regarded as a control of the Hamilton–Jacobi equation in forthcoming studies. It could, for example, model the inflow of vehicles at the entrance of a stretch of highway. It is a given datum in this paper.

The solution of this Hamilton–Jacobi equation has no shocks but is not necessarily differentiable. It is only upper semicontinuous. Actually, the nondifferentiability of the cumulated number of vehicles is closely related to the presence of the shocks of the solution to the Lighthill–Whitham–Richards equation (see, for instance, [39, 40, 41]).

Since the Lighthill–Whitham–Richards equation and the Hamilton–Jacobi equation model the same physical phenomenon, and since both formulations are equivalently used in the highway transportation literature, we single out in this paper the study of the evolution of the cumulated number of vehicles in order to leverage the extensive knowledge of Hamilton–Jacobi equations for which control and viability techniques can be applied [65, 67, 68, 69, 76, 77, 81].

**1.2. Contributions of the paper.** We shall revisit this Hamilton–Jacobi equation by answering new questions as follows:

- introducing a nontrivial right-hand side;
- involving Dirichlet conditions;
- and, above all, imposing *inequality constraints* on the solution, for instance, upper bounds on the cumulated number of vehicles, depending on time and space variables.

For this purpose, we suggest using a novel point of view based on the concept of capture basin of a target viable in an environment extensively studied in the framework of viability theory; i.e., given a closed subset of a finite dimensional vector space regarded as an environment, a closed subset of this environment considered as a target and a control system, the viable capture basin is the subset of initial states of the environment from which starts at least one evolution governed by the control system viable in the environment until the finite time when it reaches the target (see Definition 3.3). It happens that the *hypograph* of the solution to the Hamilton–Jacobi

equation satisfying initial and Dirichlet conditions as well as inequality constraints is the capture basin of an auxiliary target (involving initial and boundary conditions) viable in an auxiliary environment (involving inequality constraints) under an auxiliary control system (involving the flux function of the Hamilton–Jacobi equation).

Hence, anticipating this property, we define the *viability hypsolution* of the Dirichlet problem for this Hamilton–Jacobi equation with constraints from this property as being a viable capture basin (see Definition 4.1). Then we proceed by translating properties of viable capture basins (see [7], for instance) in the language of partial differential equations for this particular case. We shall prove that the viability hypsolution

1. is the *unique* generalized solution in the Barron–Jensen/Frankowska sense<sup>1</sup> (a weaker concept of viscosity solution introduced by Crandall, Evans, and Lions in [44, 43] for continuous solutions adapted to the case when solution is only semicontinuous): Theorem 9.1;
2. is equivalently the *unique* upper semicontinuous solution in the contingent Frankowska sense:<sup>2</sup> Theorem 8.1;
3. satisfies the sup-linearity property and depends “hypocontinuously” on the initial and Dirichlet conditions;
4. is represented by the Lax–Hopf formula [1] (see Theorem 5.1) in the absence of inequality constraints, a more involved representation formula (see Theorem 5.5) in the presence of inequality constraints, upper estimates (maximum principle; see Proposition 5.3), and lower estimates (see Proposition 5.4).

The results presented in this article have since been applied to highway traffic data [30, 29], using available algorithms to solve, in particular, viability problems numerically [80, 37, 38].

**1.3. Outline of the paper.** In order to make the paper more readable, section 3 gathers some definitions, notations, and basic prerequisites of viability theory and convex analysis for the convenience of readers who are not familiar with these topics. We then state the problem and the main assumptions, which will not be repeated. We next define the viability hypsolution to the nonhomogeneous Dirichlet/initial value problem for our class of Hamilton–Jacobi equations under inequality constraints as the capture basin of a target summarizing the Dirichlet/initial data viable in a target associated with inequality constraints. Then, we translate the properties of capture basins into the viability hypsolution, starting with a general representation formula providing Lax–Hopf formulas in the absence of inequality constraints. We next check that the viability hypsolution satisfies the Dirichlet and initial conditions as well as the inequality constraints. The last three sections are devoted to the proof that the viability hypsolution is a solution to the Hamilton–Jacobi partial differential equation

---

<sup>1</sup>Frankowska proved that the epigraph of the value function of an optimal control problem—assumed to be only lower semicontinuous—is semipermeable (i.e., invariant and backward viable) under a (natural) auxiliary system. Furthermore, when it is continuous, its epigraph is viable and its hypograph invariant [53, 54, 56]. By duality, the latter property is equivalent to the fact that the value function is a viscosity solution of the associated Hamilton–Jacobi equation in the sense of Crandall and Lions. See also [26, 22, 8] for more details. Such concepts have been extended to solutions of systems of first order partial differential equations without boundary conditions by Frankowska and the first author (see [14, 15, 16, 17, 18, 19] and Chapter 8 of [5]). See also [11, 12].

<sup>2</sup>Contingent inequalities were first introduced in [4] for characterizing Lyapunov functions and value functions of a class of control problems and later, used in [84, 85] to investigate infinitesimal properties of Lyapunov and value functions in differential games. The “backward inequality” was introduced for the first time in [55, 56] to prove uniqueness of lower semicontinuous solutions of Hamilton–Jacobi–Bellman equations. See also [23, 25, 27, 28, 34, 35].

in two equivalent dual generalized senses by translating both the viability theorem and the invariance theorem characterizing the capture basin in terms of either tangential conditions or normal conditions, as it was done in a long series of papers by Frankowska. Using tangential conditions, we express the viability hyposolution as a solution to the Hamilton–Jacobi partial differential equation couched in terms of contingent hypoderivatives, whereas using normal conditions, we characterize it in terms of superdifferentials, as it was done independently by Barron–Jensen and Frankowska, in the spirit of nonsmooth analysis and viscosity solutions. The presence of inequality constraints complicates the technical formulation of the concept of solution at points where the solution touches the boundary of the constraint, above all in the superdifferential formulation, justifying the reason why we conclude this paper with this dual characterization.

**2. Statement of the problem.** This section states the problem of interest for this article. Section 3 provides all prerequisites for the concepts used in the later sections for a reader not familiar with viability theory and convex analysis. No prerequisites from viability theory are required to read this section.

**2.1. Notation.** For notational convenience, and in order to avoid multiplication of the letters used in the article, we have used the letters  $\sigma$  and  $\tau$  in several different ways, which depend on context; i.e., for  $\sigma$ , we have the following definitions, based on context:

- Support function for some compact convex subset  $A \subset X$ , where  $\sigma_A(v) := \sigma(A, v) := \sup_{u \in A} \langle u, v \rangle$  is the support function of  $A$ . Note that the first argument of  $\sigma$  is a set, while the second is a vector.
- Auxiliary min inf function  $\sigma(t, x, u) := \min(t, \tau(x, u))$ , defined in Theorem 5.1. Note that this function has three arguments, which are one scalar  $t$  and two vectors  $x$  and  $u$  of  $X$ .
- Auxiliary min inf functional  $\sigma(t, x, u(\cdot)) = \min(t, \tau(x, u(\cdot)))$ , defined in the proof of Theorem 5.1. Note that this function has three arguments, which are one scalar  $t$ , one vector  $x \in X$ , and function  $u(\cdot)$  (measurable, integrable).

Similarly for the notation  $\tau$  is used as a

- Dummy variable  $\tau$ , for example, in integrals. Note that  $\tau$  has no argument.
- Pseudotime  $\tau(t)$ , for example, in (13). Note that  $\tau(t)$  has one argument  $t$  which corresponds to the running time of the corresponding differential inclusion.
- Auxiliary inf function  $\tau(x, u) := \inf_{x+tu \notin K} t$ , defined in Theorem 5.1. Note that this function has two inputs, which are vectors  $x$  and  $u$  of  $X$ .
- Auxiliary inf functional  $\tau(x, u(\cdot)) := \inf_{x+\int_0^t u(\tau) d\tau \notin K} t$ , defined in the proof of Theorem 5.1. Note that this function has two inputs, which is one vector  $x \in X$  and function  $u(\cdot)$  (measurable, integrable).

We will use this notation in the rest of the article, and in each of the cases of interest, the context, i.e., the number of arguments of  $\tau$ , provides the proper definition.

**2.2. Assumptions.** We set  $X := \mathbb{R}^n$ . Let us consider

1. a concave function  $\psi : X \mapsto \mathbb{R}$  satisfying growth conditions

$$\forall v \in X, \quad \beta - \sigma_A(v) \leq \psi(v) \leq \delta - \sigma_A(v)$$

for some compact convex subset  $A \subset X$ , where  $\sigma_A(v) := \sup_{u \in A} \langle u, v \rangle$  is the support function of  $A$  and where  $\beta \leq \delta$ .

2. a bounded continuous function  $v : \mathbb{R}_+ \mapsto \text{Dom}(\psi)$ .

3. an upper semicontinuous initial datum  $\mathbf{N}_0 : X \mapsto \mathbb{R}_+$ . We set  $\mathbf{N}_0(0, x) := \mathbf{N}_0(x)$  and  $\mathbf{N}_0(t, x) := -\infty$  if  $t > 0$ .
4. a closed subset  $K \subset X$  with nonempty interior  $\text{Int}(K) =: \Omega$  and boundary  $\partial K =: \Gamma$ .
5. an upper semicontinuous boundary datum  $\gamma : \mathbb{R}_+ \times X \mapsto \mathbb{R}$ , satisfying<sup>3</sup>

$$\forall x \in \partial K, \quad \mathbf{N}_0(x) = \gamma(0, x) \quad \text{and} \quad \forall t \geq 0, \quad \forall x \in \text{Int}(K), \quad \gamma(t, x) = -\infty.$$

6. a Lipschitz function  $\mathbf{b} : \mathbb{R}_+ \times X \mapsto \mathbb{R} \cup \{-\infty\}$  setting the upper constraint.

We shall also assume in this paper that the data satisfy the following consistency conditions:

$$(1) \quad \left\{ \begin{array}{l} \text{(i)} \quad \forall x \in \partial K, \quad \mathbf{N}_0(x) = \gamma(0, x); \\ \text{(ii)} \quad \forall t \geq 0, \quad \forall x \in K, \quad \max(\mathbf{N}_0(t, x), \gamma(t, x)) \leq \mathbf{b}(t, x); \\ \text{(iii)} \quad \forall 0 \leq r \leq s, \quad \forall x \in \partial K, \quad \forall y \in \partial K, \quad \gamma(r, x) - \gamma(s, y) \leq \left\langle \frac{1}{s-r} \int_r^s v(\tau) d\tau, x - y \right\rangle; \\ \text{(iv)} \quad \forall x \in K, \quad \forall y \in \partial K, \quad \mathbf{N}_0(x) \leq \inf_{s \geq 0} \left( \gamma(s, y) + \left\langle \frac{1}{s} \int_0^s v(\tau) d\tau, x - y \right\rangle \right), \end{array} \right.$$

which are needed only to prove that the Dirichlet/initial conditions are satisfied (see Theorem 6.1). When the function  $v(\cdot) \equiv v$  is constant, they boil down to

$$\left\{ \begin{array}{l} \text{(i)} \quad \forall x \in \partial K, \quad \mathbf{N}_0(x) = \gamma(0, x); \\ \text{(ii)} \quad \forall t \geq 0, \quad \forall x \in K, \quad \max(\mathbf{N}_0(t, x), \gamma(t, x)) \leq \mathbf{b}(t, x); \\ \text{(iii)} \quad \forall 0 \leq r \leq s, \quad \forall x \in \partial K, \quad y \in \partial K, \quad \gamma(r, x) - \gamma(s, y) \leq \langle v, x - y \rangle; \\ \text{(iv)} \quad \forall x \in K, \quad y \in \partial K, \quad \mathbf{N}_0(x) \leq \inf_{s \geq 0} \gamma(s, y) + \langle v, x - y \rangle. \end{array} \right.$$

Under the above mentioned assumptions that are assumed throughout this paper, we shall solve the existence of a solution to the *nonhomogenous Hamilton–Jacobi equation*

$$(2) \quad \forall t > 0, \quad x \in \text{Int}(K), \quad \frac{\partial \mathbf{N}(t, x)}{\partial t} + \psi \left( \frac{\partial \mathbf{N}(t, x)}{\partial x} \right) = \psi(v(t))$$

satisfying the *initial and Dirichlet conditions*

$$(3) \quad \left\{ \begin{array}{l} \text{(i)} \quad \forall x \in K, \quad \mathbf{N}(0, x) = \mathbf{N}_0(x) \text{ (initial condition),} \\ \text{(ii)} \quad \forall t \geq 0, \quad \forall x \in \partial K, \quad \mathbf{N}(t, x) = \gamma(t, x) \text{ (Dirichlet boundary condition)} \end{array} \right.$$

and the *viability constraints*

$$(4) \quad \forall t \geq 0, \quad x \in K, \quad \mathbf{N}(t, x) \leq \mathbf{b}(t, x) \text{ (upper inequality constraint).}$$

<sup>3</sup>This is not mandatory. We can take any function such that  $\text{Dom}(\gamma) \subset K$  is strictly contained in  $K$ , an instance which may be useful for defining “guards” in impulse or hybrid systems, for instance. Boundary conditions are obtained when  $\text{Dom}(\gamma) = \partial K$ .

*Example.* This equation is motivated by a commonly used first order model equation in highway traffic (*Lighthill–Whitham–Richards* equation) when  $X := \mathbb{R}$  and  $K := [\xi, +\infty[$ ,  $\psi$  a concave flux function vanishing at density 0 and at a jam density  $\omega > 0$  and  $\mathbf{N}(t, x)$  is the cumulated number of vehicles at time  $t$  and at location  $x \in K$ . Consistency conditions (1) read in this case:  $\mathbf{N}_0(\xi) = \gamma(0, \xi)$  and

$$(5) \quad \left\{ \begin{array}{l} \text{(i)} \quad \forall t \geq 0, \forall x \in K, \max(\mathbf{N}_0(t, x), \gamma(t, x)) \leq \mathbf{b}(t, x); \\ \text{(ii)} \quad \forall 0 \leq r \leq s, \gamma(r, \xi) - \gamma(s, \xi) \leq 0 \text{ (monotonocity)}; \\ \text{(iii)} \quad \forall x \in K, \mathbf{N}_0(x) \leq \inf_{s \geq 0} \left( \gamma(s, \xi) + \left\langle \frac{1}{s} \int_0^s v(\tau) d\tau, x - \xi \right\rangle \right). \end{array} \right.$$

Then the trapezoidal flux function (such as the one proposed by Daganzo [45, 46]) defined by

$$\psi(v) = \begin{cases} \nu^b v & \text{if } v \leq \gamma^b, \\ \delta & \text{if } v \in [\gamma^b, \gamma^\sharp], \\ \nu^\sharp(\omega - v) & \text{if } v \geq \gamma^\sharp, \end{cases}$$

and the Greenshield flux function

$$\psi(v) = \begin{cases} \nu v & \text{if } v \leq 0, \\ \frac{\nu}{\omega} v(\omega - v) & \text{if } v \in [0, \omega], \\ \nu(\omega - v) & \text{if } v \geq \omega \end{cases}$$

satisfy the assumptions on the function  $\psi$  with  $A := [-\nu^b, +\nu^\sharp]$  and  $A := [-\nu, +\nu]$ , respectively (see Lemma 7.2 in section 7).

We characterize the solution to this nonhomogenous Dirichlet/initial value problem with inequality constraints through the capture basin of a target defined by the Dirichlet/initial conditions viable in an environment defined by inequality constraints under an adequate control system.

**3. Prerequisite from viability theory and convex analysis.** Readers familiar with convex analysis and viability theory can skip this section and proceed directly to section 4.

**3.1. Some prerequisites from viability theory.** Here,  $X := \mathbb{R}^n$  and  $Y := \mathbb{R}^m$  denote finite dimensional vector spaces. Let  $f : X \times Y \mapsto X$  be a single-valued map describing the dynamics of a control system and  $U : X \rightsquigarrow Y$  the set-valued map describing the state-dependent constraints on the controls.

First, any solution to a control system with state-dependent constraints on the controls

$$\begin{cases} \text{(i)} & x'(t) = f(x(t), u(t)), \\ \text{(ii)} & u(t) \in U(x(t)) \end{cases}$$

can be regarded as a solution to the differential inclusion  $x'(t) \in F(x(t))$ , where the right-hand side is defined by  $F(x) := f(x, U(x)) := \{f(x, u)\}_{u \in U(x)}$ .

We denote by  $\mathcal{S}(x) \subset \mathcal{C}(0, \infty; X)$  the set of *absolutely continuous functions*  $t \mapsto x(t) \in X$  satisfying

$$\text{for almost all } t \geq 0, \quad x'(t) \in F(x(t))$$

starting at time 0 at  $x$ :  $x(0) = x$ . The set-valued map  $\mathcal{S} : X \rightsquigarrow \mathcal{C}(0, \infty; X)$  is called the *solution map* associated with  $F$ .

Therefore, from now on, as long as we do not need to implicate explicitly the controls in our study, we shall replace control problems by differential inclusions.

We shall say that  $K$  is *locally viable under  $F$*  if from every  $x \in K$  starts a solution  $x(\cdot)$  to the differential inclusion  $x' \in F(x)$  viable in  $K$  on the nonempty interval  $[0, T_x[$  in the sense that

$$\forall t \in [0, T_x[, \quad x(t) \in K$$

and that  $K$  is *viable* if we can take  $T_x = +\infty$ . It is *locally backward invariant under  $F$*  if for every  $t_0 \in ]0, +\infty[$ ,  $x \in K$ , for all solutions  $x(\cdot)$  to the differential inclusion  $x' \in F(x)$  arriving at  $x$  at time  $t_0$ , there exists  $s \in [0, t_0[$  such that  $x(\cdot)$  is viable in  $K$  on the interval  $[s, t_0]$ , and *backward invariant* if we can take  $s = 0$ .

We denote by

$$\text{Graph}(F) := \{(x, y) \in X \times Y \mid y \in F(x)\}$$

the *graph* of a set-valued map  $F : X \rightsquigarrow Y$  and by  $\text{Dom}(F) := \{x \in X \mid F(x) \neq \emptyset\}$  its *domain*.

Most of the results of viability theory are true whenever we assume that the dynamics is Marchaud as follows.

DEFINITION 3.1 (Marchaud map). *We shall say that  $F$  is a Marchaud map if*

$$\left\{ \begin{array}{ll} \text{(i)} & \text{the graph of } F \text{ is closed,} \\ \text{(ii)} & \text{the values } F(x) \text{ of } F \text{ are convex,} \\ \text{(iii)} & \text{the growth of } F \text{ is linear:} \\ & \exists c > 0 \mid \forall x \in X, \|F(x)\| := \sup_{v \in F(x)} \|v\| \leq c(\|x\| + 1). \end{array} \right.$$

*We shall say that  $F$  is  $\lambda$ -Lipschitz if*

$$\forall x, y \in X, \quad F(x) \subset F(y) + \lambda\|x - y\|B,$$

*where  $B$  is the unit ball.*

This covers the case of *Marchaud control systems*, where  $(x, u) \mapsto f(x, u)$  is continuous, affine with respect to the controls  $u$  and with linear growth, and when  $U$  is Marchaud.

We recall the following version of the important Theorem 3.5.2 of [5].

THEOREM 3.2 (the stability theorem). *Assume that  $F : X \rightsquigarrow X$  is Marchaud. Then the solution map  $\mathcal{S}$  is upper semicompact with nonempty values; this means that whenever  $x_n \in X$  converge to  $x$  in  $X$  and  $x_n(\cdot) \in \mathcal{S}(x_n)$  is a solution to the differential inclusion  $x' \in F(x)$  starting at  $x_n$ , there exists a subsequence (again denoted by  $x_n(\cdot)$ ) converging to a solution  $x(\cdot) \in \mathcal{S}(x)$  uniformly on compact intervals.*

We shall also need some other prerequisites from [5].

DEFINITION 3.3 (capture basin of a target). *Let  $C \subset K \subset X$  be two subsets,  $C$  being regarded as a target,  $K$  as a constrained set. The subset  $\text{Capt}(K, C)$  of initial*

states  $x_0 \in K$  such that  $C$  is reached in finite time before possibly leaving  $K$  by at least one solution  $x(\cdot) \in \mathcal{S}(x_0)$  starting at  $x_0$  is called the viable-capture basin of  $C$  in  $K$ . A subset  $K$  is a repeller under  $F$  if all solutions starting from  $K$  leave  $K$  in finite time. A subset  $D$  is locally backward invariant relative to  $K$  if all backward solutions starting from  $D$  viable in  $K$  are actually viable in  $K$ .

We recall the following result of [10].

**THEOREM 3.4** (fixed-point characterization of capture basins). *The viable-capture basin  $\text{Capt}(K, C)$  of a target  $C$  viable in  $K$  is*

1. the largest subset  $D$  satisfying  $C \subset D \subset K$  and  $D \subset \text{Capt}(D, C)$ ,
2. the smallest subset  $D$  satisfying  $C \subset D \subset K$  and  $\text{Capt}(K, D) \subset D$ , and
3. the unique subset  $D$  satisfying  $C \subset D \subset K$  and

$$D = \text{Capt}(K, D) = \text{Capt}(D, C).$$

The subset  $K \setminus C$  denotes the intersection of  $K$  and the complement of  $C$ ; i.e., it is the set of elements of  $K$  which do not belong to  $C$ . We can derive the following characterization of capture basin (see [7]).

**THEOREM 3.5** (viability characterization of capture basins). *Let us assume that  $F$  is Marchaud and that the subsets  $C \subset K$  and  $K$  are closed. If  $K \setminus C$  is a repeller (this is the case when  $K$  itself is a repeller), then the viable-capture basin  $\text{Capt}(K, C)$  of the target  $C$  under  $\mathcal{S}$  is the unique closed subset satisfying  $C \subset D \subset K$  and*

$$(6) \quad \begin{cases} \text{(i)} & D \setminus C \text{ is locally viable under } \mathcal{S}, \\ \text{(ii)} & D \text{ is locally backward invariant relative to } K. \end{cases}$$

The contingent cone  $T_L(x)$  to  $L \subset X$  at  $x \in L$  is the set of directions  $v \in X$  such that there exist sequences  $h_n > 0$  converging to 0 and  $v_n$  converging to  $v$  satisfying  $x + h_n v_n \in L$  for every  $n$  (see, for instance, [13] or [79] for more details). The (regular) normal cone is the polar cone  $N_L(x) := (T_L(x))^\circ$  of the contingent cone.

**DEFINITION 3.6** (Frankowska property). *Let us consider a set-valued map  $F : X \rightrightarrows X$  and two subsets  $C \subset K$  and  $K$ . We shall say that a subset  $D$  between  $C$  and  $K$  satisfies the Frankowska property with respect to  $F$  if*

$$(7) \quad \begin{cases} \text{(i)} & \forall x \in D \setminus C, \quad F(x) \cap T_D(x) \neq \emptyset; \\ \text{(ii)} & \forall x \in D \cap \text{Int}(K), \quad -F(x) \subset T_D(x); \\ \text{(iii)} & \forall x \in D \cap \partial K, \quad -F(x) \cap T_K(x) \subset T_D(x). \end{cases}$$

Actually, conditions (7)(ii), (iii) boil down to the same condition,

$$\forall x \in D, \quad -F(x) \cap T_K(x) \subset T_D(x).$$

When  $K$  is further assumed to be backward locally invariant, the above conditions (7) boil down to

$$(8) \quad \begin{cases} \text{(i)} & \forall x \in D \setminus C, \quad F(x) \cap T_D(x) \neq \emptyset; \\ \text{(ii)} & \forall x \in D, \quad -F(x) \subset T_D(x). \end{cases}$$

Theorem 3.5 and the viability<sup>4</sup> and invariance theorems imply the following.

<sup>4</sup>See, for instance, Theorems 3.2.4, 3.3.2, and 3.5.2 of [5].

**THEOREM 3.7** (tangential characterization of capture basins). *Let us assume that  $F$  is Marchaud, that  $K$  is closed, and that a closed subset  $C$  satisfies  $\text{Viab}_F(K \setminus C) = \emptyset$ . Then the viable-capture basin  $\text{Capt}_F^K(C)$  is*

1. the largest closed subset  $D$  satisfying  $C \subset D \subset K$  and

$$(9) \quad \forall x \in D \setminus C, \quad F(x) \cap T_D(x) \neq \emptyset;$$

2. the unique closed subset  $D$  satisfying the Frankowska property (7) if  $F$  is Lipschitz.

We provide the dual characterization of the capture basin in terms of normal cones due to Frankowska.

**LEMMA 3.8** (normal characterization of capture basins). *Let us assume that*

$$\forall x \in K, \quad 0 \in \text{Int}(F(x) + T_K(x)).$$

*Then property (7) is equivalent to the dual property*

$$(10) \quad \begin{cases} \text{(i)} & \forall x \in D \setminus C, \quad \forall p \in N_D(x), \quad \sigma(F(x), -p) \geq 0; \\ \text{(ii)} & \forall x \in D \cap \text{Int}(K), \quad \forall p \in N_D(x), \quad \sigma(F(x), -p) \leq 0; \\ \text{(iii)} & \forall x \in D \cap \partial K, \quad \forall p \in N_D(x), \quad \inf_{q \in N_K(x)} \sigma(F(x), q - p) \leq 0. \end{cases}$$

*Proof.* Whenever  $0 \in \text{Int}(F(x) + T_K(x))$ , Proposition 3.9 on page 50 of [6] implies that the support function of  $-F(x) \cap T_K(x)$  is the inf-convolution of the support functions of  $-F(x)$  and  $T_K(x)$  as follows:

$$\sigma(-F(x) \cap T_K(x), p) = \inf_{q \in N_K(x)} \sigma(F(x), q - p).$$

Consequently, inclusion  $-F(x) \cap T_K(x) \subset T_D(x)$  is equivalent to

$$\forall p, \quad \inf_{q \in N_K(x)} \sigma(F(x), q - p) \leq \sigma(T_D(x), p),$$

which can be written

$$\forall p \in N_D(x), \quad \inf_{q \in N_K(x)} \sigma(F(x), q - p) \leq 0.$$

This concludes the proof.  $\square$

**3.2. Some prerequisites of convex analysis.** We gather in this section notations and some results on convex analysis for the convenience of the reader not familiar with this topic. Since the authors of most books on convex analysis have chosen to study convex functions rather than concave ones, we have chosen to associate with the concave function  $\psi$  the Fenchel transform  $\varphi^*$  of  $\varphi := -\psi$  rather than the “concave Fenchel” transform  $\psi^\boxtimes$  defined by the concave function

$$\psi^\boxtimes(u) := \inf_{p \in \text{Dom}(\psi)} [\langle p, u \rangle - \psi(p)] = -\varphi^*(-u).$$

The basic theorem of convex analysis states that  $\psi = \psi^{\boxtimes\boxtimes}$  if and only if  $\psi$  is concave, upper semicontinuous, and nontrivial (i.e.,  $\text{Dom}(\psi) := \{p \mid \varphi(p) > -\infty\} \neq \emptyset$ ).

The epigraph  $\mathcal{E}p(\varphi)$  of an extended function  $\varphi$  is the set of pairs  $(x, \lambda) \in X \times \mathbb{R}$  such that  $\varphi(x) \leq \lambda$ , and the hypograph  $\mathcal{H}yp(\psi)$  of a function  $\psi$  is the set of pairs  $(p, \mu) \in X \times \mathbb{R}$  such that  $\mu \leq \psi(p)$ . Note that the hypograph of  $\psi$  is related to the epigraph of  $\varphi$  by the relation

$$(p, \lambda) \in \mathcal{H}yp(\psi) \text{ if and only if } (p, -\lambda) \in \mathcal{E}p(\varphi).$$

An extended function is lower semicontinuous if and only if its epigraph is closed and is upper semicontinuous if and only if its hypograph is closed.

DEFINITION 3.9 (hypoderivatives and superdifferentials). *The hypoderivative  $D_{\downarrow}\psi(p)$  and the epiderivative  $D_{\uparrow}\varphi(p)$  are related to the tangent cones of the hypograph of  $\psi$  and epigraph of  $\varphi$  by the relations*

$$\mathcal{H}yp(D_{\downarrow}\psi(p)) := T_{\mathcal{H}yp(\psi)}(p, \psi(p)) \text{ and } \mathcal{E}p(D_{\uparrow}\varphi(p)) := T_{\mathcal{E}p(\varphi)}(p, \varphi(p)).$$

*The superdifferential  $\partial_+\psi(p)$  of the concave function  $\psi$  at  $p$  is defined by*

$$u \in \partial_+\psi(p) \text{ if } \forall v \in X, \langle u, v \rangle \geq D_{\downarrow}\psi(p)(v),$$

*and the subdifferential  $\partial_-\varphi(p)$  is defined by*

$$u \in \partial_-\varphi(p) \text{ if } \forall v \in X, \langle u, v \rangle \leq D_{\uparrow}\varphi(p)(v).$$

We infer that

$$\forall v \in X, D_{\downarrow}\psi(p)(v) = -D_{\uparrow}\varphi(p)(v)$$

and that

$$u \in \partial_+\psi(p) \text{ if and only if } u \in -\partial_-\varphi(p).$$

The polar cone  $P^-$  of a given set  $P$  is defined by

$$P^- = \{p \in X^* \mid \forall x \in P, \langle p, x \rangle \leq 0\},$$

where  $X^*$  is the dual space of  $X$ , and the normal cone  $N_K(x) := T_K(x)^-$  to  $K$  at  $x \in K$  we use in this paper is the polar cone to the contingent cone to  $K$  at  $x \in K$ . The superdifferential  $\partial_+\psi(p)$  and the subdifferential  $\partial_-\varphi(p)$  are related to the normal cones of the hypograph of  $\psi$  and epigraph of  $\varphi$  by the relations

$$u \in \partial_+\psi(p) \text{ if and only if } (-u, 1) \in N_{\mathcal{H}yp(\psi)}(p, \psi(p))$$

and

$$u \in \partial_-\varphi(p) \text{ if and only if } (u, -1) \in N_{\mathcal{E}p(\varphi)}(p, \varphi(p)).$$

Recall the Legendre inversion formula

$$u \in -\partial_+\psi(p) \text{ if and only if } p \in \partial_-\varphi^*(u)$$

and the (decreasing) monotonicity property of superdifferential maps  $p \rightsquigarrow \partial_+\psi(p)$  of a concave function,

$$\forall u_i \in \partial_+\psi(p_i), i = 1, 2, \langle u_1 - u_2, p_1 - p_2 \rangle \leq 0.$$

The subdifferential  $\partial_-\sigma(K, p)$  of the support function is defined by the support zone  $\{u \in K \text{ such that } \sigma(K, p) = \langle p, u \rangle\}$  of  $p$  in  $K$ . See [6] or [79] for more details.

**4. The viability hyposolution.** The assumption that the flux function  $\psi$  is concave and upper semicontinuous plays a crucial role for defining the viability hyposolution. Indeed, the Fenchel theorem allows us to characterize it by

$$(11) \quad \psi(p) = \inf_{u \in \text{Dom}(\varphi^*)} [\varphi^*(u) - \langle p, u \rangle],$$

where  $\varphi^*$  is the Fenchel conjugate function, which is the convex lower semicontinuous function defined by

$$(12) \quad \varphi^*(u) := \sup_{p \in \text{Dom}(\psi)} [\langle p, u \rangle + \psi(p)].$$

We introduce the auxiliary characteristic control system,

$$(13) \quad \begin{cases} \tau'(t) = -1, \\ x'(t) = u(t), \\ y'(t) = \varphi^*(u(t)) - \psi(v(\tau(t))), \text{ where } u(t) \in \text{Dom}(\varphi^*). \end{cases}$$

The function  $\tau(t)$  corresponds to a *countdown*, i.e., a pseudotime decaying at rate  $-1$ . This technique of augmentation of a dynamics by  $\tau'(t) = -1$  is common in the Hamilton–Jacobi partial differential equation literature; see, for example, [55, 56]. To be rigorous, we have to mention *once and for all* that the controls  $u(\cdot)$  are measurable integrable functions with values in  $\text{Dom}(\varphi^*)$ , and thus, ranging over  $L^1(0, \infty; \text{Dom}(\varphi^*))$ , and that the above system of differential equations is valid for almost all  $t \geq 0$ .

We set  $\mathbf{c}(t, x) := \max(\mathbf{N}_0(t, x), \gamma(t, x))$ , defined by

$$\mathbf{c}(t, x) := \begin{cases} -\infty & \text{if } t > 0 \text{ and } x \in \Omega := \text{Int}(K), \\ \mathbf{N}_0(x) & \text{if } t = 0 \text{ and } x \in K, \\ \gamma(t, x) & \text{if } t \geq 0 \text{ and } x \in \Gamma := \partial K. \end{cases}$$

We introduce the environment  $\mathcal{K} := \mathcal{Hyp}(\mathbf{b})$  is the subset of triples  $(T, x, y) \subset \mathbb{R}_+ \times X \times \mathbb{R}$  such that  $y \leq \mathbf{b}(T, x)$  (this is the *hypograph* of the function  $\mathbf{b}$ ) and the target  $\mathcal{C} := \mathcal{Hyp}(\mathbf{c})$  defined as the subset of triples  $(T, x, y) \subset \mathbb{R}_+ \times X \times \mathbb{R}$  such that  $y \leq \mathbf{c}(T, x)$  (which is the *hypograph* of the function  $\mathbf{c}$ ).

**DEFINITION 4.1** (the viability hyposolution). *The capture basin  $\text{Capt}_{(13)}(\mathcal{K}, \mathcal{C})$  of a target  $\mathcal{C}$  viable in the environment  $\mathcal{K}$  under control system (13) is the subset of initial states  $(t, x, y)$  such that there exists a measurable control  $u(\cdot)$  such that the associated solution*

$$s \mapsto \left( t - s, x + \int_0^s u(\tau) d\tau, y + \int_0^s (\varphi^*(u(\tau)) - \psi(v(t - \tau))) d\tau \right)$$

*is viable in  $\mathcal{K}$  until it reaches the target  $\mathcal{C}$ .*

*The viability hyposolution  $\mathbf{N}$  is defined by*

$$(14) \quad \mathbf{N}(t, x) := \sup_{(t, x, y) \in \text{Capt}_{(13)}(\mathcal{K}, \mathcal{C})} y.$$

Note that  $\mathcal{Hyp}(\mathbf{M}) \subset \mathcal{Hyp}(\mathbf{N})$  if and only if  $\mathbf{N}$  is pointwise larger than  $\mathbf{M}$ . Therefore, using hypographs, the two order relations coincide.

We shall prove the following.

**THEOREM 4.2** (nonhomogenous Dirichlet/initial value problem with inequality constraints). *The viability hypsolution  $\mathbf{N}$  defined by (14) is the largest upper semicontinuous solution to Hamilton–Jacobi equation (2) satisfying initial and Dirichlet conditions (3) and inequality constraints (4) in both the contingent solution sense (see (28)) and in the contingent normal sense (see (31)). If the functions  $\psi$ ,  $\varphi^*$ , and  $v$  are furthermore Lipschitz, then the viability hypsolution  $\mathbf{N}$  is its unique upper semicontinuous solution in both the contingent Frankowska sense (see (29) and (30)) and in the Barron-Jensen/Frankowska sense (see (32), (33) and Theorems 8.1 and 9.1 for the precise statement).*

*Remark.* Note that the concept of “largest solution” coincides with the pointwise one. Inequalities (32) and (33) defining the concept of generalized solutions depend on the type of assumption made on the flux function  $\psi$ . The present work uses a standard assumption in transportation engineering, namely that the flux  $\psi$  is *concave*, whereas a majority of mathematical studies of Hamilton–Jacobi partial differential equations assume that  $\psi$  is *convex*. This change induces an unusual modification of the signs in the inequalities defining the concept of Barron-Jensen/Frankowska solutions. Under the assumption of convex fluxes, this solution would be lower semicontinuous (and sometimes called the lower semicontinuous solution to Hamilton–Jacobi equations). Under the assumption imposed by transportation engineering considerations, the present solution is upper semicontinuous and the signs in inequalities (32) and (33) are changed. The mathematical formulation of the engineering problem thus led to a slightly unusual framework for solving this Hamilton–Jacobi equation. The convex version of this paper will appear in the forthcoming book [9].

We shall derive this theorem and other results from the properties of capture basins gathered in [7, 10]. Since the capture basin of a union of targets is the union of the capture basins of these targets, we infer that whenever  $\mathbf{c} := \sup_i \mathbf{c}_i$  is the upper envelope of a family of functions  $\mathbf{c}_i$ , then the viability hypsolution is the upper envelope

$$\forall t \geq 0, x \in X, \quad \mathbf{N}(t, x) = \sup_i \mathbf{N}_{\mathbf{c}_i}(t, x)$$

of the solutions  $\mathbf{N}_{\mathbf{c}_i}$  (sup-linearity property).

In particular, since  $\mathbf{c}(t, x) := \max(\mathbf{N}_0(t, x), \gamma(t, x))$  (extended to  $-\infty$  when  $t > 0$  or  $x \in \text{Int}(K)$ ), we obtain the decomposition formula

$$(15) \quad \mathbf{N}(t, x) = \max(\mathbf{N}_{\mathbf{N}_0}(t, \mathbf{x}), \mathbf{N}_\gamma(t, \mathbf{x}))$$

in terms of initial condition component  $\mathbf{N}_{\mathbf{N}_0}$  and the Dirichlet component  $\mathbf{N}_\gamma$  of the viability hypsolution  $\mathbf{N}$  defined by

$$\begin{cases} \mathbf{N}_{\mathbf{N}_0}(t, x) := \sup_{(t, x, y) \in \text{Capt}_{(13)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{N}_0))} y, \\ \mathbf{N}_\gamma(t, x) := \sup_{(t, x, y) \in \text{Capt}_{(13)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\gamma))} y. \end{cases}$$

The viability hypsolution depends continuously on the data in the following sense: If the hypographs of a sequence of initial data  $\mathbf{c}_j$  converge in the upper Painlevé–Kuratowski sense (see, for instance, [13]) to the hypograph of data  $\mathbf{c}$ , then the upper

Painlevé–Kuratowski limit of the hypographs of the solutions  $\mathbf{N}_j$  associated with data  $\mathbf{c}_j$  is contained in the hypograph of the hyposolution  $\mathbf{N}$  associated with data  $\mathbf{c}$  (upper hypocontinuity property). If the functions  $\psi$ ,  $\varphi^*$ , and  $v$  are furthermore Lipschitz, the hypograph of the hyposolution  $\mathbf{N}$  associated with data  $\mathbf{c}$  is contained in the lower Painlevé–Kuratowski limit of the hypographs of the solutions  $\mathbf{N}_j$  associated with data  $\mathbf{c}_j$  (lower hypocontinuity property), so that both the upper and lower limits coincide with the hypograph of the hyposolution  $\mathbf{N}$  (hypoconvergence of the solutions; see [13] or [79] for a definition). These statements follow from Theorem 6.6 of [7] stating that if the system is both Marchaud and Lipschitz, the capture basin of a Painlevé–Kuratowski limit of targets is the Painlevé–Kuratowski limit of the capture basins of the targets.

5. Lax–Hopf formula and estimates of the solution.

**5.1. The Lax–Hopf formula for Dirichlet problems.** When there is no inequality constraint, we prove that the viability hyposolution can be represented explicitly as a simple maximization problem involving the Fenchel conjugate  $\varphi^*$  defined by (12).

**THEOREM 5.1** (the Lax–Hopf formula). *Let us consider the case without inequality constraints and set*

$$\tau(x, u) := \inf_{x+tu \notin K} t \quad \text{and} \quad \sigma(t, x, u) := \min(t, \tau(x, u)).$$

Then the viability hyposolution (17) can be written

$$(16) \quad \left\{ \begin{array}{l} \mathbf{N}(t, x) \\ = \sup_{\{u \in \text{Dom}(\varphi^*)\}} \left[ \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \sigma(t, x, u)\varphi^*(u) \right. \\ \qquad \qquad \qquad \left. + \int_{t-\sigma(t, x, u)}^t (\psi(v(\tau)))d\tau \right]. \end{array} \right.$$

Using the decomposition  $\mathbf{N}(t, x) = \max(\mathbf{N}_{\mathbf{N}_0}(t, x), \mathbf{N}_\gamma(t, x))$ , we derive the more explicit formula

$$(17) \quad \left\{ \begin{array}{l} \mathbf{N}_{\mathbf{N}_0}(t, x) = \sup_{u \in \text{Dom}(\varphi^*)} (\mathbf{N}_0(x + tu) - t\varphi^*(u)) + \int_0^t \psi(v(\tau))d\tau, \\ \mathbf{N}_\gamma(t, x) = \sup_{\{u \in \text{Dom}(\varphi^*) \mid \tau(x, u) \leq t\}} \left[ \gamma(t - \tau(x, u), x + \tau(x, u)u) - \tau(x, u)\varphi^*(u) \right. \\ \qquad \qquad \qquad \left. + \int_{t-\tau(x, u)}^t \psi(v(\tau))d\tau \right] \end{array} \right.$$

involving the initial and Dirichlet conditions.

*Proof.* Let us associate the following with  $u(\cdot)$ :

$$\tau(x, u(\cdot)) := \inf_{x + \int_0^t u(\tau)d\tau \notin K} t \quad \text{and} \quad \sigma(t, x, u(\cdot)) = \min(t, \tau(x, u(\cdot))).$$

The formula is derived from the general representation formula

$$\left\{ \begin{array}{l} \mathbf{N}(t, x) = \sup_{u(\cdot)} \left[ \mathbf{c} \left( t - \sigma(t, x, u(\cdot)), x + \int_0^{\sigma(t, x, u(\cdot))} u(\tau) d\tau \right) - \int_0^{\sigma(t, x, u(\cdot))} \varphi^*(u(\tau)) d\tau \right. \\ \left. + \int_{t-\sigma(t, x, u(\cdot))}^t \psi(v(\tau)) d\tau \right] \end{array} \right.$$

of the viability hypsolution without constraints given by Corollary 5.6.

We proceed in two steps.

1. Taking constant controls  $u(\cdot) \equiv u$  and observing that  $\tau(x, u) = \tau(x, u(\cdot))$ , we infer that

$$\begin{aligned} \sup_{u \in \text{Dom}(\varphi^*)} & \left( \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \sigma(t, x, u)\varphi^*(u) \right) \\ & + \int_{t-\sigma(t, x, u)}^t \psi(v(\tau)) d\tau \leq \mathbf{N}(t, x). \end{aligned}$$

2. Let us associate with  $u(\cdot)$  the function  $\hat{u}$  defined by  $\hat{u}(s) := \frac{1}{s} \int_0^s u(\tau) d\tau$ . We first observe that

$$\tau(x, u(\cdot)) = \tau(x, \hat{u}(\tau(x, u(\cdot)))).$$

Since  $\varphi^*$  is convex and lower semicontinuous and  $\psi$  is concave and upper semicontinuous, the Jensen inequality implies

$$\varphi^* \left( \frac{1}{s} \int_0^s u(\tau) d\tau \right) \leq \frac{1}{s} \int_0^s \varphi^*(u(\tau)) d\tau$$

and

$$\frac{1}{s} \int_0^s \psi(v(t - \tau)) d\tau \leq \psi \left( \frac{1}{s} \int_{t-s}^t v(\tau) d\tau \right),$$

and thus

$$(18) \quad \int_0^s \psi(v(t - \tau)) d\tau - \int_0^s \varphi^*(u(\tau)) d\tau \leq s \left( \psi \left( \frac{1}{s} \int_{t-s}^t v(\tau) d\tau \right) - \varphi^*(\hat{u}(s)) \right).$$

Consequently, setting  $t^\# := \sigma(t, x, u(\cdot)) = \tau(x, \hat{u}(\sigma(t, x, u(\cdot))))$  and  $u^\# := \hat{u}(t^\#)$ , we obtain inequalities

$$\left\{ \begin{array}{l} \mathbf{c} \left( t - t^\#, x + \int_0^{t^\#} u(\tau) d\tau \right) - \int_0^{t^\#} \varphi^*(u(\tau)) d\tau + \int_{t-t^\#}^t \psi(v(\tau)) d\tau \\ \leq \mathbf{c}(t - t^\#, x + t^\# u^\#) - t^\# \varphi^*(u^\#) + \int_{t-t^\#}^t \psi(v(\tau)) d\tau \\ \leq \sup_{\{u \in \text{Dom}(\varphi^*)\}} \left( \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \sigma(t, x, u)\varphi^*(u) \right) \\ \quad + \int_{t-\sigma(t, x, u)}^t \psi(v(\tau)) d\tau. \end{array} \right.$$

Therefore, by taking the supremum, we obtain

$$\begin{aligned} \mathbf{N}(t, x) \leq \sup_{u \in \text{Dom}(\varphi^*)} & \left( \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \sigma(t, x, u)\varphi^*(u) \right) \\ & + \int_{t-\sigma(t, x, u)}^t \psi(v(\tau))d\tau. \end{aligned}$$

This completes the proof of the Lax–Hopf inequality.

**COROLLARY 5.2** (case of the traffic model). *When  $X := \mathbb{R}$ ,  $K := [\xi, +\infty[$ ,  $\psi$  is a concave flux function vanishing at density 0 and at a jam density  $\omega > 0$ , and  $\mathbf{N}(t, x)$  is the cumulated number of vehicles at time  $t$  and at location  $x \in K$ . Consistency conditions (5) imply the existence of a unique upper semicontinuous solution  $\mathbf{N}(t, x) = \max(\mathbf{N}_{\mathbf{N}_0}(t, x), \mathbf{N}_\gamma(t, x))$  to this problem in the Barron–Jensen/Frankowska sense satisfying the Lax–Hopf formula*

$$(19) \quad \begin{cases} \mathbf{N}_{\mathbf{N}_0}(t, x) = \sup_{u \in \text{Dom}(\varphi^*)} \left( \mathbf{N}_0(x + tu) - t\varphi^*(u) + \int_0^t \psi(v(t - \tau))d\tau \right), \\ \mathbf{N}_\gamma(t, x) = \sup_{\{u \in \text{Dom}(\varphi^*) \mid u \leq \frac{\xi - x}{t}\}} \left( \gamma\left(t - \frac{\xi - x}{u}, \xi\right) - \frac{\xi - x}{u}\varphi^*(u) + \int_0^{\frac{\xi - x}{u}} \psi(v(t - \tau))d\tau \right). \end{cases}$$

**5.2. A posteriori estimates.** The maximum principle, an a priori upper estimate of a solution of a partial differential equation (whether it exists or not) is here obtained as an a posteriori estimate, a property of the *viability hypsolution*.

**PROPOSITION 5.3** (upper estimate of the viability hypsolution). *The viability hypsolution satisfies*

$$\mathbf{N}(t, x) \leq \sup_{u \in \text{Dom}(\varphi^*)} \left( \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \left\langle u, \int_{t-\sigma(t, x, u)}^t v(\tau)d\tau \right\rangle \right).$$

Consequently, the viability hypsolution satisfies the following (a posteriori instead of a priori) estimate

$$\mathbf{N}(t, x) \leq \sup_{t \geq 0, x \in K} \mathbf{c}(t, x) + t \text{Diam}(\text{Dom}(\varphi^*)) \sup_{t \geq 0} \|v(t)\|$$

(maximum principle).

*Proof.* Fix  $u \in \text{Dom}(\varphi^*)$  and set  $\sigma(t, x, u) =: s$ . Definition (12) of the conjugate function implies

$$(20) \quad \psi\left(\frac{1}{s} \int_{t-s}^t v(\tau)d\tau\right) - \varphi^*(u) \leq -\left\langle \frac{1}{s} \int_{t-s}^t v(\tau)d\tau, u \right\rangle.$$

Consequently,

$$\begin{cases} \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \sigma(t, x, u)\varphi^*(u) + \int_{t-\sigma(t, x, u)}^t (\psi(v(\tau)))d\tau \\ \leq \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \left\langle u, \int_{t-\sigma(t, x, u)}^t v(\tau)d\tau \right\rangle \\ \leq \sup_{w \in \text{Dom}(\varphi^*)} \left( \mathbf{c}(t - \sigma(t, x, w), x + \sigma(t, x, w)w) - \left\langle w, \int_{t-\sigma(t, x, w)}^t v(\tau)d\tau \right\rangle \right). \end{cases}$$

Taking the supremum over  $u \in \text{Dom}(\varphi^*)$ , Lax-Hopf formula (16) implies the upper estimate

$$\mathbf{N}(t, x) \leq \sup_{u \in \text{Dom}(\varphi^*)} \left( \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \left\langle u, \int_{t-\sigma(t, x, u)}^t v(\tau) d\tau \right\rangle \right).$$

This completes the proof.  $\square$

In the same way, we provide a lower estimate of the solution.

**PROPOSITION 5.4** (lower estimate). *Assume that  $v(t) := v$  is constant and, for simplicity, that the function  $\psi$  is differentiable. Then*

$$\mathbf{c}(t - \sigma(t, x, -\psi'(v)), x - \sigma(t, x, -\psi'(v))\psi'(v)) + \sigma(t, x, \psi'(v)) \langle v, \psi'(v) \rangle \leq \mathbf{N}(t, x).$$

Consequently, the hyposolution is nonnegative on its positivity domain  $\text{Dom}_+(\mathbf{N})$ , defined as the subset of pairs  $(t, x) \in \mathbb{R}_+ \times K$  such that

$$\mathbf{c}(t - \sigma(t, x, -\psi'(v)), x - \sigma(t, x, -\psi'(v))\psi'(v)) + \sigma(t, x, -\psi'(v)) \langle v, \psi'(v) \rangle \geq 0.$$

*Proof.* By Definition 3.9 of the superdifferential,

$$\forall u \in \partial_+ \psi(v), \quad \psi(v) - \varphi^*(-u) = \langle v, u \rangle.$$

Therefore, if  $\psi$  is differentiable, taking  $u := -\psi'(v)$  as the unique element of  $-\partial_+ \psi(v) = \partial_- \varphi(v)$ , the Legendre equality  $\psi(v) - \varphi^*(-\psi'(v)) = \langle v, \psi'(v) \rangle$  yields

$$\begin{cases} \mathbf{c}(t - \sigma(t, x, -\psi'(v)), x - \sigma(t, x, -\psi'(v))\psi'(v)) + \sigma(t, x, -\psi'(v)) \langle v, \psi'(v) \rangle \\ = \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) - \sigma(t, x, u) \langle v, u \rangle \\ = \mathbf{c}(t - \sigma(t, x, u), x + \sigma(t, x, u)u) + \sigma(t, x, u)(\psi(v) - \varphi^*(u)) \leq \mathbf{N}(t, x) \end{cases}$$

thanks to the Lax-Hopf formula.  $\square$

**5.3. General representation formula.** We have derived Lax-Hopf formula (16) from a general representation formula (21) valid when there is viability constraints.

**THEOREM 5.5** (representation formula of the viability solution (the case with constraints)). *We already set*

$$\tau(x, u(\cdot)) := \inf_{x + \int_0^t u(\tau) d\tau \notin K} t \quad \text{and} \quad \sigma(t, x, u(\cdot)) = \min(t, \tau(x, u(\cdot))).$$

The viability hyposolution can be represented in the form

$$(21) \quad \begin{cases} \mathbf{N}(t, x) = \sup_{u(\cdot)} \left[ \min \left( \mathbf{c} \left( t - \sigma(t, x, u(\cdot)), x + \int_0^{\sigma(t, x, u(\cdot))} u(\tau) d\tau \right) \right. \right. \\ \left. \left. - \int_0^{\sigma(t, x, u(\cdot))} \varphi^*(u(\tau)) d\tau + \int_{t-\sigma(t, x, u(\cdot))}^t \psi(v(\tau)) d\tau, \right. \right. \\ \left. \left. \inf_{s \in [0, \sigma(t, x, u(\cdot))]} \left( \mathbf{b} \left( t - s, x + \int_0^s u(\tau) d\tau \right) - \int_0^s \varphi^*(u(\tau)) d\tau + \int_{t-s}^t \psi(v(\tau)) d\tau \right) \right) \right]. \end{cases}$$

Using the decomposition  $\mathbf{N}(t, x) = \max(\mathbf{N}_{N_0}(t, x), \mathbf{N}_\gamma(t, x))$ , this formula boils down to

$$\left\{ \begin{array}{l} \mathbf{N}_{N_0}(t, x) = \sup_{u(\cdot)} \left[ \min \left( \mathbf{N}_0 \left( x + \int_0^t u(\tau) d\tau \right) - \int_0^t \varphi^*(u(\tau)) d\tau + \int_0^t \psi(v(\tau)) d\tau, \right. \right. \\ \left. \left. \inf_{s \in [0, t]} \left( \mathbf{b} \left( t - s, x + \int_0^s u(\tau) d\tau \right) - \int_0^s \varphi^*(u(\tau)) d\tau + \int_{t-s}^t \psi(v(\tau)) d\tau \right) \right] \end{array} \right.$$

and

$$\left\{ \begin{array}{l} \mathbf{N}_\gamma(t, x) = \sup_{\{u(\cdot) | \tau(x, u(\cdot)) \leq t\}} \left[ \min \left( \gamma \left( t - \tau(x, u(\cdot)), x + \int_0^{\tau(x, u(\cdot))} u(\tau) d\tau \right) \right. \right. \\ \left. \left. - \int_0^{\tau(x, u(\cdot))} \varphi^*(u(\tau)) d\tau + \int_{t-\tau(x, u(\cdot))}^t \psi(v(\tau)) d\tau, \right. \right. \\ \left. \left. \inf_{s \in [0, \tau(x, u(\cdot))]} \left( \mathbf{b} \left( t - s, x + \int_0^s u(\tau) d\tau \right) - \int_0^s \varphi^*(u(\tau)) d\tau + \int_{t-s}^t \psi(v(\tau)) d\tau \right) \right] \end{array} \right.$$

*Proof.* We begin by observing that a solution  $(\tau(\cdot), x(\cdot), y(\cdot))$  to control system (13) starting from  $(t, x, y)$  is given by  $\tau(s) = t - s$ ,  $x(s) = x + \int_0^s u(r) dr$  and

$$y(s) = y + \int_0^s (\varphi^*(u(r)) - \psi(v(t-r))) dr$$

for some  $u(\cdot)$ .

Therefore, to say that  $(t, x, y)$  belongs to the capture basin  $\text{Capt}_{(13)}(\mathcal{K}, \mathcal{C})$  amounts to saying that there exists a solution  $(\tau(\cdot), x(\cdot), y(\cdot))$  to the characteristic control system (13) starting from  $(t, x, y)$  and  $t^* \in [0, t]$  such that

1.  $(t - t^*, x(t^*), y(t^*))$  belongs to the target  $\mathcal{C}$ , i.e., such that

$$\begin{aligned} y(t^*) &:= y + \int_0^{t^*} (\varphi^*(u(\tau)) - \psi(v(t-\tau))) d\tau \leq \mathbf{c}(t - t^*, x(t^*)) \\ &= \mathbf{c} \left( t - t^*, x + \int_0^{t^*} u(\tau) d\tau \right). \end{aligned}$$

2. For all  $s \in [0, t^*]$ ,  $(t - s, x(s), y(s))$  belongs to the environment  $\mathcal{K}$ , i.e., such that

$$\begin{aligned} y(s) &= y + \int_0^s (\varphi^*(u(\tau)) - \psi(v(t-\tau))) d\tau \leq \mathbf{b}(t - s, x(s)) \\ &= \mathbf{b} \left( t - s, x + \int_0^s u(\tau) d\tau \right). \end{aligned}$$

This implies that

$$y \leq \min \left( \begin{array}{l} \mathbf{c} \left( t - t^*, x + \int_0^{t^*} u(\tau) d\tau \right) - \int_0^{t^*} (\varphi^*(u(\tau)) - \psi(v(t-\tau))) d\tau, \\ \inf_{s \in [0, t^*]} \mathbf{b} \left( t - s, x + \int_0^s u(\tau) d\tau \right) - \int_0^s (\varphi^*(u(\tau)) - \psi(v(t-\tau))) d\tau \end{array} \right).$$

Since  $y$  is finite, this implies that  $\mathbf{c}(t - t^*, x + \int_0^{t^*} u(\tau) d\tau)$  must be finite, and thus, that

1. either  $t - t^* = 0$ , in which case  $\mathbf{c}(t - t^*, x + \int_0^{t^*} u(\tau) d\tau) = \mathbf{N}_0(x + \int_0^t u(\tau) d\tau)$ ;
2. or  $x(t^*) \in \partial K$ , which means that  $t^* = \tau(x, u(\cdot)) = \sigma(t, x, u(\cdot)) \leq t$ , in which case

$$\mathbf{c}\left(t - t^*, x + \int_0^{t^*} u(\tau) d\tau\right) = \gamma\left(t - \sigma(t, x, u(\cdot)), x + \int_0^{\sigma(t, x, u(\cdot))} u(\tau) d\tau\right).$$

This implies that  $\mathbf{N}(t, x) \leq \mathbf{V}(t, x)$ , where

$$\left\{ \begin{array}{l} \mathbf{V}(t, x) = \sup_{u(\cdot)} \left( \min \left( \mathbf{c}\left(t - \sigma(t, x, u(\cdot)), x + \int_0^{\sigma(t, x, u(\cdot))} u(\tau) d\tau\right) \right. \right. \\ \quad \left. \left. - \int_0^{\sigma(t, x, u(\cdot))} \varphi^*(u(\tau)) d\tau + \int_{t - \sigma(t, x, u(\cdot))}^t \psi(v(\tau)) d\tau, \right. \right. \\ \left. \inf_{s \in [0, \sigma(t, x, u(\cdot))]} \left( \mathbf{b}\left(t - s, x + \int_0^s u(\tau) d\tau\right) - \int_0^s \varphi^*(u(\tau)) d\tau + \int_{t-s}^t \psi(v(\tau)) d\tau \right) \right) \end{array} \right\}.$$

For proving the converse inequality, we associate with every  $\varepsilon > 0$  a control  $t \mapsto u_\varepsilon(t) \in \text{Dom}(\varphi^*)$  such that

$$\left\{ \begin{array}{l} \mathbf{V}(t, x) - \varepsilon \leq \min \left( \mathbf{c}\left(t - \sigma(t, x, u_\varepsilon(\cdot)), x + \int_0^{\sigma(t, x, u_\varepsilon(\cdot))} u_\varepsilon(\tau) d\tau\right) \right. \\ \quad \left. - \int_0^{\sigma(t, x, u_\varepsilon(\cdot))} \varphi^*(u_\varepsilon(\tau)) d\tau + \int_{t - \sigma(t, x, u_\varepsilon(\cdot))}^t \psi(v(\tau)) d\tau, \right. \\ \left. \inf_{s \in [0, \sigma(t, x, u_\varepsilon(\cdot))]} \left( \mathbf{b}\left(t - s, x + \int_0^s u_\varepsilon(\tau) d\tau\right) - \int_0^s \varphi^*(u_\varepsilon(\tau)) d\tau + \int_{t-s}^t \psi(v(\tau)) d\tau \right) \right) \end{array} \right\}.$$

Therefore, setting  $x_\varepsilon(t) := x + \int_0^t u_\varepsilon(s) ds$  and

$$y_\varepsilon(t) := \mathbf{V}(t, x) - \varepsilon + \int_0^t (\varphi^*(u_\varepsilon(r)) - \psi(v(t - r))) dr$$

we observe that the function  $s \mapsto (t - s, x_\varepsilon(s), y_\varepsilon(s))$  starts from  $(t, x, \mathbf{V}(t, x) - \varepsilon)$ , is a solution to characteristic control system (13), viable in  $\mathcal{K}$  for  $s \leq \sigma(t, x, u_\varepsilon(\cdot))$  because

$$y_\varepsilon(s) = \mathbf{V}(t, x) - \varepsilon + \int_0^s (\varphi^*(u_\varepsilon(r)) - \psi(v(t - r))) dr \leq \mathbf{b}(t - s, x_\varepsilon(s)),$$

and reaches the target  $\mathcal{C} := \text{Hyp}(\mathbf{c})$  at time  $t_\varepsilon := \sigma(t, x, u_\varepsilon(\cdot))$ ,

$$y_\varepsilon(t_\varepsilon) = \mathbf{V}(t, x) - \varepsilon + \int_0^{t_\varepsilon} (\varphi^*(u_\varepsilon(r)) - \psi(v(t - r))) dr \leq \mathbf{c}(t - t_\varepsilon, x_\varepsilon(t_\varepsilon)).$$

This implies that  $(t, x, \mathbf{V}(t, x) - \varepsilon)$  belongs to the capture basin  $\text{Capt}_{(13)}(\mathcal{K}, \mathcal{C})$ , and thus, that  $\mathbf{V}(t, x) - \varepsilon \leq \mathbf{N}(t, x)$ . Letting  $\varepsilon$  converge to 0 provides the converse inequality, and thus, the representation formula we were looking for.  $\square$

COROLLARY 5.6 (representation formula of the viability solution (the case without constraints)). *Without inequality constraints, the viability hypsolution can be represented in the form*

$$\left\{ \begin{array}{l} N(t, x) = \sup_{u(\cdot)} \left( \int_{t-\sigma(t, x, u(\cdot))}^t \psi(v(\tau)) d\tau \right. \\ \left. + \mathbf{c} \left( t - \sigma(t, x, u(\cdot)), x + \int_0^{\sigma(t, x, u(\cdot))} u(\tau) d\tau \right) - \int_0^{\sigma(t, x, u(\cdot))} \varphi^*(u(\tau)) d\tau \right). \end{array} \right.$$

**6. Dirichlet/initial conditions and inequality constraints.** We begin by checking that the viability hypsolution satisfies the initial condition, the Dirichlet condition, and the inequality constraints.

THEOREM 6.1 (Dirichlet/initial conditions and inequality constraints). *Consistency conditions (1) imply that the viability hypsolution satisfies the initial and Dirichlet conditions (3) and inequality constraints (4).*

*Proof.* Inclusions

$$\mathcal{C} := \mathcal{Hyp}(\mathbf{c}) \subset \text{Capt}_{(13)}(\mathcal{K}, \mathcal{C}) \subset \mathcal{K} := \mathcal{Hyp}(\mathbf{b})$$

imply that

$$\forall t \geq 0, \forall x \in K, \quad \mathbf{c}(t, x) \leq \mathbf{N}(t, x) \leq \mathbf{b}(t, x),$$

and thus inequality constraint  $\mathbf{N}(t, x) \leq \mathbf{b}(t, x)$  and inequalities  $\mathbf{N}_0(x) \leq \mathbf{N}(0, x)$  for all  $x \in K$  and  $\gamma(t, x) \leq \mathbf{N}(t, x)$  for all  $t \geq 0$  and  $x \in \partial K$ . We now prove by contradiction that consistency conditions (1) imply converse inequalities  $\mathbf{N}_0(x) \geq \mathbf{N}(0, x)$  for all  $x \in K$  and  $\gamma(t, x) \geq \mathbf{N}(t, x)$  for all  $t \geq 0$  and  $x \in \partial K$  that we summarize in

$$\forall (t, x) \in \text{Dom}(\mathbf{c}), \quad \mathbf{N}(t, x) \leq \mathbf{c}(t, x).$$

Assume that there exist  $(t, \xi) \in \text{Dom}(\mathbf{c})$  and  $\varepsilon > 0$  such that

$$\mathbf{N}(t, \xi) = \mathbf{c}(t, \xi) + \varepsilon.$$

Since  $(t, \xi, \mathbf{N}(t, \xi))$  belongs to the capture basin  $\text{Capt}_{(13)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c}))$ , there exists a solution  $(\tau(\cdot), x(\cdot), y(\cdot))$  to the characteristic control system (13) starting from  $(t, \xi, \mathbf{N}(t, \xi))$  and  $t^* > 0$  such that  $(t - t^*, x(t^*), y(t^*))$  belongs to the hypograph  $\mathcal{Hyp}(\mathbf{c})$ ; i.e., setting  $x(t^*) = \xi + \int_0^{t^*} u(\tau) d\tau = \eta$ , we obtain

$$y(t^*) = \mathbf{N}(t, \xi) + \int_0^{t^*} \varphi^*(u(\tau)) d\tau - \int_0^{t^*} \psi(v(t - \tau)) d\tau \leq \mathbf{c}(t - t^*, \eta).$$

Inequality (18) and definition (20) imply

$$(22) \quad \int_0^s \psi(v(t - \tau)) d\tau - \int_0^s \varphi^*(u(\tau)) d\tau \leq - \left\langle \frac{1}{s} \int_{t-s}^t v(\tau) d\tau, \widehat{u}(s) \right\rangle.$$

Piecing these inequalities together and taking  $s = t^*$ , we infer that

$$\begin{cases} \mathbf{c}(t, \xi) + \varepsilon + \left\langle \frac{1}{t^*} \int_{t-t^*}^t v(\tau) d\tau, \eta - \xi \right\rangle \\ \leq \mathbf{N}(t, \xi) + \int_0^{t^*} \varphi^*(u(\tau)) d\tau - \int_0^{t^*} \psi(v(t - \tau)) d\tau \leq \mathbf{c}(t - t^*, \eta), \end{cases}$$

from which we deduce that

$$\varepsilon \leq \mathbf{c}(t - t^*, \eta) - \mathbf{c}(t, \xi) - \left\langle \frac{1}{t^*} \int_{t-t^*}^t v(\tau) d\tau, \eta - \xi \right\rangle.$$

Consistency conditions (1) can be written in the form

$$\forall 0 \leq r \leq s, \forall x \in K, y \in \partial K, \mathbf{c}(r, x) - \mathbf{c}(s, y) \leq \left\langle \frac{1}{s-r} \int_r^s v(\tau) d\tau, x - y \right\rangle.$$

Taking  $r := t - t^*$ ,  $s := t$ ,  $x := \eta$ , and  $y := \xi$ , we obtain the contradiction  $\varepsilon \leq 0$ , and thus, we proved that for any  $(t, \xi) \in \text{Dom}(\mathbf{c})$ ,  $\mathbf{N}(t, \xi) = \mathbf{c}(t, \xi)$ .  $\square$

**7. Other auxiliary systems.** For proving that the viability hypsolution is the solution, in a generalized sense, to the Hamilton-Jacobi partial differential equation derived from the tangential or normal conditions characterizing capture basins, we need assumptions that control system (13) does not satisfy.

The two inequalities characterizing the Barron-Jensen/Frankowska solution follow from the two inclusions characterizing the Frankowska property of the capture basin (Definition 3.6). One is derived from the viability theorem and requires the assumption that  $F$  is Marchaud (upper semicontinuous, linear growth, with convex images); the other one is derived from the invariance theorem, valid whenever  $F$  is Lipschitz with closed values, without bounds on the size of their images (see Theorems 3.7 and 3.8). This is the reason why we introduce below two new systems, (23) and (24). The first one complies with the “Marchaud assumptions” of the viability theorem, so that the capture basin under it will satisfy the first inclusion of the Frankowska property, the second one to the “Lipschitz assumptions” of the invariance theorem, so that the capture basin under it will satisfy the second inclusion of the Frankowska property. The aim of this section is to derive from the inclusions of the Frankowska property the corresponding inequalities defining the Barron-Jensen/Frankowska property. However, to conclude, we need to prove that the capture basin is the same under the original system and the two new ones. This is achieved by our proof; i.e., the capture basin being the same under the three systems, it captures these two properties, and thus, these two inequalities, each valid under the assumptions made (convexity *with* bounds for the one deriving from the viability theorem and Lipschitz property *without* bounds for the other one deriving from the invariance theorem).

It happens that the capture basin of the hypograph of  $\mathbf{c}$  viable in the hypograph of  $\mathbf{b}$  under control system (13) is still the capture basin under other auxiliary systems which satisfy these assumptions, so we shall be able to transfer the theorems concerning capture basins.

The function  $\psi$  being concave and finite, it is then continuous so that, the function  $v(\cdot)$  being bounded, the constant

$$\alpha := \sup_{u \in \text{Dom}(\varphi^*)} \varphi^*(u) - \inf_{\tau \geq 0} \psi(v(\tau))$$

is finite by Lemma 7.3. The new characteristic control systems are defined by

$$(23) \quad \begin{cases} \tau'(t) = -1, \\ x'(t) = u(t) \\ y'(t) = -\psi(v(\tau(t))) + \varphi^*(u(t)) + \pi(t) \end{cases} \quad \begin{array}{l} \text{where } u(t) \in \text{Dom}(\varphi^*), \\ \text{where } \pi(t) \in [0, \alpha + \psi(v(\tau(t)) - \varphi^*(u(t)))] \end{array}$$

and

$$(24) \quad \begin{cases} \tau'(t) = -1, \\ x'(t) = u(t) \\ y'(t) = -\psi(v(\tau(t))) + \varphi^*(u(t)) + \pi(t) \end{cases} \quad \begin{array}{l} \text{where } u(t) \in \text{Dom}(\varphi^*), \\ \text{where } \pi(t) \geq 0, \end{array}$$

where we added a new control  $\pi$  ranging over different intervals.

LEMMA 7.1 (equality between capture basins). *The capture basins of the hypograph of the function  $\mathbf{c}$  by systems (13), (23), and (24) coincide as follows:*

$$\text{Capt}_{(24)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})) = \text{Capt}_{(23)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})) = \text{Capt}_{(13)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})).$$

Furthermore,

$$\text{Capt}_{(23)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})) = \text{Capt}_{(23)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})) - \{0\} \times \{0\} \times \mathbb{R}_+$$

(where in a vector space,  $A - B := \{a - b\}_{a \in A, b \in B}$ ).

*Proof.* Inclusions

$$\text{Capt}_{(13)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})) \subset \text{Capt}_{(23)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})) \subset \text{Capt}_{(24)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c}))$$

are obvious. For proving that

$$\text{Capt}_{(24)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})) \subset \text{Capt}_{(13)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c})),$$

let us consider an element  $(t, x, y) \in \text{Capt}_{(24)}(\text{Hyp}(\mathbf{b}), \text{Hyp}(\mathbf{c}))$ . This means that there exist  $u(\cdot) \in L^1(0, +\infty; \text{Dom}(\varphi^*))$  and a corresponding solution  $(\tau(\cdot), x(\cdot), y(\cdot))$  to the characteristic control system (24) starting from  $(t, x, y)$  given by  $\tau(s) = t - s$ ,  $x(s) = x + \int_0^s u(r) dr$ , and

$$(25) \quad y(s) \geq y - \int_0^s (\psi(v(t-r)) - \varphi^*(u(r))) dr$$

and there exists  $t^* \in [0, t]$  such that  $(t-t^*, x(t^*), y(t^*)) \in \text{Hyp}(\mathbf{c})$  and, for all  $s \in [0, t^*]$ ,  $(t-s, x(s), y(s)) \in \text{Hyp}(\mathbf{b})$ . Setting

$$y_0(s) := y + \int_0^s (\varphi^*(u(r)) - \psi(v(t-r))) dr$$

we infer that  $(\tau(\cdot), x(\cdot), y_0(\cdot))$  is a solution to the characteristic control system (13) starting from  $(t, x, y)$  viable in the environment  $\mathcal{Hyp}(\mathbf{b})$  because

$$\forall s \in [0, t^*], \quad y_0(s) \leq y(s) \leq \mathbf{b}(t-s, x(s))$$

until time  $t^*$ , where it reaches the target  $\mathcal{Hyp}(\mathbf{c})$  because

$$y_0(t^*) \leq y(t^*) \leq \mathbf{c}(t-t^*, x(t^*)).$$

This means that  $(t, x, y) \in \text{Capt}_{(13)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c}))$ .

We also observe that whenever  $(t, x, y) \in \text{Capt}_{(24)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c}))$  and  $z \leq y$ , inequality (25) implies that

$$y(s) \geq y - \int_0^s (\psi(v(t-r)) - \varphi^*(u(r))) dr \geq z - \int_0^s (\psi(v(t-r)) - \varphi^*(u(r))) dr$$

and thus that  $(t, x, z)$  also belongs to the capture basin, so that,

$$\text{Capt}_{(23)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c})) = \text{Capt}_{(23)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c})) - \{0\} \times \{0\} \times \mathbb{R}_+.$$

The proof is completed.  $\square$

We also need the following.

**LEMMA 7.2.** *Let  $\psi : X \mapsto \mathbb{R}$  be an upper semicontinuous concave function. The domain of its Fenchel transform  $\varphi^*$  is contained in a closed convex subset  $A$  if and only if the function  $\psi$  satisfies inequality*

$$\exists \beta \in \mathbb{R} \text{ such that } \forall v \in X, \quad \beta - \sigma_A(v) \leq \psi(v).$$

*Its Fenchel transform  $\varphi^*$  is bounded on a convex subset  $A$  if and only if the function  $\psi$  satisfies*

$$\exists \delta \in \mathbb{R} \text{ such that } \forall v \in X^*, \quad \psi(v) \leq \delta - \sigma_A(v).$$

*Proof.* Since  $\psi(0) = \inf_{u \in \text{Dom}(\varphi^*)} \varphi^*(u)$ , we infer that

$$\forall v \in X, \quad \forall u \in \text{Dom}(\varphi^*), \quad \psi(0) - \sigma_{\text{Dom}(\varphi^*)}(v) \leq \varphi^*(u) - \langle u, v \rangle$$

so that, by taking the infimum over  $u$ , we obtain inequality  $\psi(0) - \sigma_{\text{Dom}(\varphi^*)}(v) \leq \psi(v)$ . It is enough to set  $\beta := \psi(0)$  and to take  $A := \text{Dom}(\varphi^*)$ . Conversely, assume that for all  $v \in X$ ,  $\psi(v) \geq \beta - \sigma_A(v)$ . We shall prove that  $\text{Dom}(\varphi^*) \subset A$ . If not, there would exist  $u \in \text{Dom}(\varphi^*) \setminus A$ . The separation theorem states there exist  $p_0 \in X$  and  $\varepsilon > 0$  such that  $\varepsilon \leq \langle p_0, u \rangle - \sigma_A(p_0)$ . Consequently, for every  $\lambda > 0$ ,

$$\lambda \varepsilon \leq \langle \lambda p_0, u \rangle - \sigma_A(\lambda p_0) \leq \langle \lambda p_0, u \rangle + \psi(\lambda p_0) - \beta \leq \varphi^*(u) - \beta$$

by assumption and by the definition of  $\varphi^*$ . Letting  $\lambda \mapsto +\infty$  implies that  $\varphi^*(u) = +\infty$ , i.e., that  $u \notin \text{Dom}(\varphi^*)$ , a contradiction.

For proving the second statement, we observe that if  $\delta := \sup_{u \in \text{Dom}(\varphi^*)} \varphi^*(u) < +\infty$  is finite, then

$$\psi(v) \leq \delta + \inf_{u \in \text{Dom}(\varphi^*)} \langle v, -u \rangle = \delta - \sigma_{\text{Dom}(\varphi^*)}(v)$$

so that the inequality holds true with  $A := \text{Dom}(\varphi^*)$ . Conversely, inequality  $\psi(v) \leq \delta - \sigma_A(v)$  implies that

$$\forall u \in A, \quad \varphi^*(u) \leq \sup_{v \in \text{Dom}(\psi)} [\langle v, u \rangle + \delta - \sigma_A(v)] < +\infty$$

is bounded on  $A$ , and thus, on  $\text{Dom}(\varphi^*)$  whenever this domain is contained in  $A$ .  $\square$

Control systems (23) and (24) are actually differential inclusions

$$(\tau'(t), x'(t), y'(t)) \in F(\tau(t), x(t), y(t)),$$

where

$$(26) \quad F(\tau, x, y) := \{(-1, u, -\psi(v(\tau)) + \varphi^*(u) + \pi)\}_{u \in \text{Dom}(\varphi^*), \pi \in [0, \alpha + \psi(v(\tau)) - \varphi^*(u)]}$$

and

$$(\tau'(t), x'(t), y'(t)) \in F_\infty(\tau(t), x(t), y(t)),$$

where

$$(27) \quad F_\infty(\tau, x, y) := \{(-1, u, -\psi(v(\tau)) + \varphi^*(u) + \pi)\}_{u \in \text{Dom}(\varphi^*), \pi \geq 0},$$

respectively.

LEMMA 7.3. *The set-valued map  $F$  is Marchaud and, if the functions  $\psi$ ,  $\varphi^*$ , and  $v$  are Lipschitz, the set-valued map  $F_\infty$  is Lipschitz with closed images.*

*Proof.* For proving that the set-valued map  $F$  is Marchaud, we shall check successively that

1. *the values  $F(\tau, x, y)$  of the set-valued map  $F$  are convex.* Indeed, for convex weight  $\lambda_i \geq 0$  such that  $\sum \lambda_i = 1$ , we can write

$$\sum \lambda_i (-1, u_i, -\psi(v(\tau)) + \varphi^*(u_i) + \pi_i) = (-1, \bar{u}, \varphi^*(\bar{u}) - \psi(v(\tau)) + \bar{\pi}),$$

where  $\bar{u} := \sum \lambda_i u_i$  and

$$\bar{\pi} := \sum \lambda_i \varphi^*(u_i) - \varphi^*\left(\sum \lambda_i u_i\right) + \sum \lambda_i \pi_i.$$

Since the domain of  $\varphi^*$  is convex,  $\bar{u} \in \text{Dom}(\varphi^*)$ . We observe that  $\bar{\pi}$  is non-negative and smaller than or equal to  $\alpha + \psi(v(\tau)) - \varphi^*(\bar{u})$  because

$$\begin{cases} \bar{\pi} \leq \sum \lambda_i \varphi^*(u_i) - \varphi^*(\sum \lambda_i u_i) + \sum \lambda_i (\alpha + \psi(v(\tau)) - \varphi^*(u_i)) \\ = \alpha + \psi(v(\tau)) - \varphi^*(\sum \lambda_i u_i). \end{cases}$$

2. *the graph of the set-valued map  $F$  is closed.* Indeed, let us consider a sequence of elements  $((\tau_n, x_n, y_n), (-1, u_n, \lambda_n))$  of the graph of  $F$  converging to  $((\tau, x, y), (-1, u, \lambda))$ , where  $\lambda_n := -\psi(v(\tau_n)) + \varphi^*(u_n) + \pi_n$  and where  $\pi_n \in [0, \alpha + \psi(v(\tau_n)) - \varphi^*(u_n)]$ .

Since the function  $(\tau, x, y, u) \mapsto \varphi^*(u) - \psi(v(\tau))$  is lower semicontinuous and since

$$(\tau_n, x_n, y_n, u_n, \lambda_n) = (\tau_n, x_n, y_n, u_n, -\psi(v(\tau_n)) + \varphi^*(u_n) + \pi_n)$$

belongs to the epigraph of this function (because  $\pi_n$  is positive by construction), which is closed, we deduce that the limit  $(\tau, x, y, u, \lambda)$  also belongs to this epigraph, i.e., that  $\lambda \geq \varphi^*(u) - \psi(v(\tau))$ . It is enough to set  $\pi := \lambda - \varphi^*(u) - \psi(v(\tau)) \geq 0$ , which from now on defines  $\pi$ . Recall that  $\pi_n = \lambda_n + \psi(v(\tau_n)) - \varphi^*(u_n) \leq \alpha + \mathbf{I}(\tau_n, x_n) - \varphi^*(u_n)$  by construction of  $\pi_n$ . Therefore,  $\lambda_n \leq \alpha$ . Therefore, taking the limit,  $\lambda = \pi + \varphi^*(u) - \psi(v(\tau)) \leq \alpha$ . In summary, the limit  $((\tau, x, y), (-1, u, \lambda))$  of elements  $((\tau_n, x_n, y_n), (-1, u_n, \lambda_n))$  belongs to the graph of  $F$  since  $\lambda = -\psi(v(\tau)) + \varphi^*(u) + \pi$ , where  $\pi \in [0, \alpha + \psi(v(\tau)) - \varphi^*(u)]$ .

3. *the images  $F(\tau, x, y)$  of  $F$  are bounded.* This follows from Lemma 7.2 because  $\text{Dom}(\varphi^*)$  is bounded and

$$\varphi^*(u) - \psi(v(\tau)) + \pi \leq \alpha := \sup_{u \in \text{Dom}(\varphi^*)} \varphi^*(u) - \inf_{\tau \geq 0} \psi(v(\tau))$$

is finite since  $\varphi^*$  is bounded above. Therefore

$$\|(-1, u, \varphi^*(u) - \psi(v(\tau)) + \pi)\| \leq \max(1, \|\text{Dom}(\varphi^*)\|, \alpha).$$

Hence, we have proved that the set-valued map  $F$  is Marchaud. The fact that  $F_\infty$  is Lipschitz is obvious since the functions  $\psi$ ,  $\varphi^*$ , and  $v$ , are assumed to be Lipschitz and since the controls  $u$  range over  $\mathbb{R}_+$  which, being constant, is Lipschitz.  $\square$

We thus deduce the following.

**PROPOSITION 7.4** (upper semicontinuity of the solution). *The viability hyposolution is upper semicontinuous and its hypograph satisfies*

$$\mathcal{Hyp}(\mathbf{N}) = \text{Capt}_{(23)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c})) = \text{Capt}_{(24)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c})).$$

*The viability hyposolution is concave whenever the functions  $\mathbf{b}$  and  $\mathbf{c}$  are concave.*

*Proof.* The first statement follows from Proposition 4.3 of [5] stating that under a Marchaud control system, the capture basin of a target is closed whenever the target  $\mathcal{Hyp}(\mathbf{c})$  and the environment  $\mathcal{Hyp}(\mathbf{b})$  are closed and the complement of the target in the environment is a repeller; this is the case because the first component of the system is  $\tau'(t) = -1$  which implies that all solutions  $(t - s, x(s), y(s))$  starting from any  $(t, x, y)$  leave  $\mathbb{R}_+ \times X \times \mathbb{R}$ , and thus,  $\mathcal{Hyp}(\mathbf{b}) \subset \mathbb{R}_+ \times X \times \mathbb{R}$ . Since we have proved that

$$\text{Capt}_{(23)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c})) = \text{Capt}_{(23)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c})) - \{0\} \times \{0\} \times \mathbb{R}_+,$$

we infer that  $\text{Capt}_{(23)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c}))$  is a hypograph, and thus, the hypograph of the viability hyposolution.  $\square$

**8. Contingent solution to the Hamilton–Jacobi equation.** We shall prove that the viability hyposolution to Hamilton–Jacobi equation (2) (see Definition 4.1) is the *contingent solution* by characterizing them in terms of tangent cones and translating them into terms of contingent hyposolutions.

**THEOREM 8.1** (contingent Frankowska solution). *The viability hyposolution  $\mathbf{N}$  is the largest upper semicontinuous solution satisfying*

$$(28) \quad \psi(v(t)) \geq \inf_{u \in \text{Dom}(\varphi^*)} (\varphi^*(u) - D_\downarrow \mathbf{N}(t, x)(-1, u))$$

*and the initial/Dirichlet conditions and the inequality constraints. If the functions  $\psi$ ,  $\varphi^*$ , and  $v$  are furthermore Lipschitz, then  $\mathbf{N}$  is the smallest upper semicontinuous solution satisfying the following:*

1. If  $\mathbf{N}(t, x) < \mathbf{b}(t, x)$ , then

$$(29) \quad \psi(v(t)) \leq \inf_{u \in \text{Dom}(\varphi^*)} (D_{\downarrow} \mathbf{N}(t, x)(1, -u) + \varphi^*(u)).$$

2. If  $\mathbf{N}(t, x) = \mathbf{b}(t, x)$ , then

$$(30) \quad \psi(v(t)) \leq \inf_{\{u | \psi(v(t)) \leq D_{\downarrow} \mathbf{b}(t, x)(1, -u) + \varphi^*(u)\}} (D_{\downarrow} \mathbf{N}(t, x)(1, -u) + \varphi^*(u)).$$

We need the following technical lemma on tangent cones to hypographs for proving Theorem 8.1.

LEMMA 8.2 (tangent cones to hypographs). *If  $\psi : X \mapsto \mathbf{R}_+ \cup \{-\infty\}$  is an extended function and if  $D_{\downarrow} \psi(p)(dp)$  is finite, then, for every  $w < \psi(p)$  and every  $\mu \in \mathbf{R}$ , the pair  $(dp, \mu)$  belongs to the contingent cone  $T_{\mathcal{Hyp}(\psi)}(p, w)$  to the hypograph of  $\psi$  at  $(p, w)$ .*

*Proof.* Let  $(dp, \lambda)$  belong to  $T_{\mathcal{Hyp}(\psi)}(p, \psi(p))$ . Then we know that there exist sequences  $h_n > 0$  converging to 0,  $dp_n$  converging to  $dp$ , and  $\lambda_n$  converging to  $\lambda$  such that  $(p + h_n dp_n, \psi(p) + h_n \lambda_n)$  belongs to  $\mathcal{Hyp}(\psi)$ . Therefore, for  $w < \psi(p)$  and  $\mu \in \mathbf{R}$  and  $h_n$  small enough,

$$(p + h_n dp_n, w + h_n \mu) = (p + h_n dp_n, \psi(p) + h_n \lambda_n) + (0, w - \psi(p) + h_n(\mu - \lambda_n)) \in \mathcal{Hyp}(\psi)$$

belongs to the hypograph of  $\psi$  because  $w - \psi(p) + h_n(\mu - \lambda_n) \leq 0$  for  $h_n$  small enough. Therefore, since  $dp_n \rightarrow dp$  and  $\mu_n := \mu \rightarrow \mu$ , we infer that  $(dp, \mu) \in T_{\mathcal{Hyp}(\psi)}(p, w)$ .  $\square$

*Proof of Theorem 8.1.* Observe first that

$$(t, x, y) \in \mathcal{Hyp}(\mathbf{N}) \setminus \mathcal{Hyp}(\mathbf{c}) \text{ if and only if } t > 0, x \in \text{Int}(K), \text{ and } y \leq \mathbf{N}(t, x).$$

Indeed,  $\mathcal{Hyp}(\mathbf{N}) \setminus \mathcal{Hyp}(\mathbf{c})$  is the set of  $(t, x, y)$  such that  $\mathbf{c}(t, x) < y \leq \mathbf{N}(t, x)$ . This is automatically satisfied when  $t > 0$  and  $x \in \text{Int}(K)$  whenever  $y \leq \mathbf{N}(t, x)$  since in this case,  $\mathbf{c}(t, x) = -\infty$ . It is impossible otherwise since, by Theorem 6.1  $\mathbf{N}(t, x) = \mathbf{c}(t, x)$ .

Theorem 4.6 of [7] states that since  $F$  is Marchaud by Lemma 7.3, the capture basin is the largest closed subset between the hypograph of  $\mathbf{c}$  and  $\mathbb{R}_+ \times X \times \mathbb{R}$  such that  $\mathcal{Hyp}(\mathbf{N}) \setminus \mathcal{Hyp}(\mathbf{c})$  is locally viable under  $F$ .

Theorems 3.2.4 and 3.3.4 of [7] state that  $\mathcal{Hyp}(\mathbf{N}) \setminus \mathcal{Hyp}(\mathbf{c})$  is locally viable under  $F$  if and only if for all  $t > 0$ , for all  $x \in X$ , for all  $y \leq \mathbf{N}(t, x)$ ,  $\exists u \in \text{Dom}(\varphi^*)$ ,  $\exists \pi \in [0, \alpha + \psi(v(t)) - \varphi^*(u)]$ , such that

$$(-1, u, -\psi(v(t)) + \varphi^*(u) + \pi) \in T_{\mathcal{Hyp}(\mathbf{N})}(t, x, y).$$

If  $y = \mathbf{N}(t, x)$ , then

$$T_{\mathcal{Hyp}(\mathbf{N})}(t, x, \mathbf{N}(t, x)) =: \mathcal{Hyp}(D_{\downarrow} \mathbf{N}(t, x))$$

so that we infer that there exists  $u \in \text{Dom}(\varphi^*)$

$$-\psi(v(t)) + \varphi^*(u) + \pi \leq D_{\downarrow} \mathbf{N}(t, x)(-1, u)$$

from which inequality (28) ensues.

Conversely, since  $D_{\downarrow} \mathbf{N}(t, x)(-1, \cdot)$  is upper semicontinuous and the domain of  $\varphi^*$  is compact, inequality (28) implies the existence of  $u \in \text{Dom}(\varphi^*)$  such that

$$(-1, u, -\psi(v(t)) + \varphi^*(u) + \pi) \in T_{\mathcal{Hyp}(\mathbf{N})}(t, x, \mathbf{N}(t, x)).$$

When  $y < \mathbf{N}(t, x)$ , then Lemma 8.2 implies that

$$(-1, u, -\psi(v(t)) + \varphi^*(u) + \pi) \in T_{\mathcal{Hyp}(\mathbf{N})}(t, x, y)$$

because  $(-1, u)$  belongs to the domain of  $D_{\downarrow} \mathbf{N}(t, x)$ .

By Theorems 4.7 and 4.10 of [7], the capture basin is the smallest closed subset between the hypographs of  $\mathbf{c}$  and  $\mathbf{b}$  such that  $\mathcal{Hyp}(\mathbf{N})$  is backward invariant with respect to  $\mathcal{Hyp}(\mathbf{b})$ . Since  $F_{\infty}$  is Lipschitz by Lemma 7.3 whenever the functions  $\psi$ ,  $\varphi^*$ , and  $v$  are Lipschitz, the invariance theorem (Theorem 5.3.4 in [5]) states that  $\mathcal{Hyp}(\mathbf{N})$  is backward invariant with respect to  $\mathcal{Hyp}(\mathbf{b})$  under  $F_{\infty}$  if and only if

$$\forall (t, x, y) \in \mathcal{Hyp}(\mathbf{N}), \quad F_{\infty}(t, x, y) \cap T_{\mathcal{Hyp}(\mathbf{b})}(t, x, y) \subset T_{\mathcal{Hyp}(\mathbf{N})}(t, x, y).$$

Since the function  $\mathbf{b}$  is assumed to be continuous,

$$\text{Int}(\mathcal{Hyp}(\mathbf{b})) = \{(t, x, y) \text{ such that } y < \mathbf{b}(t, x)\}.$$

Therefore, we have to investigate the following two cases:

1. For all  $(t, x, y) \in \mathcal{Hyp}(\mathbf{N}) \cap \text{Int}(\mathcal{Hyp}(\mathbf{b}))$ . Then

$$\begin{aligned} \forall t \geq 0, \quad \forall x \in X, \quad \forall y \leq \mathbf{N}(t, x), \quad \forall u \in \text{Dom}(\varphi^*), \quad \forall \pi \geq 0, \\ (1, -u, \psi(v(t)) - \varphi^*(u) - \pi) \in T_{\mathcal{Hyp}(\mathbf{N})}(t, x, y). \end{aligned}$$

If  $y = \mathbf{N}(t, x)$ , then we infer that for all  $u \in \text{Dom}(\varphi^*)$ ,

$$\psi(v(t)) - \varphi^*(u) \leq D_{\downarrow} \mathbf{N}(t, x)(1, -u)$$

from which we derive inequality (29). Conversely, since for all  $u \in \text{Dom}(\varphi^*)$ ,  $(1, -u)$  belongs to the domain of  $D_{\downarrow} \mathbf{N}(t, x)$ , we derive that

$$(1, -u, \psi(v(t)) - \varphi^*(u) - \pi) \in T_{\mathcal{Hyp}(\mathbf{N})}(t, x, y)$$

holds true.

2. For all  $(t, x, y) \in \mathcal{Hyp}(\mathbf{N}) \cap \partial(\mathcal{Hyp}(\mathbf{b}))$ , and in this case,  $y = \mathbf{N}(t, x) = \mathbf{b}(t, x)$ . Then,  $\forall t \geq 0, \forall x \in X, \forall u \in \text{Dom}(\varphi^*), \forall \pi \geq 0$  such that

$$(1, -u, \psi(v(t)) - \varphi^*(u) - \pi) \in T_{\mathcal{Hyp}(\mathbf{b})}(t, x, y)$$

we have

$$(1, -u, \psi(v(t)) - \varphi^*(u) - \pi) \in T_{\mathcal{Hyp}(\mathbf{N})}(t, x, y).$$

This means that whenever

$$\psi(v(t)) \leq D_{\downarrow} \mathbf{b}(t, x)(1, -u) + \varphi^*(u),$$

then

$$\psi(v(t)) \leq D_{\downarrow} \mathbf{N}(t, x)(1, -u) + \varphi^*(u),$$

which is (30).

Theorem 5.5 states that the viability hyposolution is the valuation function (21) of the underlying optimal control problem (13).

The *associated regulation map*  $R$  for regulating the optimal evolutions is thus defined by

$$\forall t > 0, x \in X, R(t, x) := \{u \mid 0 \leq D_{\downarrow} \mathbf{N}(t, x)(-1, u) - \varphi^*(u) + \psi(v(t))\}.$$

One can prove that the optimal solutions of the control problem are governed by the control system

$$\begin{cases} \tau'(s) = -1, \\ x'(s) = u(s) \in R(\tau(s), x(s)), \\ y'(s) = \varphi^*(u(s)) - \psi(v(\tau(s))). \end{cases}$$

This motivates a further study of the regulation map. If the solution  $\mathbf{N}$  is differentiable, the regulation map can be written in the form

$$R(t, x) := \left\{ u \mid 0 \leq -\frac{\partial \mathbf{N}(t, x)}{\partial t} + \frac{\partial \mathbf{N}(t, x)}{\partial x} u - \varphi^*(u) + \psi(v(t)) \right\}.$$

The elements  $u$  maximizing the right-hand side are the elements belonging to

$$-\partial_+ \psi \left( \frac{\partial \mathbf{N}(t, x)}{\partial x} \right).$$

Consequently,

$$-\partial_+ \psi \left( \frac{\partial \mathbf{N}(t, x)}{\partial x} \right) \subset R(t, x).$$

Actually, approximations of the regulation map and thus, optimal evolutions, as well as the solution to the Hamilton–Jacobi–Bellman equation are provided by the capture basin algorithm.

**9. Barron-Jensen/Frankowska solution to the Hamilton–Jacobi equation.** Instead of characterizing capture basins in terms of tangent cones and translating them into terms of contingent Frankowska hypolutions, we translate them into the equivalent formulation of Barron-Jensen/Frankowska solutions, a weaker concept of viscosity solutions requiring only the upper semicontinuity of the solution instead of its continuity.

**THEOREM 9.1** (Barron-Jensen/Frankowska solution). *The viability hyposolution  $\mathbf{N}$  is the largest upper semicontinuous solution between  $\mathbf{c}$  and  $\mathbf{b}$  satisfying*

$$(31) \quad \begin{cases} \text{(i)} & \forall t > 0, \forall x \in \text{Int}(K), \forall (p_t, p_x) \in \partial_+ \mathbf{N}(t, x), p_t + \psi(p_x) \leq \psi(v(t)), \\ \text{(ii)} & \forall t > 0, \forall x \in \text{Int}(K), \forall (p_t, p_x) \in (\text{Dom}(D_{\downarrow} \mathbf{N}(t, x)))^-, \\ & p_t - \sigma(\text{Dom}(\varphi^*), p_x) \leq 0. \end{cases}$$

*If the functions  $\psi$ ,  $\varphi^*$ , and  $v$  are furthermore Lipschitz, then  $\mathbf{N}$  is the smallest upper semicontinuous solution between  $\mathbf{c}$  and  $\mathbf{b}$  satisfying the following:*

1. *If  $\mathbf{N}(t, x) < \mathbf{b}(t, x)$ , then*

$$(32) \quad \begin{cases} \text{(i)} & \forall t \geq 0, \forall x \in K \text{ such that} \\ & \mathbf{N}(t, x) < \mathbf{b}(t, x), \forall (p_t, p_x) \in \partial_+ \mathbf{N}(t, x), \\ & p_t + \psi(p_x) \geq \psi(v(t)); \\ \text{(ii)} & \forall t \geq 0, \forall x \in K \text{ such that} \\ & \mathbf{N}(t, x) < \mathbf{b}(t, x), \forall (p_t, p_x) \in (\text{Dom}(D_{\downarrow} \mathbf{N}(t, x)))^-, \\ & p_t - \sigma(\text{Dom}(\varphi^*), p_x) \geq 0. \end{cases}$$

2. If  $\mathbf{N}(t, x) = \mathbf{b}(t, x)$ , then

$$(33) \quad \begin{cases} \forall (p_t, p_x) \in \partial_+ \mathbf{N}(t, x), \exists (q_t, q_x) \in \partial_+ \mathbf{b}(t, x) \text{ and } 0 < \mu < 1 \text{ such that} \\ \text{either } p_t - q_t - \sigma(\text{Dom}(\varphi^*), p_x - q_x) \geq 0 \\ \text{or } \frac{p_t - \mu q_t}{1 - \mu} + \psi\left(\frac{p_x - \mu q_x}{1 - \mu}\right) \geq \psi(v(t)). \end{cases}$$

Thus, the unique upper semicontinuous solution satisfies all these properties.

Observe that under the Lipschitz assumptions, the viability hypsolution satisfies

$$(34) \quad \begin{cases} \text{(i)} & \forall t > 0, \forall x \in \text{Int}(K) \text{ such that } \mathbf{N}(t, x) < \mathbf{b}(t, x), \\ & \forall (p_t, p_x) \in \partial_+ \mathbf{N}(t, x), p_t + \psi(p_x) = \psi(v(t)), \\ \text{(ii)} & \forall (p_t, p_x) \in (\text{Dom}(D_\downarrow \mathbf{N}(t, x)))^-, p_t - \sigma(\text{Dom}(\varphi^*), p_x) = 0. \end{cases}$$

We need the following technical lemma on normal cones to hypographs for proving Theorem 9.1.

LEMMA 9.2 (normal cones to hypographs). *A pair  $(u, \lambda)$  belongs to the normal cone  $N_{\mathcal{Hyp}(\psi)}(p, w)$  to the hypograph of  $\psi$  at  $(p, w)$  if and only*

1. *if  $w = \psi(p)$ ; then either*

- $\lambda = 0$  and  $u \in (\text{Dom}(D_\downarrow \psi(p)))^-$  or
- $\lambda > 0$  and  $u \in -\lambda \partial_+ \psi(p)$ .

2. *if  $w < \psi(p)$ ; then  $\lambda = 0$  and  $u \in (\text{Dom}(D_\downarrow \psi(p)))^-$ .*

*In particular, if the domain of  $D_\downarrow \psi(p)$  is dense in  $X$ , then  $(u, \lambda)$  belongs to the normal cone  $N_{\mathcal{Hyp}(\psi)}(p, w)$  to the hypograph of  $\psi$  at  $(p, w)$  if and only if  $\lambda = 0$  and  $u = 0$ . This is the case whenever  $\psi$  is Lipschitz around  $p$ .*

*Proof.* Let us consider now a pair  $(u, \lambda)$  belonging to the normal cone  $N_{\mathcal{Hyp}(\psi)}(p, w) := (T_{\mathcal{Hyp}(\psi)}(p, w))^-$  to the hypograph of  $\psi$  at  $(p, w)$ . Therefore,

$$\forall (dp, \mu) \in T_{\mathcal{Hyp}(\psi)}(p, w), \quad \langle (dp, \mu), (u, \lambda) \rangle = \langle u, dp \rangle + \lambda \mu \leq 0.$$

Examine first the case when  $w = \psi(p)$ , for which  $(dp, \mu) \in T_{\mathcal{Hyp}(\psi)}(p, \psi(p))$  if and only if  $dp \in \text{Dom}(D_\downarrow \psi(p))$  and  $\mu \leq D_\downarrow \psi(p)(dp)$ . If  $\lambda < 0$ , we obtain a contradiction because, when  $\mu \rightarrow -\infty$ ,  $\langle u, dp \rangle + \lambda \mu \rightarrow +\infty$ . Hence

- either  $\lambda > 0$ , and thus, dividing by  $\lambda$  and taking  $\mu := D_\downarrow \psi(p)(dp)$ , we obtain

$$\forall dp \in \text{Dom}(D_\downarrow \psi(p)), \quad \left\langle \frac{u}{\lambda}, dp \right\rangle + D_\downarrow \psi(p)(dp) \leq 0$$

which means that  $-\frac{u}{\lambda} \in \partial_+ \psi(p)$ ;

- or  $\lambda = 0$  and we obtain

$$\forall dp \in \text{Dom}(D_\downarrow \psi(p)), \quad \langle u, dp \rangle \leq 0,$$

which means that  $u \in (\text{Dom}(D_\downarrow \psi(p)))^-$  by definition of the polar cone.

When  $w < \psi(p)$ , inequalities

$$\forall (dp, \mu) \in T_{\mathcal{Hyp}(\psi)}(p, w), \quad \langle (dp, \mu), (u, \lambda) \rangle = \langle u, dp \rangle + \lambda \mu \leq 0$$

imply that  $\lambda = 0$  thanks to Lemma 8.2; otherwise,  $\lambda \mu$  converges to  $+\infty$  when  $\mu \rightarrow +\infty$  when  $\lambda > 0$ , and when  $\mu \rightarrow -\infty$  when  $\lambda < 0$  since  $\mu$  is allowed to range over  $\mathbb{R}$ . Therefore  $u \in (\text{Dom}(D_\downarrow \psi(p)))^-$  because whenever  $dp \in \text{Dom}(D_\downarrow \psi(p))$  and  $\mu \in \mathbb{R}$ ,

then  $(dp, \mu) \in T_{\mathcal{Hyp}(\psi)}(p, w)$ . If the domain  $D_{\downarrow}\psi(p)$  is dense in  $X$ , then the polar cone  $(\text{Dom}(D_{\downarrow}\psi(p)))^-$  is  $\{0\}$ , and thus  $u = 0$ .  $\square$

*Proof of Theorem 9.1.* Proposition 7.4 states that the hypograph of the viability hyposolution satisfies

$$\mathcal{Hyp}(\mathbf{N}) = \text{Capt}_{(23)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c})) = \text{Capt}_{(24)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c})).$$

Theorem 3.4 states that  $\text{Capt}_{(23)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c}))$  is the *largest* subset  $\mathcal{D}$  between  $\mathcal{C}$  and  $\mathcal{K}$  such that  $\mathcal{D} \setminus \mathcal{C}$  is locally viable.

Taking  $\mathcal{D} := \mathcal{Hyp}(\mathbf{N})$ , Theorems 3.2.4 and 3.3.4 of [5] state that  $\mathcal{Hyp}(\mathbf{N}) \setminus \mathcal{Hyp}(\mathbf{c})$  is locally viable under  $F$  if and only if for all  $t > 0$ , for all  $x \in \text{Int}(K)$ , for all  $y \leq \mathbf{N}(t, x)$ ,  $\exists u \in \text{Dom}(\varphi^*)$ ,  $\exists \pi \in [0, \alpha + \psi(v(t)) - \varphi^*(u)]$ , such that for all  $(-p_t, -p_x, \lambda) \in N_{\mathcal{Hyp}(\mathbf{N})}(t, x, y)$ ,

$$(35) \quad \begin{cases} \langle (-p_t, -p_x, \lambda), (-1, u, -\psi(v(t)) + \varphi^*(u) + \pi) \rangle \\ = p_t - \langle p_x, u \rangle + \lambda(-\psi(v(t)) + \varphi^*(u) + \pi) \leq 0. \end{cases}$$

By Lemma 9.2, if  $y = \mathbf{N}(t, x)$ ,  $(-p_t, -p_x, \lambda) \in N_{\mathcal{Hyp}(\mathbf{N})}(t, x, y)$  means that either  $\lambda > 0$ , and that, taking  $\lambda = 1$ ,  $(p_t, p_x) \in \partial_+ \mathbf{N}(t, x)$ , or that  $\lambda = 0$ , and that  $(p_t, p_x) \in (\text{Dom}(D_{\downarrow} \mathbf{N}(t, x)))^-$ . If  $y < \mathbf{N}(t, x)$ ,  $(-p_t, -p_x, \lambda) \in N_{\mathcal{Hyp}(\mathbf{N})}(t, x, y)$  means also that  $\lambda = 0$ , and that  $(p_t, p_x) \in (\text{Dom}(D_{\downarrow} \mathbf{N}(t, x)))^-$ .

Consequently, condition (35) can be written in the following form:

- The case when  $y = \mathbf{N}(t, x)$  and  $\lambda = 1$ :

$$\begin{cases} \forall t > 0, \forall x \in \text{Int}(K), \forall (p_t, p_x) \in \partial_+ \mathbf{N}(t, x), \text{ then} \\ p_t - \psi(v(t)) + \inf_{u \in \text{Dom}(\varphi^*)} [\varphi^*(u) - \langle p_x, u \rangle] \\ = p_t - \psi(v(t)) + \psi(p_x) \leq 0. \end{cases}$$

- The case when  $y \leq \mathbf{N}(t, x)$  and  $\lambda = 0$ :

$$\begin{cases} \forall t > 0, \forall x \in \text{Int}(K), \forall (p_t, p_x) \in (\text{Dom}(D_{\downarrow} \mathbf{N}(t, x)))^-, \text{ then} \\ p_t - \sup_{u \in \text{Dom}(\varphi^*)} \langle p_x, u \rangle = p_t - \sigma(\text{Dom}(\varphi^*), p_x) \leq 0. \end{cases}$$

(Recall that this condition disappears whenever the viability hyposolution  $\mathbf{N}$  is hypodifferentiable, and, in particular, when the hyposolution is Lipschitz.)

*Proof of inequalities (32) and (33).* Theorem 3.4 states that  $\text{Capt}_{(24)}(\mathcal{Hyp}(\mathbf{b}), \mathcal{Hyp}(\mathbf{c}))$  is the *smallest* subset  $\mathcal{D}$  between  $\mathcal{C}$  and  $\mathcal{K}$  such that  $\mathcal{D}$  is backward invariant with respect to  $\mathcal{K}$ . Theorem 3.7 and Lemma 3.8 state that  $\mathcal{D} := \mathcal{Hyp}(\mathbf{N})$  is backward invariant with respect to  $\mathcal{Hyp}(\mathbf{b})$  under (24) if and only if one of the following holds:

1. For all  $(t, x, y) \in \mathcal{Hyp}(\mathbf{N}) \cap \text{Int}(\mathcal{Hyp}(\mathbf{b}))$ ,

$$\forall (-p_t - p_x, \lambda) \in N_{\mathcal{Hyp}(\mathbf{N})}(t, x, y), \quad \sigma(F_{\infty}(x), (p_t, p_x, -\lambda)) \leq 0.$$

Since the function  $\mathbf{b}$  is assumed to be continuous,

$$\text{Int}(\mathcal{Hyp}(\mathbf{b})) = \{(t, x, y) \text{ such that } y < \mathbf{b}(t, x)\},$$

the first case means that  $y \leq \mathbf{N}(t, x) < \mathbf{b}(t, x)$  and the above condition implies that

$$(36) \quad \begin{cases} \forall (-p_t - p_x, \lambda) \in N_{\mathcal{Hyp}(\mathbf{N})}(t, x, y), \\ \langle (p_t, p_x, -\lambda), (-1, u, -\psi(v(t)) + \varphi^*(u) + \pi) \rangle \\ = -p_t + \langle p_x, u \rangle + \lambda(\psi(v(t)) - \varphi^*(u) - \pi) \leq 0. \end{cases}$$

This implies that  $\lambda \geq 0$ .

Consequently, condition (36) can be written in the following form:

- The case when  $y = \mathbf{N}(t, x) < \mathbf{b}(t, x)$  and  $\lambda = 1$ :

$$\begin{cases} \forall t > 0, \forall x \in X, \forall (p_t, p_x) \in \partial_+ \mathbf{N}(t, x), \text{ then} \\ -p_t + \psi(v(t)) + \sup_{u \in \text{Dom}(\varphi^*)} [\langle p_x, u \rangle - \varphi^*(u)] \\ = -p_t + \psi(v(t)) - \psi(p_x) \leq 0. \end{cases}$$

- The case when  $y \leq \mathbf{N}(t, x)$  and  $\lambda = 0$ :

$$\begin{cases} \forall t > 0, \forall x \in X, \forall (p_t, p_x) \in (\text{Dom}(D_+ \mathbf{N}(t, x)))^-, \text{ then} \\ -p_t + \sup_{u \in \text{Dom}(\varphi^*)} \langle p_x, u \rangle = -p_t + \sigma(\text{Dom}(\varphi^*), p_x) \leq 0. \end{cases}$$

2. For all  $(t, x, y) \in \mathcal{Hyp}(\mathbf{N}) \cap \partial(\mathcal{Hyp}(\mathbf{b}))$ , and in this case,  $y = \mathbf{N}(t, x) = \mathbf{b}(t, x)$  and

$$\begin{cases} \forall (-p_t - p_x, \lambda) \in N_{\mathcal{Hyp}(\mathbf{N})}(t, x, y), \exists (-q_t - q_x, \mu) \in N_{\mathcal{Hyp}(\mathbf{b})}(t, x, y) \\ \text{such that } \sigma(F_\infty(x), (p_t - q_t, p_x - q_x, \mu - \lambda)) \leq 0, \end{cases}$$

where  $\lambda \geq 0$  and  $\mu > 0$  since we have assumed that  $\mathbf{b}$  is Lipschitz, and thus hypodifferentiable. This can be translated into the following form:

$$-p_t + q_t + \sup_u (\langle p_x - q_x, u \rangle + (\mu - \lambda)(\varphi^*(u)) + \sup_{\pi \geq 0} (\mu - \lambda)[\pi - \psi(v(t))]) \leq 0.$$

This implies that  $\lambda \geq \mu > 0$ .

- The case when  $\lambda - \mu = 0$ . It happens when both  $(p_t, p_x) \in \partial_+ \mathbf{N}(t, x)$  and  $(q_t, q_x) \in \partial_+ \mathbf{b}(t, x)$ . In this case, the above inequality boils down to

$$-p_t + q_t + \sigma(\text{Dom}(\varphi^*), p_x - q_x) \leq 0.$$

- The case when  $\lambda - \mu > 0$ . The condition states that for every  $\lambda > 0$  and  $(p_t, p_x) \in \partial_+ \mathbf{N}(t, x)$ , there exist  $0 < \mu < \lambda$  and  $(q_t, q_x) \in \partial_+ \mathbf{b}(t, x)$  such that

$$-\frac{\lambda p_t - \mu q_t}{\lambda - \mu} + \sup_u \left( \left\langle \frac{\lambda p_x - \mu q_x}{\lambda - \mu}, u \right\rangle - \varphi^*(u) \right) + \psi(v(t)) \leq 0,$$

which can be written

$$-\frac{\lambda p_t - \mu q_t}{\lambda - \mu} - \psi \left( \frac{\lambda p_x - \mu q_x}{\lambda - \mu} \right) + \psi(v(t)) \leq 0.$$

This completes the proof.  $\square$

## MEAN-VARIANCE HEDGING UNDER PARTIAL INFORMATION\*

MICHAEL MANIA<sup>†</sup>, REVAZ TEVZADZE<sup>‡</sup>, AND TEIMURAZ TORONJADZE<sup>†</sup>

**Abstract.** We consider the mean-variance hedging problem under partial information. The underlying asset price process follows a continuous semimartingale, and strategies have to be constructed when only part of the information in the market is available. We show that the initial mean-variance hedging problem is equivalent to a new mean-variance hedging problem with an additional correction term, which is formulated in terms of observable processes. We prove that the value process of the reduced problem is a square trinomial with coefficients satisfying a triangle system of backward stochastic differential equations and the filtered wealth process of the optimal hedging strategy is characterized as a solution of a linear forward equation.

**Key words.** backward stochastic differential equation, semimartingale market model, incomplete markets, mean-variance hedging, partial information

**AMS subject classifications.** 90A09, 60H30, 90C39

**DOI.** 10.1137/070700061

**1. Introduction.** In the problem of derivative pricing and hedging it is usually assumed that the hedging strategies have to be constructed by using all market information. However, in reality, investors acting in a market have limited access to the information flow. For example, an investor may observe just stock prices, but stock appreciation rates depend on some unobservable factors; one may think that stock prices can be observed only at some time intervals or up to some random moment before an expiration date, or an investor would like to price and hedge a contingent claim whose payoff depends on an unobservable asset, and he observes the prices of an asset correlated with the underlying asset. Besides, investors may not be able to use all available information even if they have access to the full market flow. In all such cases, investors are forced to make decisions based on only a part of the market information.

We study a mean-variance hedging problem under partial information when the asset price process is a continuous semimartingale and the flow of observable events do not necessarily contain all information on prices of the underlying asset.

We assume that the dynamics of the price process of the asset traded on the market is described by a continuous semimartingale  $S = (S_t, t \in [0, T])$  defined on a filtered probability space  $(\Omega, \mathcal{A}, (\mathcal{A}_t, t \in [0, T]), P)$ , satisfying the usual conditions, where  $\mathcal{A} = \mathcal{A}_T$  and  $T < \infty$  is the fixed time horizon. Suppose that the interest rate is equal to zero and the asset price process satisfies the structure condition; i.e., the process  $S$  admits the decomposition

$$(1.1) \quad S_t = S_0 + N_t + \int_0^t \lambda_u d\langle N \rangle_u, \quad \langle \lambda \cdot N \rangle_T < \infty \quad \text{a.s.},$$

where  $N$  is a continuous  $\mathcal{A}$ -local martingale and  $\lambda$  is an  $\mathcal{A}$ -predictable process.

---

Let  $G$  be a filtration smaller than  $\mathcal{A}$ :

$$G_t \subseteq \mathcal{A}_t \quad \text{for every } t \in [0, T].$$

The filtration  $G$  represents the information that the hedger has at his disposal; i.e., hedging strategies have to be constructed using only information available in  $G$ .

Let  $H$  be a  $P$ -square integrable  $\mathcal{A}_T$ -measurable random variable, representing the payoff of a contingent claim at time  $T$ .

We consider the mean-variance hedging problem

$$(1.2) \quad \text{to minimize } E[(X_T^{x,\pi} - H)^2] \quad \text{over all } \pi \in \Pi(G),$$

where  $\Pi(G)$  is a class of  $G$ -predictable  $S$ -integrable processes. Here  $X_t^{x,\pi} = x + \int_0^t \pi_u dS_u$  is the wealth process starting from initial capital  $x$ , determined by the self-financing trading strategy  $\pi \in \Pi(G)$ .

In the case  $G = \mathcal{A}$  of complete information, the mean-variance hedging problem was introduced by Föllmer and Sondermann [8] in the case when  $S$  is a martingale and then developed by several authors for a price process admitting a trend (see, e.g., [6], [12], [25], [26], [24], [10], [11]).

Asset pricing with partial information under various setups has been considered. The mean-variance hedging problem under partial information was first studied by Di Masi, Platen, and Runggaldier [3] when the stock price process is a martingale and the prices are observed only at discrete time moments. For general filtrations and when the asset price process is a martingale, this problem was solved by Schweizer [27] in terms of  $G$ -predictable projections. Pham [22] considered the mean-variance hedging problem for a general semimartingale model, assuming that the observable filtration contains the augmented filtration  $F^S$  generated by the asset price process  $S$

$$(1.3) \quad F_t^S \subseteq G_t \quad \text{for every } t \in [0, T].$$

In this paper, using the variance-optimal martingale measure with respect to the filtration  $G$  and suitable Kunita–Watanabe decomposition, the theory developed by Gouriéroux, Laurent, and Pham [10] and Rheinländer and Schweizer [23] to the case of partial information was extended.

If  $G$  is not containing  $F^S$ , then  $S$  is not a  $G$ -semimartingale and the problem is more involved. Let us introduce an additional filtration  $F = (F_t, t \in [0, T])$ , which is an augmented filtration generated by  $F^S$  and  $G$ .

Then the price process  $S$  is a continuous  $F$ -semimartingale, and the canonical decomposition of  $S$  with respect to the filtration  $F$  is of the form

$$(1.4) \quad S_t = S_0 + \int_0^t \widehat{\lambda}_u^F d\langle M \rangle_u + M_t,$$

where  $\widehat{\lambda}^F$  is the  $F$ -predictable projection of  $\lambda$  and

$$M_t = N_t + \int_0^t [\lambda_u - \widehat{\lambda}_u^F] d\langle N \rangle_u$$

is a continuous  $F$ -local martingale. Besides  $\langle M \rangle = \langle N \rangle$ , and these brackets are  $F^S$ -predictable.

Throughout the paper we shall make the following assumptions:

(A)  $\langle M \rangle$  is  $G$ -predictable and  $d\langle M \rangle_t dP$  a.e.  $\hat{\lambda}^F = \hat{\lambda}^G$ ; hence  $P$ -a.s. for each  $t$

$$E(\lambda_t | F_{t-}^S \vee G_t) = E(\lambda_t | G_t);$$

(B) any  $G$ -martingale is an  $F$ -local martingale;

(C) the filtration  $G$  is continuous; i.e., all  $G$ -local martingales are continuous;

(D) there exists a martingale measure for  $S$  (on  $F_T$ ) that satisfies the reverse Hölder condition.

*Remark.* It is evident that if  $F^S \subseteq G$ , then  $\langle M \rangle$  is  $G$ -predictable. Besides, in this case  $G = F$ , and conditions (A) and (B) are satisfied.

We shall use the notation  $\hat{Y}_t$  for the process of the  $G$ -projection of  $Y$ . Condition (A) implies that

$$\hat{S}_t = E(S_t | G_t) = S_0 + \int_0^t \hat{\lambda}_u d\langle M \rangle_u + \widehat{M}_t.$$

Let

$$H_t = E(H | F_t) = EH + \int_0^t h_u dM_u + L_t$$

and

$$H_t = EH + \int_0^t h_u^G d\widehat{M}_u + L_t^G$$

be the Galtchouk–Kunita–Watanabe (GKW) decompositions of  $H_t = E(H | F_t)$  with respect to local martingales  $M$  and  $\widehat{M}$ , where  $h$  and  $h^G$  are  $F$ -predictable processes and  $L$  and  $L^G$  are local martingales strongly orthogonal to  $M$  and  $\widehat{M}$ , respectively.

We show (Theorem 3.1) that the initial mean-variance hedging problem (1.2) is equivalent to the problem to minimize the expression

$$(1.5) \quad E \left[ \left( x + \int_0^T \pi_u d\hat{S}_u - \hat{H}_T \right)^2 + \int_0^T \left( \pi_u^2 (1 - \rho_u^2) + 2\pi_u \tilde{h}_u \right) d\langle M \rangle_u \right]$$

over all  $\pi \in \Pi(G)$ , where

$$\tilde{h}_t = \widehat{h}_t^G \rho_t^2 - \hat{h}_t \quad \text{and} \quad \rho_t^2 = \frac{d\langle \widehat{M} \rangle_t}{d\langle M \rangle_t}.$$

Thus, the problem (1.5), equivalent to (1.2), is formulated in terms of  $G$ -adapted processes. One can say that (1.5) is the mean-variance hedging problem under complete information with an additional correction term.

Let us introduce the value process of the problem (1.5):

$$(1.6) \quad V^H(t, x) = \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ \left( x + \int_t^T \pi_u d\hat{S}_u - \hat{H}_T \right)^2 + \int_t^T \left[ \pi_u^2 (1 - \rho_u^2) + 2\pi_u \tilde{h}_u \right] d\langle M \rangle_u | G_t \right].$$

We show in Theorem 4.1 that the value function of the problem (1.5) admits a representation

$$V^H(t, x) = V_t(0) - 2V_t(1)x + V_t(2)x^2,$$

where the coefficients  $V_t(0)$ ,  $V_t(1)$ , and  $V_t(2)$  satisfy a triangle system of backward stochastic differential equations (BSDEs). Besides, the filtered wealth process of the optimal hedging strategy is characterized as a solution of the linear forward equation

$$(1.7) \quad \begin{aligned} \widehat{X}_t^* = x &- \int_0^t \frac{\rho_u^2 \varphi_u(2) + \widehat{\lambda}_u V_u(2)}{1 - \rho_u^2 + \rho_u^2 V_u(2)} \widehat{X}_u^* d\widehat{S}_u \\ &+ \int_0^t \frac{\rho_u^2 \varphi_u(1) + \widehat{\lambda}_u V_u(1) + \widetilde{h}_u}{1 - \rho_u^2 + \rho_u^2 V_u(2)} d\widehat{S}_u. \end{aligned}$$

Note that if  $F^S \subseteq G$ , then

$$(1.8) \quad \rho = 1, \quad \widetilde{h} = 0, \quad \widehat{M} = M, \quad \text{and} \quad \widehat{S} = S.$$

In the case of complete information ( $G = \mathcal{A}$ ), in addition to (1.8) we have  $\widehat{\lambda} = \lambda$  and  $\widehat{M} = N$ , and (1.7) gives equations for the optimal wealth process from [19].

In section 5 we consider a diffusion market model, which consists of two assets  $S$  and  $\eta$ , where  $S_t$  is a state of a process being controlled and  $\eta_t$  is the observation process. Suppose that  $S_t$  and  $\eta_t$  are governed by

$$\begin{aligned} dS_t &= \mu_t dt + \sigma_t dw_t^0, \\ d\eta_t &= a_t dt + b_t dw_t, \end{aligned}$$

where  $w^0$  and  $w$  are Brownian motions with correlation  $\rho$  and the coefficients  $\mu, \sigma, a$ , and  $b$  are  $\mathcal{F}^\eta$ -adapted. In this case  $\mathcal{A}_t = \mathcal{F}_t = \mathcal{F}_t^{S, \eta}$ , and the flow of observable events is  $\mathcal{G}_t = \mathcal{F}_t^\eta$ . As an application of Theorem 4.1 we also consider a diffusion market model with constant coefficients and assume that an investor observes the price process  $S$  only up to a random moment  $\tau$  before the expiration date  $T$ . In this case we give an explicit solution of (1.2).

**2. Main definitions and auxiliary facts.** Denote by  $\mathcal{M}^e(F)$  the set of equivalent martingale measures for  $S$ , i.e., the set of probability measures  $Q$  equivalent to  $P$  such that  $S$  is a  $F$ -local martingale under  $Q$ .

Let

$$\mathcal{M}_2^e(F) = \{Q \in \mathcal{M}^e(F) : EZ_T^2(Q) < \infty\},$$

where  $Z_t(Q)$  is the density process (with respect to the filtration  $F$ ) of  $Q$  relative to  $P$ . We assume that  $\mathcal{M}_2^e(F) \neq \emptyset$ .

*Remark 2.1.* Note that  $\mathcal{M}_2^e(\mathcal{A}) \neq \emptyset$  implies that  $\mathcal{M}_2^e(F) \neq \emptyset$  (see Remark 2.1 from Pham [22]).

It follows from (1.4) and condition (A), that the density process  $Z_t(Q)$  of any element  $Q$  of  $\mathcal{M}^e(F)$  is expressed as an exponential martingale of the form

$$\mathcal{E}_t(-\widehat{\lambda} \cdot M + L),$$

where  $L$  is a  $F$ -local martingale strongly orthogonal to  $M$  and  $\mathcal{E}_t(X)$  is the Doleans-Dade exponential of  $X$ .

If the local martingale  $Z_t^{min} = \mathcal{E}_t(-\hat{\lambda} \cdot M)$  is a true martingale,  $dQ^{min}/dP = Z_T^{min}$  defines the minimal martingale measure for  $S$ .

Recall that a measure  $Q$  satisfies the reverse Hölder inequality  $R_2(P)$  if there exists a constant  $C$  such that

$$E\left(\frac{Z_T^2(Q)}{Z_\tau^2(Q)}|F_\tau\right) \leq C, \quad P\text{-a.s.}$$

for every  $F$ -stopping time  $\tau$ .

*Remark 2.2.* If there exists a measure  $Q \in \mathcal{M}^e(F)$  that satisfies the reverse Hölder inequality  $R_2(P)$ , then according to Theorem 3.4 of Kazamaki [14] the martingale  $M^Q = -\hat{\lambda} \cdot M + L$  belongs to the class  $BMO$  and hence  $-\hat{\lambda} \cdot M$  also belongs to  $BMO$ , i.e.,

$$(2.1) \quad E\left(\int_\tau^T \hat{\lambda}_u^2 d\langle M \rangle_u | F_\tau\right) \leq \text{const}$$

for every stopping time  $\tau$ . Therefore, it follows from Theorem 2.3 of [14] that  $\mathcal{E}_t(-\hat{\lambda} \cdot M)$  is a true martingale. So, condition (D) implies that the minimal martingale measure exists (but  $Z^{min}$  is not necessarily square integrable).

Let us make some remarks on conditions (B) and (C).

*Remark 2.3.* Condition (B) is satisfied if and only if the  $\sigma$ -algebras  $F_t^S \vee G_t$  and  $G_T$  are conditionally independent given  $G_t$  for all  $t \in [0, T]$  (see Theorem 9.29 from Jacod [13]).

*Remark 2.4.* Condition (C) is weaker than the assumption that the filtration  $F$  is continuous. The continuity of the filtration  $F$  and condition (B) imply the continuity of the filtration  $G$ , but the converse is not true in general. Note that filtrations  $F$  and  $F^S$  can be discontinuous. Recall that the continuity of a filtration means that all local martingales with respect to this filtration are continuous.

By  $\mu^K$  we denote the Dolean measure of an increasing process  $K$ . For all unexplained notations concerning the martingale theory used below, we refer the reader to [5], [18], [13].

Let  $\Pi(F)$  be the space of all  $F$ -predictable  $S$ -integrable processes  $\pi$  such that the stochastic integral

$$(\pi \cdot S)_t = \int_0^t \pi_u dS_u, \quad t \in [0, T],$$

is in the  $\mathcal{S}^2$  space of semimartingales, i.e.,

$$E\left(\int_0^T \pi_s^2 d\langle M \rangle_s\right) + E\left(\int_0^T |\pi_s \hat{\lambda}_s| d\langle M \rangle_s\right)^2 < \infty.$$

Denote by  $\Pi(G)$  the subspace of  $\Pi(F)$  of  $G$ -predictable strategies.

*Remark 2.5.* Since  $\hat{\lambda} \cdot M \in BMO$  (see Remark 2.2), it follows from the proof of Theorem 2.5 of Kazamaki [14] that

$$\begin{aligned} E\left(\int_0^T |\pi_u \hat{\lambda}_u| d\langle M \rangle_u\right)^2 &= E\langle |\pi| \cdot M, |\hat{\lambda}| \cdot M \rangle_T^2 \\ &\leq 2\|\hat{\lambda} \cdot M\|_{BMO} E\int_0^T \pi^2 d\langle M \rangle_u < \infty. \end{aligned}$$

Therefore, under condition (D) the  $G$ -predictable (resp.,  $F$ -predictable) strategy  $\pi$  belongs to the class  $\Pi(G)$  (resp.,  $\Pi(F)$ ) if and only if  $E \int_0^T \pi_s^2 d\langle M \rangle_s < \infty$ .

Define  $J_T^2(F)$  and  $J_T^2(G)$  as spaces of terminal values of stochastic integrals, i.e.,

$$J_T^2(F) = \{(\pi \cdot S)_T : \pi \in \Pi(F)\}.$$

$$J_T^2(G) = \{(\pi \cdot S)_T : \pi \in \Pi(G)\}.$$

For convenience we give some assertions from [4], which establishes necessary and sufficient conditions for the closedness of the space  $J_T^2(F)$  in  $L^2$ .

PROPOSITION 2.1. *Let  $S$  be a continuous semimartingale. Then the following assertions are equivalent:*

- (1) *There is a martingale measure  $Q \in \mathcal{M}^e(F)$ , and  $J_T^2(F)$  is closed in  $L^2$ .*
- (2) *There is a martingale measure  $Q \in \mathcal{M}^e(F)$  that satisfies the reverse Hölder condition  $R_2(P)$ .*
- (3) *There is a constant  $C$  such that for all  $\pi \in \Pi(F)$  we have*

$$\|\sup_{t \leq T} (\pi \cdot S)_t\|_{L^2(P)} \leq C \|(\pi \cdot S)_T\|_{L^2(P)}.$$

- (4) *There is a constant  $c$  such that for every stopping time  $\tau$ , every  $A \in \mathcal{F}_\tau$ , and every  $\pi \in \Pi(F)$ , with  $\pi = \pi I_{[\tau, T]}$ , we have*

$$\|I_A - (\pi \cdot S)_T\|_{L^2(P)} \geq cP(A)^{1/2}.$$

Note that assertion (4) implies that for every stopping time  $\tau$  and for every  $\pi \in \Pi(G)$  we have

$$(2.2) \quad E \left( \left( 1 + \int_\tau^T \pi_u dS_u \right)^2 / F_\tau \right) \geq c.$$

Now we recall some known assertions from the filtering theory. The following proposition can be proved similarly to [18].

PROPOSITION 2.2. *If conditions (A), (B), and (C) are satisfied, then for any continuous  $F$ -local martingale  $M$ , with  $M_0 = 0$ , and any  $G$ -local martingale  $m^G$*

$$(2.3) \quad \widehat{M}_t = E(M_t | G_t) = \int_0^t \frac{d\langle \widehat{M}, m^G \rangle_u}{d\langle m^G \rangle_u} dm_u^G + L_t^G,$$

where  $L^G$  is a local martingale orthogonal to  $m^G$ .

It follows from this proposition that for any  $G$ -predictable,  $M$ -integrable process  $\pi$  and any  $G$ -martingale  $m^G$

$$\begin{aligned} \langle \widehat{(\pi \cdot M)}, m^G \rangle_t &= \int_0^t \pi_u \frac{d\langle \widehat{M}, m^G \rangle_u}{d\langle m^G \rangle_u} d\langle m^G \rangle_u \\ &= \int_0^t \pi_u d\langle \widehat{M}, m^G \rangle_u = \langle \pi \cdot \widehat{M}, m^G \rangle_t. \end{aligned}$$

Hence, for any  $G$ -predictable,  $M$ -integrable process  $\pi$

$$(2.4) \quad (\widehat{(\pi \cdot M)})_t = E \left( \int_0^t \pi_s dM_s | G_t \right) = \int_0^t \pi_s d\widehat{M}_s.$$

Since  $\pi, \lambda$ , and  $\langle M \rangle$  are  $G$ -predictable, from (2.4) we have

$$(2.5) \quad \widehat{(\pi \cdot S)}_t = E \left( \int_0^t \pi_u dS_u | G_t \right) = \int_0^t \pi_u d\widehat{S}_u,$$

where

$$\widehat{S}_t = S_0 + \int_0^t \widehat{\lambda}_u d\langle M \rangle_u + \widehat{M}_t.$$

**3. Separation principle: The optimality principle.** Let us introduce the value function of the problem (1.2) defined as

$$(3.1) \quad U^H(t, x) = \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left( \left( x + \int_t^T \pi_u dS_u - H \right)^2 | G_t \right).$$

By the GKW decomposition

$$(3.2) \quad H_t = E(H | F_t) = EH + \int_0^t h_u dM_u + L_t$$

for a  $F$ -predictable,  $M$ -integrable process  $h$  and a local martingale  $L$  strongly orthogonal to  $M$ . We shall use also the GKW decompositions of  $H_t = E(H | F_t)$  with respect to the local martingale  $\widehat{M}$

$$(3.3) \quad H_t = EH + \int_0^t h_u^G d\widehat{M}_u + L_t^G,$$

where  $h^G$  is a  $F$ -predictable process and  $L^G$  is a  $F$ -local martingale strongly orthogonal to  $\widehat{M}$ .

It follows from Proposition 2.2 (applied for  $m^G = \widehat{M}$ ) and Lemma A.1 that

$$(3.4) \quad \langle E(H | G.), \widehat{M} \rangle_t = \int_0^t \widehat{h}_u^G \rho_u^2 d\langle M \rangle_u.$$

We shall use the notation

$$(3.5) \quad \widetilde{h}_t = \widehat{h}_t^G \rho_t^2 - \widehat{h}_t.$$

Note that  $\widetilde{h}$  belongs to the class  $\Pi(G)$  by Lemma A.2.

Let us introduce now a new optimization problem, equivalent to the initial mean-variance hedging problem (1.2), to minimize the expression

$$(3.6) \quad E \left[ \left( x + \int_0^T \pi_u d\widehat{S}_u - \widehat{H}_T \right)^2 + \int_0^T \left( \pi_u^2 (1 - \rho_u^2) + 2\pi_u \widetilde{h}_u \right) d\langle M \rangle_u \right]$$

over all  $\pi \in \Pi(G)$ . Recall that  $\widehat{S}_t = E(S_t | G_t) = S_0 + \int_0^t \widehat{\lambda}_u d\langle M \rangle_u + \widehat{M}_t$ .

**THEOREM 3.1.** *Let conditions (A), (B), and (C) be satisfied. Then the initial mean-variance hedging problem (1.2) is equivalent to the problem (3.6). In particular,*

for any  $\pi \in \Pi(G)$  and  $t \in [0, T]$

$$(3.7) \quad E \left[ \left( x + \int_t^T \pi_u dS_u - H \right)^2 | G_t \right] = E \left[ \left( H - \widehat{H}_T \right)^2 | G_t \right] \\ + E \left[ \left( x + \int_t^T \pi_u d\widehat{S}_u - \widehat{H}_T \right)^2 + \int_t^T \left( \pi_u^2 (1 - \rho_u^2) + 2\pi_u \tilde{h}_u \right) d\langle M \rangle_u | G_t \right].$$

*Proof.* We have

$$(3.8) \quad E \left[ \left( x + \int_t^T \pi_u dS_u - H \right)^2 | G_t \right] \\ = E \left[ \left( x + \int_t^T \pi_u d\widehat{S}_u - H + \int_t^T \pi_u d(M_u - \widehat{M}_u) \right)^2 | G_t \right] \\ = E \left[ \left( x + \int_t^T \pi_u d\widehat{S}_u - H \right)^2 | G_t \right] \\ + 2E \left[ \left( x + \int_t^T \pi_u d\widehat{S}_u - H \right) \left( \int_t^T \pi_u d(M_u - \widehat{M}_u) \right) | G_t \right] \\ + E \left[ \left( \int_t^T \pi_u d(M_u - \widehat{M}_u) \right)^2 | G_t \right] = I_1 + 2I_2 + I_3.$$

It is evident that

$$(3.9) \quad I_1 = E \left[ \left( x + \int_t^T \pi_u d\widehat{S}_u - \widehat{H}_T \right)^2 | G_t \right] + E \left[ \left( H - \widehat{H}_T \right)^2 | G_t \right].$$

Since  $\pi, \widehat{\lambda}$ , and  $\widehat{\langle M \rangle}$  are  $G_T$ -measurable and the  $\sigma$ -algebras  $F_t^S \vee G_t$  and  $G_T$  are conditionally independent given  $G_t$  (see Remark 2.3), it follows from (2.4) that

$$(3.10) \quad E \left[ \int_t^T \pi_u \widehat{\lambda}_u d\langle M \rangle_u \int_t^T \pi_u d(M_u - \widehat{M}_u) | G_t \right] \\ = E \left[ \int_t^T \pi_u \widehat{\lambda}_u d\langle M \rangle_u \int_0^T \pi_u d(M_u - \widehat{M}_u) | G_t \right] \\ - E \left[ \int_t^T \pi_u \widehat{\lambda}_u d\langle M \rangle_u \int_0^t \pi_u d(M_u - \widehat{M}_u) | G_t \right] \\ = E \left[ \int_t^T \pi_u \widehat{\lambda}_u d\langle M \rangle_u E \left( \int_0^T \pi_u d(M_u - \widehat{M}_u) | G_T \right) | G_t \right] \\ - E \left[ \int_t^T \pi_u \widehat{\lambda}_u d\langle M \rangle_u | G_t \right] E \left[ \int_0^t \pi_u d(M_u - \widehat{M}_u) | G_t \right] \\ = 0.$$

On the other hand, by using decomposition (3.2), equality (3.4), properties of square characteristics of martingales, and the projection theorem, we obtain

$$\begin{aligned}
 & E \left[ H \int_t^T \pi_u d(M_u - \widehat{M}_u) | G_t \right] \\
 &= E \left[ H \int_t^T \pi_u dM_u | G_t \right] - E \left[ \widehat{H}_T \int_t^T \pi_u d\widehat{M}_u | G_t \right] \\
 &= E \left[ \int_t^T \pi_u d\langle M, E(H|F) \rangle_u | G_t \right] - E \left[ \int_t^T \pi_u d\langle \widehat{H}, \widehat{M} \rangle_u | G_t \right] \\
 &= E \left[ \int_t^T \pi_u h_u d\langle M \rangle_u | G_t \right] - E \left[ \int_t^T \pi_u \widehat{h}_u^G \rho_u^2 d\langle M \rangle_u | G_t \right] \\
 (3.11) \quad &= E \left[ \int_t^T \pi_u (\widehat{h}_u - \widehat{h}_u^G \rho_u^2) d\langle M \rangle_u | G_t \right] = -E \left[ \int_t^T \pi_u \widetilde{h}_u d\langle M \rangle_u | G_t \right].
 \end{aligned}$$

Finally, it is easy to verify that

$$\begin{aligned}
 (3.12) \quad & 2E \left[ \int_t^T \pi_u \widehat{M}_u \int_t^T \pi_u d(M_u - \widehat{M}_u) | G_t \right] + E \left[ \left( \int_t^T \pi_u d(M_u - \widehat{M}_u) \right)^2 | G_t \right] \\
 &= E \left[ \left( \int_t^T \pi_u^2 d\langle M \rangle_u - \int_t^T \pi_u^2 d\langle \widehat{M} \rangle_u \right) | G_t \right] = E \left[ \int_t^T \pi_u^2 (1 - \rho_u^2) d\langle M \rangle_u | G_t \right].
 \end{aligned}$$

Therefore (3.8), (3.9), (3.10), (3.11), and (3.12) imply the validity of equality (3.7).  $\square$

Thus, it follows from Theorem 3.1 that the optimization problems (1.2) and (3.6) are equivalent. Therefore it is sufficient to solve the problem (3.6), which is formulated in terms of  $G$ -adapted processes. One can say that (3.6) is a mean-variance hedging problem under complete information with a correction term and can be solved by using methods for complete information.

Let us introduce the value process of the problem (3.6)

$$\begin{aligned}
 V^H(t, x) &= \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ \left( x + \int_t^T \pi_u d\widehat{S}_u - \widehat{H}_T \right)^2 \right. \\
 (3.13) \quad & \left. + \int_t^T \left[ \pi_u^2 (1 - \rho_u^2) + 2\pi_u \widetilde{h}_u \right] d\langle M \rangle_u | G_t \right].
 \end{aligned}$$

It follows from Theorem 3.1 that

$$(3.14) \quad U^H(t, x) = V^H(t, x) + E[(H - \widehat{H}_T)^2 | G_t].$$

The optimality principle takes in this case the following form.

**PROPOSITION 3.1** (optimality principle). *Let conditions (A), (B) and (C) be satisfied. Then*

(a) *for all  $x \in R$ ,  $\pi \in \Pi(G)$ , and  $s \in [0, T]$  the process*

$$V^H \left( t, x + \int_s^t \pi_u d\widehat{S}_u \right) + \int_s^t \left[ \pi_u^2 (1 - \rho_u^2) + 2\pi_u \widetilde{h}_u \right] d\langle M \rangle_u$$

is a submartingale on  $[s, T]$ , admitting an right continuous with left limits (RCLL) modification.

(b)  $\pi^*$  is optimal if and only if the process

$$V^H \left( t, x + \int_s^t \pi_u^* d\widehat{S}_u \right) + \int_s^t \left[ (\pi_u^*)^2 (1 - \rho_u^2) + 2\pi_u^* \tilde{h}_u \right] d\langle M \rangle_u$$

is a martingale.

This assertion can be proved in a standard manner (see, e.g., [7], [15]). The proof more adapted to this case one can see in [19].

Let

$$V(t, x) = \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ \left( x + \int_t^T \pi_u d\widehat{S}_u \right)^2 + \int_t^T \pi_u^2 (1 - \rho_u^2) d\langle M \rangle_u | G_t \right]$$

and

$$V_t(2) = \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ \left( 1 + \int_t^T \pi_u d\widehat{S}_u \right)^2 + \int_t^T \pi_u^2 (1 - \rho_u^2) d\langle M \rangle_u | G_t \right].$$

It is evident that  $V(t, x)$  (resp.,  $V_t(2)$ ) is the value process of the optimization problem (3.6) in the case  $H = 0$  (resp.,  $H = 0$  and  $x = 1$ ), i.e.,

$$V(t, x) = V^0(t, x) \quad \text{and} \quad V_t(2) = V^0(t, 1).$$

Since  $\Pi(G)$  is a cone, we have

$$\begin{aligned} V(t, x) &= x^2 \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ \left( 1 + \int_t^T \frac{\pi_u}{x} d\widehat{S}_u \right)^2 \right. \\ (3.15) \quad &\quad \left. + \int_t^T \left( \frac{\pi_u}{x} \right)^2 (1 - \rho_u^2) d\langle M \rangle_u | G_t \right] = x^2 V_t(2). \end{aligned}$$

Therefore from Proposition 3.1 and equality (3.15) we have the following.

COROLLARY 3.1. (a) *The process*

$$V_t(2) \left( 1 + \int_s^t \pi_u d\widehat{S}_u \right)^2 + \int_s^t (\pi_u)^2 (1 - \rho_u^2) d\langle M \rangle_u,$$

$t \geq s$ , is a submartingale for all  $\pi \in \Pi(G)$  and  $s \in [0, T]$ .

(b)  $\pi^*$  is optimal if and only if

$$V_t(2) \left( 1 + \int_s^t \pi_u^* d\widehat{S}_u \right)^2 + \int_s^t (\pi_u^*)^2 (1 - \rho_u^2) d\langle M \rangle_u,$$

$t \geq s$ , is a martingale.

Note that in the case  $H = 0$  from Theorem 3.1 we have

$$\begin{aligned} (3.16) \quad & E \left[ \left( 1 + \int_t^T \pi_u dS_u \right)^2 \middle| G_t \right] \\ &= E \left[ \left( 1 + \int_t^T \pi_u d\widehat{S}_u \right)^2 + \int_t^T \pi_u^2 (1 - \rho_u^2) d\langle M \rangle_u \middle| G_t \right] \end{aligned}$$

and, hence,

$$(3.17) \quad V_t(2) = U^0(t, 1).$$

LEMMA 3.1. *Let conditions (A)–(D) be satisfied. Then there is a constant  $1 \geq c > 0$  such that  $V_t(2) \geq c$  for all  $t \in [0, T]$  a.s. and*

$$(3.18) \quad 1 - \rho_t^2 + \rho_t^2 V_t(2) \geq c \quad \mu^{(M)} \text{ a.e.}$$

*Proof.* Let

$$V_t^F(2) = \operatorname{ess\,inf}_{\pi \in \Pi(F)} E \left[ \left( 1 + \int_t^T \pi_u dS_u \right)^2 \middle| F_t \right].$$

It follows from assertion (4) of Proposition 2.1 that there is a constant  $c > 0$  such that  $V_t^F(2) \geq c$  for all  $t \in [0, T]$  a.s. Note that  $c \leq 1$  since  $V^F \leq 1$ . Then by (3.17)

$$\begin{aligned} V_t(2) = U^0(t, 1) &= \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ \left( 1 + \int_t^T \pi_u dS_u \right)^2 \middle| G_t \right] \\ &= \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ E \left( \left( 1 + \int_t^T \pi_u dS_u \right)^2 \middle| F_t \right) \middle| G_t \right] \\ &\geq E(V_t^F(2) | G_t) \geq c. \end{aligned}$$

Therefore, since  $\rho_t^2 \leq 1$  by Lemma A.1,

$$1 - \rho_t^2 + \rho_t^2 V_t(2) \geq 1 - \rho_t^2 + \rho_t^2 c \geq \inf_{r \in [0, 1]} (1 - r + rc) = c. \quad \square$$

**4. BSDEs for the value process.** Let us consider the semimartingale backward equation

$$(4.1) \quad Y_t = Y_0 + \int_0^t f(u, Y_u, \psi_u) d\langle m \rangle_u + \int_0^t \psi_u dm_u + L_t$$

with the boundary condition

$$(4.2) \quad Y_T = \eta,$$

where  $\eta$  is an integrable  $G_T$ -measurable random variable,  $f : \Omega \times [0, T] \times R^2 \rightarrow R$  is  $\mathcal{P} \times \mathcal{B}(R^2)$  measurable, and  $m$  is a local martingale. A solution of (4.1)–(4.2) is a triple  $(Y, \psi, L)$ , where  $Y$  is a special semimartingale,  $\psi$  is a predictable  $m$ -integrable process, and  $L$  a local martingale strongly orthogonal to  $m$ . Sometimes we call  $Y$  alone the solution of (4.1)–(4.2), keeping in mind that  $\psi \cdot m + L$  is the martingale part of  $Y$ .

Backward stochastic differential equations have been introduced in [1] for the linear case as the equations for the adjoint process in the stochastic maximum principle. The semimartingale backward equation, as a stochastic version of the Bellman equation in an optimal control problem, was first derived in [2]. The BSDE with more general nonlinear generators was introduced in [21] for the case of Brownian filtration, where the existence and uniqueness of a solution of BSDEs with generators satisfying

the global Lipschitz condition was established. These results were generalized for generators with quadratic growth in [16], [17] for BSDEs driven by a Brownian motion and in [20], [28] for BSDEs driven by martingales. But conditions imposed in these papers are too restrictive for our needs. We prove here the existence and uniqueness of a solution by directly showing that the unique solution of the BSDE that we consider is the value of the problem.

In this section we characterize optimal strategies in terms of solutions of suitable semimartingale backward equations.

**THEOREM 4.1.** *Let  $H$  be a square integrable  $F_T$ -measurable random variable, and let conditions (A), (B), (C), and (D) be satisfied. Then the value function of the problem (3.6) admits a representation*

$$(4.3) \quad V^H(t, x) = V_t(0) - 2V_t(1)x + V_t(2)x^2,$$

where the processes  $V_t(0)$ ,  $V_t(1)$ , and  $V_t(2)$  satisfy the following system of backward equations:

$$(4.4) \quad \begin{aligned} Y_t(2) &= Y_0(2) + \int_0^t \frac{(\psi_s(2)\rho_s^2 + \widehat{\lambda}_s Y_s(2))^2}{1 - \rho_s^2 + \rho_s^2 Y_s(2)} d\langle M \rangle_s \\ &\quad + \int_0^t \psi_s(2) d\widehat{M}_s + L_t(2), \quad Y_T(2) = 1, \end{aligned}$$

$$(4.5) \quad \begin{aligned} Y_t(1) &= Y_0(1) + \int_0^t \frac{(\psi_s(2)\rho_s^2 + \widehat{\lambda}_s Y_s(2))(\psi_s(1)\rho_s^2 + \widehat{\lambda}_s Y_s(1) - \tilde{h}_s)}{1 - \rho_s^2 + \rho_s^2 Y_s(2)} d\langle M \rangle_s \\ &\quad + \int_0^t \psi_s(1) d\widehat{M}_s + L_t(1), \quad Y_T(1) = E(H|G_T), \end{aligned}$$

$$(4.6) \quad \begin{aligned} Y_t(0) &= Y_0(0) + \int_0^t \frac{(\psi_s(1)\rho_s^2 + \widehat{\lambda}_s Y_s(1) - \tilde{h}_s)^2}{1 - \rho_s^2 + \rho_s^2 Y_s(2)} d\langle M \rangle_s \\ &\quad + \int_0^t \psi_s(0) d\widehat{M}_s + L_t(0), \quad Y_T(0) = E^2(H|G_T), \end{aligned}$$

where  $L(2)$ ,  $L(1)$ , and  $L(0)$  are  $G$ -local martingales orthogonal to  $\widehat{M}$ .

Besides, the optimal filtered wealth process  $\widehat{X}_t^{x, \pi^*} = x + \int_0^t \pi_u^* d\widehat{S}_u$  is a solution of the linear equation

$$(4.7) \quad \begin{aligned} \widehat{X}_t^* &= x - \int_0^t \frac{\rho_u^2 \psi_u(2) + \widehat{\lambda}_u Y_u(2)}{1 - \rho_u^2 + \rho_u^2 Y_u(2)} \widehat{X}_u^* d\widehat{S}_u \\ &\quad + \int_0^t \frac{\psi_u(1)\rho_u^2 + \widehat{\lambda}_u Y_u(1) - \tilde{h}_u}{1 - \rho_u^2 + \rho_u^2 Y_u(2)} d\widehat{S}_u. \end{aligned}$$

*Proof.* Similarly to the case of complete information one can show that the optimal strategy exists and that  $V^H(t, x)$  is a square trinomial of the form (4.3) (see, e.g., [19]). More precisely the space of stochastic integrals

$$J_{t,T}^2(G) = \left\{ \int_t^T \pi_u dS_u : \pi \in \Pi(G) \right\}$$

is closed by Proposition 2.1, since  $\langle M \rangle$  is  $G$ -predictable. Hence there exists optimal strategy  $\pi^*(t, x) \in \Pi(G)$  and  $U^H(t, x) = E[|H - x - \int_t^T \pi_u^*(t, x) dS_u|^2 | G_t]$ . Since

$\int_t^T \pi_u^*(t, x) dS_u$  coincides with the orthogonal projection of  $H - x \in L^2$  on the closed subspace of stochastic integrals, then the optimal strategy is linear with respect to  $x$ , i.e.,  $\pi_u^*(t, x) = \pi_u^0(t) + x\pi_u^1(t)$ . This implies that the value function  $U^H(t, x)$  is a square trinomial. It follows from the equality (3.14) that  $V^H(t, x)$  is also a square trinomial, and it admits the representation (4.3).

Let us show that  $V_t(0)$ ,  $V_t(1)$ , and  $V_t(2)$  satisfy the system (4.4)–(4.6). It is evident that

$$(4.8) \quad \begin{aligned} V_t(0) = V^H(t, 0) = \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ \left( \int_t^T \pi_u d\widehat{S}_u - \widehat{H}_T \right)^2 \right. \\ \left. + \int_t^T [\pi_u^2 (1 - \rho_u^2) + 2\pi_u \tilde{h}_u] d\langle M \rangle_u | G_t \right] \end{aligned}$$

and

$$(4.9) \quad \begin{aligned} V_t(2) = V^0(t, 1) = \operatorname{ess\,inf}_{\pi \in \Pi(G)} E \left[ \left( 1 + \int_t^T \pi_u d\widehat{S}_u \right)^2 \right. \\ \left. + \int_t^T \pi_u^2 (1 - \rho_u^2) d\langle M \rangle_u | G_t \right]. \end{aligned}$$

Therefore, it follows from the optimality principle (taking  $\pi = 0$ ) that  $V_t(0)$  and  $V_t(2)$  are RCLL  $G$ -submartingales and

$$\begin{aligned} V_t(2) &\leq E(V_T(2)|G_t) \leq 1, \\ V_t(0) &\leq E(E^2(H|G_T)|G_t) \leq E(H^2|G_t). \end{aligned}$$

Since

$$(4.10) \quad V_t(1) = \frac{1}{2}(V_t(0) + V_t(2) - V^H(t, 1)),$$

the process  $V_t(1)$  is also a special semimartingale, and since  $V_t(0) - 2V_t(1)x + V_t(2)x^2 = V^H(t, x) \geq 0$  for all  $x \in R$ , we have  $V_t^2(1) \leq V_t(0)V_t(2)$ ; hence

$$V_t^2(1) \leq E(H^2|G_t).$$

Expressions (4.8), (4.9), and (3.13) imply that  $V_T(0) = E^2(H|G_T)$ ,  $V_T(2) = 1$ , and  $V^H(T, x) = (x - E(H|G_T))^2$ . Therefore from (4.10) we have  $V_T(1) = E(H|G_T)$ , and  $V(0)$ ,  $V(1)$ , and  $V(2)$  satisfy the boundary conditions.

Thus, the coefficients  $V_t(i)$ ,  $i = 0, 1, 2$ , are special semimartingales, and they admit the decomposition

$$(4.11) \quad V_t(i) = V_0(i) + A_t(i) + \int_0^t \varphi_s(i) d\widehat{M}_s + m_t(i), \quad i = 0, 1, 2,$$

where  $m(0)$ ,  $m(1)$ , and  $m(2)$  are  $G$ -local martingales strongly orthogonal to  $\widehat{M}$  and  $A(0)$ ,  $A(1)$ , and  $A(2)$  are  $G$ -predictable processes of finite variation.

There exists an increasing continuous  $G$ -predictable process  $K$  such that

$$\langle M \rangle_t = \int_0^t \nu_u dK_u, \quad A_t(i) = \int_0^t a_u(i) dK_u, \quad i = 0, 1, 2,$$

where  $\nu$  and  $a(i)$ ,  $i = 0, 1, 2$ , are  $G$ -predictable processes.

Let  $\widehat{X}_{s,t}^{x,\pi} \equiv x + \int_s^t \pi_u d\widehat{S}_u$  and

$$Y_{s,t}^{x,\pi} \equiv V^H\left(t, \widehat{X}_{s,t}^{x,\pi}\right) + \int_s^t \left[\pi_u^2(1 - \rho_u^2) + 2\pi_u \tilde{h}_u\right] d\langle M \rangle_u.$$

Then by using (4.3), (4.11), and the Itô formula for any  $t \geq s$  we have

$$\begin{aligned} \left(\widehat{X}_{s,t}^{x,\pi}\right)^2 &= x + \int_s^t \left[2\pi_u \widehat{\lambda}_u \widehat{X}_{s,u}^{x,\pi} + \pi_u^2 \rho_u^2\right] d\langle M \rangle_u \\ &\quad + 2 \int_s^t \pi_u \widehat{X}_{s,u}^{x,\pi} d\widehat{M}_u \end{aligned} \quad (4.12)$$

and

$$\begin{aligned} Y_{s,t}^{x,\pi} - V^H(s, x) &= \int_s^t \left[ \left(\widehat{X}_{s,u}^{x,\pi}\right)^2 a_u(2) - 2\widehat{X}_{s,u}^{x,\pi} a_u(1) + a_u(0) \right] dK_u \\ &\quad + \int_s^t \left[ \pi_u^2(1 - \rho_u^2 + \rho_u^2 V_{u-}(2)) + 2\pi_u \widehat{X}_{s,u}^{x,\pi} \left(\widehat{\lambda}_u V_{u-}(2) + \varphi_u(2)\rho_u^2\right) \right. \\ &\quad \left. - 2\pi_u \left(V_{u-}(1)\widehat{\lambda}_u + \varphi_u(1)\rho_u^2 - \tilde{h}_u\right) \right] \nu_u dK_u + m_t - m_s, \end{aligned} \quad (4.13)$$

where  $m$  is a local martingale.

Let

$$\begin{aligned} G(\pi, x) &= G(\omega, u, \pi, x) = \pi^2(1 - \rho_u^2 + \rho_u^2 V_{u-}(2)) + 2\pi x \left(\widehat{\lambda}_u V_{u-}(2) + \varphi_u(2)\rho_u^2\right) \\ &\quad - 2\pi(V_{u-}(1)\widehat{\lambda}_u + \varphi_u(1)\rho_u^2 - \tilde{h}_u). \end{aligned}$$

It follows from the optimality principle that for each  $\pi \in \Pi(G)$  the process

$$\begin{aligned} &\int_s^t \left[ \left(\widehat{X}_{s,u}^{x,\pi}\right)^2 a_u(2) - 2\widehat{X}_{s,u}^{x,\pi} a_u(1) + a_u(0) \right] dK_u \\ &\quad + \int_s^t G\left(\pi_u, \widehat{X}_{s,u}^{x,\pi}\right) \nu_u dK_u \end{aligned} \quad (4.14)$$

is increasing for any  $s$  on  $s \leq t \leq T$ , and for the optimal strategy  $\pi^*$  we have the equality

$$\begin{aligned} &\int_s^t \left[ \left(\widehat{X}_{s,u}^{x,\pi^*}\right)^2 a_u(2) - 2\widehat{X}_{s,u}^{x,\pi^*} a_u(1) + a_u(0) \right] dK_u \\ &= - \int_s^t G\left(\pi_u^*, \widehat{X}_{s,u}^{x,\pi^*}\right) \nu_u dK_u. \end{aligned} \quad (4.15)$$

Since  $\nu_u dK_u = d\langle M \rangle_u$  is continuous, without loss of generality one can assume that the process  $K$  is continuous (see [19] for details). Therefore, by taking in (4.14)  $\tau_s(\varepsilon) = \inf\{t \geq s : K_t - K_s \geq \varepsilon\}$  instead of  $t$ , we have that for any  $\varepsilon > 0$  and  $s \geq 0$

$$\begin{aligned} &\frac{1}{\varepsilon} \int_s^{\tau_s(\varepsilon)} \left[ \left(\widehat{X}_{s,u}^{x,\pi}\right)^2 a_u(2) - 2\widehat{X}_{s,u}^{x,\pi} a_u(1) + a_u(0) \right] dK_u \\ &\geq -\frac{1}{\varepsilon} \int_s^{\tau_s(\varepsilon)} G\left(\pi_u, \widehat{X}_{s,u}^{x,\pi}\right) \nu_u dK_u. \end{aligned} \quad (4.16)$$

By passing to the limit in (4.16) as  $\varepsilon \rightarrow 0$ , from Proposition B of [19] we obtain

$$x^2 a_u(2) - 2x a_u(1) + a_u(0) \geq -G(\pi_u, x) \nu_u, \quad \mu^K\text{-a.e.},$$

for all  $\pi \in \Pi(G)$ . Similarly from (4.15) we have that  $\mu^K$ -a.e.

$$x^2 a_u(2) - 2x a_u(1) + a_u(0) = -G(\pi_u^*, x) \nu_u$$

and hence

$$(4.17) \quad x^2 a_u(2) - 2x a_u(1) + a_u(0) = -\nu_u \operatorname{ess\,inf}_{\pi \in \Pi(G)} G(\pi_u, x).$$

The infimum in (4.17) is attained for the strategy

$$(4.18) \quad \hat{\pi}_t = \frac{V_t(1)\hat{\lambda}_t + \varphi_t(1)\rho_t^2 - \tilde{h}_t - x(V_t(2)\hat{\lambda}_t + \varphi_t(2)\rho_t^2)}{1 - \rho_t^2 + \rho_t^2 V_t(2)}.$$

From here we can conclude that

$$(4.19) \quad \begin{aligned} \operatorname{ess\,inf}_{\pi \in \Pi(G)} G(\pi_t, x) &\geq G(\hat{\pi}_t, x) \\ &= -\frac{\left(V_t(1)\hat{\lambda}_t + \varphi_t(1)\rho_t^2 - \tilde{h}_t - x(V_t(2)\hat{\lambda}_t + \varphi_t(2)\rho_t^2)\right)^2}{1 - \rho_t^2 + \rho_t^2 V_t(2)}. \end{aligned}$$

Let  $\pi_t^n = I_{[0, \tau_n]}(t) \hat{\pi}_t$ , where  $\tau_n = \inf\{t : |V_t(1)| \geq n\}$ .

It follows from Lemmas A.2, 3.1, and A.3 that  $\pi^n \in \Pi(G)$  for every  $n \geq 1$  and hence

$$\operatorname{ess\,inf}_{\pi \in \Pi(G)} G(\pi_t, x) \leq G(\pi_t^n, x)$$

for all  $n \geq 1$ . Therefore

$$(4.20) \quad \operatorname{ess\,inf}_{\pi \in \Pi(G)} G(\pi_t, x) \leq \lim_{n \rightarrow \infty} G(\pi_t^n, x) = G(\hat{\pi}_t, x).$$

Thus (4.17), (4.19), and (4.20) imply that

$$(4.21) \quad \begin{aligned} &x^2 a_t(2) - 2x a_t(1) + a_t(0) \\ &= \nu_t \frac{(V_t(1)\hat{\lambda}_t + \varphi_t(1)\rho_t^2 - \tilde{h}_t - x(V_t(2)\hat{\lambda}_t + \varphi_t(2)\rho_t^2))^2}{1 - \rho_t^2 + \rho_t^2 V_t(2)}, \quad \mu^K\text{-a.e.}, \end{aligned}$$

and by equalizing the coefficients of square trinomials in (4.21) (and integrating with respect to  $dK$ ) we obtain

$$(4.22) \quad A_t(2) = \int_0^t \frac{(\varphi_s(2)\rho_s^2 + \hat{\lambda}_s V_s(2))^2}{1 - \rho_s^2 + \rho_s^2 V_s(2)} d\langle M \rangle_s,$$

$$(4.23) \quad A_t(1) = \int_0^t \frac{(\varphi_s(2)\rho_s^2 + \hat{\lambda}_s V_s(2))(\varphi_s(1)\rho_s^2 + \hat{\lambda}_s V_s(1) - \tilde{h}_s)}{1 - \rho_s^2 + \rho_s^2 V_s(2)} d\langle M \rangle_s,$$

$$(4.24) \quad A_t(0) = \int_0^t \frac{(\varphi_s(1)\rho_s^2 + \hat{\lambda}_s V_s(1) - \tilde{h}_s)^2}{1 - \rho_s^2 + \rho_s^2 V_s(2)} d\langle M \rangle_s,$$

which, together with (4.11), implies that the triples  $(V(i), \varphi(i), m(i))$ ,  $i = 0, 1, 2$ , satisfy the system (4.4)–(4.6).

Note that  $A(0)$  and  $A(2)$  are integrable increasing processes and relations (4.22) and (4.24) imply that the strategy  $\hat{\pi}$  defined by (4.18) belongs to the class  $\Pi(G)$ .

Let us show now that if the strategy  $\pi^* \in \Pi(G)$  is optimal, then the corresponding filtered wealth process  $\hat{X}_t^{\pi^*} = x + \int_0^t \pi_u^* d\hat{S}_u$  is a solution of (4.7).

By the optimality principle the process

$$Y_t^{\pi^*} = V^H\left(t, \hat{X}_t^{\pi^*}\right) + \int_0^t \left[ (\pi_u^*)^2 (1 - \rho_u^2) + 2\pi_u^* \tilde{h}_u \right] d\langle M \rangle_u$$

is a martingale. By using the Itô formula we have

$$\begin{aligned} Y_t^{\pi^*} &= \int_0^t \left( \hat{X}_u^{\pi^*} \right)^2 dA_u(2) - 2 \int_0^t \hat{X}_u^{\pi^*} dA_u(1) + A_t(0) \\ &\quad + \int_0^t G\left(\pi_u^*, \hat{X}_u^{\pi^*}\right) d\langle M \rangle_u + N_t, \end{aligned}$$

where  $N$  is a martingale. Therefore by applying equalities (4.22), (4.23), and (4.24) we obtain

$$\begin{aligned} Y_t^{\pi^*} &= \int_0^t \left( \pi_u^* - \frac{V_u(1)\hat{\lambda}_u + \varphi_u(1)\rho_u^2 - \tilde{h}_u}{1 - \rho_u^2 + \rho_u^2 V_u(2)} \right. \\ &\quad \left. + \hat{X}_u^{\pi^*} \frac{V_u(2)\hat{\lambda}_u + \varphi_u(2)\rho_u^2}{1 - \rho_u^2 + \rho_u^2 V_u(2)} \right)^2 (1 - \rho_u^2 + \rho_u^2 V_u(2)) d\langle M \rangle_u + N_t, \end{aligned}$$

which implies that  $\mu^{\langle M \rangle}$ -a.e.

$$\pi_u^* = \frac{V_u(1)\hat{\lambda}_u + \varphi_u(1)\rho_u^2 - \tilde{h}_u}{1 - \rho_u^2 + \rho_u^2 V_u(2)} - \hat{X}_u^{\pi^*} \frac{(V_u(2)\hat{\lambda}_u + \varphi_u(2)\rho_u^2)}{1 - \rho_u^2 + \rho_u^2 V_u(2)}.$$

By integrating both parts of this equality with respect to  $d\hat{S}$  (and adding then  $x$  to the both parts), we obtain that  $\hat{X}^{\pi^*}$  satisfies (4.7).  $\square$

The uniqueness of the system (4.4)–(4.6) we shall prove under following condition (D\*), stronger than condition (D).

Assume that

(D\*)

$$\int_0^T \frac{\hat{\lambda}_u^2}{\rho_u^2} d\langle M \rangle_u \leq C.$$

Since  $\rho^2 \leq 1$  (Lemma A.1), it follows from (D\*) that the mean-variance tradeoff of  $S$  is bounded, i.e.,

$$\int_0^T \hat{\lambda}_u^2 d\langle M \rangle_u \leq C,$$

which implies (see, e.g., Kazamaki [14]) that the minimal martingale measure for  $S$  exists and satisfies the reverse Hölder condition  $R_2(P)$ . So, condition (D\*) implies

condition (D). Besides, it follows from condition (D\*) that the minimal martingale measure  $\widehat{Q}^{min}$  for  $\widehat{S}$

$$d\widehat{Q}^{min} = \mathcal{E}_T \left( -\frac{\widehat{\lambda}}{\rho^2} \cdot \widehat{M} \right)$$

also exists and satisfies the reverse Hölder condition. Indeed, condition (D\*) implies that  $\mathcal{E}_t(-2\frac{\widehat{\lambda}}{\rho^2} \cdot \widehat{M})$  is a  $G$ -martingale and hence

$$E \left( \mathcal{E}_{tT}^2 \left( -\frac{\widehat{\lambda}}{\rho^2} \cdot \widehat{M} \right) | G_t \right) = E \left( \mathcal{E}_{tT} \left( -2\frac{\widehat{\lambda}}{\rho^2} \cdot \widehat{M} \right) e^{\int_t^T \frac{\widehat{\lambda}_u^2}{\rho_u^2} d\langle M \rangle_u} G_t \right) \leq e^C.$$

Recall that the process  $Z$  belongs to the class  $D$  if the family of random variables  $Z_\tau I_{(\tau \leq T)}$  for all stopping times  $\tau$  is uniformly integrable.

**THEOREM 4.2.** *Let conditions (A), (B), (C), and (D\*) be satisfied. If a triple  $(Y(0), Y(1), Y(2))$ , where  $Y(0) \in D$ ,  $Y^2(1) \in D$ , and  $c \leq Y(2) \leq C$  for some constants  $0 < c < C$ , is a solution of the system (4.4)–(4.6), then such a solution is unique and coincides with the triple  $(V(0), V(1), V(2))$ .*

*Proof.* Let  $Y(2)$  be a bounded strictly positive solution of (4.4), and let

$$\int_0^t \psi_u(2) d\widehat{M}_u + L_t(2)$$

be the martingale part of  $Y(2)$ .

Since  $Y(2)$  solves (4.4), it follows from the Itô formula that for any  $\pi \in \Pi(G)$  the process

$$(4.25) \quad Y_t^\pi = Y_t(2) \left( 1 + \int_s^t \pi_u d\widehat{S}_u \right)^2 + \int_s^t \pi_u^2 (1 - \rho_u^2) d\langle M \rangle_u,$$

$t \geq s$ , is a local submartingale.

Since  $\pi \in \Pi(G)$ , from Lemma A.1 and the Doob inequality we have

$$(4.26) \quad \begin{aligned} & E \sup_{t \leq T} \left( 1 + \int_0^t \pi_u d\widehat{S}_u \right)^2 \\ & \leq \text{const} \left( 1 + E \int_0^T \pi_u^2 \rho_u^2 d\langle M \rangle_u \right) + E \left( \int_0^T |\pi_u \widehat{\lambda}_u| d\langle M \rangle_u \right)^2 < \infty. \end{aligned}$$

Therefore, by taking in mind that  $Y(2)$  is bounded and  $\pi \in \Pi(G)$  we obtain

$$E \left( \sup_{s \leq u \leq T} Y_u^\pi \right)^2 < \infty,$$

which implies that  $Y^\pi \in D$ . Thus  $Y^\pi$  is a submartingale (as a local submartingale from the class  $D$ ), and by the boundary condition  $Y_T(2) = 1$  we obtain

$$Y_s(2) \leq E \left( \left( 1 + \int_s^T \pi_u d\widehat{S}_u \right)^2 + \int_s^T \pi_u^2 (1 - \rho_u^2) d\langle M \rangle_u | G_s \right)$$

for all  $\pi \in \Pi(G)$  and hence

$$(4.27) \quad Y_t(2) \leq V_t(2).$$

Let

$$\tilde{\pi}_t = -\frac{\hat{\lambda}_t Y_t(2) + \psi_t(2) \rho_t^2}{1 - \rho_t^2 + \rho_t^2 Y_t(2)} \mathcal{E}_t \left( -\frac{\hat{\lambda} Y(2) + \psi(2) \rho^2}{1 - \rho^2 + \rho^2 Y(2)} \cdot \hat{S} \right).$$

Since  $1 + \int_0^t \tilde{\pi}_u d\hat{S}_u = \mathcal{E}_t \left( -\frac{\hat{\lambda} Y(2) + \psi(2) \rho^2}{1 - \rho^2 + \rho^2 Y(2)} \cdot \hat{S} \right)$ , it follows from (4.4) and the Itô formula that the process  $Y^{\tilde{\pi}}$  defined by (4.25) is a positive local martingale and hence a supermartingale. Therefore

$$(4.28) \quad Y_s(2) \geq E \left( \left( 1 + \int_s^T \tilde{\pi}_u d\hat{S}_u \right)^2 + \int_s^T \tilde{\pi}_u^2 (1 - \rho_u^2) d\langle M \rangle_u | G_s \right).$$

Let us show that  $\tilde{\pi}$  belongs to the class  $\Pi(G)$ .

From (4.28) and (4.27) we have for every  $s \in [0, T]$

$$(4.29) \quad E \left( \left( 1 + \int_s^T \tilde{\pi}_u d\hat{S}_u \right)^2 + \int_s^T \tilde{\pi}_u^2 (1 - \rho_u^2) d\langle M \rangle_u | G_s \right) \leq Y_s(2) \leq V_s(2) \leq 1$$

and hence

$$(4.30) \quad E \left( 1 + \int_0^T \tilde{\pi}_u d\hat{S}_u \right)^2 \leq 1,$$

$$(4.31) \quad E \int_0^T \tilde{\pi}_u^2 (1 - \rho_u^2) d\langle M \rangle_u \leq 1.$$

By (D\*) the minimal martingale measure  $\hat{Q}^{min}$  for  $\hat{S}$  satisfies the reverse Hölder condition, and hence all conditions of Proposition 2.1 are satisfied. Therefore the norm

$$E \left( \int_0^T \tilde{\pi}_s^2 \rho_s^2 d\langle M \rangle_s \right) + E \left( \int_0^T |\tilde{\pi}_s \hat{\lambda}_s| d\langle M \rangle_s \right)^2$$

is estimated by  $E(1 + \int_0^T \tilde{\pi}_u d\hat{S}_u)^2$  and hence

$$E \int_0^T \tilde{\pi}_u^2 \rho_u^2 d\langle M \rangle_u < \infty, \quad E \left( \int_0^T |\tilde{\pi}_s \hat{\lambda}_s| d\langle M \rangle_s \right)^2 < \infty.$$

It follows from (4.31) and the latter inequality that  $\tilde{\pi} \in \Pi(G)$ , and from (4.28) we obtain

$$Y_t(2) \geq V_t(2),$$

which together with (4.27) gives the equality  $Y_t(2) = V_t(2)$ .

Thus  $V(2)$  is a unique bounded strictly positive solution of (4.4). Besides,

$$(4.32) \quad \int_0^t \psi_u(2) d\widehat{M}_u = \int_0^t \varphi_u(2) d\widehat{M}_u, \quad L_t(2) = m_t(2)$$

for all  $t$ ,  $P$ -a.s.

Let  $Y(1)$  be a solution of (4.5) such that  $Y^2(1) \in D$ . By the Itô formula the process

$$(4.33) \quad \begin{aligned} R_t = Y_t(1) \mathcal{E}_t \left( -\frac{\varphi(2)\rho^2 + \widehat{\lambda}V(2)}{1 - \rho^2 + \rho^2V(2)} \cdot \widehat{S} \right) \\ + \int_0^t \mathcal{E}_u \left( -\frac{\varphi(2)\rho^2 + \widehat{\lambda}V(2)}{1 - \rho^2 + \rho^2V(2)} \cdot \widehat{S} \right) \frac{(\varphi_u(2)\rho_u^2 + \widehat{\lambda}_uV_u(2))\tilde{h}_u}{1 - \rho_u^2 + \rho_u^2V_u(2)} d\langle M \rangle_u \end{aligned}$$

is a local martingale. Let us show that  $R_t$  is a martingale.

As was already shown, the strategy

$$\tilde{\pi}_u = \frac{\psi_u(2)\rho_u^2 + \widehat{\lambda}_uY_u(2)}{1 - \rho^2 + \rho^2Y_u(2)} \mathcal{E}_u \left( -\frac{\psi(2)\rho^2 + \widehat{\lambda}Y(2)}{1 - \rho^2 + \rho^2Y(2)} \cdot \widehat{S} \right)$$

belongs to the class  $\Pi(G)$ .

Therefore (see (4.26)),

$$(4.34) \quad E \sup_{t \leq T} \mathcal{E}_t^2 \left( -\frac{\psi(2)\rho^2 + \widehat{\lambda}Y(2)}{1 - \rho^2 + \rho^2Y(2)} \cdot \widehat{S} \right) = E \sup_{t \leq T} \left( 1 + \int_0^t \tilde{\pi}_u d\widehat{S} \right)^2 < \infty,$$

and hence

$$Y_t(1) \mathcal{E}_t \left( -\frac{\varphi(2)\rho^2 + \widehat{\lambda}V(2)}{1 - \rho^2 + \rho^2V(2)} \cdot \widehat{S} \right) \in D.$$

On the other hand, the second term of (4.33) is the process of integrable variation, since  $\tilde{\pi} \in \Pi(G)$  and  $\tilde{h} \in \Pi(G)$  (see Lemma A.2) imply that

$$\begin{aligned} E \int_0^T \left| \mathcal{E}_u \left( -\frac{\varphi(2)\rho^2 + \widehat{\lambda}V(2)}{1 - \rho^2 + \rho^2V(2)} \cdot \widehat{S} \right) \frac{(\varphi_u(2)\rho_u^2 + \widehat{\lambda}_uV_u(2))\tilde{h}_u}{1 - \rho_u^2 + \rho_u^2V_u(2)} \right| d\langle M \rangle_u \\ = E \int_0^T |\tilde{\pi}_u \tilde{h}_u| d\langle M \rangle_u \leq E^{1/2} \int_0^T \tilde{\pi}_u^2 d\langle M \rangle_u E^{1/2} \int_0^T \tilde{h}_u^2 d\langle M \rangle_u < \infty. \end{aligned}$$

Therefore, the process  $R_t$  belongs to the class  $D$ , and hence it is a true martingale. By using the martingale property and the boundary condition we obtain

$$(4.35) \quad \begin{aligned} Y_t(1) = E \left( \widehat{H}_T \mathcal{E}_{tT} \left( -\frac{\varphi(2)\rho^2 + \widehat{\lambda}V(2)}{1 - \rho^2 + \rho^2V(2)} \cdot \widehat{S} \right) \right. \\ \left. + \int_t^T \mathcal{E}_{tu} \left( -\frac{\varphi(2)\rho^2 + \widehat{\lambda}V(2)}{1 - \rho^2 + \rho^2V(2)} \cdot \widehat{S} \right) \frac{(\varphi_u(2)\rho_u^2 + \widehat{\lambda}_uV_u(2))\tilde{h}_u}{1 - \rho_u^2 + \rho_u^2V_u(2)} d\langle M \rangle_u \middle| G_t \right). \end{aligned}$$

Thus, any solution of (4.5) is expressed explicitly in terms of  $(V(2), \varphi(2))$  in the form (4.35). Hence the solution of (4.5) is unique, and it coincides with  $V_t(1)$ .

It is evident that the solution of (4.6) is also unique.  $\square$

*Remark 4.1.* In the case  $F^S \subseteq G$  we have  $\rho_t = 1, \tilde{h}_t = 0$ , and  $\hat{S}_t = S_t$ , and (4.7) takes the form

$$\begin{aligned} \hat{X}_t^* &= x - \int_0^t \frac{\psi_u(2) + \hat{\lambda}_u Y_u(2)}{Y_u(2)} \hat{X}_u^* dS_u \\ &\quad + \int_0^t \frac{\psi_u(1) + \hat{\lambda}_u Y_u(1)}{Y_u(2)} dS_u. \end{aligned}$$

**COROLLARY 4.1.** *In addition to conditions (A)–(C) assume that  $\rho$  is a constant and the mean-variance tradeoff  $\langle \hat{\lambda} \cdot M \rangle_T$  is deterministic. Then the solution of (4.4) is the triple  $(Y(2), \psi(2), L(2))$ , with  $\psi(2) = 0, L(2) = 0$ , and*

$$(4.36) \quad Y_t(2) = V_t(2) = \nu \left( \rho, 1 - \rho^2 + \langle \hat{\lambda} \cdot M \rangle_T - \langle \hat{\lambda} \cdot M \rangle_t \right),$$

where  $\nu(\rho, \alpha)$  is the root of the equation

$$(4.37) \quad \frac{1 - \rho^2}{x} - \rho^2 \ln x = \alpha.$$

Besides,

$$(4.38) \quad \begin{aligned} Y_t(1) &= E \left( H \mathcal{E}_{tT} \left( -\frac{\hat{\lambda} V(2)}{1 - \rho^2 + \rho^2 V(2)} \cdot \hat{S} \right) \right. \\ &\quad \left. + \int_t^T \mathcal{E}_{tu} \left( -\frac{\hat{\lambda} V(2)}{1 - \rho^2 + \rho^2 V(2)} \cdot \hat{S} \right) \frac{\lambda_u V_u(2) \tilde{h}_u}{1 - \rho^2 + \rho^2 V_u(2)} d\langle M \rangle_u | G_t \right) \end{aligned}$$

uniquely solves (4.5), and the optimal filtered wealth process satisfies the linear equation

$$(4.39) \quad \begin{aligned} \hat{X}_t^* &= x - \int_0^t \frac{\hat{\lambda}_u V_u(2)}{1 - \rho^2 + \rho^2 V_u(2)} \hat{X}_u^* d\hat{S}_u \\ &\quad + \int_0^t \frac{\varphi_u(1)\rho^2 + \hat{\lambda}_u V_u(1) - \tilde{h}_u}{1 - \rho^2 + \rho^2 V_u(2)} d\hat{S}_u. \end{aligned}$$

*Proof.* The function  $f(x) = \frac{1-\rho^2}{x} - \rho^2 \ln x$  is differentiable and strictly decreasing on  $]0, \infty[$  and takes all values from  $] -\infty, +\infty[$ . So (4.37) admits a unique solution for all  $\alpha$ . Besides, the inverse function  $\alpha(x)$  is differentiable. Therefore  $Y_t(2)$  is a process of finite variation, and it is adapted since  $\langle \hat{\lambda} \cdot M \rangle_T$  is deterministic.

By definition of  $Y_t(2)$  we have that for all  $t \in [0, T]$

$$\frac{1 - \rho^2}{Y_t(2)} - \rho^2 \ln Y_t(2) = 1 - \rho^2 + \langle \hat{\lambda} \cdot M \rangle_T - \langle \hat{\lambda} \cdot M \rangle_t.$$

It is evident that for  $\alpha = 1 - \rho^2$  the solution of (4.37) is equal to 1, and it follows from (4.36) that  $Y(2)$  satisfies the boundary condition  $Y_T(2) = 1$ . Therefore

$$\begin{aligned} &\frac{1 - \rho^2}{Y_t(2)} - \rho^2 \ln Y_t(2) - (1 - \rho^2) \\ &= -(1 - \rho^2) \int_t^T d \frac{1}{Y_u(2)} + \rho^2 \int_t^T d \ln Y_u(2) \\ &= \int_t^T \left( \frac{1 - \rho^2}{Y_u^2(2)} + \frac{\rho^2}{Y_u(2)} \right) dY_u(2) \end{aligned}$$

and

$$\int_t^T \frac{1 - \rho^2 + \rho^2 Y_u(2)}{Y_u^2(2)} dY_u(2) = \langle \hat{\lambda} \cdot M \rangle_T - \langle \hat{\lambda} \cdot M \rangle_t$$

for all  $t \in [0, T]$ . Hence

$$\int_0^t \frac{1 - \rho^2 + \rho^2 Y_u(2)}{Y_u^2(2)} dY_u(2) = \langle \hat{\lambda} \cdot M \rangle_t,$$

and, by integrating both parts of this equality with respect to  $Y(2)/(1 - \rho^2 + \rho^2 Y(2))$ , we obtain that  $Y(2)$  satisfies

$$(4.40) \quad Y_t(2) = Y_0(2) + \int_0^t \frac{Y_u^2(2) \hat{\lambda}_u^2}{1 - \rho^2 + \rho^2 Y_u(2)} d\langle M \rangle_u,$$

which implies that the triple  $(Y(2), \psi(2) = 0, L(2) = 0)$  satisfies (4.4) and  $Y(2) = V(2)$  by Theorem 4.2. Equations (4.38) and (4.39) follow from (4.35) and (4.7), respectively, by taking  $\varphi(2) = 0$ .  $\square$

*Remark 4.2.* In case  $F^S \subseteq G$  we have  $\widehat{M} = M$  and  $\rho = 1$ . Therefore (4.40) is linear and  $Y_t(2) = e^{\langle \hat{\lambda} \cdot M \rangle_t - \langle \hat{\lambda} \cdot M \rangle_T}$ . In the case  $\mathcal{A} = G$  of complete information,  $Y_t(2) = e^{\langle \lambda \cdot N \rangle_t - \langle \lambda \cdot N \rangle_T}$ .

## 5. Diffusion market model.

*Example 1.* Let us consider the financial market model

$$\begin{aligned} d\tilde{S}_t &= \tilde{S}_t \mu_t(\eta) dt + \tilde{S}_t \sigma_t(\eta) dw_t^0, \\ d\eta_t &= a_t(\eta) dt + b_t(\eta) dw_t, \end{aligned}$$

subjected to initial conditions. Here  $w^0$  and  $w$  are correlated Brownian motions with  $Edw_t^0 dw_t = \rho dt, \rho \in (-1, 1)$ .

Let us write

$$w_t = \rho w_t^0 + \sqrt{1 - \rho^2} w_t^1,$$

where  $w^0$  and  $w^1$  are independent Brownian motions. It is evident that  $w^\perp = -\sqrt{1 - \rho^2} w^0 + \rho w^1$  is a Brownian motion independent of  $w$ , and one can express Brownian motions  $w^0$  and  $w^1$  in terms of  $w$  and  $w^\perp$  as

$$(5.1) \quad w_t^0 = \rho w_t - \sqrt{1 - \rho^2} w_t^\perp, \quad w_t^1 = \sqrt{1 - \rho^2} w_t + \rho w_t^\perp.$$

Suppose that  $b^2 > 0$ ,  $\sigma^2 > 0$ , and coefficients  $\mu, \sigma, a$ , and  $b$  are such that  $F_t^{S, \eta} = F_t^{w^0, w}$  and  $F_t^\eta = F_t^w$ .

We assume that an agent would like to hedge a contingent claim  $H$  (which can be a function of  $S_T$  and  $\eta_T$ ) using only observations based on the process  $\eta$ . So the stochastic basis will be  $(\Omega, \mathcal{F}, F_t, P)$ , where  $F_t$  is the natural filtration of  $(w^0, w)$  and the flow of observable events is  $G_t = F_t^w$ .

Also denote  $dS_t = \mu_t dt + \sigma_t dw_t^0$ , so that  $d\tilde{S}_t = \tilde{S}_t dS_t$  and  $S$  is the return of the stock.

Let  $\tilde{\pi}_t$  be the number of shares of the stock at time  $t$ . Then  $\pi_t = \tilde{\pi}_t \tilde{S}_t$  represents an amount of money invested in the stock at the time  $t \in [0, T]$ . We consider the mean-

variance hedging problem

(5.2)

$$\text{to minimize } E \left[ \left( x + \int_0^T \tilde{\pi}_t d\tilde{S}_t - H \right)^2 \right] \quad \text{over all } \tilde{\pi} \text{ for which } \tilde{\pi}\tilde{S} \in \Pi(G),$$

which is equivalent to studying the mean-variance hedging problem

$$\text{to minimize } E \left[ \left( x + \int_0^T \pi_t dS_t - H \right)^2 \right] \quad \text{over all } \pi \in \Pi(G).$$

*Remark 5.1.* Since  $S$  is not  $G$ -adapted,  $\tilde{\pi}_t$  and  $\tilde{\pi}_t\tilde{S}_t$  cannot be simultaneously  $G$ -predictable and the problem

$$\text{to minimize } E \left[ \left( x + \int_0^T \tilde{\pi}_t d\tilde{S}_t - H \right)^2 \right] \quad \text{over all } \tilde{\pi} \in \Pi(G)$$

is not equivalent to the problem (5.2). In this setting, condition (A) is not satisfied, and it needs separate consideration.

By comparing with (1.1) we get that in this case

$$M_t = \int_0^t \sigma_s dw_s^0, \quad \langle M \rangle_t = \int_0^t \sigma_s^2 ds, \quad \lambda_t = \frac{\mu_t}{\sigma_t^2}.$$

It is evident that  $w$  is a Brownian motion also with respect to the filtration  $F^{w^0, w^1}$  and condition (B) is satisfied. Therefore by Proposition 2.2

$$\widehat{M}_t = \rho \int_0^t \sigma_s dw_s.$$

By the integral representation theorem the GKW decompositions (3.2) and (3.3) take the following forms:

$$(5.3) \quad c_H = EH, \quad H_t = c_H + \int_0^t h_s \sigma_s dw_s^0 + \int_0^t h_s^1 dw_s^1,$$

$$(5.4) \quad H_t = c_H + \rho \int_0^t h_s^G \sigma_s dw_s + \int_0^t h_s^\perp dw_s^\perp.$$

By putting expressions (5.1) for  $w^0$  and  $w^1$  in (5.3) and equalizing integrands of (5.3) and (5.4), we obtain

$$h_t = \rho^2 h_t^G - \sqrt{1 - \rho^2} \frac{h_t^\perp}{\sigma_t}$$

and hence

$$\widehat{h}_t = \rho^2 \widehat{h}_t^G - \sqrt{1 - \rho^2} \frac{\widehat{h}_t^\perp}{\sigma_t}.$$

Therefore by the definition of  $\tilde{h}$

$$(5.5) \quad \tilde{h}_t = \rho^2 \widehat{h}_t^G - \widehat{h}_t = \sqrt{1 - \rho^2} \frac{\widehat{h}_t^\perp}{\sigma_t}.$$

By using notations

$$Z_s(0) = \rho\sigma_s\varphi_s(0), \quad Z_s(1) = \rho\sigma_s\varphi_s(1), \quad Z_s(2) = \rho\sigma_s\varphi_s(2), \quad \theta_s = \frac{\mu_s}{\sigma_s},$$

we obtain the following corollary of Theorem 4.1.

**COROLLARY 5.1.** *Let  $H$  be a square integrable  $F_T$ -measurable random variable. Then the processes  $V_t(0), V_t(1)$ , and  $V_t(2)$  from (4.3) satisfy the following system of backward equations:*

$$(5.6) \quad V_t(2) = V_0(2) + \int_0^t \frac{(\rho Z_s(2) + \theta_s V_s(2))^2}{1 - \rho^2 + \rho^2 V_s(2)} ds + \int_0^t Z_s(2) dw_s, \quad V_T(2) = 1,$$

$$(5.7) \quad \begin{aligned} V_t(1) &= V_0(1) + \int_0^t \frac{(\rho Z_s(2) + \theta_s V_s(2)) (\rho Z_s(1) + \theta_s V_s(1) - \sqrt{1 - \rho^2} \hat{h}_s^\perp)}{1 - \rho^2 + \rho^2 V_s(2)} ds \\ &\quad + \int_0^t Z_s(1) dw_s, \quad V_T(1) = E(H|G_T), \end{aligned}$$

$$(5.8) \quad \begin{aligned} V_t(0) &= V_0(0) + \int_0^t \frac{(\rho Z_s(1) + \theta_s V_s(1) - \sqrt{1 - \rho^2} \hat{h}_s^\perp)^2}{1 - \rho^2 + \rho^2 V_s(2)} ds \\ &\quad + \int_0^t Z_s(0) dw_s, \quad V_T(0) = E^2(H|G_T). \end{aligned}$$

Besides, the optimal wealth process  $\hat{X}^*$  satisfies the linear equation

$$(5.9) \quad \begin{aligned} \hat{X}_t^* &= x - \int_0^t \frac{\rho Z_s(2) + \theta_s V_s(2)}{1 - \rho^2 + \rho^2 V_s(2)} \hat{X}_s^* (\theta_s ds + \rho dw_s) \\ &\quad + \int_0^t \frac{\rho Z_s(1) + \theta_s V_s(1) - \sqrt{1 - \rho^2} \hat{h}_s^\perp}{1 - \rho^2 + \rho^2 V_s(2)} (\theta_s ds + \rho dw_s). \end{aligned}$$

Suppose now that  $\theta_t$  and  $\sigma_t$  are deterministic. Then the solution of (5.6) is the pair  $(V_t(2), Z_t(2))$ , where  $Z(2) = 0$  and  $V(2)$  satisfies the ordinary differential equation

$$(5.10) \quad \frac{dV_t(2)}{dt} = \frac{\theta_t^2 V_t^2(2)}{1 - \rho^2 + \rho^2 V_t(2)}, \quad V_T(2) = 1.$$

By solving this equation we obtain

$$(5.11) \quad V_t(2) = \nu \left( \rho, 1 - \rho^2 + \int_t^T \theta_s^2 ds \right) \equiv \nu_t^{\theta, \rho},$$

where  $\nu(\rho, \alpha)$  is the solution of (4.37). From (5.10) it follows that

$$(5.12) \quad \left( \ln \nu_t^{\theta, \rho} \right)' = \frac{\theta_t^2 \nu_t^{\theta, \rho}}{1 - \rho^2 + \rho^2 \nu_t^{\theta, \rho}} \quad \text{and} \quad \ln \frac{\nu_s^{\theta, \rho}}{\nu_t^{\theta, \rho}} = \int_t^s \frac{\theta_r^2 \nu_r^{\theta, \rho} dr}{1 - \rho^2 + \rho^2 \nu_r^{\theta, \rho}}.$$

If we solve the linear BSDE (5.7) and use (5.12), we obtain

$$\begin{aligned} V_t(1) &= E \left[ \widehat{H}_T(w) \mathcal{E}_{tT} \left( - \int_0^\cdot \frac{\theta_r \nu_r^{\theta, \rho}}{1 - \rho^2 + \rho^2 \nu_r^{\theta, \rho}} (\theta_r dr + \rho dw_r) \right) \middle| G_t \right], \\ \int_t^T \frac{\theta_s \nu_s^{\theta, \rho} \sigma_s}{1 - \rho^2 + \rho^2 \nu_s^{\theta, \rho}} E \left[ \tilde{h}_s(w) \mathcal{E}_{ts} \left( - \int_0^\cdot \frac{\theta_r \nu_r^{\theta, \rho}}{1 - \rho^2 + \rho^2 \nu_r^{\theta, \rho}} (\theta_r dr + \rho dw_r) \right) \middle| G_t \right] ds \\ &= \nu_t^{\theta, \rho} E \left[ \widehat{H}_T(w) \mathcal{E}_{tT} \left( - \int_0^\cdot \frac{\theta_r \nu_r^{\theta, \rho}}{1 - \rho^2 + \rho^2 \nu_r^{\theta, \rho}} \rho dw_r \right) \middle| G_t \right] \\ &+ \nu_t^{\theta, \rho} \int_t^T \frac{\mu_s}{1 - \rho^2 + \rho^2 \nu_s^{\theta, \rho}} E \left[ \tilde{h}_s(w) \mathcal{E}_{ts} \left( - \int_0^\cdot \frac{\theta_r \nu_r^{\theta, \rho}}{1 - \rho^2 + \rho^2 \nu_r^{\theta, \rho}} \rho dw_r \right) \middle| G_t \right] ds. \end{aligned}$$

By using the Girsanov theorem we finally get

$$\begin{aligned} V_t(1) &= \nu_t^{\theta, \rho} E \left[ \widehat{H}_T \left( \rho \int_0^\cdot \frac{\theta_r \nu_r^{\theta, \rho}}{1 - \rho^2 + \rho^2 \nu_r^{\theta, \rho}} dr + w \right) \middle| G_t \right] \\ (5.13) \quad &+ \nu_t^{\theta, \rho} \int_t^T \frac{\mu_s}{1 - \rho^2 + \rho^2 \nu_s^{\theta, \rho}} E \left[ \tilde{h}_s \left( \rho \int_0^\cdot \frac{\theta_r \nu_r^{\theta, \rho}}{1 - \rho^2 + \rho^2 \nu_r^{\theta, \rho}} dr + w \right) \middle| G_t \right] ds. \end{aligned}$$

Besides, the optimal strategy is of the form

$$\begin{aligned} \pi_t^* &= - \frac{\theta_t V_t(2)}{(1 - \rho^2 + \rho^2 V_t(2)) \sigma_t} \widehat{X}_t^* \\ &+ \frac{\rho Z_t(1) + \theta_t V_t(1) - \sqrt{1 - \rho^2} \widehat{h}_t^\perp}{(1 - \rho^2 + \rho^2 V_t(2)) \sigma_t}. \quad \square \end{aligned}$$

If in addition  $\mu$  and  $\sigma$  are constants and the contingent claim is of the form  $H = \mathcal{H}(S_T, \eta_T)$ , then one can give an explicit expressions also for  $\tilde{h}$ ,  $\widehat{h}^\perp$ ,  $\widehat{H}$ , and  $Z(1)$ .

*Example 2.* In Frey and Runggaldier [9] the incomplete-information situation arises, assuming that the hedger is unable to monitor the asset continuously but is confined to observations at discrete random points in time  $\tau_1, \tau_2, \dots, \tau_n$ . Perhaps it is more natural to assume that the hedger has access to price information on full intervals  $[\sigma_1, \tau_1], [\sigma_2, \tau_2], \dots, [\sigma_n, \tau_n]$ . For the models with nonzero drifts, even the case  $n = 1$  is nontrivial. Here we consider this case in detail.

Let us consider the financial market model

$$d\tilde{S}_t = \mu \tilde{S}_t dt + \sigma \tilde{S}_t dW_t, \quad S_0 = S,$$

where  $W$  is a standard Brownian motion and the coefficients  $\mu$  and  $\sigma$  are constants. Assume that an investor observes only the returns  $S_t - S_0 = \int_0^t \frac{1}{S_u} d\tilde{S}_u$  of the stock prices up to a random moment  $\tau$  before the expiration date  $T$ . Let  $\mathcal{A}_t = F_t^S$ , and let  $\tau$  be a stopping time with respect to  $F^S$ . Then the filtration  $G_t$  of observable events is equal to the filtration  $F_{t \wedge \tau}^S$ .

Consider the mean-variance hedging problem

$$\text{to minimize } E \left[ \left( x + \int_0^T \pi_t dS_t - H \right)^2 \right] \quad \text{over all } \pi \in \Pi(G),$$

where  $\pi_t$  is a dollar amount invested in the stock at time  $t$ .

By comparing with (1.1) we get that in this case

$$N_t = M_t = \sigma W_t, \quad \langle M \rangle_t = \sigma^2 t, \quad \lambda_t = \frac{\mu}{\sigma^2}.$$

Let  $\theta = \frac{\mu}{\sigma}$ . The measure  $Q$  defined by  $dQ = \mathcal{E}_T(\theta W)dP$  is a unique martingale measure for  $S$ , and it is evident that  $Q$  satisfies the reverse Hölder condition. It is also evident that any  $G$ -martingale is  $F^S$ -martingale and that conditions (A)–(C) are satisfied. Besides,

$$(5.14) \quad E(W_t|G_t) = W_{t \wedge \tau}, \quad \hat{S}_t = \mu t + \sigma W_{t \wedge \tau} \quad \text{and} \quad \rho_t = I_{\{t \leq \tau\}}.$$

By the integral representation theorem

$$(5.15) \quad E(H|F_t^S) = EH + \int_0^t h_u \sigma dW_u$$

for  $F$ -predictable  $W$ -integrable process  $h$ . On the other hand, by the GKW decomposition with respect to the martingale  $W^\tau = (W_{t \wedge \tau}, t \in [0, T])$ ,

$$(5.16) \quad E(H|F_t^S) = EH + \int_0^t h_u^G \sigma dW_u^\tau + L_t^G$$

for  $F^S$ -predictable process  $h^G$  and  $F^S$  martingale  $L^G$  strongly orthogonal to  $W^\tau$ . Therefore, by equalizing the right-hand sides of (5.15) and (5.16) and taking the mutual characteristics of both parts with  $W^\tau$ , we obtain  $\int_0^{t \wedge \tau} (h_u^G \rho_u^2 - h_u) du = 0$  and hence

$$(5.17) \quad \int_0^t \tilde{h}_u du = \int_0^t (\hat{h}_u^G I_{(u \leq \tau)} - \hat{h}_u) du = - \int_0^t I_{(u > \tau)} E(h_u | F_\tau^S) du.$$

Therefore, by using notations

$$Z_s(0) = \rho \sigma \varphi_s(0), \quad Z_s(1) = \rho \sigma \varphi_s(1), \quad Z_s(2) = \rho \sigma \varphi_s(2),$$

it follows from Theorem 4.1 that the processes  $(V_t(2), Z_t(2))$  and  $(V_t(1), Z_t(1))$  satisfy the following system of backward equations:

$$(5.18) \quad \begin{aligned} V_t(2) &= V_0(2) + \int_0^{t \wedge \tau} \frac{(Z_s(2) + \theta V_s(2))^2}{V_s(2)} ds + \int_{t \wedge \tau}^t \theta^2 V_s^2(2) ds \\ &+ \int_0^{t \wedge \tau} Z_s(2) dW_s, \quad V_T(2) = 1, \end{aligned}$$

$$(5.19) \quad \begin{aligned} V_t(1) &= V_0(1) + \int_0^{t \wedge \tau} \frac{(Z_s(2) + \theta V_s(2))(Z_s(1) + \theta V_s(1))}{V_s(2)} ds \\ &+ \int_{t \wedge \tau}^t \theta V_s(2) (\theta V_s(1) + E(h_s | F_\tau^S)) ds \\ &+ \int_0^{t \wedge \tau} Z_s(1) dW_s, \quad V_T(1) = E(H|G_T). \end{aligned}$$

Equation (5.18) admits in this case an explicit solution. To obtain the solution one should solve first the equation

$$(5.20) \quad U_t = U_0 + \int_0^t \theta^2 U_s^2 ds, \quad U_T = 1,$$

in the time interval  $[\tau, T]$  and then the BSDE

$$(5.21) \quad V_t(2) = V_0(2) + \int_0^t \frac{(Z_s(2) + \theta V_s(2))^2}{V_s(2)} ds + \int_0^t Z_s(2) dW_s$$

in the interval  $[0, \tau]$ , with the boundary condition  $V_\tau(2) = U_\tau$ . The solution of (5.20) is

$$U_t = \frac{1}{1 + \theta^2(T - t)},$$

and the solution of (5.21) is expressed as

$$V_t(2) = \frac{1}{E((1 + \theta^2(T - \tau))\mathcal{E}_{t,\tau}^2(-\theta W)|F_t^S)}$$

(this can be verified by applying the Itô formula for the process  $V_t^{-1}(2)\mathcal{E}_t^2(-\theta W)$  and by using the fact that this process is a martingale). Therefore

$$(5.22) \quad V_t(2) = \begin{cases} \frac{1}{1 + \theta^2(T - t)} & \text{if } t \geq \tau, \\ \frac{1}{E((1 + \theta^2(T - \tau))\mathcal{E}_{t,\tau}^2(-\theta W)|F_t^S)} & \text{if } t \leq \tau. \end{cases}$$

According to (4.37), taking in mind (5.14), (5.17), and the fact that  $e^{-\int_t^T \theta^2 V_u(2) du} = \frac{1}{1 + \theta^2(T - t)}$  on the set  $t \geq \tau$ , the solution of (5.19) is equal to

(5.23)

$$\begin{aligned} V_t(1) = & E\left(\frac{H}{1 + \theta^2(T - t)} + \int_t^T \frac{\theta V_u(2) h_u du}{1 + \theta^2(T - u)} | F_\tau^S\right) I_{(t > \tau)} \\ & + E\left(\mathcal{E}_{t,\tau}\left(-\frac{\varphi(2) + \lambda V(2)}{V(2)} \cdot S\right) \left(\frac{H}{1 + \theta^2(T - \tau)} + \int_\tau^T \frac{\theta V_u(2) h_u du}{1 + \theta^2(T - u)}\right) | F_t^S\right) I_{(t \leq \tau)}. \end{aligned}$$

By Theorem 4.1 the optimal filtered wealth process is a solution of a linear SDE, which takes in this case the following form:

$$(5.24) \quad \begin{aligned} \hat{X}_t^* = & x - \int_0^{t \wedge \tau} \frac{\varphi_u(2) + \theta V_u(2)}{V_u(2)} \hat{X}_u^* (\theta du + dW_u) - \int_{t \wedge \tau}^t \theta^2 V_u(2) \hat{X}_u^* du \\ & + \int_0^{t \wedge \tau} \frac{\varphi_u(1) + \theta V_u(1)}{V_u(2)} (\theta du + dW_u) + \int_{t \wedge \tau}^t (\theta^2 V_u(1) + \mu E(h_u | F_\tau^S)) du. \end{aligned}$$

The optimal strategy is equal to

$$(5.25) \quad \begin{aligned} \pi_t^* = & \left[ -\frac{\varphi_t(2) + \theta V_t(2)}{V_t(2)} I_{(t \leq \tau)} - \theta^2 V_t(2) I_{(t > \tau)} \right] \hat{X}_t^* \\ & + \frac{\varphi_t(1) + \theta V_t(1)}{V_t(2)} I_{(t \leq \tau)} + (\theta^2 V_t(1) + \mu E(h_t | F_\tau^S)) I_{(t > \tau)}, \end{aligned}$$

where  $\hat{X}_t^*$  is a solution of the linear equation (5.24),  $V(2)$  and  $V(1)$  are given by (5.22) and (5.23), and  $\varphi(2)$  and  $\varphi(1)$  are integrands of their martingale parts, respectively. In particular the optimal strategy in time interval  $[\tau, T]$  (i.e., after interrupting observations) is of the form

$$(5.26) \quad \pi_t^* = -\theta^2 V_t(2) \hat{X}_t^* + \theta^2 V_t(1) + \mu E(h_t | F_\tau^S),$$

where

$$\widehat{X}_t^* = \frac{\widehat{X}_\tau^*}{1 + \theta^2(t - \tau)} - \int_\tau^t (\theta^2 V_u(1) - \mu E(h_u | F_\tau^S)) \frac{1}{1 + \theta^2(t - u)} du.$$

For instance, if  $\tau$  is deterministic, then  $V_t(2)$  is also deterministic:

$$V_t(2) = \begin{cases} \frac{1}{1 + \theta^2(T - t)} & \text{if } t \geq \tau, \\ \frac{1}{1 + \theta^2(T - t)} e^{-\theta^2(\tau - t)} & \text{if } t \leq \tau, \end{cases}$$

and  $\varphi(2) = 0$ .

Note that it is not optimal to do nothing after interrupting observations, and in order to act optimally one should change the strategy deterministically as it is given by (5.26).

**Appendix A.** For convenience we give the proofs of the following assertions used in the paper.

LEMMA A.1. *Let conditions (A)–(C) be satisfied and  $\widehat{M}_t = E(M_t | G_t)$ . Then  $\langle \widehat{M} \rangle$  is absolutely continuous w.r.t.  $\langle M \rangle$  and  $\mu^{(M)}$  a.e.*

$$\rho_t^2 = \frac{d\langle \widehat{M} \rangle_t}{d\langle M \rangle_t} \leq 1.$$

*Proof.* By (2.4) for any bounded  $G$ -predictable process  $h$

$$\begin{aligned} E \int_0^t h_s^2 d\langle \widehat{M} \rangle_s &= E \left( \int_0^t h_s d\widehat{M}_s \right)^2 = E \left( E \left( \int_0^t h_s dM_s | G_t \right) \right)^2 \\ (A.1) \qquad \qquad \qquad &\leq E \left( \int_0^t h_s dM_s \right)^2 = E \int_0^t h_s^2 d\langle M \rangle_s, \end{aligned}$$

which implies that  $\langle \widehat{M} \rangle$  is absolutely continuous w.r.t.  $\langle M \rangle$ , i.e.,

$$\langle \widehat{M} \rangle_t = \int_0^t \rho_s^2 d\langle M \rangle_s$$

for a  $G$ -predictable process  $\rho$ .  $\square$

Moreover (A.1) implies that the process  $\langle M \rangle - \langle \widehat{M} \rangle$  is increasing and hence  $\rho^2 \leq 1$   $\mu^{(M)}$  a.e.

LEMMA A.2. *Let  $H \in L^2(P, F_T)$ , and let conditions (A)–(C) be satisfied. Then*

$$E \int_0^T \tilde{h}_u^2 d\langle M \rangle_u < \infty.$$

*Proof.* It is evident that

$$E \int_0^T (h_u^G)^2 d\langle \widehat{M} \rangle_u < \infty, \quad E \int_0^T h_u^2 d\langle M \rangle_u < \infty.$$

Therefore, by the definition of  $\tilde{h}$  and Lemma A.1,

$$\begin{aligned} & E \int_0^T \tilde{h}_u^2 d\langle M \rangle_u \\ & \leq 2E \int_0^T \hat{h}_u^2 d\langle M \rangle_u + 2E \int_0^T \left( \widehat{h}_u^G \right)^2 \rho_u^4 d\langle M \rangle_u \\ & \leq 2E \int_0^T h_u^2 d\langle M \rangle_u + 2E \int_0^T \left( h_u^G \right)^2 \rho_u^2 d\langle \widehat{M} \rangle_u < \infty. \end{aligned}$$

Thus  $\tilde{h} \in \Pi(G)$  by Remark 2.5.  $\square$

LEMMA A.3. (a) Let  $Y = (Y_t, t \in [0, T])$  be a bounded positive submartingale with the canonical decomposition

$$Y_t = Y_0 + B_t + m_t,$$

where  $B$  is a predictable increasing process and  $m$  is a martingale. Then  $m \in BMO$ .

(b) In particular the martingale part of  $V(2)$  belongs to  $BMO$ . If  $H$  is bounded, then martingale parts of  $V(0)$  and  $V(1)$  also belong to the class  $BMO$ , i.e., for  $i = 0, 1, 2$ ,

$$(A.2) \quad E \left( \int_{\tau}^T \varphi_u^2(i) \rho_u^2 d\langle M \rangle_u | G_{\tau} \right) + E (\langle m(i) \rangle_T - \langle m(i) \rangle_{\tau} | G_{\tau}) \leq C$$

for every stopping time  $\tau$ .

*Proof.* By applying the Itô formula for  $Y_T^2 - Y_{\tau}^2$  we have

$$(A.3) \quad \langle m \rangle_T - \langle m \rangle_{\tau} + 2 \int_{\tau}^T Y_u dB_u + 2 \int_{\tau}^T Y_u dm_u = Y_T^2 - Y_{\tau}^2 \leq \text{const}$$

Since  $Y$  is positive and  $B$  is an increasing process, by taking conditional expectations in (A.3) we obtain

$$E(\langle m \rangle_T - \langle m \rangle_{\tau} | F_{\tau}) \leq \text{const}$$

for any stopping time  $\tau$ , and hence  $m \in BMO$ .

(A.2) follows from assertion (a) applied for positive submartingales  $V(0)$ ,  $V(2)$ , and  $V(0) + V(2) - 2V(1)$ . For the case  $i = 1$  one should take into account also the inequality

$$\langle m(1) \rangle_t \leq \text{const}(\langle m(0) + m(2) - 2m(1) \rangle_t + \langle m(0) \rangle_t + \langle m(2) \rangle_t). \quad \square$$

## A KNOWLEDGE-GRADIENT POLICY FOR SEQUENTIAL INFORMATION COLLECTION\*

PETER I. FRAZIER<sup>†</sup>, WARREN B. POWELL<sup>†</sup>, AND SAVAS DAYANIK<sup>†</sup>

**Abstract.** In a sequential Bayesian ranking and selection problem with independent normal populations and common known variance, we study a previously introduced measurement policy which we refer to as the knowledge-gradient policy. This policy myopically maximizes the expected increment in the value of information in each time period, where the value is measured according to the terminal utility function. We show that the knowledge-gradient policy is optimal both when the horizon is a single time period and in the limit as the horizon extends to infinity. We show furthermore that, in some special cases, the knowledge-gradient policy is optimal regardless of the length of any given fixed total sampling horizon. We bound the knowledge-gradient policy's suboptimality in the remaining cases, and show through simulations that it performs competitively with or significantly better than other policies.

**Key words.** ranking and selection, Bayesian statistics, sequential decision analysis

**1. Introduction.** We consider a ranking and selection problem in which we are faced with  $M \geq 2$  alternatives, each of which can be measured sequentially to estimate its constant but unknown underlying average performance. The measurements are noisy, and as we obtain more measurements, our estimates become more accurate. We assume normally distributed measurement noise and independent normal Bayesian priors for each alternative's underlying average performance. We have a budget of  $N$  measurements to spread over the  $M$  alternatives before deciding which is best. The goal is to choose the alternative with the best underlying average performance.

Information collection problems of this type arise in a number of applications:

- (i) Choosing the chemical compound from a library of existing test compounds that has the greatest effectiveness against a particular disease. A compound's effectiveness may be measured by exposing cultured cells infected with the disease to the compound and observing the result. The compound found most effective will be developed into a drug for treating the disease.
- (ii) Choosing the most efficient of several alternative assembly line configurations. We may spend a certain short amount of time testing different configurations, but once we put one particular configuration into production, that choice will remain in production for a period of several years.
- (iii) Selecting the best of several policies applied to a stochastic Markov decision process. The policies may be evaluated only through Monte Carlo simulation, so a method of ranking and selection is needed to determine which policy is best. This selection may be as part of a larger algorithm for finding the optimal policy as in evolutionary policy iteration [3].

In this article we study a measurement policy introduced in [16] under the name of the  $(R_1, \dots, R_1)$  policy, and referred to herein as the knowledge-gradient (KG) policy. We briefly describe this policy and leave further description for section 4.1. Let  $\mu_x^n$  and  $(\sigma_x^n)^2$  denote the mean and variance of the posterior predictive distribution for the unknown value of alternative  $x$  after the first  $n$  measurements. Then the KG policy is the policy that chooses its  $(n+1)$ st measurement  $X^{KG}((\mu_1^n, \sigma_1^n), \dots, (\mu_M^n, \sigma_M^n))$  from within  $\{1, \dots, M\}$  to maximize the single-period expected increase in value,  $\mathbb{E}_n[(\max_{x'} \mu_{x'}^{n+1}) - (\max_{x'} \mu_{x'}^n)]$ , where  $\mathbb{E}_n$  indicates the conditional expectation with respect to what is known after the first  $n$  measurements. That is,

$$X^{KG}((\mu_1^n, \sigma_1^n), \dots, (\mu_M^n, \sigma_M^n)) \in \arg \max_{x^n \in \{1, \dots, M\}} \mathbb{E}_n \left[ (\max_{x'} \mu_{x'}^{n+1}) - (\max_{x'} \mu_{x'}^n) \right].$$

In this expression the expectation is implicitly a function of  $x^n$ , the measurement decision at time  $n$ . If the maximum is attained by more than one alternative, then we choose the one with the smallest index. As the terminal reward is given by  $\max_{x=1, \dots, M} \mu_x^N$ , this policy is like a gradient ascent algorithm on a utility surface with domain parameterized by the state of knowledge  $((\mu_1, \sigma_1), \dots, (\mu_M, \sigma_M))$ . It may also be viewed as a single-step Bayesian look-ahead policy.

In this work we continue the analysis of [16]. We demonstrate that the KG policy, introduced there as the most rudimentary of a collection of potential policies and studied for its simplicity but neglected thereafter, is actually a powerful and efficient tool for ranking and selection that should be considered for application alongside current state-of-the-art policies. As discussed in detail in section 2, a number of other sequential Bayesian look-ahead policies have been derived in recent years by solving a sequence of single-stage optimization problems just as the KG policy does, and, among these, the optimal computing budget allocation for linear loss of [18] and the LL(S) policy of [12] assume situations most similar to the one assumed here. The KG policy differs, however, from these other policies in that it solves its single-stage problem exactly, while the other policies must use approximations. We believe that solving the look-ahead problem exactly offers an advantage.

After formulating the problem in section 3 and defining the policy in section 4, we show in section 5 that the KG policy is optimal in the limit as  $N \rightarrow \infty$  in the sense that the policy incurs no opportunity cost in the limit as infinitely many measurements are allowed. Also, by its construction and as noted in [16], KG is optimal when there is only one measurement remaining. This provides optimality guarantees at two extremes:  $N$  large and  $N$  small. While many policies are asymptotically optimal without performing particularly well in the finite sample case, a policy with both kinds of optimality satisfies a more stringent performance check. For example, the equal-allocation policy is asymptotically optimal, but it is not optimal when  $N = 1$ , except in certain special cases, and performs poorly overall. In the other extreme, myopic policies for generic Markov decision processes often perform poorly because they ignore long-term rewards. By being optimal for both  $N = 1$  and  $N = \infty$ , KG avoids the problem that most afflicts other myopic policies, while retaining single-sample optimality.

In accordance with our belief that optimality at two extremes suggests good performance in the region between, we provide a bound on the policy's suboptimality for finite  $N$  in section 6. In section 7 we introduce the KG persistence property and use it to show both optimality for the case when  $M = 2$  and for a further special case in which the means and variances are ordered. Our proof that KG is optimal when

$M = 2$  confirms a claim made by Gupta and Miescke [15], who showed its optimality among deterministic policies for  $M = 2$ , but did not offer a formal proof for optimality among sequential policies. Finally, in section 8, we demonstrate in numerical experiments that KG performs competitively against the other policies discussed here. In particular, the KG policy is best according to the measure of average performance across a number of randomly generated problems, and the margin by which it outperforms the best competing policies on the most favorable problems is significantly larger than the margin by which it is outperformed on the most unfavorable problems.

**2. Literature review.** The KG policy was introduced in [16] as the simplest of a collection of look-ahead policies and was studied because its simplicity provided tractability, but this simple policy has seldom been studied or applied in the years since. Instead, a number of more complex Bayesian look-ahead policies have been introduced. A series of researchers beginning with [4] and continuing with [5], [9], [7], [8], [6] proposed and then refined a family of policies known as the optimal computing budget allocation (OCBA). These policies are derived by formulating a static optimization problem in which one chooses the measurements to maximize the probability of later correctly selecting the best alternative. OCBA policies solve this optimization problem by approximating the objective function with various bounds and relaxations, and by assuming that the predictive mean will remain unchanged by measurement. They then solve the approximate problem using gradient ascent or greedy heuristics, or with an asymptotic solution that is exact in the limit as the number of measurements in the second stage is large. All OCBA policies assume normal samples with known sampling variance, but in practice one may estimate this variance through sampling.

Any OCBA policy can be extended to multistage or fully sequential problems by performing the second stage of the two-stage policy repeatedly, at each stage calling all previous measurements the first stage and the set of measurements to be taken next the second stage. It is in this extension that one sees the similarity to the one-step Bayesian look-ahead approach of KG, which extends the one-stage policy which is optimal with one measurement remaining to a sequential policy by supposing at each point in time that the current measurement will be the last.

The OCBA policies mentioned above are designed to maximize the probability of correctly selecting the best alternative, while KG is designed to maximize the expected value of the chosen alternative. These different objective functions are also termed 0–1 loss and linear loss, respectively. They are similar but not identical, 0–1 loss perhaps being more appropriate when knowledge of the identity of the best is intrinsically valuable (and where accidentally choosing the second best is nearly as harmful as choosing the worst), and linear loss being more appropriate when value is obtained directly by implementing the chosen alternative.

Recently [18] introduced an OCBA policy designed to minimize expected linear loss. Although more similar to KG than other OCBA policies, it differs in that it uses the Bonferroni inequality to approximate the linear loss objective function for a single stage, and then solves the approximate problem using a second approximation which is accurate in the limit as the second stage is large. This is in contrast to KG, which solves the single-stage problem exactly. The OCBA policy in [18] does not assume, as the other OCBA approaches do, that the posterior predictive mean is equal to the prior predictive mean, and in this regard it is more similar to the approach of [12] discussed below.

A set of Bayesian look-ahead ranking and selection policies distinct from OCBA

were introduced in [12]. They differ by not assuming the predictive means equal through time and by allowing the sampling variance to be unknown. This causes the posterior predictive mean to be student- $t$  distributed, inducing an optimization problem governing the second-stage allocation with an objective function that is somewhat different from that in OCBA formulations. This objective function, corresponding to expected loss, is bounded below, and this lower bound is then approximately minimized. The resulting solution minimizes the lower bound exactly in the limit as sampling costs are small, or as the number of second-stage measurements is large.

Six policies are derived in total by considering both 0–1 and linear loss under three different settings: two-stage measurements with a budget constraint; two-stage without a budget constraint; and sequential. Among these policies, the one most similar to KG is LL(S), which uses linear loss in a sequential setting, allocating  $\tau$  measurements at a time.

In [10] an unknown-variance version of the KG policy was developed under the name LL<sub>1</sub>. The authors compared LL<sub>1</sub> to LL(S) using Monte Carlo simulations and found that LL<sub>1</sub> performed well for a small sampling budget, but degraded in performance as the sampling budget increased. We briefly discuss how these results relate to our own in section 8.

In addition to the Bayesian approaches to sequentially ranking and selecting normal populations described thus far, a substantial amount of progress has been made using a frequentist approach. We do not review this literature in detail, but state only that an overview may be found in [1] and that a more recent policy which performs quite well in the multistage setting with normal rewards is given in [23], [22]. Other sequential and staged policies for independent normal rewards with frequentist guarantees include those in [25], [27], [17], [26], and [24].

Sequential tests also exist which choose measurements based upon confidence bounds for the value  $Y_x$ . Such tests include interval estimation [19], which was developed for on-line bandit-style learning in a reinforcement learning setting, and upper confidence bound estimation [3], which was developed for estimating value functions for Markov decision processes. Both tests form frequentist confidence intervals for each  $Y_x$  and then select the alternative with the largest upper bound on its confidence interval for measurement. Such policies have general applicability beyond the independent normal setting discussed here.

**3. Problem formulation.** We state a formal model for our problem, including transition and objective functions. We then formulate the problem as a dynamic program.

**3.1. A formal model.** Let  $(\Omega, \mathcal{F}, \mathbb{P})$  be a probability space and let  $\{1, \dots, M\}$  be the set of alternatives. For each  $x \in \{1, \dots, M\}$  define a random variable  $Y_x$  to be the true underlying value of alternative  $x$ . We assume a Bayesian setting for the problem in which we have a multivariate normal prior predictive distribution for the random vector  $Y$ , and we further assume that the components of  $Y$  are independent under the prior and that  $\max_{x=1, \dots, M} |Y_x|$  is integrable. We will be allotted exactly  $N$  measurements, and time will be indexed using  $n$  with the first measurement decision made at time 0. At each time  $0 \leq n < N$ , we choose an alternative  $x^n$  to measure. Let  $\varepsilon^{n+1}$  be the measurement error, which we assume is normally distributed with mean 0 and a finite known variance  $(\sigma^\varepsilon)^2$  that is the same across all alternatives. We also assume that errors are independent of each other and of the random vector  $Y$ . Then define  $\hat{y}^{n+1} = Y_x + \varepsilon^{n+1}$  to be the measurement value observed. At time  $N$ , we choose an implementation decision  $x^N$  based on the measurements recorded, and we

receive an implementation reward  $\hat{y}^{N+1}$ . We assume that the reward is unbiased, so that  $\hat{y}^{N+1}$  satisfies  $\mathbb{E}[\hat{y}^{N+1}|Y, x^N] = Y_{x^N}$ . Define the filtration  $(\mathcal{F}^n)_{n=0}^N$  by letting  $\mathcal{F}^n$  be the sigma-algebra generated by  $x^0, \hat{y}^1, x^1, \dots, x^{n-1}, \hat{y}^n$ . We will use the notation  $\mathbb{E}_n[\cdot]$  to indicate  $\mathbb{E}[\cdot | \mathcal{F}^n]$ , the conditional expectation taken with respect to  $\mathcal{F}^n$ . Measurement and implementation decisions  $x^n$  are restricted to be  $\mathcal{F}^n$ -measurable so that decisions may depend only on measurements observed and decisions made in the past.

Let  $\mu^0 := \mathbb{E}[Y]$  and  $\Sigma^0 := \text{Cov}[Y]$  be the mean and covariance of the predictive distribution for  $Y$  so that  $Y$  has prior predictive distribution  $\mathcal{N}(\mu^0, \Sigma^0)$  and  $\Sigma^0$  is a diagonal covariance matrix. Note that our assumed integrability of  $\max_x |Y_x|$  is equivalent to assuming integrability of every  $Y_x$  because  $|Y_{x'}| \leq \max_x |Y_x|$  and  $\max_x |Y_x| \leq |Y_1| + \dots + |Y_M|$ , which is equivalent to assuming  $\Sigma_{xx}^0$  finite for every  $x$ .

We will use the Bayes rule to form a sequence of posterior predictive distributions for  $Y$  from this prior and the successive measurements. Let  $\mu^n := \mathbb{E}_n[Y]$  be the mean vector and  $\Sigma^n := \text{Cov}[Y | \mathcal{F}^n]$  the covariance matrix of the predictive distribution after  $n$  measurements have been made. Because the error term  $\varepsilon^{n+1}$  is independent and normally distributed, the predictive distribution for  $Y$  will remain normal with independent components, and  $\Sigma^n$  will be diagonal almost surely. We write  $(\sigma_x^n)^2$  to refer to the diagonal component  $\Sigma_{xx}^n$  of the covariance matrix. Then  $Y_x \sim \mathcal{N}(\mu_x^n, (\sigma_x^n)^2)$  conditionally on  $\mathcal{F}^n$ . We will also write  $\beta_x^n := (\sigma_x^n)^{-2}$  to refer to the precision of the predictive distribution for  $Y_x$ ,  $\beta^n := (\beta_1^n, \dots, \beta_M^n)$  to refer to the vector of precisions, and  $\beta^\varepsilon := (\sigma^\varepsilon)^{-2}$  to refer to the measurement precision. Note that  $\sigma^\varepsilon < \infty$  implies  $\beta^\varepsilon > 0$ .

Our goal will be to choose the measurement policy  $(x^0, \dots, x^{N-1})$  and implementation decision  $x^N$  that maximizes  $\mathbb{E}[Y_{x^N}]$ . The implementation decision  $x^N$  that maximizes  $\mathbb{E}_N[Y_{x^N}] = \mu_x^N$  is any element of  $\arg \max_x \mu_x^N$ , and the value achieved is  $\max_x \mu_x^N$ . Thus, letting  $\Pi$  be the set of measurement strategies  $\pi = (x^0, \dots, x^{N-1})$  adapted to the filtration, we may write our problem's objective function as

$$(1) \quad \sup_{\pi \in \Pi} \mathbb{E}^\pi \left[ \max_x \mu_x^N \right].$$

**3.2. State space and transition function.** Our state space is the space of all possible predictive distributions for  $Y$ . It can be shown by induction that these are all multivariate normal with independent components. We formally define the state space  $\mathbb{S}$  by  $\mathbb{S} := \mathbb{R}^M \times (0, \infty]^M$ , and it consists of points  $s = (\mu, \beta)$  where, for each  $x \in \{1, \dots, M\}$ ,  $\mu_x$  and  $\beta_x$  are, respectively, the mean and precision of a normal distribution. We will write  $S^n := (\mu^n, \beta^n)$  to refer to the state at time  $n$ . The notation  $S^n$  will refer to a random variable, while  $s$  will refer to a fixed point in the state space.

Fix a time  $n$ . We use the Bayes rule to update the predictive distribution of  $Y_x$  conditioned on  $\mathcal{F}^n$  to reflect the observation  $\hat{y}^{n+1} = Y_x + \varepsilon^{n+1}$ , obtaining a posterior predictive distribution conditioned on  $\mathcal{F}^{n+1}$ . Since  $\varepsilon^{n+1}$  is an independent normal random variable and the family of normal distributions is closed under sampling, the posterior predictive distribution is also normal. Thus our posterior predictive distribution for  $Y_x$  is  $\mathcal{N}(\mu_x^{n+1}, 1/\beta_x^{n+1})$ , and writing it as a function of the prior and the observation reduces to writing  $\mu^{n+1}$  and  $\beta^{n+1}$  as functions of  $\mu^n$ ,  $\beta^n$ , and  $\hat{y}^{n+1}$ . The Bayes rule tells us that these functions are

$$(2) \quad \mu_x^{n+1} = \begin{cases} [\beta_x^n \mu_x^n + \beta^\varepsilon \hat{y}^{n+1}] / \beta_x^{n+1} & \text{if } x^n = x, \\ \mu_x^n & \text{otherwise,} \end{cases}$$

$$(3) \quad \beta_x^{n+1} = \begin{cases} \beta_x^n + \beta^\epsilon & \text{if } x^n = x, \\ \beta_x^n & \text{otherwise.} \end{cases}$$

Conditionally on  $\mathcal{F}^n$ , the random variable  $\mu^{n+1}$  has a multivariate normal distribution whose mean and variance we can compute. First, we use the tower property of conditional expectation and the definitions of  $\mu^n$  and  $\mu^{n+1}$  as the predictive means of  $Y$  given  $\mathcal{F}^n$  and  $\mathcal{F}^{n+1}$ , respectively, to write  $\mathbb{E}_n[\mu^{n+1}] = \mathbb{E}_n[\mathbb{E}_{n+1}[Y]] = \mathbb{E}_n[Y] = \mu^n$ . Then we compute the variance of  $\mu^{n+1}$  componentwise. For those alternatives  $x \neq x^n$  that we do not measure, our posterior is equal to our prior and  $\mu^{n+1} = \mu^n$ . This shows that  $\text{Var}[\mu_x^{n+1} | \mathcal{F}^n] = 0$  if  $x \neq x^n$ . For  $x = x^n$  this variance is generally positive. Let us define

$$(4) \quad \tilde{\sigma}_x^n := \sqrt{\text{Var}[\mu_x^{n+1} | \mathcal{F}^n, x^n = x]},$$

so that  $(\tilde{\sigma}_x^n)^2$  is equal to  $\text{Var}[\mu_x^{n+1} | \mathcal{F}^n, x^n = x]$ . This variance may be interpreted as the variance of the *change* in the predictive mean  $\mu_x^{n+1} - \mu_x^n$  caused by a measurement as  $\text{Var}[\mu_x^{n+1} | \mathcal{F}^n, x^n = x] = \text{Var}[\mu_x^{n+1} - \mu_x^n | \mathcal{F}^n, x^n = x]$ . As shown in the following proposition, it is also equal to the reduction in predictive variance, i.e., the reduction in “uncertainty,” caused by a measurement.

**PROPOSITION 3.1.** *For every  $x = 1, \dots, M$ , we have  $(\tilde{\sigma}_x^n)^2 = (\sigma_x^n)^2 - (\sigma_x^{n+1})^2$ .*

*Proof.* We begin with the relation

$$(\mu_x^{n+1} - Y_x) = (\mu_x^{n+1} - \mu_x^n) + (\mu_x^n - Y_x).$$

Squaring both sides, taking the expectation with respect to  $\mathcal{F}^{n+1}$ , and noting that  $(\sigma_x^{n+1})^2 = \mathbb{E}_{n+1}[(Y_x - \mu_x^{n+1})^2]$  gives

$$\begin{aligned} (\sigma_x^{n+1})^2 &= \mathbb{E}_{n+1}[(\mu_x^n - Y_x)^2] \\ &\quad + 2\mathbb{E}_{n+1}[(\mu_x^n - Y_x)(\mu_x^{n+1} - \mu_x^n)] + \mathbb{E}_{n+1}[(\mu_x^{n+1} - \mu_x^n)^2] \\ &= \mathbb{E}_{n+1}[(\mu_x^n - Y_x)^2] + 2(\mu_x^n - \mu_x^{n+1})(\mu_x^{n+1} - \mu_x^n) + (\mu_x^{n+1} - \mu_x^n)^2 \\ &= \mathbb{E}_{n+1}[(\mu_x^n - Y_x)^2] - (\mu_x^{n+1} - \mu_x^n)^2. \end{aligned}$$

Since  $\sigma_x^{n+1} \in \mathcal{F}^n$ , we may take the expectation with respect to  $\mathcal{F}^n$  to get

$$\begin{aligned} (\sigma_x^{n+1})^2 &= \mathbb{E}_n[\mathbb{E}_{n+1}[(\mu_x^n - Y_x)^2]] - \mathbb{E}_n[(\mu_x^{n+1} - \mu_x^n)^2] \\ &= \mathbb{E}_n[(\mu_x^n - Y_x)^2] - \mathbb{E}_n[(\mu_x^{n+1} - \mu_x^n)^2] \\ &= (\sigma_x^n)^2 - (\tilde{\sigma}_x^n)^2. \quad \square \end{aligned}$$

To more easily compute  $\tilde{\sigma}_x^n$ , define a function  $\tilde{\sigma} : (0, \infty] \mapsto [0, \infty)$  by

$$(5) \quad \tilde{\sigma}(\beta_x) = \sqrt{(\beta_x)^{-1} - (\beta_x + \beta^\epsilon)^{-1}}.$$

Then we have that  $\tilde{\sigma}_x^n = \tilde{\sigma}(\beta_x^n)$  by Proposition 3.1 applied to the identities  $(\sigma_x^{n+1})^2 = (\beta_x^{n+1})^{-1} = (\beta_x^n + \beta^\epsilon)^{-1}$  and  $(\sigma_x^n)^2 = (\beta_x^n)^{-1}$ .

**Remark 3.1.** For  $\beta_x \in (0, \infty)$ , we have that  $(\tilde{\sigma}(\beta_x))^2 = \beta^\epsilon / [(\beta_x + \beta^\epsilon)\beta_x]$  is strictly decreasing in  $\beta_x$ , and thus so is  $\tilde{\sigma}(\beta_x)$ .

Since  $\mu_{x^n}^{n+1}$  is a normal random variable with conditional mean  $\mu_{x^n}^n$  and conditional variance  $(\tilde{\sigma}(\beta_{x^n}^n))^2$  under  $\mathcal{F}^n$ , we can write in terms of an  $\mathcal{F}^n$  adapted sequence  $Z^1, \dots, Z^N$  of standard normal random variables,

$$(6) \quad \mu^{n+1} = \mu^n + \tilde{\sigma}(\beta_{x^n}^n) Z^{n+1} e_{x^n},$$

$$(7) \quad \beta^{n+1} = \beta^n + \beta^\epsilon e_{x^n},$$

where  $e_x$  is a vector in  $\mathbb{R}^M$  with all components zero except for component  $x$ , which is equal to 1. We also define a function  $T : \mathbb{S} \times \{1, \dots, M\} \times \mathbb{R} \mapsto \mathbb{S}$  by

$$(8) \quad T((\mu, \beta), x, z) := (\mu + \tilde{\sigma}(\beta_x) z e_x, \beta + \beta^\epsilon e_x),$$

so that  $S^{n+1} = T(S^n, x^n, Z^{n+1})$ . This is our transition function.

We briefly recall and summarize the random variables which play a role in the measurement process. The underlying and unknown value of alternative  $x$  is denoted  $Y_x$  and is randomly fixed at the beginning of the measurement process. At time  $n$ ,  $\mu_x^n$  is our best estimate of  $Y_x$ , and  $\beta_x^n$  is the precision with which we make this estimate. The result of our time  $n$  measurement causes us to update this estimate to  $\mu_x^{n+1}$ , which we now know with precision  $\beta_x^{n+1}$ . This change from  $\mu_x^n$  to  $\mu_x^{n+1}$  is random, and furthermore is normally distributed with mean 0 and standard deviation  $\tilde{\sigma}(\beta_x^n)$  when we measure alternative  $x$ .

One may think of  $Y_x$  as fixed and of  $\mu_x^n$  as converging toward  $Y_x$  while  $\beta_x^n$  converges to infinity under some appropriately exploratory sampling strategy. It is also appropriate, however, to fix  $\mu_x^n$  and  $\beta_x^n$  (this is the essential content of conditioning on  $\mathcal{F}^n$ ) and think of  $Y_x$  as an unknown quantity. From this viewpoint,  $Y_x$  is random and, furthermore, is normally distributed with predictive mean  $\mu_x^n$  and precision  $\beta_x^n$ . This randomness does not imply that  $Y_x$  must be chosen again according to the predictive normal distribution, but instead the predictive normal distribution only quantifies our uncertain knowledge of the value  $Y_x$  adopted when it was first chosen.

**3.3. Dynamic program.** We apply a dynamic programming approach to our problem. In this approach, the value function is defined as the value of the optimal policy given a particular state  $S^n$  at a particular time  $n$ , and may also be determined recursively through Bellman's equation. If the value function can be computed efficiently, the optimal policy may then also be computed from it. Although in this problem the "curse of dimensionality" makes direct computation of the value function difficult even for  $M$  as small as 3, the dynamic programming principle still provides a valuable method for studying the problem.

The terminal value function  $V^N : \mathbb{S} \mapsto \mathbb{R}$  is given by (1) as

$$(9) \quad V^N(s) := \max_{x \in \{1, \dots, M\}} \mu_x \quad \text{for every } s = (\mu, \beta) \in \mathbb{S}.$$

The dynamic programming principle tells us that the value function at any other time  $0 \leq n < N$  is given recursively by

$$(10) \quad V^n(s) = \max_{x \in \{1, \dots, M\}} \mathbb{E} [V^{n+1}(T(s, x, Z^{n+1}))], \quad s \in \mathbb{S}.$$

We define the Q-factors,  $Q^n : \mathbb{S} \times \{1, \dots, M\} \mapsto \mathbb{R}$ , as

$$(11) \quad Q^n(s, x) := \mathbb{E} [V^{n+1}(T(s, x, Z^{n+1}))], \quad s \in \mathbb{S},$$

and the dynamic programming principle tells us that any policy whose measurement decisions satisfy

$$(12) \quad X^{*n}(s) \in \arg \max_{x \in \{1, \dots, M\}} Q^n(s, x), \quad s \in \mathbb{S},$$

is optimal. Finally, we define the value of a measurement policy  $\pi \in \Pi$  as

$$(13) \quad V^{n, \pi}(s) := \mathbb{E}^\pi [V^N(S^N) \mid S^n = s], \quad s \in \mathbb{S}.$$

This same object might also be thought of as the reward-to-go from state  $s$  at time  $n$  under policy  $\pi$ .

Later we will need several preliminary results concerning the benefit of measurement. First, the following proposition states that, under the optimal policy, it is always better to make a measurement than to measure nothing at all. Here, the value of measuring alternative  $x$  when  $S^n = s$  at time  $n$  is  $Q^n(s, x)$ , and the value of making no measurement is  $V^{n+1}(s)$ . The proof is left until Appendix A.

**PROPOSITION 3.2.**  $Q^n(s, x) \geq V^{n+1}(s)$  for every  $0 \leq n < N$ ,  $s \in \mathbb{S}$ , and  $x \in \{1, \dots, M\}$ .

We see as a corollary to this proposition that the optimal policy will never measure an alternative with zero variance (i.e., with infinite precision) unless all the other alternatives also have zero variance. In other words, there is no value to measuring something that we know perfectly. This is stated precisely in the following corollary.

**COROLLARY 3.1.** Let  $i, j \in \{1, \dots, M\}$ ,  $n < N$ , and  $s = (\mu, \beta) \in \mathbb{S}$ . If  $\beta_j = \infty$ , then  $Q^n(s, i) \geq Q^n(s, j)$ .

*Proof.* Since  $\tilde{\sigma}(\beta_j) = \tilde{\sigma}(\infty) = 0$  and  $\beta_j + \beta^\epsilon = \beta_j$ ,

$$T(s, j, Z^{n+1}) = (\mu + \tilde{\sigma}(\beta_j)Z^{n+1}e_j, \beta + \beta^\epsilon e_j) = (\mu, \beta) = s.$$

Then, by Proposition 3.2,

$$Q^n(s, j) = \mathbb{E} [V^{n+1}(T(s, j, Z^{n+1}))] = V^{n+1}(s) \leq Q^n(s, i). \quad \square$$

We also have a second corollary to the proposition. Proposition 3.2 allowed arbitrarily specifying the alternative to which the extra measurement would be applied, while this corollary points out that the extra measurement may be made according to the optimal policy, in which case  $Q^n(s, x)$  is equal to  $V^n(s)$ . We will use this corollary in section 6 to bound the suboptimality of KG.

**COROLLARY 3.2.**  $V^{n+1}(s) \leq V^n(s)$  for all states  $s \in \mathbb{S}$ .

*Proof.* In Proposition 3.2, take the extra measurement  $x$  to be the measurement made by the optimal policy in state  $s$ .  $\square$

Let us say that a policy  $\pi$  is *stationary* if  $X^{\pi, n}(s) = X^{\pi, 0}(s)$  for all  $s \in \mathbb{S}$  and all  $n = 1, \dots, N - 1$ . In this case we denote  $X^{\pi, n}$  simply by  $X^\pi$ . Corollary 3.2 showed that the value of the optimal policy increases as more measurements are allowed, and we will see in Theorem 3.1 below that this monotonicity also holds for stationary policies.

**THEOREM 3.1.**  $V^{\pi, n}(s) \geq V^{\pi, n+1}(s)$  for every stationary policy  $\pi$  and every state  $s \in \mathbb{S}$ .

The proof is left until Appendix A. We will need this theorem when showing both asymptotic optimality and bounded suboptimality of KG.

**4. The knowledge-gradient policy.** In our problem, the entire reward is received after the final measurement. We may formulate an equivalent problem in which the reward is given in pieces over time, but the total reward given is identical. We define the KG policy as that policy which maximizes the single period reward under this alternate formulation. We will see later that this KG policy is optimal in several cases and has bounded suboptimality in all others. This policy was first introduced in [16] under the name of the  $(R_1, \dots, R_1)$  policy.

**4.1. Definition.** The problem given by (1) has a terminal reward  $V^N(S^N) := \max_x \mu_x^N$ , but no rewards at any other times. We restructure these rewards by writing  $V^N(S^N)$  as a telescoping sequence,

$$\max_x \mu_x^N = [V^N(S^N) - V^N(S^{N-1})] + \dots + [V^N(S^{n+1}) - V^N(S^n)] + V^N(S^n).$$

Thus, the problem that provides single period reward  $V^N(S^n)$  at time  $n$  and  $V^N(S^k) - V^N(S^{k-1})$  at times  $k = n + 1, \dots, N$  is equivalent to problem (1) because the total reward provided is the same in each case. The KG policy  $\pi^{KG}$  is defined as the policy that chooses its measurements to maximize the expectation of the single period reward provided under this alternate formulation,  $\mathbb{E}_n [V^N(T(S^n, x, Z^{n+1})) - V^N(S^n)]$ . Since the  $(Z^n)_{n=1}^N$  are independent and identically distributed normal random variables, we may take  $Z$  to be a generic standard normal random variable and write the decision function of the KG policy  $X^{KG} : \mathbb{S} \mapsto \{1, \dots, M\}$  as

$$(14) \quad X^{KG}(s) \in \arg \max_{x \in \{1, \dots, M\}} \mathbb{E} [V^N(T(s, x, Z)) - V^N(s)] \quad \text{for every } s \in \mathbb{S},$$

where ties in the  $\arg \max$  are broken by choosing the alternative with the smaller index. Note that KG is stationary in time so we drop the time index  $n$  when we write  $X^{KG}$ . Since  $V^N(s)$  does not depend on  $x$ , the KG policy may be rewritten as

$$(15) \quad X^{KG}(s) \in \arg \max_{x \in \{1, \dots, M\}} \mathbb{E} [V^N(T(s, x, Z))] = \arg \max_{x \in \{1, \dots, M\}} Q^{N-1}(s, x).$$

*Remark 4.1.* As noted in [16], KG is optimal by construction when  $N = 1$ . This is because  $V^{N-1} = V^{KG, N-1}$  by (12) and (15), where  $V^{KG, n}$  denotes the value of the KG policy at time  $n$  and is defined according to (13) with the policy  $\pi$  fixed to KG.

If we think of  $V^N(\cdot)$  as a utility function, or as a measure of the amount of “knowledge” contained in a state, we see from (14) that the KG policy chooses its decisions in the direction of steepest expected ascent of this measure. This is the reason behind the name *knowledge-gradient policy*. One may also view it as a single-step look-ahead policy.

**4.2. Computation.** It was already known in [16] that an exact and computationally tractable expression exists for  $X^{KG}$ . We present it here.

For each  $x \in \{1, \dots, M\}$  define a function  $\zeta_x : \mathbb{S} \mapsto [0, \infty)$  by

$$(16) \quad \zeta_x(s) := - \left| \frac{\mu_x - \max_{x' \neq x} \mu_{x'}}{\tilde{\sigma}(\beta_x)} \right|.$$

Except for the sign,  $\zeta_x(S^n)$  is the minimum distance, in terms of the number of standard deviations  $\tilde{\sigma}(\beta_x^n)$ , that a measurement of alternative  $x$  must alter  $\mu_x^{n+1}$  from its premeasurement value of  $\mu_x^n$  to make  $\arg \max_{x'} \mu_{x'}^{n+1} \neq \arg \max_{x'} \mu_{x'}^n$ —that is, to

change the identity of the alternative with the largest conditional expected value. In addition, define the function  $f : \mathbb{R} \mapsto \mathbb{R}$  as

$$(17) \quad f(z) := z\Phi(z) + \varphi(z),$$

where  $\Phi(z)$  is the normal cumulative distribution function and  $\varphi(z)$  is the normal probability density function. Then the following theorem provides an efficient way to compute KG's decisions. The proof may be found in Appendix A.

**THEOREM 4.1.** *For every  $s = (\mu, \beta) \in \mathbb{S}$ , we have*

$$(18) \quad Q^{N-1}(s, x) = \max_{x'} \mu_{x'} + \tilde{\sigma}(\beta_x) f(\zeta_x(s)),$$

$$(19) \quad X^{KG}(s) \in \arg \max_{x \in \{1, \dots, M\}} \tilde{\sigma}(\beta_x) f(\zeta_x(s))$$

with ties broken by choosing the alternative with the smallest index.

The term  $Q^{N-1}(s, x) - \max_{x'} \mu_{x'} = \tilde{\sigma}(\beta_x) f(\zeta_x(s))$  is in some sense the expected value of the information that would be obtained by measuring alternative  $x$  and is sometimes called the “expected value of information,” or EVI, e.g., in [12] and [10].

Computation of the KG policy via (19) scales linearly with the number of alternatives  $M$ . This compares well with other policies that might be used on this problem. To compute the KG policy at time  $n$ , we must first find the largest and second largest  $\mu_x^n$  across all alternatives  $x$ , which will be used to compute  $\zeta_x^n := \zeta_x(S^n)$ . This may be implemented either by an initial pass through the alternatives at each time period, or by storing and updating the two values across time periods. Once we have the largest and second largest  $\mu_x^n$ , we iterate through the alternatives, calculating  $\tilde{\sigma}(\beta_x^n) f(\zeta_x^n)$  for each one and returning the alternative with the largest value for this expression. This iteration may be streamlined by recomputing the expression only for those alternatives that changed  $\zeta_x^n$  or  $\beta_x^n$  from the previous iteration.

The following remark, which is an easily obtained consequence of Theorems 1 and 2 in [16] and may also be obtained directly from (18), may also be used to accelerate the computation of the KG policy by eliminating some alternatives from consideration. It is also useful for proving later results. It states that if an alternative dominates another in both mean and variance, then of the two, KG prefers the dominating alternative.

**Remark 4.2.** For every  $s = (\mu, \beta) \in \mathbb{S}$  such that  $\mu_j \geq \mu_i$  and  $\beta_j \leq \beta_i$  we have  $Q^{N-1}(s, j) \geq Q^{N-1}(s, i)$ .

Finally, during computation, we may also use the following remark to eliminate some alternatives from consideration, again improving the speed with which we may compute the KG policy.

**Remark 4.3.** Take  $n = N - 1$  in Corollary 3.1. If  $\beta_j = \infty$  for some  $j \in \{1, \dots, M\}$  (that is, if the predictive distribution  $\mathcal{N}(\mu_j, 1/\beta_j)$  for  $Y_j$  is a point mass), then  $Q^{N-1}(S, i) \geq Q^{N-1}(S, j)$  for every  $i \in \{1, \dots, M\}$ .

Thus, KG will never measure an alternative with zero variance unless every alternative has zero variance. Corollary 3.1 shows that the optimal policy shares this behavior of preferring not to measure any alternative whose true value is known perfectly.

**4.3. Behavior.** KG balances two considerations when it chooses its measurement decisions. First, it prefers to measure those alternatives about which comparatively little is known. These alternatives  $x$  are the ones whose predictive distributions

have large variance  $(\sigma_x^n)^2$  or, equivalently, have small precision  $\beta_x^n$ . Thus, we have that if KG prefers to measure some alternative  $i$  over another alternative  $j$ , then it would still prefer to measure alternative  $i$  over  $j$  if the predictive variance of  $i$  were increased.

Second, KG prefers to measure alternatives  $x$  with  $|\mu_x^n - \max_{x' \neq x} \mu_{x'}^n|$  close to 0. We call  $-|\mu_x^n - \max_{x' \neq x} \mu_{x'}^n|$  the *unnormalized influence* and  $\zeta_x^n = -|\mu_x^n - \max_{x' \neq x} \mu_{x'}^n|/\tilde{\sigma}(\beta_x^n)$  the *normalized influence*, or simply the *influence*, of alternative  $x$ , where  $\tilde{\sigma}(\beta_x^n)$  is understood as a normalization term because predictions for different alternatives have different variances and comparison does not make sense unless we standardize these differences. Measurements of alternatives with large influence are more likely to cause a change in the optimal implementation decision; that is, to cause  $\arg \max_{x'} \mu_{x'}^n \neq \arg \max_{x'} \mu_{x'}^{n+1}$ . KG's preference for small predictive precision and large influence are formalized in Propositions 4.1 and 4.2, but first we calculate the derivative of  $f$ , as defined in (17), in a lemma.

LEMMA 4.1. *We have  $f'(z) = \Phi(z) \geq 0$  for every  $z \in \mathbb{R}$ .*

*Proof.* First note that  $\frac{d}{dz} e^{-z^2/2} = -ze^{-z^2/2}$ , showing that  $\varphi'(z) = -z\varphi(z)$ . From this we see that  $f$  has nonnegative derivative  $f'(z) = \Phi(z) + z\varphi(z) - z\varphi(z) = \Phi(z)$ , which completes the proof.  $\square$

PROPOSITION 4.1. *Let states  $s = (\mu, \beta) \in \mathbb{S}$ ,  $s' = (\mu', \beta') \in \mathbb{S}$  and alternatives  $i, j \in \{1, \dots, M\}$  satisfy the following criteria:  $\zeta_i(s') > \zeta_i(s)$ ,  $\zeta_j(s') = \zeta_j(s)$ ,  $\beta'_i < \beta_i$ , and  $\beta'_j = \beta_j$ . If  $Q^{N-1}(s, i) > Q^{N-1}(s, j)$ , then  $Q^{N-1}(s', i) > Q^{N-1}(s', j)$ .*

*Proof.* First,  $\tilde{\sigma}(\beta'_i) \geq \tilde{\sigma}(\beta_i)$  by Remark 3.1 and  $f(\zeta_i(s')) \geq f(\zeta_i(s))$  by Lemma 4.1. By (18),  $Q^{N-1}(s', i) > Q^{N-1}(s, i)$ . Also, the equalities  $\tilde{\sigma}(\beta'_j) = \tilde{\sigma}(\beta_j)$  and  $f(\zeta_j(s')) = f(\zeta_j(s))$  imply through (18) that  $Q^{N-1}(s', j) = Q^{N-1}(s, j)$ . Thus, if  $Q^{N-1}(s, i) > Q^{N-1}(s, j)$ , then  $Q^{N-1}(s', i) \geq Q^{N-1}(s, i) > Q^{N-1}(s, j) = Q^{N-1}(s', j)$ .  $\square$

PROPOSITION 4.2. *If alternative  $i$  and state  $s = (\mu, \beta)$  are such that  $\zeta_i(s) \geq \zeta_j(s)$  and  $\beta_i < \beta_j$  for every alternative  $j \neq i$ , then  $X^{KG}(s) = i$ .*

*Proof.* Let  $j$  be an alternative different from  $i$ . Then  $\tilde{\sigma}(\beta_i) > \tilde{\sigma}(\beta_j)$  by Remark 3.1 and  $f(\zeta_i(s)) \geq f(\zeta_j(s))$  by Lemma 4.1. This implies that  $Q^{N-1}(s, i) > Q^{N-1}(s, j)$  by Proposition 4.1. Since this is true for all  $j \neq i$ , we have that  $i = \arg \max_j Q^{N-1}(s, j) = X^{KG}(s)$  where the arg max is unique.  $\square$

It is also interesting to note that increasing the predictive mean of a single alternative usually, but not universally, encourages KG to measure it. Thus, having a large predictive mean is similar, but not identical, to having a large unnormalized influence. We formalize this in the following proposition.

PROPOSITION 4.3. *If KG prefers alternative  $i$  in state  $(\mu, \beta)$ , then it also prefers the same alternative  $i$  in state  $(\mu + a e_i, \beta)$  for all positive real numbers  $a$  such that  $\mu_i + a \leq \max_x \mu_x$ , i.e., for  $0 \leq a \leq -\mu_i + \max_x \mu_x$ .*

We leave the proof until Appendix A.

**5. Asymptotic optimality.** In this section we show that the KG policy is asymptotically optimal in the limit as the number of measurements  $N$  grows large. This means that, given the opportunity to measure infinitely often, KG will discover which alternative is best. In some sense, this is a convergence result because it shows that the policy's estimate of which alternative is best will converge to the alternative that is truly best.

The KG policy is not alone in possessing this property. Indeed, the following well-known policies are all asymptotically optimal: the equal-allocation policy which distributes its measurements in a round-robin fashion equally among the alternatives; the uniform exploration policy which randomly chooses its measurements with equal

probability across the alternatives; and the Boltzmann exploration policy discussed in section 8 which randomly chooses its measurements according to exponentially weighted probabilities.

These policies differ from KG in that they explore for exploration's sake and for the long-term benefit it provides, while KG is purely myopic. Moreover, we argue that KG's asymptotic optimality is notable exactly because the policy is entirely myopic, maximizing its single-period expected reward without regard for the long-term. This is not generally the case with myopic policies for other problems. That a myopic policy is also optimal in the long-term shows that this ranking and selection problem has a special structure, and it foreshadows what is further suggested by our numerical experiments: that this myopic policy, KG, performs quite well in many cases which are neither myopic nor asymptotic.

In addition, one policy, interval estimation, performs very well in our numerical experiments but is not asymptotically optimal as in some cases it "sticks," measuring one alternative only and obtaining its true value perfectly without learning about the others [19]. Indeed, one can construct cases in which this policy's performance is arbitrarily bad compared to any asymptotically optimal policy. Although a policy's asymptotic optimality is not evidence of quality by itself, its absence should raise concern among those who might use a policy lacking it. Finally, a natural question is whether other policies, such as those in the OCBA family and those proposed in [12], are asymptotically optimal. This question is currently open as these other policies are more complex and require more care during analysis than does KG. Nevertheless, we believe that the proof techniques applied here may be extended to show that many other Bayesian look-ahead policies are also asymptotically optimal.

To show that KG is asymptotically optimal, we begin by showing in Proposition 5.1 that the asymptotic value of a policy is well defined and bounded above by the value  $\mathbb{E} \max_x Y_x$  of learning every alternative exactly. Then we show in Proposition 5.2 that this value is achieved by any stationary policy that measures every alternative infinitely often. Thus, any stationary policy that samples every alternative infinitely often is asymptotically optimal. Finally, we show in Theorem 5.1 that KG is asymptotically optimal. The proof centers on the notion that, as the number of times an alternative is measured increases, the variance of the value of that alternative shrinks toward 0. Eventually, that variance will be so low that KG will prefer to measure another alternative. This argument is used to show that KG samples every alternative infinitely often and thus is asymptotically optimal.

Since we will be varying the number  $N$  of measurements allowed, we use the notation  $V^0(\cdot; N)$  to denote the value function at time 0 when the problem's terminal time is  $N$ . We then define the *asymptotic value function*  $V(\cdot; \infty)$  by the limit  $V(s; \infty) := \lim_{N \rightarrow \infty} V^0(s; N)$  for  $s \in \mathbb{S}$ . Similarly, we denote the *asymptotic value function for stationary policy*  $\pi$  by  $V^\pi(\cdot; \infty)$  and define it by  $V^\pi(s; \infty) := \lim_{N \rightarrow \infty} V^{\pi,0}(s; N)$  for  $s \in \mathbb{S}$ . Proposition 5.1 shows that both limits exist.

If  $V^\pi(s; \infty)$  is equal to  $V(s; \infty)$  for every  $s \in \mathbb{S}$ , then  $\pi$  is said to be *asymptotically optimal*. In particular, if a stationary policy  $\pi$  achieves the upper bound  $U(\cdot)$  on  $V(\cdot; \infty)$  shown in Proposition 5.1, then  $\pi$  must be asymptotically optimal. We will use this later to show that KG is asymptotically optimal. The proof of Proposition 5.1 is found in Appendix A.

**PROPOSITION 5.1.** *Let  $s \in \mathbb{S}$ . Then the limit  $V(s; \infty)$  exists and is bounded above by*

$$(20) \quad U(s) := \mathbb{E} \left[ \max_x Y_x \mid S^0 = s \right] < \infty,$$

where we recall that  $\{Y_x\}_{x \in \{1, \dots, M\}}$  are independent and  $Y_x \sim \mathcal{N}(\mu_x^0, (\beta_x^0)^{-1})$ . Furthermore,  $V^\pi(s; \infty)$  exists and is finite for every stationary policy  $\pi$ .

For any finite terminal time  $N$  we define the random variable  $\eta_x^N$  as the number of times that alternative  $x$  is measured up to but not including the terminal time  $N$ . We also define  $\eta_x^\infty$  as the limit of the  $\eta_x^N$ ; namely,

$$\eta_x^N := \sum_{k=1}^N 1_{\{x^k=x\}} \quad \text{and} \quad \eta_x^\infty := \lim_{N \rightarrow \infty} \eta_x^N.$$

The limit  $\eta_x^\infty$  exists because  $\eta_x^N$  is nondecreasing in  $N$  a.s. Note that we allow the limit  $\eta_x^\infty$  to be infinite.

Proposition 5.2 formalizes the idea that if we measure every alternative infinitely often, then we eventually learn the true value of every alternative. This implies asymptotic optimality. We then use Proposition 5.2 in the proof of Theorem 5.1 to show that KG is asymptotically optimal. The proofs for both Theorem 5.1 and Proposition 5.2 are found in Appendix A.

**PROPOSITION 5.2.** *If  $\pi$  is a stationary policy under which  $\eta_x^\infty = \infty$  a.s. for every  $x$ , then  $\pi$  is asymptotically optimal.*

**THEOREM 5.1.** *The KG policy is asymptotically optimal and has value  $U(S^0)$ .*

**6. Bound on suboptimality.** We have shown that KG is optimal when  $N = 1$  and in the limit as  $N \rightarrow \infty$ . In this section we address the range of  $N$  between these extremes by bounding KG's suboptimality in this region. This bound will be tight for small  $N$  and will grow as  $N$  increases.

We begin with a theorem that implies our bound as a corollary. This theorem shows that there is a limit on how much we may learn through any single measurement.

**THEOREM 6.1.** *Let  $s = (\mu, \beta) \in \mathbb{S}$  and  $c = (2\pi)^{-1/2} \max_x \tilde{\sigma}(\beta_x)$ . Then*

$$V^n(s) \leq V^{N-1}(s) + c(N - n - 1).$$

The proof is found in Appendix A. We combine this result with Theorem 3.1 to bound KG's suboptimality. Here,  $V^{KG,n}(s)$  is the value of the KG policy at time  $n$  when  $S^n = s$ .

**COROLLARY 6.1.** *Let  $s = (\mu, \beta) \in \mathbb{S}$  and  $c = (2\pi)^{-1/2} \max_x \tilde{\sigma}(\beta_x)$ . Then*

$$V^n(s) - V^{KG,n}(s) \leq c(N - n - 1).$$

*Proof.* By Remark 4.1, we have  $V^{N-1}(s) = V^{KG,N-1}(s)$ . From Theorem 3.1 we have  $V^{KG,N-1}(s) \leq V^{KG,n}(s)$ . Substituting the inequality  $V^{N-1}(s) \leq V^{KG,n}(s)$  into Theorem 6.1 shows the corollary.  $\square$

**7. Optimality for finite horizon special cases.** We saw in Remark 4.1 that KG is optimal when  $N = 1$ . We will show that KG is optimal in two other special cases: first, when there are only two alternatives to measure; second, when the measurements are free from noise,  $(\sigma^\varepsilon)^2 = 0$ , and when the parameters of the time 0 prior can be ordered by  $\mu_1^0 \geq \mu_2^0 \geq \dots \geq \mu_M^0$  and  $\sigma_{11}^0 \geq \sigma_{22}^0 \geq \dots \geq \sigma_{MM}^0$ . Before showing optimality under these conditions, we first define and discuss a property called the KG persistence property. This property is useful because it provides a sufficient condition for optimality.

**7.1. Persistence of the knowledge-gradient policy.** Proofs of the optimality of the KG policy in these special cases is based on the KG persistence property. A problem setting is said to have the KG persistence property if, operating the problem under some policy other than KG, an alternative preferred by KG will remain preferred until the alternative is measured. Below, in Theorem 7.1, we show that if a problem setting has the KG persistence property, then KG is optimal in that problem setting. Before stating this theorem, we formally define the KG persistence property and an associated term, “covering of the future.”

**DEFINITION 7.1.** *A sequence of subsets of  $\mathbb{S}$ ,  $\{\mathbb{S}^n\}_{n=k}^N$ , is called a covering of the future from  $k$  if  $T(s, x, Z^{n+1}) \in \mathbb{S}^{n+1}$  a.s. for every  $s \in \mathbb{S}^n$ ,  $x \in \{1, \dots, M\}$ , and  $n \in \{k, \dots, N-1\}$ .*

**DEFINITION 7.2.** *We say that the KG persistence property holds on a covering  $\{\mathbb{S}^n\}_{n=k}^N$  of the future from  $k$  if  $X^{KG}(T(s, x, Z^{n+1})) = X^{KG}(s)$  a.s. for every  $s \in \mathbb{S}^n$ ,  $x \neq X^{KG}(s)$ , and  $n \in \{k, \dots, N-1\}$ .*

This KG persistence property gives us a sufficient condition for the optimality of the KG policy, as stated in the following theorem.

**THEOREM 7.1.** *If the KG persistence property holds on a covering  $\{\mathbb{S}^n\}_{n=k}^N$  of the future from  $k$  for some  $k \in \{0 \dots N-1\}$ , then  $V^{KG,k}(s) = V^k(s)$  for every  $s \in \mathbb{S}^k$ .*

We leave the proof until Appendix A, but we give a sketch here. Consider a time  $n < N-1$  and the alternative that KG prefers. If the problem setting has the KG persistence property, then, even if we do not measure that alternative now, KG will continue to prefer it until we reach the final measurement  $N-1$ . At this measurement, KG is optimal by construction and so it is now provably optimal to measure this persistent alternative. Thus, there exists an optimal policy that measures the persistent alternative a.s., and by the temporal symmetry in the model, there exists an optimal policy that measures the persistent alternative immediately at time  $n$ . This argument is used with induction to show that there exists an optimal policy making the same measurements as KG.

**7.2. Optimality for two alternatives.** We use the KG persistence principle to show that KG is optimal when there are exactly two alternatives to consider, i.e.,  $M = 2$ . In this case we will see that the optimal policy is one that, at each decision point, measures the alternative with the largest variance. This policy is actually deterministic, and it was shown in [15] that this policy is optimal among the class of deterministic policies. Theorem 7.2 extends this result to show that this same policy is also optimal among the class of fully sequential policies. It is not generally true that the best deterministic policy is also as good as or better than every sequential policy, but Theorem 7.2 shows that this is exactly the case for this particular problem.

We will see that the policy of measuring the alternative with the largest variance is optimal because knowing the correct implementation decision is the same as knowing the true sign of  $Y_1 - Y_2$ . Each measurement measures only one of  $Y_1$  or  $Y_2$ , and an equal reduction in variance for  $Y_1$  or  $Y_2$  contributes equally to the overall reduction in variance of  $Y_1 - Y_2$ , regardless of which expected value is bigger. Thus, the best way to learn about the difference between points  $Y_1 - Y_2$  is to measure that point about which the least is known.

To show that KG is optimal when  $M = 2$ , we need to show that KG persistence holds when  $M = 2$  and then refer to Theorem 7.1.

**LEMMA 7.1.** *If  $M = 2$ , then  $X^{KG}(s) \in \arg \min_x \beta_x$  for each  $s = (\mu, \beta) \in \mathbb{S}$  with ties broken by choosing the alternative with the smaller index.*

*Proof.* By (19) from Theorem 4.1, it is enough to show equality between the sets

$\arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(s))$  and  $\arg \min_x \beta_x$ . When  $M = 2$ ,  $\zeta_x(s) = -|\mu_1 - \mu_2|/\tilde{\sigma}(\beta_x)$ , so  $\arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(s)) = \arg \max_x \tilde{\sigma}(\beta_x) f(-|\mu_1 - \mu_2|/\tilde{\sigma}(\beta_x))$ . The function  $\tilde{\sigma}$  is strictly decreasing by Remark 3.1. This fact will be used on its own, and it also implies that  $-|\mu_1 - \mu_2|/\tilde{\sigma}(\beta_x)$  is a decreasing function of  $\beta_x$ . The function  $f$  is nondecreasing by Lemma 4.1, so the function  $\beta_x \mapsto f(-|\mu_1 - \mu_2|/\tilde{\sigma}(\beta_x))$  is the composition of a nondecreasing function with a nonincreasing function and is thus itself nonincreasing. Thus, the function  $\beta_x \mapsto \tilde{\sigma}(\beta_x) f(-|\mu_1 - \mu_2|/\tilde{\sigma}(\beta_x))$  is the product of a strictly decreasing function with a nonincreasing function and is thus itself strictly decreasing. This implies that  $\arg \max_x \tilde{\sigma}(\beta_x) f(-|\mu_1 - \mu_2|/\tilde{\sigma}(\beta_x)) = \arg \min_x \beta_x$ .  $\square$

**THEOREM 7.2.** *If  $M = 2$ , then KG is optimal.*

*Proof.* Let  $\mathbb{S}^n = \mathbb{S}$  for all  $n$ , and note that  $\{\mathbb{S}^n\}_{n=0}^N$  is a covering of the future from 0. We will show that the KG persistence property holds on  $\{\mathbb{S}^n\}_{n=0}^N$ .

Let  $n \in \{0, \dots, N-1\}$  and  $s = (\mu, \beta) \in \mathbb{S}$ . First consider the case when  $\beta_1 \leq \beta_2$ . By Lemma 7.1,  $X^{KG}(s) = 1$ . The precision component of  $T(s, 2, Z^{n+1})$  is  $(\beta_1, \beta_2 + \beta^\epsilon)$ . Since  $\beta_1 \leq \beta_2 \leq \beta_2 + \beta^\epsilon$  and by Lemma 7.1,  $X^{KG}(T(s, 2, Z^{n+1})) = 1$  a.s.

Now consider the case when  $\beta_1 > \beta_2$ . By Lemma 7.1,  $X^{KG}(s) = 2$ . The precision component of  $T(s, 1, Z^{n+1})$  is  $(\beta_1 + \beta^\epsilon, \beta_2)$ . Since  $\beta_1 + \beta^\epsilon \geq \beta_1 > \beta_2$  and by Lemma 7.1,  $X^{KG}(T(s, 1, Z^{n+1})) = 2$  a.s.

In both cases,  $x \neq X^{KG}(s)$  implies  $X^{KG}(T(s, x, Z^{n+1})) = X^{KG}(s)$  a.s., so KG persistence holds. Then, by Theorem 7.1,  $V^{KG,0}(s) = V^0(s)$  for every  $s \in \mathbb{S}$ , and KG is optimal.  $\square$

This theorem is founded on the intuition that the policy that learns the most is also the one that changes our beliefs the most. This has a comparison in other measurement problems—for example, the problem in which we have a quadratic function with known second derivative and we measure the first derivative to find the maximum of the function. In this case the optimal policy is also the one that maximizes the variance of the change in our final belief with respect to our current belief. In both cases we measure the change between our current and final beliefs by taking the variance. In other problems the variance is likely not the right measure of change, but the same intuition would apply with some other measure of change.

**7.3. Optimality when the state space is ordered.** The KG policy is also optimal when there is no measurement noise, i.e.,  $(\sigma^\epsilon)^2 = 0$ , and when the components of  $S^0$  may be ordered in such a way that we have  $\mu_1^0 \geq \dots \geq \mu_M^0$  together with  $\beta_1^0 \leq \dots \leq \beta_M^0$ . In other words, the optimality result requires that we may order the alternatives with increasing means while simultaneously ordering them with increasing variances. With the assumption of no measurement noise, the problem is interesting only if the number of alternatives  $M$  is larger than the measurement budget  $N$ .

We present this optimality result formally in the theorem below, but first, as these conditions are particularly restrictive, we motivate them with an example. Consider a problem in marketing research in which we have a collection of potential advertising campaigns, some of which are more ambitious than others. The predictive distributions for the value obtained from the ambitious campaigns have larger mean but larger variance as well. We may test a few of these campaigns in test markets before committing to one of them. We will assume that the number of test markets allowed is smaller than the number of potential campaigns. If we are willing to make two additional assumptions—that loss is linear and that test markets give us perfect knowledge of the campaign's true value—then the example meets the conditions of the theorem. These additional assumptions would not be met perfectly satisfied in reality, but it is not too unreasonable to imagine situations in which loss would be

approximately linear, and in which the knowledge obtained from a test market would be large enough that one would not wish to perform a second test market. With this marketing application as an illustrative example, we expect that this sort of ordering of means and variances may also occur in financial applications, or wherever greater expected reward brings greater risk along with it.

**THEOREM 7.3.** *If  $(\sigma^\varepsilon)^2 = 0$  and  $s = (\mu, \beta) \in \mathbb{S}$  is such that the implication*

$$(\beta_i \neq \infty \text{ and } \beta_j \neq \infty \text{ and } \beta_i < \beta_j) \implies \mu_i \geq \mu_j$$

*holds for every  $i, j \in \{1, \dots, M\}$ , then  $V^0(s) = V^{KG,0}(s)$ .*

The full proof can be found in Appendix A, but the essential idea is that when this ordering holds, the tension between exploration and exploitation is gone, and KG will simply choose that alternative with the largest variance. This is because the alternative with the largest variance is also the alternative with the largest mean among those which are not yet perfectly known. This ordering by variances is persistent, as it was in the  $M = 2$  case. Thus, the KG persistence property holds and KG is optimal.

**8. Computational experiments.** We compared KG against other sampling policies using Monte Carlo simulation on 100 randomly generated problems and found that it performs competitively. In particular, KG performed best when measured by average performance across all the problems, and the margin by which it outperformed the best competing policies in favorable cases was significantly larger than the margin by which it was outperformed in unfavorable cases. Its comparative performance was particularly good when the measurement budget was not much larger than the number of alternatives to measure, and we would argue that performing well in these cases is particularly important.

The space of problems is parameterized by a number of measurements  $N$ , a number of alternatives  $M$ , an initial precision  $\beta^0 \in (0, \infty]^M$ , an initial mean  $\mu^0 \in \mathbb{R}^M$ , and a measurement noise  $(\sigma^\varepsilon)^2 \in [0, \infty)$ . We chose a collection of 100 problems randomly generated within this space according to the following distribution:  $M$  was integer-valued between 2 and 100.  $N$  was chosen by first choosing  $M$  and then choosing a ratio  $N/M$  uniformly from the set  $\{1, 3, 10\}$ . Each  $\mu_x$  was uniformly distributed in the interval  $[-1, 1]$ , and each  $\beta_x$  was independently chosen as 1 with probability .9 and 1000 with probability .1. The noise variance  $(\sigma^\varepsilon)^2$  was set to 1 in all cases.

For each problem, we performed simulations in which true function values were generated independently according to the prior. Rather than collecting the value obtained by the policy in each simulation, we collected the opportunity cost realized, where the opportunity cost is the difference in true value between the best option and the option chosen by the policy. The difference in expected opportunity cost is the same as the difference in policy value, but samples of opportunity cost have less error, and this allowed us to obtain accurate estimates with fewer simulations. We ran  $10^5$  simulations for each policy.

We compared KG against seven other policies: the OCBA for linear loss of [18], the LL(S) policy of [12], the interval estimation (IE) policy of [19], Boltzmann exploration (see, e.g., [28]), equal allocation, and exploitation. Several of these policies required choosing one or more parameters, which we did by simulating several choices on all 100 problems and taking the parameters whose resulting opportunity cost was smallest when summed over all 100 problems. We briefly describe each policy and its tuning.

- **OCBA.** This policy has three parameters: the number of alternatives to allocate to in each stage,  $m$ ; the number of measurements to allocate to each

alternative in the first stage,  $n_0$ ; and the number of measurements per chosen alternative to allocate in each stage,  $\tau$ . We set  $n_0$  to 0 because our prior is informative and thus may be thought of as already providing the results of a first stage. To calibrate  $m$  and  $\tau$ , we ran initial experiments with 5000 samples each with settings of  $m = 1, \tau \in \{1, 2, 5, 10\}$ , and also with  $\tau = 1, m \in \{2, 5, 10\}$ . We found that  $m = 1, \tau = 1$  performed best.

- *LL(S) for known variance.* The LL(S) policy allows normal measurement errors with *unknown* variance and uses a normal-gamma prior for the unknown mean and measurement precision. We adapted this policy to the known-variance case by taking the limit as the gamma prior on the precision becomes a point mass at the known variance. Details can be found in Appendix B. The policy has two parameters,  $n_0$  and  $\tau$ . We set  $n_0$  to 0 as we did with OCBA. We tested the values 1, 2, 3, 4, 5, 10 for  $\tau$  on our collection of 100 problems with 5000 samples for each problem and found that  $\tau = 1$  worked best for every problem. This is the value we used in comparison with KG.
- *Interval estimation.* IE is parameterized by  $z_{\alpha/2}$ . As [19] suggests that values of 2, 2.5, or 3 often work best for  $z_{\alpha/2}$ , we tested values between 2 and 4 in increments of .1 and found that  $z_{\alpha/2} = 3.1$  worked best. Although we found IE worked very well when properly tuned, we also found it to be very sensitive to the choice of tuning parameter.
- *Boltzmann exploration.* Boltzmann exploration chooses its measurements by  $\mathbb{P}\{x^n = x \mid \mathcal{F}^n\} = \frac{\exp(\mu_x^n/T^n)}{\sum_{x'=1}^M \exp(\mu_{x'}^n/T^n)}$ , where the policy is parameterized by a decreasing sequence of “temperature” coefficients  $(T^n)_{n=0}^{N-1}$ . We tuned this temperature sequence within the set of exponentially decreasing sequences defined by  $T^{n+1} = \gamma T^n$  for some constant  $\gamma \in (0, 1]$ . The set of all such sequences is parameterized by  $\gamma$  and  $T^N$ . We tested  $\gamma \in \{.1, .5, .8, .9, 1\}$  with  $T^N \in \{.1, 1, 10\}$  and found that  $\gamma = 1$  performed best. We then tested the set of possible  $T^N$  between .1 and 10 with  $\gamma$  fixed to 1 and found that  $T^N = .55$  performed best.
- *Equal allocation.* The equal-allocation policy is  $x^n \in \arg \min_x \beta_x^n$ , since we think of the prior as providing the results of some previous first-stage measurements, and we interpret  $\beta_x^n/\beta^e$  as the number of measurements of alternative  $x$  taken by time  $n$ . It requires no tuning.
- *Exploitation.* The exploitation policy is  $x^n \in \arg \max_x \mu_x$ . It requires no tuning.

The work required to tune other policies highlights one practical advantage of KG policy: it requires no tuning.

**8.1. Results.** On each of the 100 randomly generated problems, we took  $10^5$  samples of opportunity cost from every policy. The distribution of opportunity cost is not normal, as it is positive a.s. and often equal to 0. We averaged groups of 500 samples to obtain approximately normal samples from which we estimated expected opportunity cost as well as standard errors on these estimates. The difference in value between KG and any other policy on any particular problem was then estimated as the difference in sampled opportunity costs, with standard error equal to the square root of the sum of the squared standard errors. The resulting standard errors of the difference, reporting maximum and averaged values across the 100 problems, were .0018 and .0007 for IE; .0018 and .0007 for OCBA; .0019 and .0007 for LL(S); .0020 and .0009 for Boltzmann exploration; .0024 and .0013 for equal allocation; and .0026 and .0021 for exploitation.

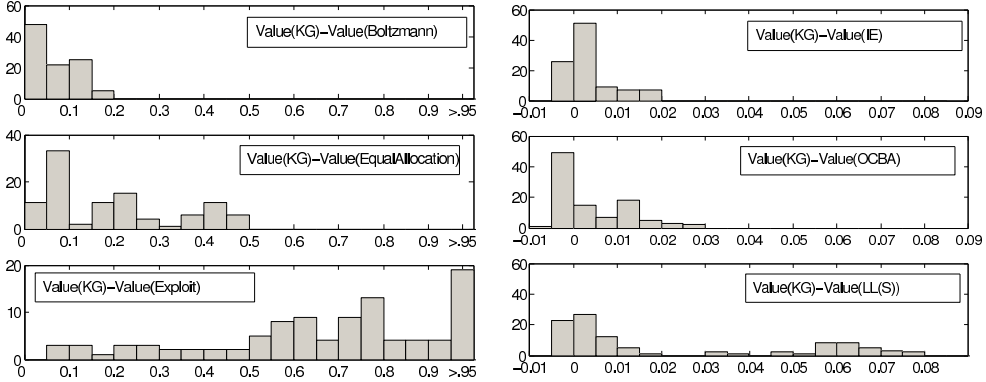

FIG. 1. Histogram of the sampled difference in value for competing policies aggregated across the 100 randomly generated problems.

We show in Figure 1 the sample estimates of  $V^{KG} - V^\pi$  aggregated across the randomly generated problems for each of the competing policies  $\pi$ . Bars to the right of 0 indicate that KG outperformed the plotted policy on those problems, and bars to the left indicate the converse. Note that the scale of the histograms in the right-hand plots is much smaller than in the left-hand plots. The histograms show that Boltzmann exploration, equal allocation, and exploitation policies were all outperformed by KG in every problem setting tested, while IE, OCBA for linear loss, and the LL(S) policy performed relatively better. Each of these three better competing policies performed better than KG on some problems and were outperformed on others; however, the tail to the right of 0 is larger than to the left. This indicates that the amount by which KG outperformed the competing policies was significantly larger than the amount by which it was outperformed.

We note a seeming discrepancy between our numerical work and that of Chick, Branke, and Schmidt [10], who tested a variance-unknown version of the KG policy called  $LL_1$ . They found that  $LL_1$  performed well in small-sample settings, but poorly elsewhere. In contrast, we found that KG, a very similar policy, performed quite well overall. We believe that the difference lies in the stopping rule used. We simply stopped our sampling policies after a fixed horizon  $N$ , but [10] drew many of its conclusions from experiments using the expected opportunity cost Bonferonni (EOC Bonf) stopping rule introduced in [2]. In experiments not pictured here we found that KG also performed poorly with EOC Bonf stopping, but much better when it was stopped using a stopping rule that we introduce now.

This new rule stops as soon as the expected myopic value of the next measurement, as determined by  $Q^{N-1}(s, x) - \max_{x'} \mu_{x'} = \tilde{\sigma}(\beta_x) f(\zeta_x(s))$ , drops below a threshold  $c$ . That is, the number of measurements  $N$  to take under this rule is defined by  $N = \inf\{n \geq 0 : \tilde{\sigma}(\beta_x^n) f(\zeta_x(S^n)) < c\}$ . The threshold  $c$  should be interpreted as the cost of one measurement. Since the expected marginal value of each subsequent measurement decreases on average, it is reasonable to stop measuring as soon as the marginal expected value of the next measurement drops below its cost. Replacing EOC Bonf with this new stopping rule may improve the performance of the KG sampling policy enough to make it competitive with LL(S) and other commonly used policies in an adaptive stopping setting. Our initial experiments suggest that this may be the case, but space limitations prevent a thorough discussion of the experimental issues.

**9. Conclusion.** The KG measurement policy, as first proposed in [16] and as analyzed here, has several attractive features. Under the assumption of independent normally distributed priors with normal sampling errors of common known variance, we showed that the policy is optimal in both extremes of the number of measurements allowed ( $N = 1$  and  $N \rightarrow \infty$ ), as well as in other special cases, and has bounded suboptimality in the remaining cases. We showed numerically that it performs competitively with, or significantly better than, several other sequential measurement policies in a broad class of problem settings. In addition, KG is simple in concept, easy to implement, fast to compute, and requires no tuning. This simplicity may make it an attractive alternative to its more complex but similarly performing cousins, the OCBA and the LL(S) policy.

One important limitation of the version of the policy discussed herein is its assumption of common known variance, which often fails to be met in practice. To lift this assumption, it is possible to place a normal-gamma prior on the unknown means and variances, as was done in [12], and recompute the optimal single-step look ahead policy. Indeed, if we begin with a noninformative normal-gamma prior for the true mean  $Y_x$  and unknown sampling variance  $\beta_x^\epsilon$  of alternative  $x$ , and after sampling have vectors of statistics  $(\mu, \hat{\sigma}^2, n)$  where  $(\mu_x, \hat{\sigma}_x^2, n_x)$  indicate the sample mean, sample variance, and number of samples taken for alternative  $x$ , then a calculation similar to that of Theorem 4.1 reveals that the corresponding KG policy is  $\arg \max_x \tilde{\sigma}_x f_{n_x-1}(\zeta_x)$ , where we must redefine  $\tilde{\sigma}_x := \sqrt{\hat{\sigma}^2/n_x(n_x+1)}$ , leave  $\zeta_x$  defined as before, and define  $f_n(z) := \frac{\nu+z^2}{\nu-1} \varphi_\nu(z) + z\Phi_\nu(z)$ , where  $\varphi_\nu$  and  $\Phi_\nu$  are, respectively, the probability density function and cumulative density function of the student- $t$  distribution with  $\nu$  degrees of freedom. This provides a version of KG for the unknown-variance case. This was derived earlier and independently in [10], and is discussed there in much greater detail, together with a numerical analysis of its properties.

Additionally, the KG policy as described herein has used a fixed number of samples instead of an adaptive stopping rule, while [2] has shown that such rules generally improve the efficiency of budgeted ranking and selection policies. Nevertheless, as implied briefly in section 8 and as discussed in [10], one can certainly use an adaptive stopping rule with the KG sampling policy. Future work is needed to assess the quality of such adaptively stopped policies, and to determine which stopping rules are best to use with KG, but this is by no means an insurmountable obstacle.

Other limitations would seem to present more difficulty. The use of common random numbers has proved immensely beneficial for simulation-based ranking and selection. References [11] and [14] discuss Bayesian ranking and selection policies taking advantage of common random numbers, as does [21] for the frequentist formulation, and it may be possible to extend the KG approach along these lines as well. Indeed, KG's benefits may be overshadowed by its inability to leverage common random numbers in simulation-based ranking and selection unless this extension can be made. In addition, KG assumes the alternatives have a common measurement cost, while in practice it may be more expensive or time consuming to measure some alternatives than others. It may be possible to lift this restriction by dividing the benefit of measurement by the cost so as to obtain a normalized quantity for comparison (a benefit per unit cost), but it may also be that the OCBA approach is more appropriate in such instances.

Despite these limitations, KG has great potential for application. As demonstrated here, it should be considered a reasonable alternative to other measurement policies for those applications that meet its assumptions of a fixed sampling budget

and normally distributed errors with common known variance.

### Appendix A. Proofs.

**Proof of Proposition 3.2.** We proceed by induction on  $n$ . For  $n = N - 1$  and  $s = (\mu, \beta)$  we have

$$\begin{aligned} Q^{N-1}(s, x) &= \mathbb{E} [V^N(T(s, x, Z^N))] = \mathbb{E} \left[ (\mu_x + \tilde{\sigma}(\beta_x) Z^N) \vee \max_{x' \neq x} \mu_{x'} \right] \\ &\geq \mu_x \vee \max_{x' \neq x} \mu_{x'} = V^N(s), \end{aligned}$$

where the inequality is justified by Jensen's inequality and the convexity of the max operator. Now we prove the induction step. For  $0 \leq n < N$ ,

$$\begin{aligned} Q^n(s, x) &= \mathbb{E} [V^{n+1}(T(s, x, Z^{n+1}))] = \mathbb{E} \left[ \max_{x' \in \{1, \dots, M\}} Q^{n+1}(T(s, x, Z^{n+1}), x') \right] \\ &\geq \max_{x' \in \{1, \dots, M\}} \mathbb{E} [Q^{n+1}(T(s, x, Z^{n+1}), x')] \\ (21) \quad &= \max_{x' \in \{1, \dots, M\}} \mathbb{E} [V^{n+2}(T(T(s, x, Z^{n+1}), x'), Z^{n+2})]. \end{aligned}$$

In this equation both decisions  $x$  and  $x'$  are fixed, so the state to which we arrive when we measure  $x$  first and  $x'$  second,  $T(T(s, x, Z^{n+1}), x', Z^{n+2})$ , is equal in distribution to the state to which we arrive when we measure  $x'$  first and  $x$  second,  $T(T(s, x', Z^{n+2}), x, Z^{n+1})$ . This allows us to exchange the time-order of the decisions  $x$  and  $x'$  in (21) to write

$$\begin{aligned} Q^n(s, x) &\geq \max_{x' \in \{1, \dots, M\}} \mathbb{E} [V^{n+2}(T(T(s, x', Z^{n+2}), x, Z^{n+1}))] \\ &= \max_{x' \in \{1, \dots, M\}} \mathbb{E} [\mathbb{E} [V^{n+2}(T(T(s, x', Z^{n+2}), x, Z^{n+1})) \mid Z^{n+2}]] \\ &= \max_{x' \in \{1, \dots, M\}} \mathbb{E} [Q^{n+1}(T(s, x', Z^{n+2}), x)]. \end{aligned}$$

Then the induction hypothesis tells us that

$$Q^{n+1}(T(s, x', Z^{n+2}), x) \geq V^{n+2}(T(s, x', Z^{n+2})) \text{ a.s.,}$$

allowing us to write

$$Q^n(s, x) \geq \max_{x' \in \{1, \dots, M\}} \mathbb{E} [V^{n+2}(T(s, x', Z^{n+2}))] = \max_{x' \in \{1, \dots, M\}} Q^{n+1}(s, x') = V^{n+1}(s).$$

**Proof of Theorem 3.1.** We proceed by induction on  $n$ . Consider the base case, which is  $n = N - 1$ . Fix  $s = (\mu, \beta) \in \mathbb{S}$ . Then  $V^N(s) = \max_x \mu_x$  is convex in its arguments, so we can employ Jensen's inequality to write

$$\begin{aligned} V^{\pi, N-1}(s) &= \mathbb{E} [V^{\pi, N}(T(s, X^\pi(s), Z^N))] \geq V^{\pi, N}(\mathbb{E} [T(s, X^\pi(s), Z^N)]) \\ &= V^{\pi, N}(\mu, \beta + \beta^\epsilon e_{X^\pi(s)}) = V^{\pi, N}(\mu, \beta) = V^{\pi, N}(s). \end{aligned}$$

Now consider the induction step. For  $n < N - 1$ ,

$$V^{\pi, n}(s) = \mathbb{E} [V^{\pi, n+1}(T(s, X^\pi(s), Z^{n+1}))] \geq \mathbb{E} [V^{\pi, n+2}(T(s, X^\pi(s), Z^{n+1}))]$$

by the induction hypothesis. Then, by the definition of  $V^{\pi, n+1}$  in terms of  $V^{\pi, n+2}$  from (10), we have  $V^{\pi, n}(s) \geq V^{\pi, n+1}(s)$ .

**Proof of Theorem 4.1.** By (15), computing  $X^{KG}(s)$  reduces to computing  $Q^{N-1}(s, x)$  for each  $x \in \{1, \dots, M\}$ . By definition (11) we have, for a generic state  $s$  and standard normal random variable  $Z$ ,

$$(22) \quad Q^{N-1}(s, x) = \mathbb{E} [V^N(T(s, x, Z))] = \mathbb{E} \left[ (\mu_x + \tilde{\sigma}(\beta_x)Z) \vee \max_{x' \neq x} \mu_{x'} \right].$$

This expectation is the expectation of the maximum of a constant and a normal random variable, for which we have an analytical expression from [13]. Let  $a \in \mathbb{R}$  be an arbitrary constant and  $W \sim \mathcal{N}(b, c^2)$  an arbitrary normal random variable. Then [13] tells us that

$$(23) \quad \mathbb{E} [W \vee a] = a\Phi\left(\frac{a-b}{c}\right) + b\Phi\left(\frac{b-a}{c}\right) + c\varphi\left(\frac{a-b}{c}\right),$$

which can be rewritten as

$$\begin{aligned} \mathbb{E} [W \vee a] &= a\Phi\left(\frac{a-b}{c}\right) + b\left(1 - \Phi\left(\frac{a-b}{c}\right)\right) + c\varphi\left(\frac{a-b}{c}\right) \\ &= b + (a-b)\Phi\left(\frac{a-b}{c}\right) + c\varphi\left(\frac{a-b}{c}\right) \\ &= b + c\left[\left(\frac{a-b}{c}\right)\Phi\left(\frac{a-b}{c}\right) + \varphi\left(\frac{a-b}{c}\right)\right]. \end{aligned}$$

Fix  $x$  and consider two cases. First, consider the case that  $\mu_x > \max_{x'} \mu_{x'}$ . This is the case in which we measure an alternative that is uniquely the best according to the prior. Then  $\mu_x - \max_{x' \neq x} \mu_{x'}$  is positive and  $(\max_{x' \neq x} \mu_{x'} - \mu_x)/\tilde{\sigma}(\beta_x) = \zeta_x(s)$ . Substitute  $\zeta_x(s)$  for  $(a-b)/c$  and write (22) as

$$Q^{N-1}(s, x) = \mu_x + \tilde{\sigma}(\beta_x) [\zeta_x(s)\Phi(\zeta_x(s)) + \varphi(\zeta_x(s))] = \mu_x + \tilde{\sigma}(\beta_x)f(\zeta_x(s)),$$

which can be rewritten in our case using  $\mu_x = \max_{x'} \mu_{x'}$  as

$$(24) \quad Q^{N-1}(s, x) = \max_{x'} \mu_{x'} + \tilde{\sigma}(\beta_x)f(\zeta_x(s)).$$

Now consider the case that  $\mu_x \leq \max_{x'} \mu_{x'}$ . We rewrite (23) again using the substitution  $\Phi(-z) = 1 - \Phi(z)$  and also using the symmetric property of the normal probability density function,  $\varphi(-z) = \varphi(z)$ , as

$$\mathbb{E} [Z \vee a] = a + c\left[\left(\frac{b-a}{c}\right)\Phi\left(\frac{b-a}{c}\right) + \varphi\left(\frac{b-a}{c}\right)\right].$$

In the case we are considering,  $\mu_x - \max_{x' \neq x} \mu_{x'} \leq 0$  and  $(\mu_x - \max_{x' \neq x} \mu_{x'})/\tilde{\sigma}(\beta_x) = \zeta_x(s)$ . Substitute  $\zeta_x(s)$  for  $(b-a)/c$  and write (22) as

$$\begin{aligned} Q^{N-1}(s, x) &= \max_{x' \neq x} \mu_{x'} + \tilde{\sigma}(\beta_x) [\zeta_x(s)\Phi(\zeta_x(s)) + \varphi(\zeta_x(s))] \\ &= \max_{x' \neq x} \mu_{x'} + \tilde{\sigma}(\beta_x)f(\zeta_x(s)), \end{aligned}$$

which can be rewritten in our case using  $\max_{x' \neq x} \mu_{x'} = \max_{x'} \mu_{x'}$  as

$$(25) \quad Q^{N-1}(s, x) = \max_{x'} \mu_{x'} + \tilde{\sigma}(\beta_x) f(\zeta_x(s)).$$

In both cases the expression for  $Q^{N-1}(s, x)$  agrees with (18), and we use this expression to rewrite (15) as

$$X^{KG}(s) \in \arg \max_x \max_{x'} \mu_{x'} + \tilde{\sigma}(\beta_x) f(\zeta_x(s)) = \arg \max_{x \in \{1, \dots, M\}} \tilde{\sigma}(\beta_x) f(\zeta_x(s)),$$

since  $\max_{x'} \mu_{x'}$  does not depend on  $x$ .

**Proof of Proposition 4.3.** By Theorem 4.1, KG prefers the alternative with the largest value of  $\tilde{\sigma}(\beta_x) f(\zeta_x(S))$ . Fix  $S = (\mu, \beta)$ , and let  $a$  be as in the statement of Proposition 4.3. Let  $i$  be the alternative preferred by KG, so

$$(26) \quad i = \arg \max_{x \in \{1, \dots, M\}} \tilde{\sigma}(\beta_x) f(\zeta_x(S)),$$

where we recall that we are breaking ties by choosing the smallest index. Note that the theorem's condition on  $a$  trivializes the case when  $\mu_i = \max_x \mu_x$  because here the range of  $a$  contains only the value 0, for which the theorem is obviously true. Thus, without loss of generality we may assume  $\mu_i < \max_x \mu_x$ , and let  $j \in \arg \max_x \mu_x$ . Then  $j \neq i$ .

Let  $S' = (\mu + ae_i, \beta)$ . We will first show for all alternatives  $x \neq i$  that

$$(27) \quad \tilde{\sigma}(\beta_i) f(\zeta_i(S')) \geq \tilde{\sigma}(\beta_x) f(\zeta_x(S')).$$

This will show that  $i \in \arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S'))$ . We will then show that the implication

$$(28) \quad \tilde{\sigma}(\beta_x) f(\zeta_x(S)) < \tilde{\sigma}(\beta_i) f(\zeta_i(S)) \implies \tilde{\sigma}(\beta_x) f(\zeta_x(S')) < \tilde{\sigma}(\beta_i) f(\zeta_i(S'))$$

holds for all  $x \neq i$ . This will suffice to show the proposition because if we choose any  $x' \notin \arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S))$ , (26) will imply  $\tilde{\sigma}(\beta_{x'}) f(\zeta_{x'}(S)) < \tilde{\sigma}(\beta_i) f(\zeta_i(S))$ . The implication (28) will then imply that  $\tilde{\sigma}(\beta_{x'}) f(\zeta_{x'}(S')) < \tilde{\sigma}(\beta_i) f(\zeta_i(S'))$  and, moreover, that  $x' \notin \arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S'))$ . Taking the contrapositive of the statement

$$x' \notin \arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S)) \implies x' \notin \arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S'))$$

reveals that

$$x' \in \arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S')) \implies x' \in \arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S)).$$

By this argument, (28) implies that  $\arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S')) \subseteq \arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S))$ . Therefore  $i$  is the element of  $\arg \max_x \tilde{\sigma}(\beta_x) f(\zeta_x(S))$  with the smallest index, and thus  $i$  is the alternative that KG prefers in state  $S'$ .

We will show (27) and (28) by treating three cases separately, noting in general that  $\zeta_i(\mu, \beta) \leq \zeta_i(\mu + ae_i, \beta)$ . The first case is when  $x \neq i, j$ . Then

$$\zeta_x(S') = \zeta_x(\mu + ae_i, \beta) = \zeta_x(\mu, \beta) = \zeta_x(S).$$

Thus, (27) is true because

$$\tilde{\sigma}(\beta_i)f(\zeta_i(S')) \geq \tilde{\sigma}(\beta_i)f(\zeta_i(S)) \geq \tilde{\sigma}(\beta_x)f(\zeta_x(S)) = \tilde{\sigma}(\beta_x)f(\zeta_x(S')),$$

and (28) is true because if  $\tilde{\sigma}(\beta_x)f(\zeta_x(S)) < \tilde{\sigma}(\beta_i)f(\zeta_i(S))$ , then

$$\tilde{\sigma}(\beta_x)f(\zeta_x(S')) = \tilde{\sigma}(\beta_x)f(\zeta_x(S)) < \tilde{\sigma}(\beta_i)f(\zeta_i(S)) \leq \tilde{\sigma}(\beta_i)f(\zeta_i(S')).$$

The second case is when  $x = j$  and  $\mu_i + a < \max_{x' \neq j} \mu_{x'}$ . Then again  $\zeta_j(S') = \zeta_j(S)$  because  $j \neq i$ , and both (27) and (28) hold by the same reasoning as in the first case.

The third case is when  $x = j$  and  $\mu_i + a \geq \max_{x' \neq j} \mu_{x'}$ . Then we have  $\zeta_j(\mu + ae_i, \beta) = \frac{-|\mu_i + a - \mu_j|}{\tilde{\sigma}(\beta_j)}$ . For  $x = j$ , KG's preference of alternative  $i$  implies that  $\beta_i \leq \beta_j$ . Otherwise, by Remark 4.2 and because  $\mu_j \geq \mu_i$ , KG would prefer alternative  $j$ . This shows that

$$\zeta_i(\mu + ae_i, \beta) = \frac{-|\mu_i + a - \mu_j|}{\tilde{\sigma}(\beta_i)} \geq \frac{-|\mu_i + a - \mu_j|}{\tilde{\sigma}(\beta_j)} = \zeta_j(\mu + ae_i, \beta).$$

This shows (27). To show (28), assume the antecedent of condition (28). Since  $|\mu_j - \max_{x' \neq j} \mu_{x'}| \leq |\mu_j - \mu_i|$  and  $\tilde{\sigma}(\beta_j)f(\zeta_j(S)) < \tilde{\sigma}(\beta_i)f(\zeta_i(S))$ , it must be that  $\tilde{\sigma}(\beta_j) < \tilde{\sigma}(\beta_i)$  since otherwise  $j$  would have been KG's choice in state  $S$ . Thus,

$$\zeta_i(\mu + ae_i, \beta) = \frac{-|\mu_i + a - \mu_j|}{\tilde{\sigma}(\beta_i)} > \frac{-|\mu_i + a - \mu_j|}{\tilde{\sigma}(\beta_j)} = \zeta_j(\mu + ae_i, \beta).$$

**Proof of Proposition 5.1.** We will show that  $V^0(S^0; N)$  is a nondecreasing function of  $N$  bounded from above by  $U(S^0)$ , which will imply that the limit  $V(S^0; \infty)$  exists and is bounded as claimed. To show that  $V^0(S^0; N)$  is nondecreasing in  $N$ , note that  $V^0(S^0; N - 1) = V^1(S^0; N)$ , and thus

$$V^0(S^0; N) - V^0(S^0; N - 1) = V^0(S^0; N) - V^1(S^0; N).$$

This difference is positive by Corollary 3.2.

Now we show that  $V^0(S^0; N) \leq U(S^0)$ . For every  $N \geq 1$  and policy  $\pi$ ,

$$\begin{aligned} \mathbb{E}^\pi \left[ \max_x \mu_x^N \right] &= \mathbb{E}^\pi \left[ \max_x \mathbb{E}_N^\pi [Y_x] \right] \leq \mathbb{E}^\pi \left[ \mathbb{E}_N^\pi \left[ \max_x Y_x \right] \right] \\ &= \mathbb{E}^\pi \left[ \max_x Y_x \right] = \mathbb{E} \left[ \max_x Y_x \right]. \end{aligned}$$

This value is independent of  $\pi$  and is equal to  $U(S^0)$ . Thus

$$V^0(S^0; N) := \sup_\pi \mathbb{E}^\pi \left[ \max_x \mu_x^N \right] \leq U(S^0)$$

for every  $N \geq 1$ . Taking the limit as  $N \rightarrow \infty$  shows  $V(S^0; \infty) \leq U(S^0)$ .

Finally, we show that the limit  $V^\pi(S^0; \infty)$  exists and is finite for every stationary policy  $\pi$ . Fix a stationary policy  $\pi$ . Then Theorem 3.1 implies that  $V^{\pi, 0}(S^0; N)$  is nondecreasing in  $N$ , and  $V^{\pi, 0}(S^0; N)$  is bounded by  $V^0(S^0; N)$ , which is itself uniformly bounded in  $N$  by  $U(S^0)$ . Then  $V^\pi(S^0; \infty)$  is the limit of a nondecreasing bounded sequence. Hence, it exists.

**Proof of Proposition 5.2.** We assumed in the formal model in section 3.1 that our measurement-noise variance  $(\sigma^\varepsilon)^2$  is finite. This implies via the strong law of large numbers that the sequence of posterior predictive means  $\mu_x^N$  converges as  $\lim_{N \rightarrow \infty} \mu_x^N = Y_x$  a.s. for each  $x = 1, \dots, M$ . Thus  $\lim_{N \rightarrow \infty} \max_x \mu_x^N$  exists a.s. and in probability. We will show next that the sequence  $(\max_x \mu_x^N)_{N \geq 1}$  is uniformly integrable, and then convergence in probability together with uniform integrability implies convergence in  $L^1$  (see, e.g., [20, Theorem 3.12]). Convergence in  $L^1$  of  $\max_x \mu_x^N$  as  $N \rightarrow \infty$  implies

$$V^\pi(S^0; \infty) = \lim_{N \rightarrow \infty} \mathbb{E}^\pi \left[ \max_x \mu_x^N \right] = \mathbb{E}^\pi \left[ \lim_{N \rightarrow \infty} \max_x \mu_x^N \right] = \mathbb{E}^\pi \left[ \max_x Y_x \right] = U(S^0).$$

Proposition 5.1 showed that  $U(S^0) \geq V(S^0; \infty)$ , so  $V^\pi(S^0; \infty) = V(S^0; \infty)$  and  $\pi$  must be asymptotically optimal.

To complete the proof we must show uniform integrability of the sequence  $(\max_x \mu_x^N)_{N \geq 1}$ . For every fixed  $K$  we have

$$\begin{aligned} \mathbb{E} \left[ \max_x \mu_x^N \mid 1_{\{\max_x \mu_x^N \geq K\}} \right] &\leq \mathbb{E} \left[ \max_x |\mu_x^N| \mid 1_{\{\max_x |\mu_x^N| \geq K\}} \right] \\ &= \mathbb{E} \left[ \max_x |\mathbb{E}_N[Y_x]| \mid 1_{\{\max_x |\mathbb{E}_N[Y_x]| \geq K\}} \right] \leq \mathbb{E} \left[ \max_x \mathbb{E}_N[|Y_x|] \mid 1_{\{\max_x \mathbb{E}_N[|Y_x|] \geq K\}} \right] \\ &\leq \mathbb{E} \left[ \mathbb{E}_N \left[ \max_x |Y_x| \right] \mid 1_{\{\mathbb{E}_N[\max_x |Y_x|] \geq K\}} \right] = \mathbb{E} \left[ \mathbb{E}_N \left[ \max_x |Y_x| \mid 1_{\{\mathbb{E}_N[\max_x |Y_x|] \geq K\}} \right] \right] \\ &= \mathbb{E} \left[ \max_x |Y_x| \mid 1_{\{\mathbb{E}_N[\max_x |Y_x|] \geq K\}} \right]. \end{aligned}$$

We assumed in the formal model in section 3.1 that  $\max_x |Y_x|$  was integrable. This implies via Markov's inequality that

$$\mathbb{P} \left\{ \mathbb{E}_N \left[ \max_x |Y_x| \right] \geq K \right\} \leq \frac{\mathbb{E} [\mathbb{E}_N [\max_x |Y_x|]]}{K} = \frac{\mathbb{E} [\max_x |Y_x|]}{K}.$$

This is bounded uniformly in  $N$ , and the bound goes to zero as  $K \rightarrow \infty$ .

**Proof of Theorem 5.1.** First note that KG is stationary. We will show that  $\lim_{N \rightarrow \infty} \eta_x^N = \infty$  a.s. for all  $x$  under KG, and then Proposition 5.2 will complete the proof.

First we show that, for each  $x$ ,  $\{\mu_x^n\}_{n=0}^\infty$  is a uniformly integrable martingale with respect to the filtration  $\mathcal{F}$  and hence converges.  $\mu_x^n$  is defined by  $\mu_x^n := \mathbb{E}[Y_x \mid \mathcal{F}^n]$  and thus is  $\mathcal{F}^n$ -measurable and, by the tower property of conditional expectation, satisfies the martingale identity.  $Y_x$  is a normal random variable with finite variance. Thus,  $Y_x \in L^2 \subset L^1$ , and by the Doob uniform integrability lemma [20, Lemma 5.5], the collection of conditional expectations  $\{\mu_x^n\}_n$  is uniformly integrable (and hence each  $\mu_x^n$  is integrable). Thus,  $\{\mu_x^n\}_n$  is a uniformly integrable martingale and hence converges a.s. to an integrable random variable  $\mu_x^\infty$ . In addition,  $\lim_{n \rightarrow \infty} \beta_x^n \stackrel{a.s.}{=} \beta_x^0 + \beta^\varepsilon \eta_x^\infty$  for each  $x$ .

By the computation performed in Theorem 4.1, the Q-factors for each alternative  $x$  are continuous functions of their arguments  $(\mu, \beta)$ , and, hence,

$$\lim_{n \rightarrow \infty} Q^{N-1}(S^n; x) \stackrel{a.s.}{=} \max_{x'} \mu_{x'}^\infty + \tilde{\sigma}(\beta_x^\infty) f \left( \frac{\mu_x^\infty - \max_{x'' \neq x} \mu_{x''}^\infty}{\tilde{\sigma}(\beta_x^\infty)} \right).$$

Define  $\Omega_0$  to be the almost sure event on which this convergence holds, and define the event  $\mathcal{H}_x$  to be  $\mathcal{H}_x := \{\omega : \eta_x^\infty(\omega) < \infty\}$ . Then,

$$(29) \quad \lim_{n \rightarrow \infty} Q^{N-1}(S^n(\omega); x) > \max_{x'} \mu_{x'}^\infty(\omega) \quad \text{for all } \omega \in \mathcal{H}_x \cap \Omega_0,$$

$$(30) \quad \lim_{n \rightarrow \infty} Q^{N-1}(S^n(\omega); x) = \max_{x'} \mu_{x'}^\infty(\omega) \quad \text{for all } \omega \in \mathcal{H}_x^c \cap \Omega_0.$$

Let  $A$  be any subset of  $\{1, \dots, M\}$ , and define the event  $\mathcal{H}_A$  to be  $\mathcal{H}_A := (\cap_{x \in A} \mathcal{H}_x) \cap (\cap_{x \in A^c} \mathcal{H}_x^c)$ . We will show that, if  $A \neq \emptyset$ , then  $\mathbb{P}(\mathcal{H}_A) = 0$ . This will prove the theorem because  $\Omega = \cup_{A \subseteq \{1, \dots, M\}} \mathcal{H}_A$ , so if we know that  $A \neq \emptyset \implies \mathbb{P}(\mathcal{H}_A) = 0$ , then  $1 = \mathbb{P}(\mathcal{H}_\emptyset) = \mathbb{P}\{\lim_{n \rightarrow \infty} \eta_x^n = \infty \text{ for all } x\}$ .

Fix  $A$  nonempty and suppose for contradiction that  $\mathcal{H}_A \cap \Omega_0$  is nonempty so that we may choose  $\omega \in \mathcal{H}_A \cap \Omega_0$  to be an element of this set. By (29) and (30), for all  $x \in A$  and all  $y \in A^c$ ,

$$\lim_{n \rightarrow \infty} Q^{N-1}(S^n(\omega); x) > \lim_{n \rightarrow \infty} Q^{N-1}(S^n(\omega); y),$$

and there exists a finite number  $K_{xy}$  such that, for all  $n > K_{xy}$ ,

$$Q^{N-1}(S^n(\omega); x) > Q^{N-1}(S^n(\omega); y).$$

Let  $K := \max_{x \in A, y \in A^c} K_{xy}$  if  $A^c$  is nonempty, and let  $K := 1$  if  $A^c$  is empty. Then  $K$  is finite and for all  $n > K$  and all  $x \in A$  and  $y \in A^c$ ,

$$Q^{N-1}(S^n(\omega); x) > Q^{N-1}(S^n(\omega); y).$$

Therefore, KG distributes all measurements  $n > K$  only to alternatives in the set  $A$ , and  $\sum_{x \in A} \eta_x^\infty(\omega) = \infty$ . This is a contradiction because  $x \in A$  implies  $\omega \in \mathcal{H}_x$ , which implies  $\eta_x^\infty(\omega) < \infty$ .

Thus,  $\mathbb{P}(\mathcal{H}_\emptyset \cap \Omega_0) = 0$ , and since  $\mathbb{P}(\Omega_0) = 1$ ,  $\mathbb{P}(\mathcal{H}_\emptyset) = 0$ .

**Proof of Theorem 6.1.** Note that  $\varphi(0) = (2\pi)^{-1/2}$ , where  $\varphi$  is the normal probability density function. We will use this throughout. We induct backward over  $n$ . First, when  $n = N - 1$ , the theorem is trivially true with equality. Now, under the assumption that the theorem is true for some  $n + 1$ ,

$$\begin{aligned} V^n(s) &= \max_x \mathbb{E} [V^{n+1}(T(s, x, Z^{n+1}))] \\ &\leq \max_x \mathbb{E} \left[ V^{N-1}(T(s, x, Z^{n+1})) + \varphi(0)(N - n - 2) \max_x \tilde{\sigma}(\beta_{x'} + \beta^\epsilon 1_{\{x=x'\}}) \right]. \end{aligned}$$

Then, since  $\tilde{\sigma}$  is a decreasing function and  $\beta_{x'}^n \leq \beta_{x'}^n + \beta^\epsilon 1_{\{x=x'\}}$ ,

$$V^n(s) \leq \max_x \mathbb{E} \left[ V^{N-1}(T(s, x, Z^{n+1})) + \varphi(0)(N - n - 2) \max_{x'} \tilde{\sigma}(\beta_{x'}) \right].$$

Since the last term is a constant and does not depend on  $x$ , we may move it outside the maximum and expectation operators, giving

$$(31) \quad V^n(s) \leq \max_x \mathbb{E} [V^{N-1}(T(s, x, Z^{n+1}))] + \varphi(0)(N - n - 2) \max_{x'} \tilde{\sigma}(\beta_{x'}).$$

We will rewrite the first term on the right-hand side of this inequality as a maximum over a set of Q-factors using the definition of  $V^{N-1}$  in terms of  $Q^{N-1}$ , but before

making this substitution, let us bound  $Q^{N-1}$ . We rewrite the expression (24) for  $Q^{N-1}$  as  $Q^{N-1}(s, x') = \max_{x''} \mu_{x''} + \tilde{\sigma}(\beta_{x'}) f(\zeta_{x'}) = V^N(s) + \tilde{\sigma}(\beta_{x'}) f(\zeta_{x'})$ . Lemma 4.1 tells us that  $f$  is nondecreasing, so  $\zeta_{x'} \leq 0$  implies that  $f(\zeta_{x'}) \leq f(0) = \varphi(0)$ . Thus,

$$Q^{N-1}(s, x') \leq V^N(s) + \varphi(0) \tilde{\sigma}(\beta_{x'}).$$

Using this and the definition of the value function in terms of the Q-factors from (10) and (11), we have

$$\begin{aligned} V^{N-1}(T(s, x, Z^{n+1})) &= \max_{x'} Q^{N-1}(T(s, x, Z^{n+1}), x') \\ &\leq \max_{x'} V^N(T(s, x, Z^{n+1})) + \varphi(0) \tilde{\sigma}(\beta_{x'} + \beta^\epsilon 1_{\{x=x'\}}) \\ &= V^N(T(s, x, Z^{n+1})) + \varphi(0) \max_{x'} \tilde{\sigma}(\beta_{x'} + \beta^\epsilon 1_{\{x=x'\}}) \\ &\leq V^N(T(s, x, Z^{n+1})) + \varphi(0) \max_{x'} \tilde{\sigma}(\beta_{x'}). \end{aligned}$$

Combining this bound with (31) and moving the  $\tilde{\sigma}(\beta_x)$  outside the maximization and expectation operators, we obtain

$$\begin{aligned} V^n(s) &\leq \max_x \mathbb{E} \left[ V^N(T(s, x, Z^{n+1})) + \varphi(0) \max_{x'} \tilde{\sigma}(\beta_{x'}^n) \right] + \varphi(0)(N - n - 2) \max_{x'} \tilde{\sigma}(\beta_{x'}) \\ &= \max_x \mathbb{E} \left[ V^N(T(s, x, Z^{n+1})) \right] + \varphi(0)(N - n - 1) \max_{x'} \tilde{\sigma}(\beta_{x'}) \\ &= V^{N-1}(s) + \varphi(0)(N - n - 1) \max_{x'} \tilde{\sigma}(\beta_{x'}), \end{aligned}$$

where in the last step we used the definition of  $V^N$  in terms of  $V^{N-1}$  from (10).

**Proof of Theorem 7.1.** The proof is by induction backward on  $k$ . The theorem holds for the base case,  $k = N - 1$ , by Remark 4.1. Now let  $k < N - 1$ . Let  $\pi^*$  be an optimal policy, with decision function  $X^{*k}$  at time  $k$ . Let  $s = (\mu, \beta) \in \mathbb{S}^k$ . Then

$$(32) \quad V^k(s) = \mathbb{E} [V^{k+1}(T(s, X^{*k}(s), Z^{k+1}))] = \mathbb{E} [V^{KG, k+1}(T(s, X^{*k}(s), Z^{k+1}))]$$

by the induction hypothesis, since  $\{\mathbb{S}^n\}_{n=k+1}^N$  is a covering of the future from  $k + 1$  on which KG persistence holds, and  $T(s, X^{*k}(s), Z^{k+1}) \in \mathbb{S}^{k+1}$  a.s.

Consider two cases. In the first case, suppose  $X^{*k}(s) = X^{KG}(s)$ . By (32),

$$V^k(s) = \mathbb{E} [V^{KG, k+1}(T(s, X^{KG}(s), Z^{k+1}))] = V^{KG, k}(s).$$

In the second case, suppose  $X^{*k}(s) \neq X^{KG}(s)$ . Then, abbreviating the random state at time  $k + 1$  under the optimal policy by  $S^{k+1} = T(s, X^{*k}(s), Z^{k+1})$ ,

$$\begin{aligned} V^k(s) &= \mathbb{E} [V^{KG, k+2}(T(S^{k+1}, X^{KG}(S^{k+1}), Z^{k+2}))] \\ (33) \quad &= \mathbb{E} [V^{KG, k+2}(T(S^{k+1}, X^{KG}(s), Z^{k+2}))], \end{aligned}$$

since  $X^{KG}(s) = X^{KG}(S^{k+1})$  a.s. by the KG persistence property. Let  $S^{k+2} = T(S^{k+1}, X^{KG}(s), Z^{k+2})$ . Then  $V^k(s) = \mathbb{E} [V^{KG, k+2}(S^{k+2})]$ .

Note that  $S^{k+2}$  is the state to which we arrive when we measure  $X^{*k}(s)$  at time  $k$  and  $X^{KG}(s)$  at time  $k + 1$ . Let  $E_x = e_x(e_x)^T$  be a matrix of all zeros except for

a single 1 at row  $x$ , column  $x$ , and let  $\stackrel{d}{=}$  denote equality in distribution. Then the definition (8) of the transition function  $T$  and  $X^{KG}(s) \neq X^{*,k}(s)$  imply

$$\begin{aligned} S^{k+2} &= T(S^{k+1}, X^{KG}(s), Z^{k+2}) \\ &= T(T(s, X^{*,k}(s), Z^{k+1}), X^{KG}(s), Z^{k+2}) \\ &= \mu + \tilde{\sigma}(\beta_{X^{KG}(s)})Z^{k+1} + \tilde{\sigma}(\beta_{X^{*,k}(s)})Z^{k+2} + \beta^\epsilon E_{X^{KG}(s)} + \beta^\epsilon E_{X^{*,k}(s)} \\ &\stackrel{d}{=} \mu + \tilde{\sigma}(\beta_{X^{KG}(s)})Z^{k+2} + \tilde{\sigma}(\beta_{X^{*,k}(s)})Z^{k+1} + \beta^\epsilon E_{X^{KG}(s)} + \beta^\epsilon E_{X^{*,k}(s)} \\ &= T(T(s, X^{KG}(s), Z^{k+1}), X^{*,k}(s), Z^{k+2}). \end{aligned}$$

Thus, we have that  $V^k(s) = \mathbb{E}[V^{KG,k+2}(S^{k+2})]$  equals

$$\mathbb{E}[V^{KG,k+2}(T(T(s, X^{KG}(s), Z^{k+1}), X^{*,k}(s), Z^{k+2}))].$$

This quantity is the value of making decisions  $X^{KG}(s)$  at time  $k$ ,  $X^{*,k}(s)$  at time  $k+1$ , and then following KG afterward. This value must be less than the value of making the same decision  $X^{KG}(s)$  at time  $k$  and following the optimal policy afterward. Thus,  $V^k(s) \leq \mathbb{E}[V^{k+1}(T(s, X^{KG}(s), Z^{k+1}))]$ . Now,  $T(s, X^{KG}(s), Z^{n+1}) \in \mathbb{S}^{n+1}$  a.s., so by the induction hypothesis we may replace the optimal value function with the KG value function when operating on this state. This allows us to write

$$V^k(s) \leq \mathbb{E}[V^{KG,k+1}(T(s, X^{KG}(s), Z^{k+1}))] = V^{KG,k}(s).$$

Finally,  $V^k(s) \geq V^{KG,k}(s)$  implies  $V^k(s) = V^{KG,k}(s)$ .

**Proof of Theorem 7.3.** For  $n \in \{0, \dots, N-1\}$ , define  $\mathbb{S}^n$  to be the set of all  $s = (\mu, \beta) \in \mathbb{S}$  satisfying

$$(34) \quad (\beta_i \neq \infty \text{ and } \beta_j \neq \infty \text{ and } \beta_i < \beta_j) \implies \mu_i \geq \mu_j$$

for all  $i, j \in \{1, \dots, M\}$ . Note that the sets  $\mathbb{S}^n$  are identical for all  $n$ . We will show that  $\{\mathbb{S}^n\}$  is a covering of the future from 0.

Let  $n \in \{0, \dots, N-2\}$ ,  $x \in \{1, \dots, M\}$ ,  $s \in \mathbb{S}^n$ , and  $S^n = s$  a.s. Consider  $S^{n+1} := T(S^n, x, Z^{n+1})$ . Let  $i, j \in \{1, \dots, M\}$  meet the conditions of the implication (34) for  $S^{n+1}$ , so  $\beta_i^{n+1} \neq \infty$  and  $\beta_j^{n+1} \neq \infty$  and  $\beta_i^{n+1} < \beta_j^{n+1}$ . We will show that  $\mu_i^n \geq \mu_j^n$ , which will show that  $S^{n+1}$  meets condition (34) and is in  $\mathbb{S}^{n+1}$ .

First,  $\beta^n \leq \beta^{n+1}$  componentwise implies that  $\beta_i^n \neq \infty$  and  $\beta_j^n \neq \infty$ . Also, since  $(\sigma^\epsilon)^2 = 0$ ,  $\beta_x^{n+1} = \infty$ , which implies that  $x \neq i, j$ , and the measurement between  $S^n$  and  $S^{n+1}$  alters neither the  $i$  component nor the  $j$  component. Thus,  $\beta_i^n = \beta_i^{n+1} < \beta_j^{n+1} = \beta_j^n$ . This shows that  $i, j$  meet the conditions of the implication (34) for  $S^n$  as well as  $S^{n+1}$ . Thus, since  $S^n \in \mathbb{S}^n$ ,  $\mu_i^n \geq \mu_j^n$ . Then, again because  $x \neq i, j$  implies that the means of the  $i$  and  $j$  components did not change from time  $n$  to  $n+1$ ,  $\mu_i^{n+1} \geq \mu_j^{n+1}$ , showing that  $S^{n+1}$  meets the condition (34), and  $S^{n+1} \in \mathbb{S}^{n+1}$ . Thus,  $\{\mathbb{S}^n\}$  is a covering of the future from 0.

Now we will show that KG is persistent on  $\{\mathbb{S}^n\}$ . Let  $s \in \mathbb{S}^n$  and  $S^n = s$  a.s. Condition (34) together with Remarks 4.2 and 4.3 implies  $X^{KG}(S^n) \in \arg \min_x \beta_x^n$ , with ties broken by the smallest index. Let  $x \neq X^{KG}(S^n)$ . We showed that  $S^{n+1} := T(S^n, x, Z^{n+1}) \in \mathbb{S}^{n+1}$  a.s. Thus, again by condition (34) and Remarks 4.2 and 4.3,

$X^{KG}(S^{n+1}) \in \arg \min_{x'} \beta_{x'}^{n+1}$ . We use the state transition function for the case with  $(\sigma^\epsilon) = 0$ ,  $\beta_{x'}^{n+1} = \beta_{x'}^n + \infty 1_{\{x'=x\}}$ , and we consider two cases.

In the first case suppose  $\beta_{x'}^n < \infty$  for some  $x' \neq x$ . Then, since  $\beta_x^{n+1} = \infty$ , we have  $\beta_{x'}^{n+1} = \beta_{x'}^n < \beta_x^{n+1}$ . Thus, we may drop  $x$  from the argmin set as in

$$\arg \min_{x'} \beta_{x'}^{n+1} = \arg \min_{x' \neq x} \beta_{x'}^{n+1} = \arg \min_{x' \neq x} \beta_{x'}^n.$$

$X^{KG}(S^n)$  is the element of this set with the smallest index, and since  $X^{KG}(S^{n+1})$  is also defined to be the element of this set with the smallest index,  $X^{KG}(S^{n+1}) = X^{KG}(S^n)$ .

In the second case suppose  $\beta_{x'}^n = \infty$  for all  $x' \neq x$ . Then, by  $X^{KG} \in \arg \min_{x'} \beta_{x'}^n$ , and since  $X^{KG}(S^n) \neq x$ , we also have that  $\beta_x^n = \infty$ . The state transition rule for  $\beta$  implies that  $\beta_{x'}^{n+1} = \infty$  for all  $x'$ . Thus,  $\arg \min_{x'} \beta_{x'}^n = \{1, \dots, M\} = \arg \min_{x'} \beta_{x'}^{n+1}$ , and since the tie-breaking rule is fixed to choose the element with the smallest index,  $X^{KG}(S^{n+1}) = X^{KG}(S^n)$ .

In both cases KG is persistent on  $\{S^n\}$ , and Theorem 7.1 shows that  $V^{KG,0}(s) = V^0(s)$  for all  $s \in \mathbb{S}^0$ .

**Appendix B. Known variance LL(S) policy.** The LL(S) policy was developed for normal measurement errors with *unknown* variance and uses a normal-gamma prior for the unknown mean and measurement precision. To adapt it to the known-variance case, we take both the shape and rate parameters in the gamma prior on the measurement precision to infinity while keeping their ratio fixed to the known measurement precision  $\beta^\epsilon$ ; we obtain a prior in which the measurement precision is known perfectly and the alternative's true value is still normally distributed. Taking this limit in the allocation given by [12, Corollary 1] provides the following policy. The steps below describe how the policy allocates  $\tau$  measurements for the stage beginning at a generic time  $n$ , and should be repeated a total of  $N/\tau$  times beginning at time 0 and finishing at time  $N$ . We use the notation  $[i]$  to indicate the alternative whose  $\mu^n$  component is  $i$ th largest. That is,  $\mu_{[M]}^n \geq \dots \geq \mu_{[1]}^n$ .

- (i) For each alternative calculate  $n_i = \beta_i^n / \beta^\epsilon$ , which may be interpreted as the effective number of times alternative  $i$  has been sampled.
- (ii) Initialize  $\mathcal{S}$ , the set of alternatives under consideration for measurement in the current stage, to  $\mathcal{S} = \{1, \dots, M\}$ .
- (iii) For each  $i \in \mathcal{S} \setminus \{[M]\}$  set  $\lambda_{i,M}$  as follows. If  $[M] \notin \mathcal{S}$ , set  $\lambda_{i,M} = \beta_{[i]}^n$ . If  $[M] \in \mathcal{S}$ , set  $\lambda_{i,M} = ((\beta_{[M]}^n)^{-1} + (\beta_{[i]}^n)^{-1})^{-1}$ .
- (iv) Calculate a tentative number of samples  $r_{[i]}$  to take from alternative  $[i]$ ,

$$r_{[i]} = \frac{\tau + \sum_{j \in \mathcal{S}} n_j}{\sum_{j \in \mathcal{S}} \sqrt{\gamma_j / \gamma_{[i]}}} - n_{[i]},$$

where

$$\gamma_{[i]} = \begin{cases} \sqrt{\lambda_{i,M}} \phi \left( \sqrt{\lambda_{i,M}} (\mu_{[M]}^n - \mu_{[i]}^n) \right) & \text{if } [i] \neq [M], \\ \sum_{[j] \in \mathcal{S} \setminus \{[M]\}} \gamma_{[j]} & \text{if } [i] = [M]. \end{cases}$$

- (v) For each  $[i] \in \mathcal{S}$  with  $r_{[i]} < 0$ , remove  $[i]$  from  $\mathcal{S}$  and set  $r_{[i]} = 0$ . If any  $[i]$  was removed, then return to step (iii).
- (vi) Round the  $r_{[i]}$  to integer values so that they still sum to  $\tau$ .
- (vii) Run  $r_{[i]}$  additional samples for each alternative  $[i]$ .

## KERNEL DENSITY ESTIMATION AND GOODNESS-OF-FIT TEST IN ADAPTIVE TRACKING\*

BERNARD BERCU<sup>†</sup> AND BRUNO PORTIER<sup>‡</sup>

**Abstract.** We investigate the asymptotic properties of a recursive kernel density estimator of the driven noise of multivariate ARMAX models in adaptive tracking. We provide an almost sure pointwise and uniform strong law of large numbers as well as a pointwise and multivariate central limit theorem. We also carry out a goodness-of-fit test together with some simulation experiments.

**Key words.** adaptive control, kernel density estimation, goodness-of-fit test

**AMS subject classifications.** 93C40, 62G07, 62G10

**DOI.** 10.1137/070694739

**1. Introduction.** Since the pioneer work of Aström and Wittenmark [1], a wide range of literature is available on parametric estimation and adaptive tracking for linear regression models [4], [5], [6] [9], [13], [14], [15], [16]. However, only a few references may be found on nonparametric estimation in adaptive tracking [20], [21], [22], [25]. Our goal is to investigate the asymptotic properties of a kernel density estimator associated with the driven noise of a linear regression in adaptive tracking and to carry out a goodness-of-fit test. Consider the multivariate ARMAX model of order  $(p, q, r)$  given, for all  $n \geq 0$ , by

$$(1.1) \quad A(R)X_n = B(R)U_n + C(R)\varepsilon_n,$$

where  $X_n, U_n$ , and  $\varepsilon_n$  are the  $d$ -dimensional system output, input, and driven noise, respectively. Denote by  $R$  the shift-back operator and set

$$\begin{aligned} A(R) &= I_d - A_1R - \cdots - A_pR^p, \\ B(R) &= B_1R + \cdots + B_qR^q, \\ C(R) &= I_d + C_1R + \cdots + C_rR^r, \end{aligned}$$

where  $A_i, B_j$ , and  $C_k$  are unknown matrices and  $I_d$  is the identity matrix of order  $d$ . For the sake of simplicity, we shall assume that the high frequency gain matrix  $B_1$  is known with  $B_1 = I_d$ . Hence, the unknown parameter of the model is given by

$$\theta^t = (A_1, \dots, A_p, B_2, \dots, B_q, C_1, \dots, C_r).$$

Relation (1.1) can be rewritten as

$$(1.2) \quad X_{n+1} = \theta^t \Psi_n + U_n + \varepsilon_{n+1},$$

---

where

$$\Psi_n^t = (X_n^t, \dots, X_{n-p+1}^t, U_{n-1}^t, \dots, U_{n-q+1}^t, \varepsilon_n^t, \dots, \varepsilon_{n-r+1}^t).$$

The most common way for estimating  $\theta$  is to make use of the extended least-squares (ELS) algorithm given, for all  $n \geq 0$ , by

$$\begin{aligned}\hat{\theta}_{n+1} &= \hat{\theta}_n + S_n^{-1} \Phi_n (X_{n+1} - U_n - \hat{\theta}_n^t \Phi_n)^t, \\ \hat{\varepsilon}_{n+1} &= X_{n+1} - U_n - \hat{\theta}_n^t \Phi_n, \\ \Phi_n^t &= (X_n^t, \dots, X_{n-p+1}^t, U_{n-1}^t, \dots, U_{n-q+1}^t, \hat{\varepsilon}_n^t, \dots, \hat{\varepsilon}_{n-r+1}^t),\end{aligned}$$

where the initial value  $\hat{\theta}_0$  may be arbitrarily chosen. Moreover,

$$S_n = \sum_{i=0}^n \Phi_i \Phi_i^t + S,$$

where  $S$  is a positive definite and deterministic matrix introduced in order to avoid useless invertibility assumption. The crucial role played by the control  $U_n$  is to regulate the dynamic of the process  $(X_n)$  by forcing  $X_n$  to track step-by-step a bounded predictable reference trajectory  $x_n^*$ . Via the certainty equivalence principle [1], the adaptive tracking control  $U_n$  is given, for all  $n \geq 0$ , by

$$(1.3) \quad U_n = x_{n+1}^* - \hat{\theta}_n^t \Phi_n.$$

By substituting (1.3) into (1.2), we obtain the closed-loop system

$$(1.4) \quad X_{n+1} - x_{n+1}^* = \pi_n + \varepsilon_{n+1},$$

where

$$\pi_n = \theta^t \Psi_n - \hat{\theta}_n^t \Phi_n$$

is the prediction error at time  $n$ . In the following, we shall assume that the driven noise  $(\varepsilon_n)$  is a sequence of centered independent and identically distributed random vectors with positive definite covariance matrix  $\Gamma$  and unknown probability density function denoted by  $f$ .

The purpose of this paper is to study the asymptotic properties of a kernel density estimator (KDE) of  $f$ . Since the pioneer works of Parzen [18] and Rosenblatt [23], the asymptotic properties of such a kernel estimator have been widely investigated in the context of independent and identically distributed random variables as well as for mixing random variables. We refer the reader to [10], [11], [24] for some excellent books on density estimation for stationary processes. Although the stability of ARMAX models in adaptive tracking has been deeply investigated in the literature [9], [12], one can realize that kernel density estimation results are not available in adaptive tracking.

Let us now define our KDE of  $f$  associated with model (1.2). When the sequence  $(\varepsilon_n)$  is observable, the traditional Parzen–Rosenblatt KDE of  $f$  is given, for all  $x \in \mathbb{R}^d$  and  $n \geq 1$ , by

$$f_n(x) = \frac{1}{nh_n^d} \sum_{i=1}^n K\left(\frac{\varepsilon_i - x}{h_n}\right),$$

where the kernel  $K$  is a chosen density function and the bandwidth  $(h_n)$  is a sequence of positive real numbers decreasing to zero. In our situation, the sequence  $(\varepsilon_n)$  is of course unobservable. However, when the tracking objective is fulfilled, the prediction error  $\pi_n$  is as close as possible to zero. Consequently, via (1.4), we can choose  $X_n - x_n^*$  as a predictor of  $\varepsilon_n$ . Moreover, since we are in an adaptive tracking framework, it is more suitable to make use of a recursive kernel density estimator (RKDE) of  $f$  given, for all  $x \in \mathbb{R}^d$  and  $n \geq 1$ , by

$$(1.5) \quad \hat{f}_n(x) = \frac{1}{n} \sum_{i=1}^n \frac{1}{h_i^d} K\left(\frac{X_i - x_i^* - x}{h_i}\right).$$

Our purpose is first to show that  $\hat{f}_n$  behaves pretty well as a RKDE of  $f$  in adaptive tracking and second to carry out a goodness-of-fit test for  $f$  based on  $\hat{f}_n$ . Such a goodness-of-fit test is very popular in time series, in particular, for testing the normality hypothesis. For independent and identically distributed samples, we can mention the well-known and very popular Kolmogorov–Smirnov and Cramér–Von Mises statistical tests based on the empirical distribution function as well as the Bickel and Rosenblatt test [7] based on a KDE. Recently, for stationary autoregressive processes, several authors have proposed goodness-of-fit tests based on KDE [2], [17]. However, to the best of our knowledge, no work is concerned with asymptotic properties of KDE in adaptive tracking.

The paper is organized as follows. Section 2 is devoted to the asymptotic behavior of  $\hat{f}_n$ . We establish the almost sure pointwise and uniform convergence of  $\hat{f}_n$  to  $f$  as well as a pointwise law of iterated logarithm (LIL) and a pointwise multivariate central limit theorem (CLT). Section 3 is concerned with the goodness-of-fit test for  $f$ . Finally, some simulation experiments are given in section 4. All technical proofs are postponed in appendices.

**2. Main results.** In the following, we shall assume that the kernel  $K$  is a non-negative function, bounded with compact support, such that

$$\int_{\mathbb{R}^d} K(t) dt = 1 \quad \text{and} \quad \int_{\mathbb{R}^d} K^2(t) dt = \tau^2.$$

For example, for some  $s > 0$  and some known positive constants  $a_s, b_s, c_s$ , one can make use of the uniform kernel on the sphere of  $\mathbb{R}^d$  with radius  $s$ ,  $K(t) = a_s \mathbb{I}_{(\|t\| \leq s)}$ , the Epanechnikov kernel with scaling factor  $s$ ,  $K(t) = b_s (1 - \|t\|^2/s^2) \mathbb{I}_{(\|t\| \leq s)}$ , and the Gaussian kernel with truncation level  $s$ ,  $K(t) = c_s \exp(-\|t\|^2/2) \mathbb{I}_{(\|t\| \leq s)}$ .

Moreover, we shall assume that the bandwidth  $(h_n)$  is a sequence of positive real numbers, decreasing to zero, such that  $nh_n^d$  tends to infinity and

$$\sum_{i=1}^n h_i = O(nh_n).$$

This mild condition, due to the recursive form of  $\hat{f}_n$ , is clearly not restrictive. For example, one can choose  $h_n = n^{-\alpha}$  with  $\alpha \in ]0, 1/d[$ .

Furthermore, we shall also make use of the classical assumptions of causality and passivity as well as the traditional smoothness hypothesis on the probability density function  $f$ .

**Causality** [A1]. For all  $z \in \mathbb{C}$  with  $|z| \leq 1$ ,  $\det(z^{-1}B(z)) \neq 0$ .

**Passivity** [A2]. For all  $z \in \mathbb{C}$  with  $|z| = 1$ ,  $\det(C(z)) \neq 0$  and  $C^{-1}(z) > \frac{1}{2}I_d$ .

**Density** [A3]. The function  $f$  is positive and differentiable with bounded gradient.

We shall now propose several asymptotic results for the RKDE  $\hat{f}_n$  of  $f$ , the first one dealing with the almost sure convergence properties of  $\hat{f}_n$ .

**THEOREM 2.1.** Assume that [A1] to [A3] hold and suppose that  $(\varepsilon_n)$  has finite moment of order  $a > 2$ . In addition, assume that  $nh_n^d$  tends to infinity faster than  $(\log n)^2$ . Then, for any  $x \in \mathbb{R}^d$ ,  $\hat{f}_n(x)$  converges a.s. to  $f(x)$ . As soon as the bandwidth  $(h_n)$  satisfies  $\max(nh_n^{d+2}, n^b h_n^d) = o(\log \log n)$  for some  $b \in ]2/a, 1[$ , we also have

$$(2.1) \quad \limsup_{n \rightarrow \infty} \left( \frac{nh_n^d}{2\tau^2 \|f\|_\infty \log \log n} \right)^{1/2} \left| \hat{f}_n(x) - f(x) \right| \leq 1 \quad \text{a.s.}$$

Moreover, assume that the kernel  $K$  is Lipschitz and that the bandwidth  $(h_n)$  is given by  $h_n = n^{-\alpha}$  with  $\alpha \in ]0, 1/d[$ . Then,  $\hat{f}_n$  converges a.s. to  $f$ , uniformly on all compact sets of  $\mathbb{R}^d$  and, for any  $\beta \in ](1+c)/2, 1[$  with  $c = \max(b, \alpha d)$ ,

$$(2.2) \quad \sup_{x \in \mathbb{R}^d} \left| \hat{f}_n(x) - f(x) \right| = O(n^{-\alpha}) + o(n^{\beta-1}) \quad \text{a.s.}$$

*Proof.* The proof is given in Appendix A.  $\square$

**Remark 1.** The bandwidth condition associated with the almost sure pointwise convergence is clearly not restrictive and it is satisfied when  $h_n = n^{-\alpha}$  with  $\alpha \in ]0, 1/d[$ . In this particular case, the bandwidth condition required for the LIL is obviously satisfied as soon as  $\alpha \in ]\delta, 1/d[$  with  $\delta = \max(1/(d+2), b/d)$ .

**Remark 2.** In the particular case of controlled autoregressive process

$$(2.3) \quad X_{n+1} = A_1 X_n + \cdots + A_p X_{n-p+1} + U_n + \varepsilon_{n+1},$$

the assumptions [A1] and [A2] are clearly useless and the associated prediction errors sequence  $(\pi_n)$  satisfies (see, e.g., [5])

$$(2.4) \quad \sum_{i=0}^n \|\pi_i\|^2 = O(\log n) \quad \text{a.s.}$$

Thanks to this sharp result on the sequence  $(\pi_n)$ , we only have to assume that  $\max(nh_n^{d+2}, h_n^d \log n) = o(\log \log n)$  for the LIL. This bandwidth condition is immediately satisfied when  $h_n = n^{-\alpha}$  with  $\alpha \in ]1/(d+2), 1/d[$ . Moreover, for the uniform convergence, it is only necessary to assume that  $\beta \in ](1+\alpha d)/2, 1[$ . All of the above is also true for the scalar nonlinear controlled autoregressive process

$$(2.5) \quad X_{n+1} = \theta \varphi(X_n, \dots, X_{n-p+1}) + U_n + \varepsilon_{n+1}$$

under suitable moment assumption on  $(\varepsilon_n)$  and as soon as the function  $\varphi : \mathbb{R}^p \rightarrow \mathbb{R}$  does not increase to infinity faster than a polynomial of degree  $< 4$  [6]. We are again able to deduce such results because the associated prediction errors sequence  $(\pi_n)$  satisfies (2.4). Finally, Theorem 2.1 holds for the RKDE associated with nonlinear controlled autoregressive processes as soon as the associated prediction errors sequence  $(\pi_n)$  satisfies a stability property such as (2.4).

Our second result is a pointwise and a multivariate CLT for  $\hat{f}_n$ .

THEOREM 2.2. Assume that [A1] to [A3] hold and suppose that  $(\varepsilon_n)$  has finite moment of order  $a > 2$ . Moreover, assume that the bandwidth  $(h_n)$  satisfies  $\max(nh_n^{d+2}, n^b h_n^d) = o(1)$  for some  $b \in ]2/a, 1[$ , together with

$$(2.6) \quad \lim_{n \rightarrow \infty} \frac{h_n^d}{n} \sum_{i=1}^n h_i^{-d} = \ell_h$$

for some finite constant  $\ell_h > 0$ . Then, for any  $x \in \mathbb{R}^d$ , we have the pointwise CLT

$$(2.7) \quad G_n(x) = \sqrt{n h_n^d} \left( \hat{f}_n(x) - f(x) \right) \xrightarrow{\mathcal{L}} \mathcal{N}(0, \tau^2 \ell_h f(x)) = G(x).$$

In addition, for  $N$  distinct points  $x_1, \dots, x_N$  of  $\mathbb{R}^d$ , we also have

$$(2.8) \quad (G_n(x_1), \dots, G_n(x_N)) \xrightarrow{\mathcal{L}} (G(x_1), \dots, G(x_N)),$$

where  $G(x_1), \dots, G(x_N)$  are independent Gaussian random variables.

*Proof.* The proof is given in Appendix B.  $\square$

*Remark 3.* Convergence (2.7) is identical to the one obtained by Duflo [12] for stationary processes. Besides, it is worthless to require the bandwidth condition (2.6) for the nonrecursive KDE of  $f$ , and  $\ell_h$  has to be replaced by 1 in (2.7). Finally, if  $h_n = n^{-\alpha}$ , it is necessary to assume that  $\alpha \in ]\delta, 1/d[$  with  $\delta = \max(1/(d+2), b/d)$  and we obviously have  $\ell_h = (1 + \alpha d)^{-1}$ . In addition, for the controlled autoregressive processes given by (2.3) or (2.5), we only have to assume that  $\alpha \in ]1/(d+2), 1/d[$ .

*Remark 4.* When the density function  $f$  belongs to  $C^2(\mathbb{R}^d)$  with a bounded second derivative and for symmetric kernel  $K$ , we can relax the bandwidth condition by  $\max(nh_n^{d+4}, n^b h_n^d) = o(1)$ .

**3. Application to a goodness-of-fit test.** We shall now propose a statistical test associated with the probability density function  $f$  based on the convergence results of section 2. We wish to test

$$\mathcal{H}_0 : \langle\langle f = f_0 \rangle\rangle \quad \text{vs} \quad \mathcal{H}_1 : \langle\langle f \neq f_0 \rangle\rangle$$

where  $f_0$  is a given probability density function. It is well known that such a goodness-of-fit test is very important and it has been widely investigated in time series analysis since the pioneer works of Kolmogorov–Smirnov and Cramér–Von Mises. Indeed, many statistical procedures require the assumption of normality for the driven white noise (see, e.g., [3] or [8]). Consequently, a goodness-of-fit test for the white noise density is of particular interest. However, no such a statistical test is available in the adaptive tracking framework, although several situations require the normality assumption on the driven white noise. Our purpose is to provide a goodness-of-fit test for  $f$  based on the RKDE  $\hat{f}_n$ . Such an approach has been already used by Bickel and Rosenblatt [7]. Indeed, for the independent and identically distributed sample, they proposed a statistical test based on the integrated quadratic deviation between the true density and a KDE of  $f$ . This approach has been extended to the scalar autoregressive framework by Lee and Na [17] and more recently by Bachmann and Dette [2]. However, due to some technical reasons, it seems impossible to extend this approach to our adaptive tracking context. Therefore, we propose a new strategy and we carry out a goodness-of-fit test for  $f$  based on the multivariate CLT for  $\hat{f}_n$  together with the LIL. Our statistical test consists of a suitably normalized sum of

the quadratic deviation between the true density and the RKDE  $\widehat{f}_n$  evaluated on  $N$  distinct points of  $\mathbb{R}^d$ . More precisely, it is defined by

$$T_n(N) = \frac{1}{\tau^2 \ell_h} \sum_{j=1}^N \frac{(\widehat{f}_n(x_j) - f_0(x_j))^2}{\widehat{f}_n(x_j)},$$

where  $x_1, \dots, x_N$  are  $N$  distinct points of  $\mathbb{R}^d$ . We shall make use of

$$\sigma^2 = \frac{1}{\tau^2 \ell_h} \sum_{j=1}^N \frac{(f(x_j) - f_0(x_j))^2}{f(x_j)} \quad \text{and} \quad \lambda^2 = \frac{1}{\tau^2 \ell_h} \sum_{j=1}^N \frac{(f^2(x_j) - f_0^2(x_j))^2}{f^3(x_j)}.$$

**THEOREM 3.1.** *Assume that [A1] to [A3] hold and suppose that  $(\varepsilon_n)$  has finite moment of order  $a > 2$ . Moreover, assume that the bandwidth  $(h_n)$  shares the same assumptions as in Theorem 2.2 and is such that  $nh_n^d$  goes to infinity faster than  $(\log n)^2$ . Then, under  $\mathcal{H}_0$ ,*

$$(3.1) \quad nh_n^d T_n(N) \xrightarrow{\mathcal{L}} \chi^2(N).$$

Moreover, under  $\mathcal{H}_1$  and if one can find  $x \in \{x_1, x_2, \dots, x_N\}$  such that  $f(x) \neq f_0(x)$ , then  $T_n(N)$  converges a.s. towards  $\sigma^2$ . In addition, we also have

$$(3.2) \quad \sqrt{nh_n^d} (T_n(N) - \sigma^2) \xrightarrow{\mathcal{L}} \mathcal{N}(0, \lambda^2).$$

*Remark 5.* According to these asymptotic results, it is possible to construct a goodness-of-fit test associated with  $f$ . On the one hand, under the null hypothesis  $\mathcal{H}_0$ , we can approximate for  $n$  large enough the distribution of  $nh_n^d T_n(N)$  by a  $\chi^2(N)$  one. On the other hand, under the alternative hypothesis  $\mathcal{H}_1$ , if  $\sigma^2$  is positive,  $nh_n^d T_n(N)$  goes a.s. to infinity, which guarantees that the asymptotic power of our test is equal to 1. From a practical point of view, the null hypothesis  $\mathcal{H}_0$  will be rejected at level  $\delta$  whenever  $nh_n^d T_n(N) > a_\delta$  where  $a_\delta$  stands for the  $(1 - \delta)$  quantile of the  $\chi^2(N)$  distribution. Finally, one can observe that the weak convergence (3.2) allows us to evaluate the probability of the type II error of our test.

*Remark 6.* It is also possible to make use of the test statistic  $Z_n(N)$  defined by

$$Z_n(N) = \frac{1}{\tau^2 \ell_h} \sum_{j=1}^N \frac{(\widehat{f}_n(x_j) - f_0(x_j))^2}{f_0(x_j)}.$$

In that case, Theorem 3.1 holds with

$$\sigma^2 = \frac{1}{\tau^2 \ell_h} \sum_{j=1}^N \frac{(f(x_j) - f_0(x_j))^2}{f_0(x_j)} \quad \text{and} \quad \lambda^2 = \frac{4}{\tau^2 \ell_h} \sum_{j=1}^N \frac{(f(x_j) - f_0(x_j))^2 f(x_j)}{f_0^2(x_j)}.$$

This statistical test should improve the empirical level under  $\mathcal{H}_0$ , but it should certainly degrade the empirical power under  $\mathcal{H}_1$ . Nevertheless, it is easier to compute than  $T_n(N)$  because it allows one to avoid the division by  $\widehat{f}_n(x_j)$ , which can be equal to zero due to the use of a compactly supported kernel.

*Proof.* The proof is straightforward by use of Theorem 2.1 together with Theorem 2.2. As a matter of fact, we have the decomposition

$$(3.3) \quad T_n(N) - \sigma^2 = A_n + B_n,$$

where

$$A_n = \frac{1}{\tau^2 \ell_h} \sum_{j=1}^N \frac{\left( \widehat{f}_n(x_j) - f(x_j) \right)^2}{\widehat{f}_n(x_j)},$$

$$B_n = \frac{1}{\tau^2 \ell_h} \sum_{j=1}^N \frac{\left( \widehat{f}_n(x_j) - f(x_j) \right)}{\widehat{f}_n(x_j)} \frac{(f^2(x_j) - f_0^2(x_j))}{f(x_j)}.$$

We can deduce from (2.8) and the pointwise almost sure convergence of  $\widehat{f}_n$  to  $f$  that

$$(3.4) \quad \sqrt{\frac{n h_n^d}{\tau^2 \ell_h}} \left( \frac{\widehat{f}_n(x_1) - f(x_1)}{\sqrt{\widehat{f}_n(x_1)}}, \dots, \frac{\widehat{f}_n(x_N) - f(x_N)}{\sqrt{\widehat{f}_n(x_N)}} \right) \xrightarrow{\mathcal{L}} \mathcal{N}(0, I_N),$$

where  $I_N$  stands for the identity matrix of order  $N$ . Hence, it immediately follows from (3.4) that

$$(3.5) \quad n h_n^d A_n \xrightarrow{\mathcal{L}} \chi^2(N).$$

Consequently, we clearly obtain (3.1) from (3.3) together with (3.5) since, under the null hypothesis  $\mathcal{H}_0$ ,  $\sigma^2$  and  $B_n$  vanish. Under the alternative hypothesis  $\mathcal{H}_1$ , it is straightforward to see that  $T_n(N)$  converges a.s. towards  $\sigma^2$  via the almost sure pointwise convergence of  $\widehat{f}_n$  to  $f$ . Only convergence (3.2) remains to be proven. On the one hand, by the pointwise LIL, we infer that

$$|A_n| = O\left(\frac{\log \log n}{n h_n^d}\right) \quad \text{a.s.},$$

which implies that

$$(3.6) \quad \sqrt{n h_n^d} A_n = o(1) \quad \text{a.s.}$$

as  $n h_n^d$  goes to infinity faster than  $(\log n)^2$ . On the other hand, we can deduce from (3.4) that

$$(3.7) \quad \sqrt{n h_n^d} B_n \xrightarrow{\mathcal{L}} \mathcal{N}(0, \lambda^2).$$

Finally, convergence (3.2) immediately follows from the conjunction of (3.3), (3.6), and (3.7), which completes the proof of Theorem 3.1.  $\square$

**4. Simulation experiments.** In this section, we investigate the finite sample properties of our statistical test under both hypotheses  $\mathcal{H}_0$  and  $\mathcal{H}_1$  without some bootstrap procedure as is usual in this context of nonparametric tests. Since it has never been experimented, we shall not restrict ourselves to models of form (1.2), but

FIG. 4.1.

we will also consider some closely related stationary models. Our goal is to show that our statistical test behaves pretty well in many different situations. The different models that we will study are given as follows.

$$(WN) \quad X_n = \varepsilon_n,$$

$$(AR) \quad X_{n+1} = \theta X_n + \varepsilon_{n+1},$$

$$(ARX) \quad X_{n+1} = \theta X_n + U_n + \varepsilon_{n+1},$$

$$(NARX) \quad X_{n+1} = \theta X_n^2 + U_n + \varepsilon_{n+1},$$

where  $(\varepsilon_n)$  is a sequence of centered independent and identically distributed random variables with probability density function  $f$ . We choose  $\theta = 7/10$ ,  $\theta = 2$ , and  $\theta = 1/2$  for the AR, ARX, and NARX models, respectively. We consider three choices of noise distributions, given in Figure 4.1, that we combine two-by-two in order to study the performances of our statistical test under both  $\mathcal{H}_0$  and  $\mathcal{H}_1$ . The first one is the standard normal distribution

$$f_0(x) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{x^2}{2}\right).$$

The second one is the normalized double exponential distribution

$$f_1(x) = \frac{1}{\sqrt{2}} \exp\left(-\sqrt{2}|x|\right).$$

The last one is the standardized chi-square distribution with twelve degrees of freedom

$$f_2(x) = \frac{9}{5}(x + \sqrt{6})^5 \exp\left(-\sqrt{6}(x + \sqrt{6})\right) \mathbb{1}_{(x \geq -\sqrt{6})}.$$

For AR, ARX, and NARX models, we estimate the unknown parameter  $\theta$  by use of the standard least-squares estimator  $\hat{\theta}_n$ . For the AR model, the probability density function  $f$  is estimated using the RKDE given by (1.5) where  $X_n - x_n^*$  is replaced

by  $X_n - \hat{\theta}_n X_{n-1}$ . For ARX and NARX models, the adaptive control  $U_n$  is given by  $U_n = -\hat{\theta}_n X_n$  and  $U_n = -\hat{\theta}_n X_n^2$ , respectively.

For each model and each test of  $\mathcal{H}_0$  against  $\mathcal{H}_1$ , we base our estimations on 800 independent realizations of sample sizes  $n = 200, 500$ , and  $1000$ . We are interested in the empirical level under  $\mathcal{H}_0$  to be compared with the theoretical level equal to 5% and the empirical power under  $\mathcal{H}_1$ , as well as the closeness between the simulated distribution of our statistical test and the corresponding theoretical distribution. The implementation of our statistic test  $T_n(N)$  requires the choice of design points together with the specification of a bandwidth and a kernel for the RKDE  $\hat{f}_n$ . The RKDE  $\hat{f}_n$  is constructed by use of the Epanechnikov kernel

$$K(t) = \frac{3}{4} (1 - t^2) \mathbb{I}_{(|t| \leq 1)}$$

and the bandwidth  $h_n = n^{-1/3}$ . For the denominator of  $T_n(N)$ , we use the Gaussian kernel and the usual bandwidth  $h_n = n^{-1/5}$ . Via this choice, we avoid a possible division by zero and we provide a smoother version for the estimation of  $f$ . Finally, for ARX and NARX models, we use a short learning period of  $\tau = 100$  time steps. This learning period allows us to forget the transitory phase.

For the choice of  $N$  and the points  $x_1, \dots, x_N$ , we use the design points selection rule proposed by Poggi and Portier and fully described in [19]. More precisely, we proceed as follows. Starting from an estimate of the distribution of the driven noise, we choose  $N$  equidistant points  $x_1, \dots, x_N$  so that the density at those points is not too small and in such a way that they are sufficiently distant to ensure sufficient accuracy in the use of the multivariate CLT. Typically, we choose points  $x_1, \dots, x_N$  such that the distance between two neighboring points is  $4n^{-1/3}$ . This last condition allows us to make sure that the independence property in the multivariate CLT, which holds asymptotically, remains true for small to moderate sample sizes. We take  $N = 8, 13$ , and  $22$  equidistant points for sample sizes  $n = 200, 500$ , and  $1000$ , respectively. It should be noted that only a few number of points is needed to make a decision.

In the sequel, the abbreviations  $\mathcal{G}f_0$ ,  $\mathcal{G}f_1$ , and  $\mathcal{G}f_2$  mean that the driven noise ( $\varepsilon_n$ ) is generated with the normal  $f_0$  distribution, the double exponential  $f_1$  distribution, and the chi-square  $f_2$  distribution, respectively, while  $\mathcal{H}f_0$ ,  $\mathcal{H}f_1$ , and  $\mathcal{H}f_2$  mean that we are testing the assumptions  $\mathcal{H}_0 : \langle\langle f = f_0 \rangle\rangle$ ,  $\mathcal{H}_0 : \langle\langle f = f_1 \rangle\rangle$ , and  $\mathcal{H}_0 : \langle\langle f = f_2 \rangle\rangle$ , respectively. Finally, as we have chosen a test level  $\alpha = 5\%$  and we have generated 800 trials, the Kolmogorov–Smirnov fitting statistic in *italic* has to be compared with the critical value 0.048.

We shall now comment on the test results contained in Tables 4.1–4.4. First of all, one can verify that our statistical test behaves pretty well under  $\mathcal{H}_0$ . Indeed, for each model and each noise distribution, the empirical level is close to the 5% theoretical value level as one can realize with the values in **bold**. In addition, the simulated distribution of  $n^{2/3}T_n(N)$  is close to the  $\chi^2(N)$  distribution as one can observe with the values in *italic* of the Kolmogorov–Smirnov fitting statistic to be compared with the critical value at 5% equal to 0.048. Next, one can verify that the empirical power increases with the sample size, from 20% to 40% for  $n = 200$ , to 96% to 100% for  $n = 1000$ ; it is more difficult to decide between  $f_0$  and  $f_2$  than between  $f_1$  and  $f_2$ , which is the easier situation. Finally, if one superimposes the four tables, one can observe that the results for the different models are almost the same. In conclusion, our statistical test behaves pretty well for small to moderate sample sizes and for a large class of models.

FIG. 4.2.

Figure 4.2 illustrates the empirical level and power of our test for the NARX model. We base our estimation on 800 trials of sample size  $n = 500$  with  $N = 13$  equidistant points. The driven noise  $(\varepsilon_n)$  is generated with the normal distribution  $f_0$ , and we are successively testing the assumptions  $\mathcal{H}f_0$ ,  $\mathcal{H}f_1$ , and  $\mathcal{H}f_2$ . On the one hand, when we test the hypothesis  $\mathcal{H}f_0$ , we can observe that the distribution of our statistical test  $n^{2/3}T_n(N)$  is superimposed with the  $\chi^2(N)$  one. It clearly illustrates the good approximation of the distribution of  $n^{2/3}T_n(N)$  by a  $\chi^2(N)$  one under  $\mathcal{H}f_0$  for moderate sample size. On the other hand, when we test the hypothesis  $\mathcal{H}f_1$  as well as  $\mathcal{H}f_2$ , we can effectively see that the distribution of our statistical test  $n^{2/3}T_n(N)$  is totally different from the  $\chi^2(N)$  one. Consequently, the power of separation of our statistical test is clearly significant.

**Appendix A.** This appendix is devoted to the proof of Theorem 2.1. In order to prove the asymptotic properties of our RKDE  $\widehat{f}_n$  of  $f$ , we are led to introduce the martingale  $(M_n)$  associated with the sequence  $(\widehat{f}_n)$ . To be more precise, we infer from (1.5) that for all  $x \in \mathbb{R}^d$  and  $n \geq 1$ ,

$$(A.1) \quad n\left(\widehat{f}_n(x) - f(x)\right) = M_n(x) + R_n(x)$$

with

$$(A.2) \quad M_n(x) = \sum_{i=1}^n \left( K_i(X_i - x_i^* - x) - \mathbb{E}[K_i(X_i - x_i^* - x) | \mathcal{F}_{i-1}] \right),$$

$$(A.3) \quad R_n(x) = \sum_{i=1}^n \mathbb{E}[K_i(X_i - x_i^* - x) | \mathcal{F}_{i-1}] - n f(x),$$

where, for all  $y \in \mathbb{R}^d$ ,  $K_n(y) = h_n^{-d}K(h_n^{-1}y)$  and  $\mathcal{F}_n$  denotes the  $\sigma$ -algebra of the events occuring up to time  $n$ . The almost sure properties of  $(M_n)$  are given by the two following lemmas.

LEMMA A.1. Assume that  $nh_n^d$  tends to infinity faster than  $(\log n)^2$ . Then, for any  $x \in \mathbb{R}^d$ , we have  $M_n(x) = o(n)$  a.s. More precisely,

$$(A.4) \quad \limsup_{n \rightarrow \infty} \frac{|M_n(x)|}{\sqrt{2\tau^2 \|f\|_\infty n h_n^{-d} \log \log n}} \leq 1 \quad a.s.$$

*Proof.* For any  $x \in \mathbb{R}^d$ ,  $(M_n(x))$  is a square integrable real martingale. In addition, its increasing process  $(\langle M(x) \rangle_n)$  satisfies  $\langle M(x) \rangle_n = O(nh_n^{-d})$ . As a matter of fact, for all  $x \in \mathbb{R}^d$ ,

$$\langle M(x) \rangle_n = \sum_{i=1}^n \mathbb{E} [K_i^2 (X_i - x_i^* - x) | \mathcal{F}_{i-1}] - \sum_{i=1}^n (\mathbb{E} [K_i (X_i - x_i^* - x) | \mathcal{F}_{i-1}])^2.$$

Consequently, we deduce from (1.4) that for all  $x \in \mathbb{R}^d$

$$(A.5) \quad \langle M(x) \rangle_n \leq \sum_{i=1}^n h_i^{-2d} \int_{\mathbb{R}^d} K^2(h_i^{-1}(\pi_{i-1} + s - x)) f(s) ds.$$

Via the change of variables  $t = h_i^{-1}(\pi_{i-1} + s - x)$  into (A.5), we find that

$$\langle M(x) \rangle_n \leq \sum_{i=1}^n h_i^{-d} \int_{\mathbb{R}^d} K^2(t) f(h_i t + x - \pi_{i-1}) dt \leq \tau^2 \|f\|_\infty \sum_{i=1}^n h_i^{-d}.$$

Therefore, as  $(h_n)$  is decreasing,  $\langle M(x) \rangle_n = O(nh_n^{-d})$ . Hence, it follows from the strong law of large numbers for martingales (see, e.g., [12], Theorem 1.3.15, p. 20) that for all  $\gamma > 0$ ,

$$|M_n(x)|^2 = o(nh_n^{-d}(\log n)^{1+\gamma}) \quad a.s.,$$

which ensures that  $M_n(x) = o(n)$  a.s. since  $nh_n^d$  tends to infinity faster than  $(\log n)^2$ . Furthermore, for any  $x \in \mathbb{R}^d$ ,  $|M_n(x) - M_{n-1}(x)| \leq 2h_n^{-d} \|K\|_\infty$  which clearly implies that

$$|M_n(x) - M_{n-1}(x)| \leq C_n \sqrt{\frac{nh_n^{-d}}{\log \log n}},$$

where  $(C_n)$  is a deterministic sequence which tends to zero. Finally, we immediately obtain (A.4) from the upper bound in the law of iterated logarithm for martingales (see, e.g., [12], Theorem 6.4.24, p. 209).  $\square$

LEMMA A.2. Assume that the kernel  $K$  is Lipschitz and that the bandwidth  $(h_n)$  is given by  $h_n = n^{-\alpha}$  with  $\alpha \in ]0, 1/d[$ . Then, for any constants  $A > 0$  and  $\gamma > 0$ , we have the expanded uniform strong law

$$(A.6) \quad \sup_{\|x\| \leq An^\gamma} |M_n(x)| = o(n^\beta) \quad a.s.,$$

where  $\beta \in ](1 + \alpha d)/2, 1[$ .

*Proof.* Result (A.6) follows from the expanded uniform strong law for martingales given by Theorem 6.4.34, p. 220 of [12]. First of all, for all  $x \in \mathbb{R}^d$ , set  $\Delta M_n(x) = M_n(x) - M_{n-1}(x)$ . We already saw in the proof of Lemma A.1 that there exists two

positive constants  $a, b$  such that, for all  $n \geq 1$ ,  $\langle M(0) \rangle_n \leq an^{1+\alpha d}$  and  $|\Delta M_n(0)| \leq bn^{\alpha d}$ . In addition, since the kernel  $K$  is bounded and Lipschitz, for all  $\delta \in ]0, 1[$ , one can find some positive constant  $C_\delta$  such that, for any  $x, y \in \mathbb{R}^d$

$$(A.7) \quad |K(x) - K(y)| \leq C_\delta \|x - y\|^\delta.$$

Hence, for any  $x, y \in \mathbb{R}^d$ , we can derive that

$$|\Delta M_n(x) - \Delta M_n(y)| \leq 2 C_\delta \|x - y\|^\delta n^{\alpha(d+\delta)}.$$

Furthermore, similarly to (A.5), we have for any  $x, y \in \mathbb{R}^d$

$$\langle M(x) - M(y) \rangle_n \leq \sum_{i=1}^n i^{2\alpha d} \int_{\mathbb{R}^d} \left( K(i^\alpha(\pi_{i-1} + s - x)) - K(i^\alpha(\pi_{i-1} + s - y)) \right)^2 f(s) ds,$$

which, by the change of variables  $t = i^\alpha(\pi_{i-1} + s - x)$ , leads to

$$(A.8) \quad \langle M(x) - M(y) \rangle_n \leq \|f\|_\infty \sum_{i=1}^n i^{\alpha d} \int_{\mathbb{R}^d} (K(t) - K(t + i^\alpha(x - y)))^2 dt.$$

In addition, as  $K$  is a density function, it follows from (A.7) that

$$\int_{\mathbb{R}^d} (K(t) - K(t + i^\alpha(x - y)))^2 dt \leq 2 C_{2\delta} \|x - y\|^{2\delta} i^{2\alpha\delta}.$$

Therefore, we deduce from (A.8) that for any  $x, y \in \mathbb{R}^d$

$$\langle M(x) - M(y) \rangle_n \leq 2 C_{2\delta} \|x - y\|^{2\delta} n^{1+\alpha d+2\alpha\delta}.$$

Since the power  $\delta$  can be chosen as small as one wishes, all four conditions of Theorem 6.4.34 of [12] are fulfilled which leads to Lemma A.2.  $\square$

*Proof of Theorem 2.1.* In order to prove Theorem 2.1, it remains to study the almost sure asymptotic behavior of the remainder  $R_n(x)$  in (A.1). It follows from (A.3) that

$$\begin{aligned} R_n(x) &= \sum_{i=1}^n h_i^{-d} \int_{\mathbb{R}^d} K(h_i^{-1}(\pi_{i-1} + s - x)) f(s) ds - n f(x), \\ &= \sum_{i=1}^n \int_{\mathbb{R}^d} K(t) (f(h_i t + x - \pi_{i-1}) - f(x)) dt, \end{aligned}$$

via the change of variables  $t = h_i^{-1}(\pi_{i-1} + s - x)$ . As the density function  $f$  is differentiable with a bounded gradient, we obtain by a Taylor expansion that

$$\sup_{x \in \mathbb{R}^d} |R_n(x)| = O\left(\sum_{i=1}^n h_i\right) + O\left(\sum_{i=1}^n \|\pi_{i-1}\|\right) \quad \text{a.s.}$$

Moreover, since  $(\varepsilon_n)$  has a finite moment of order  $a > 2$ , we deduce from [A1] and [A2] together with Theorem 1 of [13] that

$$(A.9) \quad \sum_{i=1}^n \|\pi_{i-1}\|^2 = O(n^b) \quad \text{a.s.}$$

for all  $b \in ]2/a, 1[$ . Hence, it follows from (A.9) together with the Cauchy–Schwarz inequality that

$$(A.10) \quad \sup_{x \in \mathbb{R}^d} |R_n(x)| = O(nh_n) + O(\sqrt{n^{1+b}}) \quad \text{a.s.}$$

Consequently,  $R_n(x) = o(n)$  a.s., which ensures that  $\widehat{f}_n(x)$  converges a.s. to  $f(x)$ . Moreover, we obtain (2.1) from the conjunction of Lemma A.1 and result (A.10). The uniform, almost sure convergence on  $\mathbb{R}^d$  still remains to be proven. Hereafter, we take  $h_n = n^{-\alpha}$  with  $\alpha \in ]0, 1/d[$ . On the one hand, we find from Lemma A.2 with  $A = 2$  and  $\gamma = 1/2$ , that

$$(A.11) \quad \sup_{\|x\| \leq 2\sqrt{n}} |M_n(x)| = o(n^\beta) \quad \text{a.s.},$$

where  $\beta \in ](1+\alpha d)/2, 1[$ . From now on, we choose  $\beta \in ](1+c)/2, 1[$  with  $c = \max(b, \alpha d)$ . Since  $\beta > (1+b)/2$ , it implies that  $n^{1+b} = o(n^{2\beta})$ . Hence, it follows from the conjunction of (A.10) and (A.11) that

$$(A.12) \quad \sup_{\|x\| \leq 2\sqrt{n}} \left| \widehat{f}_n(x) - f(x) \right| = O(n^{-\alpha}) + o(n^{\beta-1}) \quad \text{a.s.}$$

On the other hand, we claim that

$$(A.13) \quad \sup_{\|x\| > 2\sqrt{n}} \left| \widehat{f}_n(x) - f(x) \right| = O\left(\frac{1}{n}\right) \quad \text{a.s.}$$

As a matter of fact, since  $(\varepsilon_n)$  has a finite moment of order  $a > 2$ , we infer from Lemma 2 of [13] that  $\|X_n\|^2 = O(n^b)$  a.s. for some  $b \in ]2/a, 1[$ , which implies that

$$\sup_{i \leq n} \|X_i - x_i^*\|^2 = o(n) \quad \text{a.s.}$$

Hence, for  $n$  large enough,  $\|X_i - x_i^*\| < \sqrt{n}$  a.s., which ensures that, for  $x$  such that  $\|x\| > 2\sqrt{n}$ ,  $\|X_i - x_i^* - x\| > \sqrt{n}$  a.s. Therefore, since  $K$  is compactly supported, it clearly leads to

$$(A.14) \quad \sup_{\|x\| > 2\sqrt{n}} \left| n\widehat{f}_n(x) \right| = \sup_{\|x\| > 2\sqrt{n}} \left| \sum_{i=1}^n K_i(X_i - x_i^* - x) \right| = O(1) \quad \text{a.s.}$$

In addition, since  $(\varepsilon_n)$  has a finite moment of order  $a > 2$  and  $f$  is positive, it follows that  $f(x) = O(\|x\|^{-3})$  for large values of  $x$ , leading to

$$(A.15) \quad \sup_{\|x\| > 2\sqrt{n}} f(x) = O\left(\frac{1}{n}\right).$$

Consequently, we obtain (A.13) from (A.14) and (A.15). Finally, we deduce (2.2) from (A.12) and (A.13), which completes the proof of Theorem 2.1.  $\square$

**Appendix B.** This appendix is concerned with the proof of Theorem 2.2. We first propose a CLT for the martingale  $(M_n)$ .

LEMMA B.1. Assume that [A1] to [A3] hold and suppose that  $(\varepsilon_n)$  has a finite moment of order  $a > 2$ . Moreover, assume that the bandwidth  $(h_n)$  shares the same assumptions as in Theorem 2.2. Then, for any  $x \in \mathbb{R}^d$ ,

$$(B.1) \quad \frac{M_n(x)}{\sqrt{nh_n^{-d}}} \xrightarrow{\mathcal{L}} \mathcal{N}(0, \tau^2 \ell_h f(x)).$$

*Proof.* In order to prove Lemma B.1, it is necessary to study the asymptotic behavior of the increasing process  $\langle M(x) \rangle_n$  properly normalized. For all  $i \geq 1$  and  $x \in \mathbb{R}^d$ , we have

$$\begin{aligned} \mathbb{E}[K_i(X_i - x_i^* - x) | \mathcal{F}_{i-1}] &= h_i^{-d} \int_{\mathbb{R}^d} K(h_i^{-1}(\pi_{i-1} + s - x)) f(s) \, ds, \\ &= \int_{\mathbb{R}^d} K(t) f(h_i t + x - \pi_{i-1}) \, dt \leq \|f\|_\infty, \end{aligned}$$

which implies that

$$(B.2) \quad \sum_{i=1}^n (\mathbb{E}[K_i(X_i - x_i^* - x) | \mathcal{F}_{i-1}])^2 = O(n) \quad \text{a.s.}$$

Moreover, we also have

$$\begin{aligned} \mathbb{E}[K_i^2(X_i - x_i^* - x) | \mathcal{F}_{i-1}] &= h_i^{-2d} \int_{\mathbb{R}^d} K^2(h_i^{-1}(\pi_{i-1} + s - x)) f(s) \, ds \\ &= h_i^{-d} \int_{\mathbb{R}^d} K^2(t) f(h_i t + x - \pi_{i-1}) \, dt. \end{aligned}$$

Consequently, we obtain the decomposition

$$\sum_{i=1}^n \mathbb{E}[K_i^2(X_i - x_i^* - x) | \mathcal{F}_{i-1}] = A_n + \tau^2 B_n + \tau^2 f(x) C_n,$$

where

$$\begin{aligned} A_n &= \sum_{i=1}^n h_i^{-d} \int_{\mathbb{R}^d} K^2(t) (f(h_i t + x - \pi_{i-1}) - f(x - \pi_{i-1})) \, dt, \\ B_n &= \sum_{i=1}^n h_i^{-d} (f(x - \pi_{i-1}) - f(x)), \\ C_n &= \sum_{i=1}^n h_i^{-d}. \end{aligned}$$

As the gradient of  $f$  is bounded, we clearly have  $|A_n| = O(nh_n^{1-d})$  a.s. and

$$|B_n| = O\left(\sum_{i=1}^n h_i^{-d} \|\pi_{i-1}\|\right) \quad \text{a.s.}$$

Hence, it follows from (A.9) that

$$|B_n| = O\left(h_n^{-d} \sqrt{n^{1+b}}\right) \quad \text{a.s.}$$

for all  $b \in ]2/a, 1[$ . Furthermore, we immediately get from (2.6) that  $n^{-1}h_n^d C_n$  converges to  $\ell_h$  as  $n$  goes to infinity. Putting together those three contributions, we find that

$$(B.3) \quad \lim_{n \rightarrow \infty} \frac{h_n^d}{n} \langle M(x) \rangle_n = \tau^2 \ell_h f(x) \quad \text{a.s.}$$

In order to make use of the CLT for martingales (see, e.g., [12], Corollary 2.1.10, p. 46), it remains to check that Lindeberg's condition is satisfied. For all  $a > 0$  and  $x \in \mathbb{R}^d$ , let

$$\Lambda_n(a, x) = \frac{h_n^d}{n} \sum_{i=1}^n \mathbb{E} \left[ |\Delta M_i(x)|^2 \mathbb{I}_{(|\Delta M_i(x)| \geq a \sqrt{nh_n^{-d}})} | \mathcal{F}_{i-1} \right].$$

We already saw that for all  $i \leq n$ ,  $|\Delta M_i(x)| \leq 2 h_n^{-d} \|K\|_\infty$ . Hence, we clearly have for all  $i \leq n$

$$\mathbb{I}_{(|\Delta M_i(x)| \geq a \sqrt{nh_n^{-d}})} \leq \mathbb{I}_{(2\|K\|_\infty \geq a \sqrt{nh_n^{-d}})}.$$

Consequently, we find that for all  $a > 0$  and  $x \in \mathbb{R}^d$ ,

$$\begin{aligned} \Lambda_n(a, x) &\leq \frac{h_n^d}{n} \mathbb{I}_{(2\|K\|_\infty \geq a \sqrt{nh_n^{-d}})} \sum_{i=1}^n \mathbb{E} \left[ |\Delta M_i(x)|^2 | \mathcal{F}_{i-1} \right], \\ &\leq \frac{h_n^d}{n} \mathbb{I}_{(2\|K\|_\infty \geq a \sqrt{nh_n^{-d}})} \tau^2 \|f\|_\infty \sum_{i=1}^n h_i^{-d}, \\ &\leq \tau^2 \|f\|_\infty \mathbb{I}_{(2\|K\|_\infty \geq a \sqrt{nh_n^{-d}})}. \end{aligned}$$

Therefore, as  $nh_n^d$  tends to infinity, we can deduce that, for all  $a > 0$  and  $x \in \mathbb{R}^d$ ,  $\Lambda_n(a, x)$  tends to zero a.s. Finally, Lindeberg's condition is satisfied, which achieves the proof of Lemma B.1.  $\square$

*Proof of Theorem 2.2.* We are now in position to prove Theorem 2.2. It follows from (A.1) that for any  $x \in \mathbb{R}^d$

$$(B.4) \quad \sqrt{nh_n^d} (\hat{f}_n(x) - f(x)) = \frac{M_n(x) + R_n(x)}{\sqrt{nh_n^{-d}}}.$$

Consequently, (2.7) immediately follows from (A.10) together with (B.1) and (B.4) as soon as  $\max(nh_n^{d+2}, n^b h_n^d) = o(1)$ . The multivariate CLT remains to be proven. Taking the previous results into account, it is enough to prove that for two distinct points  $x, y \in \mathbb{R}^d$ , the random vector

$$\frac{1}{\sqrt{nh_n^{-d}}} \begin{pmatrix} M_n(x) \\ M_n(y) \end{pmatrix} \xrightarrow{\mathcal{L}} \begin{pmatrix} G(x) \\ G(y) \end{pmatrix},$$

where  $G(x)$  and  $G(y)$  are two independent Gaussian random variables. We can easily show this convergence by remarking that for two distinct points  $x, y \in \mathbb{R}^d$

$$(B.5) \quad \lim_{n \rightarrow \infty} \frac{h_n^d}{n} \sum_{i=1}^n \mathbb{E} [\Delta M_i(x) \Delta M_i(y) | \mathcal{F}_{i-1}] = 0 \quad \text{a.s.}$$

Indeed, for all  $i \geq 1$ , we have

$$\begin{aligned}\mathbb{E}[\Delta M_i(x)\Delta M_i(y)|\mathcal{F}_{i-1}] &\leq \mathbb{E}[K_i(X_i - x_i - x)K_i(X_i - x_i - y)|\mathcal{F}_{i-1}], \\ &\leq \mathbb{E}[K_i(\pi_{i-1} + \varepsilon_i - x)K_i(\pi_{i-1} + \varepsilon_i - y)|\mathcal{F}_{i-1}],\end{aligned}$$

which implies that

$$\mathbb{E}[\Delta M_i(x)\Delta M_i(y)|\mathcal{F}_{i-1}] \leq h_i^{-d} \int_{\mathbb{R}^d} K(t)K(t + h_i^{-1}(x - y))f(h_it + x - \pi_{i-1})dt.$$

Therefore, as the gradient of  $f$  is bounded, we obtain from (A.9) that

$$\sum_{i=1}^n \mathbb{E}[\Delta M_i(x)\Delta M_i(y)|\mathcal{F}_{i-1}] \leq H_n(x, y) + O(nh_n^{1-d}) + O(h_n^{-d}\sqrt{n^{1+b}}) \quad \text{a.s.}$$

for all  $b \in ]2/a, 1[$ , where

$$H_n(x, y) = \sum_{i=1}^n h_i^{-d} f(x) \int_{\mathbb{R}^d} K(t)K(t + h_i^{-1}(x - y))dt.$$

However, using the fact that  $K$  is compactly supported, we can deduce that for  $i$  large enough, the integral at the right-hand side of  $H_n(x, y)$  is zero. Finally, we obtain that convergence (B.5) is satisfied, which completes the proof of Theorem 2.2.  $\square$

*Remark 7.* Result (B.5) ensures the asymptotic independence of the random variables  $G_n(x_1), \dots, G_n(x_N)$  in the multivariate CLT. Since the kernel  $K$  is compactly supported, for finite values of  $n$ , the left-hand side of (B.5) can be very small if we choose two points  $x$  and  $y$  sufficiently distant. This last point clarifies the design points selection rule described in section 4.

## IMPORTANT MOMENTS IN SYSTEMS AND CONTROL\*

CHRISTOPHER I. BYRNES<sup>†</sup> AND ANDERS LINDQUIST<sup>‡</sup>

**Abstract.** The moment problem matured from its various special forms in the late 19th and early 20th centuries to a general class of problems that continues to exert profound influence on the development of analysis and its applications to a wide variety of fields. In particular, the theory of systems and control is no exception, where the applications have historically been to circuit theory, optimal control, robust control, signal processing, spectral estimation, stochastic realization theory, and the use of the moments of a probability density. Many of these applications are also still works in progress. In this paper, we consider the generalized moment problem, expressed in terms of a basis of a finite-dimensional subspace  $\mathfrak{P}$  of the Banach space  $C[a, b]$  and a “positive” sequence  $c$ , but with a new wrinkle inspired by the applications to systems and control. We seek to parameterize solutions which are positive “rational” measures in a suitably generalized sense. Our parameterization is given in terms of smooth objects. In particular, the desired solution space arises naturally as a manifold which can be shown to be diffeomorphic to a Euclidean space and which is the domain of some canonically defined functions. The analysis of these functions, and related maps, yields interesting corollaries for the moment problem and its applications, which we compare to those in the recent literature and which play a crucial role in part of our proof.

**1. Introduction.** Given a sequence of complex numbers,  $(c_0, c_1, \dots, c_n)$ , and a basis,  $(\alpha_0, \alpha_1, \dots, \alpha_n)$ , of a (finite-dimensional) subspace  $\mathfrak{P}$  of the Banach space  $C[a, b]$  of complex-valued continuous functions defined on the real interval  $[a, b]$ , the generalized moment problem [21] is to find a positive measure  $d\mu$  such that

$$(1.1) \quad \int_a^b \alpha_k(t) d\mu(t) = c_k, \quad k = 0, 1, \dots, n.$$

This problem is a beautiful generalization of several important classical moment problems, including the power moment problem, the trigonometric moment problem, and the moment problem arising in Nevanlinna–Pick interpolation. There are, of course, necessary conditions stemming from the positivity of  $d\mu$  and whether a particular  $\alpha_k$  is real-valued or not; these will be summarized in section 2.

Among the pioneers in the use of power moments, where  $\alpha_k(t) = t^k$ , we should mention Chebyshev and his students, particularly Markov and Lyapunov, who used them in connection with the classical central limit theorem in the 19th century. On a finite interval this problem is usually called the Hausdorff moment problem and was solved by Hausdorff for an infinite sequence of moments in 1921. The power moment problem for an infinite sequence of moments on an infinite interval is known

as the Hamburger moment problem, while on the semi-infinite interval this is called the Stieltjes moment problem. We refer to [21], especially pages 166–171 and the references therein, for a more detailed historical and technical treatment.

*Remark 1.1.* In classical treatments of the power moment problems [21] it is typical to take  $\mathfrak{P}$  to be the real subspace  $\text{span}_{\mathbb{R}}\{\alpha_0, \dots, \alpha_n\}$ . While in this case the role of the functions  $\alpha_k$  are clear and familiar to any student of probability, it is reasonable to ask why we need  $\mathfrak{P}$ . One of many good reasons for this is that  $\mathfrak{P}$  is a natural space of “test functions” with which to develop necessary and sufficient conditions on the candidate moments for the solvability of the moment equations. For example, if  $p(t) = p_0 + p_1 t + \dots + p_n t^n > 0$  for all  $t \in [a, b]$ , then solvability of the moment equations for a positive measure  $d\mu$  implies that

$$(1.2) \quad \sum_{i=0}^n p_i c_i = \int_a^b p(t) d\mu > 0.$$

This has been refined, in a neat way, to give necessary and sufficient conditions for the solvability of the generalized moment problem (see [21] and the discussion in section 2).

In the trigonometric moment problem, where  $\alpha_k(t) = e^{ikt}$  defined on  $[-\pi, \pi]$ , the constants  $c_k$  are, of course, the first  $n + 1$  Fourier coefficients of  $d\mu$ . The corresponding moment problem was classically considered by Carathéodory in potential theory, where the moment conditions place a constraint on the boundary value data for Laplace’s equation on the unit disc. Through subsequent classical work by Schur, Toeplitz, Nevanlinna, Pick, and many others, this has been influential in the development of modern analysis (see, e.g., [16]). Applications of the trigonometric moment problem to systems and control also have a long and fruitful history, including the rational covariance extension problem originally posed by Kalman [18] and later observed to be related to the trigonometric moment problem in [11]. However, to be applicable to problems in spectral estimation and stochastic realization theory there are system theoretic constraints that must be added to the trigonometric moment problem, relating to the rationality of, and the degree of, a solution. These challenges were noticed early on [18, 20, 13], and the ultimate breakthroughs relied (and still do rely) on the nontrivial use of topology, nonlinear convex optimization, or a combination thereof (see [13, 9] and the SIGEST paper [4] and references therein).

*Remark 1.2.* In this setting, the classical theory was developed for a complex subspace  $\mathfrak{P}$  of “test functions” and follows, mutatis mutandis, the real case. Explicitly, in order to develop the corresponding necessary conditions it is necessary to take those  $p \in \mathfrak{P}$  for which the trigonometric polynomial  $P := \text{Re}(p)$  is positive on  $[-\pi, \pi]$ . The complex-valued enhancement of condition (1.2) is then

$$(1.3) \quad \text{Re} \left( \sum_{i=0}^n p_i c_i \right) = \frac{1}{2} \sum_{i=0}^n (\bar{p}_i c_i + p_i \bar{c}_i) = \int_{-\pi}^{\pi} P d\mu > 0.$$

One of the many gems in this classical literature is the use [21, p. 65] of the Riesz–Fejér theorem to evaluate the quadratic form on the right-hand side of (1.3), where  $P > 0$ , as

$$\sum_{i,j=0}^n c_{i-j} z_i \bar{z}_j = \bar{z}^T T_n z > 0,$$

where  $z = (z_0, \dots, z_n) \in \mathbb{C}^n \setminus 0$  and  $T_n$  is the standard Toeplitz form fashioned out of the moment sequence  $c = (c_i)$ . For a general moment problem, the form on the left-hand side of (1.3) is classically denoted by  $\langle c, p \rangle$ .

*Remark 1.3.* In both the power and the trigonometric moment problems we were led to consider the “polynomials”  $P = \operatorname{Re}(p)$  for  $p \in \mathfrak{P}$ . For this reason, the functions  $P := \operatorname{Re}(p)$  for  $p \in \mathfrak{P}$  in an arbitrary generalized moment problem are referred to as “polynomials” for  $\mathfrak{P}$ . Following this precedent, we shall refer to the ratio  $P/Q$  with  $p, q \in \mathfrak{P}$  as “rational functions” for  $\mathfrak{P}$ .

In the Nevanlinna–Pick interpolation problem for distinct interpolation points  $z_0, z_1, \dots, z_n$ , the basis functions are given by

$$\alpha_k(t) = \frac{1}{2\pi} \frac{e^{it} + z_k}{e^{it} - z_k}, \quad k = 0, 1, \dots, n,$$

which coincide on  $[-\pi, \pi]$ , modulo an additive constant, with Cauchy kernels. Higher order kernels can of course be used for multiple points. As for the case of trigonometric polynomials, it turns out that it is more helpful to identify the interval with the unit circle and, in this case, to think of  $\mathfrak{P}$  in terms of Hardy spaces. This has also led to profound developments in several complex variables and in operator theory as well as in the applications of mathematics to circuit theory [10, 17] and to robust control [25, 19, 14, 12, 22]. For this problem as well, the applications to systems and control impose additional constraints to the classical moment problem whose treatment still requires nonlinear methods drawn from geometry, topology, and/or optimization [17, 14, 2, 4].

*Remark 1.4.* For the classical Nevanlinna–Pick interpolation problem, using the Riesz–Fejér theorem, the quadratic form (1.3) can also be evaluated, with some work [21, pp. 67–69], as the value of the celebrated Pick form. Moreover, it turns out that  $\mathfrak{P}$  is a finite-dimensional coinvariant subspace of  $H^2$  so that the elements of  $\mathfrak{P}$  are rational functions  $\sigma/\tau$ , where  $\tau$  is fixed, and the “polynomials” are the real parts of elements in  $\mathfrak{P}$ . This of course implies that the “rational functions” are rational in the usual sense.

The generalized moment problem is about measures, and combining these two concepts leads us to the following definition.

DEFINITION 1.5. *Any measure of the form*

$$(1.4) \quad d\mu = \frac{P(t)}{Q(t)} dt,$$

where  $P$  and  $Q$  are positive polynomials for  $\mathfrak{P}$ , is a rational positive measure.

PROBLEM 1.6. Given a sequence of complex numbers  $c_0, c_1, \dots, c_n$  and a subspace  $\mathfrak{P}$ , the generalized moment problem for rational measures is to parameterize all positive rational measures  $\frac{P(t)}{Q(t)} dt$  such that

$$(1.5) \quad \int_a^b \alpha_k(t) \frac{P(t)}{Q(t)} dt = c_k, \quad k = 0, 1, \dots, n.$$

The problem itself is motivated by classical applications and examples, in both finite and infinite dimensions, and also reflects the importance of rational functions in systems and control. In this paper we give a concise description of all solutions of this generalized moment problem for a broad class of subspaces  $\mathfrak{P}$ .

**2. The main result.** In order to state our result, we first need to compute the dimension of  $\mathfrak{P}$  as a real vector space, taking into account the cases where a basis element is real, purely imaginary, or neither. In order for the moment equations to hold it is necessary that  $c_k$  be real whenever  $\alpha_k$  is real. Moreover, a purely imaginary moment condition can always be reduced to a real one, and henceforth we shall assume that  $\alpha_0, \dots, \alpha_{r-1}$  are real functions and  $\alpha_r, \dots, \alpha_n$  are complex-valued functions whose real and imaginary parts, taken together with  $\alpha_0, \dots, \alpha_{r-1}$ , are linearly independent over  $\mathbb{R}$ . In particular, we may regard  $\mathfrak{P}$  as a real vector space of dimension  $2n - r + 2$ . Since we have chosen a fixed basis, we may regard each

$$(2.1) \quad p := \sum_{k=0}^n p_k \alpha_k \in \mathfrak{P}$$

also as an  $(n+1)$ -tuple of points  $(p_0, p_1, \dots, p_n)$ , where  $p_0, p_1, \dots, p_{r-1}$  are real and  $p_r, p_{r+1}, \dots, p_n$  are complex. Moreover,  $p$  is determined by its real part  $P := \operatorname{Re}(p)$ , a notation we shall keep throughout. Next we define the subset  $\mathfrak{P}_+$  of those elements  $p \in \mathfrak{P}$  such that  $P > 0$ . We shall assume that  $\mathfrak{P}_+$  is nonempty and is therefore an open, convex set having dimension  $2n - r + 2$ .

The rational measures we seek as solutions have the property that  $d\mu(E) > 0$  for every Borel measurable subset  $E \subset [a, b]$  having nonzero measure. For this reason, we will seek a necessary condition expressible in terms of the slightly larger space  $\overline{\mathfrak{P}}_+ \setminus \{0\}$  of “test” functions. That is, we define  $\mathfrak{C}_+$  as the set of sequences  $c = (c_0, c_1, \dots, c_n)$  such that

$$(2.2) \quad \langle c, p \rangle := \operatorname{Re} \left\{ \sum_{k=0}^n p_k c_k \right\} = \int_a^b P \, d\mu > 0$$

for all  $p \in \overline{\mathfrak{P}}_+ \setminus \{0\}$ . We will call such a sequence *positive*. In particular,  $\mathfrak{C}_+$  is also a nonempty, open convex subset of  $\mathbb{R}^{2n-r+2}$  of dimension  $2n - r + 2$ .

*Remark 2.1.* Since we are seeking a solution to the moment problem for a smaller class of positive measure than in the classical treatment, our necessary conditions are, not surprisingly, stronger than the classical conditions. In particular, a sequence  $c$  which we call positive is referred to as *strictly positive* in [21]. A sequence  $c$  is positive *in the classical sense* if it satisfies  $\langle c, p \rangle \geq 0$  for all  $p \in \overline{\mathfrak{P}}_+$ , a condition that does not quite capture the case of positive rational measures.

We shall now fix  $c \in \mathfrak{C}_+$  and consider the set  $\mathfrak{M}_c$  of all pairs of polynomials  $(p, q)$  for which the rational measure  $P(t)/Q(t)dt$  solves Problem 1.6 for the positive sequence  $c$ . There is a natural parameterization of  $\mathfrak{M}_c$  as a submanifold of the product space  $\mathfrak{P}_+ \times \mathfrak{P}_+$ , and, as a subset of a product space,  $\mathfrak{M}_c$  comes with two mappings:

$$\pi_1 : \mathfrak{M}_c \rightarrow \mathfrak{P}_+ \quad \text{and} \quad \pi_2 : \mathfrak{M}_c \rightarrow \mathfrak{P}_+,$$

where  $\pi_1$  and  $\pi_2$  are the restrictions to  $\mathfrak{M}_c$  of the two mappings

$$\operatorname{proj}_1 : \mathfrak{P}_+ \times \mathfrak{P}_+ \rightarrow \mathfrak{P}_+ \quad \text{and} \quad \operatorname{proj}_2 : \mathfrak{P}_+ \times \mathfrak{P}_+ \rightarrow \mathfrak{P}_+,$$

defined by  $\operatorname{proj}_1(p, q) = p$  and  $\operatorname{proj}_2(p, q) = q$ .

**THEOREM 2.2.** *Suppose that  $\mathfrak{P}$  consists of Lipschitz continuous functions. Then, for each  $c \in \mathfrak{C}_+$ ,  $\mathfrak{M}_c$  is a smooth submanifold of  $\mathfrak{P}_+ \times \mathfrak{P}_+$ , diffeomorphic to  $\mathbb{R}^{2n-r+2}$ . Moreover, each of the maps  $\pi_1, \pi_2$  is a diffeomorphism of  $\mathfrak{M}_c$  onto its image, which is an open submanifold of  $\mathfrak{P}_+$ . Finally,  $\pi_1 : \mathfrak{M}_c \rightarrow \mathfrak{P}_+$  is surjective.*

*Remark 2.3.* To the best of our knowledge, all instances of the generalized moment problem that arise in systems and control involve subspaces of  $C[a, b]$  consisting of Lipschitz continuous functions. Moreover, this class of subspaces has been of considerable classical interest. For example, an important class of spaces considered in the classical literature on the generalized moment problem [21] consists of those spaces  $\mathfrak{P}$  spanned by a Chebyshev system (or T-system), which are characterized by a bound on the number of zeros for any nonzero polynomial in  $\mathfrak{P}$ . These spaces arise in important applications of the generalized moment problem, e.g., the power moment problem and the trigonometric moment problem of odd order, and have remarkable approximation properties in the Banach space  $C[a, b]$ . We remark that [21] contains a neat application, generalizing Feldbaum's theorem on the number of switchings, of Chebyshev systems to the time-optimal control of scalar-input linear control systems. For our present purposes, we recall the classical result that, if  $\mathfrak{P}$  is spanned by a Chebyshev system and contains a constant function, then, after a reparameterization,  $\mathfrak{P}$  consists of Lipschitz continuous functions [21, p. 37].

*Remark 2.4.* We have remarked that the finite-dimensional Nevanlinna–Pick problem can be recast in a Hardy space setting, where the space  $\mathfrak{P}$  is a coinvariant subspace (defined, in fact, by a finite Blaschke product) in  $H^2(\mathbb{D})$ . In a seminal paper [23], Sarason developed a vast generalization of this problem to one involving liftings of a partial isometry  $T$ , defined on an arbitrary coinvariant subspace, which commute there with the restriction of the shift operator. Among many other results, Sarason showed that, under general conditions, the lift of  $T$  has an  $H^\infty$  symbol which is *rational* with respect to the coinvariant subspace. The corresponding problem for  $T$  being a strict contraction was studied in [3], where optimization methods were used to show that the lifting of such a  $T$  always had such a generalized rational symbol. Moreover, it was shown that this symbol is completely parameterized by its numerator in parallel with the conclusion in Theorem 2.2 that  $\pi_1$  is a bijection. In this light, it is interesting to enquire whether a general version of Problem 1.6 can be formulated, and solved, in a meaningful infinite-dimensional setting.

The formulations of Definition 1.5 and Problem 1.6 for generalized rational measures and of Theorem 2.2 are new and have some appeal both for the intrinsic simplicity of the formulation and as a unification of a variety of specific applications and more general results on the moment problem. There are of course antecedents in the literature to some parts of the theorem and its corollaries. We shall review these results as a conclusion to our outline of the proof in section 3.

**3. An outline of the proof.** The proof of our main result can be reduced to several steps. The first part involves establishing some smoothness results for  $\mathfrak{M}_c$  and the maps  $\pi_1$  and  $\pi_2$ . This, of course, depends upon the ambient spaces and their properties, as investigated in section 4. In Proposition 4.1, we establish the required smoothness and prove that each of the maps  $\pi_1$  and  $\pi_2$  is a local diffeomorphism, whenever  $\mathfrak{M}_c$  is nonempty.

The final steps in the proof are to demonstrate that  $\mathfrak{M}_c$  is nonempty for each positive sequence  $c$ , that  $\pi_1$  is a bijection, and that  $\pi_2$  is an injection. For suppose that  $\mathfrak{M}_c$  is nonempty. By the inverse function theorem, the image of each  $\pi_i$  is an open subset  $U_i$  of  $\mathfrak{P}_+$ . Therefore, to say that  $\pi_1$  is also a bijection is to say that it has an inverse defined on  $U_1 = \mathfrak{P}_+$ , which from the inverse function theorem must also be differentiable. That is, the map

$$\pi_1 : \mathfrak{M}_c \rightarrow \mathfrak{P}_+$$

is a diffeomorphism. Similarly, to say that  $\pi_2$  is an injection is to say that

$$\pi_2 : \mathfrak{M}_c \rightarrow U_2$$

is a diffeomorphism. Taken together, these steps conclude the proof. The proofs of the last three steps are, however, not just set-theoretic.

For example, the analysis of the map  $\pi_2$  boils down to the analysis of a linear map between closed convex sets. If  $\mathfrak{P}$  contains the constant functions, we may, for example, choose  $q = 1$  which leads to a new constrained problem, the generalized moment problem for positive *polynomial measures*. In section 5, after proving in Lemma 5.1 that  $\pi_2$  is injective, we analyze its image using the auxiliary problem for polynomial measures. In particular, we deduce Proposition 5.5 which asserts that  $\pi_2$  fails to be surjective for general  $c$  in dimension greater than one, under the auxiliary hypothesis that the zero set of any  $p \in \mathfrak{P}$  has measure zero.

In contrast, the analysis of  $\pi_1$  is nonlinear and the result is nicer. To say that, for every  $c$  and for each  $p$ , there exists a unique  $q$  is to say that, for each fixed  $p$ , and any  $c$ , there exists a unique  $q$  so that the corresponding rational measure solves the moment problem for  $c$ . As for the map  $\pi_2$ , this results in a related constrained moment problem, which defines a smooth mapping  $F^p : \mathfrak{P}_+ \rightarrow \mathfrak{C}_+$ . We show that  $\pi_1$  is a diffeomorphism if and only if  $F^p$  is a diffeomorphism. The local smoothness results obtained in section 4 imply that  $F^p$  is a local diffeomorphism, so that  $F^p(\mathfrak{P}_+) \subset \mathfrak{C}_+$  is open. In section 6, we prove Lemma 6.3, which asserts that  $F^p$  is proper whenever  $\mathfrak{P}$  consists of Lipschitz continuous functions. In particular,  $F^p(\mathfrak{P}_+) = \mathfrak{C}_+$ , and an application of Hadamard's global inverse function theorem shows that  $F^p$  is a diffeomorphism. This has several important and interesting consequences, including Corollary 6.4, which asserts that  $\mathfrak{M}_c$  is nonempty, for each positive sequence  $c$ . In addition, we observe in Corollary 6.7 that  $\pi_1$  is surjective and hence a bijection, thereby concluding the proof of Theorem 2.2.

*Remark 3.1.* The proof of Theorem 2.2 both touches upon and gives new proofs of certain results in the literature on generalized moment problems with a degree, or a complexity, constraint. Some of these were developed in some specific applications to problems arising in systems and control and, later, in a more general setting. For example, in the SIGEST paper [4], we surveyed the trigonometric moment problem and its manifestation in our work, and the work of Georgiou, on the covariance extension problem. In [4], we also reviewed our joint work with Georgiou [2] on the Nevanlinna–Pick moment problem. In both of these problems, a specialized version of Theorem 6.5 emerged. It is fair to say that, at the time, everybody interested in this circle of problems recognized that this kind of result capped off the brilliant introduction of topological methods into these problems by Georgiou [13, 14]. Motivated by the similarities between these problems and by their common role as classical instances of the generalized moment problem, we concluded [4] with a sketch of a unified approach to both applications in the form of a constrained generalized moment problem, as treated in section 6. The resulting formulation stated a version of Theorem 6.5 for arbitrary subspaces  $\mathfrak{P}$  and referred, as did the more recent paper [7], to the unpublished report [6] for more details and proofs. However, it is also fair to say that, at the time, both the formulation of the general problem in terms of (generalized) rational measures and Theorem 2.2 remained unanticipated.

The basic technical lemma in [6] has been generalized here as Lemma 6.3 and is proved in the case when  $\mathfrak{P}$  consists of Lipschitz continuous functions. This is unlikely to be the most general form of the technical lemma but, in light of Remark 2.3, could

be the most interesting form for finite-dimensional subspaces  $\mathfrak{P}$ . A brief overview of this result and the hypotheses under which versions of Theorem 6.5 have been established can be described as follows.

- The proof of the corresponding results in [6] required that the subspace  $\mathfrak{P}$  consists of functions of class  $C^2$ .
- Georgiou [15] developed an innovative approach to the generalized moment problem with complexity constraints based on a one-parameter embedding argument, similar to the path-lifting proof of the Banach–Mazur theorem in [1]. Using this method, Georgiou was able to prove an analogue of Theorem 6.5 for subspaces  $\mathfrak{P}$  consisting of functions of class  $C^1$ .
- In [8], an alternative approach to this constrained moment problem was developed from a detailed analysis of an underlying variational problem, proving in particular that all minimizers arise as interior points. The proof holds under a condition concerning certain divergent integrals that is valid whenever  $\mathfrak{P}$  consists of Lipschitz continuous functions.

In contrast, the approach followed here avoids the use of variational methods and relies instead on nonlinear analysis, such as Hadamard’s global inverse function theorem, to give a streamlined yet self-contained proof of existence and uniqueness results for a class of constrained moment problems en route to our ultimate goal, Theorem 2.2.

**4. Some basic results on smoothness.** We now turn to the smoothness of  $\mathfrak{M}_c$  and the maps  $\pi_1$  and  $\pi_2$ . The map

$$M : \mathfrak{P}_+ \times \mathfrak{P}_+ \rightarrow \mathfrak{C}_+,$$

defined via

$$M(p, q) = \int_a^b \begin{pmatrix} \alpha_1(t) \\ \alpha_2(t) \\ \vdots \\ \alpha_n(t) \end{pmatrix} \frac{P(t)}{Q(t)} dt,$$

has  $\mathfrak{M}_c$  as its level set  $M^{-1}(c)$ .

For simplicity, we view  $\mathfrak{P}$  and  $\mathfrak{C}$  as real vector spaces, so that  $\mathfrak{P}$  is spanned by the real basis  $(\alpha_i)$ , where we have replaced a complex-valued  $(\alpha_k)$  by its real and imaginary parts. The Jacobian,  $\text{Jac}(M)_{(p_0, q_0)}$ , of  $M$  at a point  $(p_0, q_0)$  takes the form

$$(4.1) \quad \text{Jac}(M) = (\partial M / \partial p, \partial M / \partial q) = (M_p, M_q),$$

where  $M_p$  is the square matrix whose  $(i, j)$ th entry is

$$(4.2) \quad (M_p)_{(i, j)} = \int_a^b \alpha_i(t) \alpha_j(t) \frac{1}{Q(t)} dt$$

and where  $M_q$  is defined by

$$(4.3) \quad (M_q)_{(i, j)} = - \int_a^b \alpha_i(t) \alpha_j(t) \frac{P(t)}{Q^2(t)} dt,$$

each being evaluated at the point  $(p_0, q_0)$ . Thus,  $M_p$  (or  $-M_q$ ) is the Gramian matrix of the real basis  $(\alpha_i)$  with respect to the positive definite inner product defined by

$Q(t)^{-1}dt$  (or  $P(t)/Q^2(t)dt$ ) on  $C[a, b]$ . Therefore,  $\text{Jac}(M)$  has rank  $2n - r + 2$  at each point  $(p, q)$  so that, by the implicit function theorem, we obtain the following result.

**PROPOSITION 4.1.** *For each  $c \in \mathfrak{C}_+$ ,  $\mathfrak{M}_c$  is either empty or a submanifold of  $\mathfrak{P}_+ \times \mathfrak{P}_+$  of real dimension  $2n - r + 2$ .*

As restrictions of a smooth map to a smooth submanifold of the product, both  $\pi_1$  and  $\pi_2$  are smooth maps from  $\mathfrak{M}_c$  to  $\mathfrak{P}_+$ . Suppose that  $M(p_0, q_0) = c$  so that, in particular,  $\mathfrak{M}_c$  is nonempty. The tangent space  $T_{(p_0, q_0)}(\mathfrak{M}_c)$  to  $\mathfrak{M}_c$  at  $(p_0, q_0)$  is given by the kernel of  $\text{Jac}(M)_{(p_0, q_0)}$ . By inspection, we have

$$(4.4) \quad \ker \text{Jac}(M)_{(p_0, q_0)} = \left\{ \begin{bmatrix} M_p^{-1}x \\ -M_q^{-1}x \end{bmatrix} : x \in \mathbb{R}^{2n-r+2} \right\}.$$

We wish to show that

$$\text{rank } \text{Jac}(\pi_1)_{(p_0, q_0)} = 2n - r + 2.$$

This will occur if and only if

$$\dim \ker \text{Jac}(\pi_1)_{(p_0, q_0)} = 0,$$

which, since  $\pi_1 = \text{proj}_1|_{\mathfrak{M}_c}$ , is equivalent to the condition that the subspace

$$(4.5) \quad \ker \text{Jac}(\text{proj}_1)_{(p_0, q_0)} \cap \ker \text{Jac}(M)_{(p_0, q_0)}$$

is trivial. Now, since

$$\ker \text{Jac}(\text{proj}_1)_{(p_0, q_0)} = \left\{ \begin{bmatrix} 0 \\ y \end{bmatrix} : y \in \mathbb{R}^{2n-r+2} \right\},$$

the intersection (4.5) is parametrized by solutions to the equation  $M_p^{-1}x = 0$ . Since this implies  $x = 0$ , it follows that the intersection (4.5) is the trivial subspace  $\{0\}$ .

In particular, the Jacobian of  $\pi_1$  at  $(p_0, q_0)$  is nonsingular. A similar argument shows that the Jacobian of  $\pi_2$  at  $(p_0, q_0)$  is nonsingular, and, therefore, the final result in this section then follows from the inverse function theorem.
